This Catheter is made of ſilver, from the rings incluſive to F: all the reſt, together with the wire, ought to be of the hardeſt gold; becauſe it is on this end of the Catheter that the greateſt ſtreſs is laid, and ſilver has not firmneſs enough to reſiſt the efforts that theſe pieces muſt ſuſtain. And particular care muſt be taken, that all the angles and prominences be rendered very ſmooth.

I enter into theſe details of the make of the inſtrument, becauſe I have learned, to my coſt, that the workmen do not think of them.

Fig. 7. ſhews the whole mechaniſm of this Catheter, by repreſenting it open, and ſuch as it is in the bladder, while the inciſion is making.

The piece B of *fig.* 6. is here ſunk in its ſheath D; whereby the ſmall ſtyle or wire is thruſt towards the crooked end of the Catheter, and, at the ſame time, puſhes the end *b* of the ſmall moveable piece C towards the ſame part. The Catheter being thus open in the bladder, when the operator draws the inſtrument towards him, it is ſtopped by the neck of this organ, at the place marked *d d*, and then the angle *b* projects about a finger's breadth from the orifice of the bladder. Yet there are ſome ſubjects, in whom this orifice, being very wide or relaxed, gives greater way to the efforts made by the widening, *d d*, of the anterior angle of the Catheter; whereby it happens, that, inſtead of ſtopping this angle at *d d*, it lets it paſs through to *f f*, which brings the inciſion ſo much nearer the neck of the bladder: nay, I have ſeen in ſome dead bodies, in which the relaxation is ſtill greater, that the proſtate was ſomewhat concerned in the inciſion; which is no great misfortune. But even this may be eaſily avoided, by taking care, in the firſt inciſions, to diſengage the part that anſwers to the projecting angle from every thing that may hide from us the proſtate and bladder; and then, the foregoing caſe becoming viſible, it is eaſy to guard againſt it, by cauſing the projecting angle of the Catheter to be puſhed, or by puſhing it one's ſelf farther into the bladder.

This projecting part of the Catheter is not ſeen; but it is very perceiveable to the touch, through the integuments, and ſtill more ſo, after they are cut through.

I muſt not omit obſerving here, that, notwithſtanding all the care I have taken to inſtruct the inſtrument-maker in the conſtruction of this Catheter, and eſpecially of the moveable piece *b* C, in order to make it ſolid, yet it has often proved too weak to bear the effort of thruſting the part forward, which we are obliged to do on one ſide; ſo that it bent, and remained in the middle, whilſt the reſt of the Catheter was to the left ſide.

In caſe of this accident, it came into my thought to turn the Catheter up-ſide-down, ſo that the angle of the moveable piece might anſwer to the upper part of the neck of the bladder, and ſtop there, while the concave and immoveable part of the Catheter anſwered to the inciſion, and that the very end of the Catheter projected at the place where I was to open the body of the bladder. And, upon ſeveral trials, I found that this place was the very ſame which had before been pointed out by the angle of the moveable piece; therefore, when I have one of theſe Catheters, on which I cannot depend, I make uſe of it in this laſt manner, and it intirely anſwers my expectation; becauſe the fixed piece of theſe Catheters is always very ſolid, and that the angle of the moveable piece does its duty as well on the upper as on the under ſide of the neck of the bladder. It has even ſeemed to me, that the end of the inſtrument makes the greater protruſion forward. In fine, this Catheter, being almoſt ſtraight, eaſily aſſumes in the bladder every ſituation which one finds neceſſary to give it.

CATO'PTRIC *Ciſtula* (*Dict.*) — To make a Catoptric Ciſtula is to repreſent ſeveral different ſcenes of objects, when looked in at different foramina, or holes.

Provide a polygonous ciſtula, or cheſt, of the figure of the multilateral priſm A B C D E F, (*plate* XIV. *fig.* 8.) and divide its cavity by diagonal planes E B, F C, D A, interſecting each other in the center, into as many triangular locules, or cells, as the cheſt has ſides. Line the diagonal planes with plain mirrors: in the lateral planes make round holes, through which the eye may peep within the locules of the cheſt. The holes are to be covered with plain glaſſes, ground within-ſide, but not poliſhed, to prevent the objects in the

the locules from appearing too distinctly. In each locule are to be placed the different objects, whose images are to be exhibited; then, covering up the top of the chest with a thin transparent membrane or parchment to admit the light, the machine is compleat. For, from the laws of reflection, it follows, that the images of objects, placed within the angles of mirrors, are multiplied, and appear some more remote than others; whence the objects in one locule will appear to take up more room than is contained in the whole chest. By looking, therefore, through one hole only, the objects in one locule will be seen, but those multiplied, and diffused through a space much larger than the whole chest: thus every new hole will afford a new scene: according to the different angles the mirrors make with each other, the representations will be different; if they be at an angle greater than a right one, the images will be monstrous, &c. The parchment that covers the machine, may be made pellucid, by washing it several times in a very clear lye, then in fair water, and bracing it tight, and exposing it to the air to dry. If it be desired to throw any colour on the objects, it may be done by colouring the parchment. Zahnius recommends verdigrease ground in vinegar, for green; decoction of Brasil-wood for red, &c. He adds, that it ought to be varnished, to make it more pellucid.

To make a Catoptric cistula to represent the objects within it prodigiously multiplied, and diffused through a vast space.

Make a polygonous cistula or chest, as before, but without dividing the inner cavity into any apartments or locules; (*plate* XIV. *fig.* 9.) line the lateral planes C B H I, B H L A, A L M F, &c. with plane mirrors, and, at the foramina or apertures, pare off the tin and quicksilver, that the eye may see through; place any objects in the bottom M I, *e. gr.* a bird in a cage, &c. Here the eye, looking through the aperture *h i*, will see each object, placed at bottom, vastly multiplied, and the images removed at equal distances from one another. Hence, were a large multangular room, in a prince's palace, lined with large mirrors, over which were plain pellucid glasses to admit the light; it is evident the effects would be very surprizing and magnificent.

CA'TUS *Pardus*, in zoology, the name of a beast of prey, called also by some Catus montanus, and by us the cat of mountain. It is of the size of a mastiff dog, but it resembles, in all respects, the common domestic cat in shape, except that the tail is, in proportion to the creature's size, considerably shorter. It is also, if any thing, shorter, in proportion to its length, than our cat, and is of the common colour of that animal, only that it is variegated with black spots. Its throat is white, and its spots are long upon the back, and round upon the sides and legs; the beard or whiskers are plainly the same as in the cat; it is less fierce against the human species than many of the other beasts of prey, and may even be tamed. It naturally grows very fat. *Ray. Syn. Quad.*

CAVALIE'RS, *in fortification*, (*Dict.*)—Cavaliers are of various shapes, such as square (*plate* XIV. *fig.* 12.) or round, (*fig.* 10.) or like a horseshoe, or a plain line; but when they are constructed in flankers, as is usually the case, (*fig.* 11.) they are of a like figure to that flanker; leaving a space of about eight or ten yards, or more, between the parapet of the flanker and the outline of the Cavalier.

They should be faced with earth, or plank, or brick; but not with stone, because the splinters, knocked off by the enemy's cannon, would greatly annoy the troops that may be posted in the line below the Cavalier.

Any other particulars will be sufficiently known from the figures; observing, in the plans, to represent their outside limits by a double line, to express the sloping of the earth, and to put a ramp in the gorge.

CAU'DA *Ceti*, a fixed star of the second magnitude, called also by the Arabs dineb kaetos. Its longitude in the year 1700, according to Hevelius, was 28° 22′ 14″ of Pisces, and its latitude southward 2° 44′ 35″.

CAUDA *Cygni*, a fixed star of the second magnitude in the Swan's tail, called by the Arabs dinebadigege, or eldegiagick. Its longitude, according to Hevelius, in the year 1700, was 1° 16′ 45″ of Pisces, and its latitude northward 59° 57′ 33″.

CAUDA *Delphini*, a fixed star of the third magnitude, in the tail of the Dolphin. Its longitude, according to Hevelius, in the year 1700, was 9° 55′ 17″ of Aquarius, and its latitude northward 29° 9′ 20″.

CAUDA *Leonis*, a fixed star of the first magnitude, in the Lion's tail, called also by the Arabs dine beleced. Its longitude, according to Hevelius, in the year 1700, was 17° 27′ 46″ of Virgo, and its latitude northern 12° 18′ 55″.

CAUDA *Ursæ majoris*, a fixed star of the second magnitude, in the extreme part of the tail of the great Bear, called also by the Arabs alalioth and benenah. Its longitude, according to Hevelius, in the year 1700, was 22° 39′ 24″ of Virgo, and its latitude northward 59° 25′ 7″.

CAUDA *Ursæ minoris*, a fixed star of the second magnitude, in the extreme part of the tail of the lesser Bear, called also the polar star, and by the Arabs abrukabah.

CA'VEATING, in fencing, the act of disengaging, or shifting the sword from one side of the adversary's sword to the other.

Caveating is a motion whereby a man brings in an instant his sword which was presented on any side of his adversary's, generally beneath its hilt, to the opposite side; either from within, to without, or vice versa; or from having its point high, to below, or the reverse; and either on the same side it is presented in, or the opposite side.

CAUK, or *Cawk*, is used by the miners in the Peak to denote a worse sort of sparr; being a ponderous white stone found in the lead mines, and which will draw a white line like chalk, or the galactites.

It is of a much more dense and compact nature than galactites, and resembles crystals, except that it wants transparence. There is a singular process mentioned by Dr. Lister, which is that of vitrifying antimony by its means. This is done with great readiness and speed by it, and the glass, thus made, will produce some effect on other metals, which no other glass will, nor indeed any other preparation of antimony. The method of preparing it is this: take a pound of antimony, flux it clear; have in readiness an ounce or two of Cauk in a lamp red-hot, put it into the crucible to the melted antimony, and continue it in fusion; then cast it into a clean mortar not greased, decanting the clear liquor from the lump of Cauk. This process gives more than fifteen ounces of glass of antimony, like polished steel, and bright as the most refined quicksilver. The Cauk, in the mean time, is found to be diminished, not increased in its weight, and will never flux with the antimony, though ever so strong fire be given it. This is a very odd mineral, and this learned author supposes it to be allied to those white, milky, and mineral juices which are found in mines. The effect of both is evidently the same; for the milky juice of lead mines vitrifies the whole body of antimony, in the same manner that the Cauk does in this experiment. *Phil. Transf.* Numb. 110.

CA'ULIFLOWERS, are the produce of a kind of cabbage, and have of late years been so far improved in England, as to exceed, in size and goodness, any that are raised in the rest of Europe; they are in season in the months of May, June, and July, but the skill of the gardener can continue them much longer. The manner of propagating them is this:

Having procured some good seed, you must sow it before the middle of August, upon an old cucumber or melon bed, sifting earth over the seeds to a quarter of an inch in thickness: if the weather prove very hot and dry, the beds must be shaded with matts, and be lightly watered at times. In about a week's time the seeds will appear above ground, and they must be uncovered by degrees, but not exposed to too much sun at first. In a about a month more they should be pricked out on another old bed, at three inches distance, and shaded and watered, when first transplanted; but after this they must not be much watered, nor be suffered to have too much rain, which will make them black-shanked, or rotten in the stalks. In this bed they are to remain to the middle of October, when they are to be planted out for the winter season: they are then to be planted out in rich beds, and those which are to be early ripe, are to be shaded with bell glasses, two under each glass, and in February to be planted out again: the rest are to be at first set at a greater distance, and to stand.

When the Cauliflowers begin to fruit, they must be carefully watched, and some of the inner leaves must be bent down over the flower, to shade it from the sun, which would otherwise turn it yellow. The very finest of the Cauliflowers, which are not loose and frothy about the edges, and very firm, should be saved for seed; and the flower stems, as they shoot out, supported with sticks till the seeds are ripened, which must then be carefully gathered, and dried for use. *Mill. Gard. Dict.*

CA'USALTY, in metallurgy, the lighter parts of sulphureous and earthy ores of metals carried off in the water used in washing them, and subsiding afterwards from it. *Boerhaave's Chem.*

CAU'STICA (*Dict.*)—The celebrated Heister, in his Surgery, gives directions for making an excellent caustic stone, in the following manner:

Take of pot-ash, and the strongest quick-lime, equal quantities of each, for instance, six ounces; or of pot-ash, one pound, and of quick-lime, six ounces; which, when pounded separately, are to be mixed. Then, putting them in a large glass or pot, a large quantity of water is to be poured upon them; and they are to stand for an hour or two, till they are sufficiently incorporated with each other: then what is colliquated is to be separated from the subsiding mass, strained through a linen cloth, and condensed in an iron vessel over the fire. After which this consistent mass, being put into a crucible, is to be fused over a brisk fire, till it assumes the consistence of oil. Then it is to be poured into a vessel or mortar; and, before it is entirely cold, it is either to be cut to pieces, or broken, and kept for use, in a close-stopped glass, in a dry place.

From this glass we take what is sufficient for opening an abscess, and apply it either whole, or grossly pounded in a mortar, securing it on the part affected. If any moist substance is laid upon the Caustic, it generally operates, and corrodes the subjacent parts sooner, in the space of an hour or two, for instance; but, when it becomes old, it generally loses its corrosive quality.

Boerhaave's method of preparing the lapis septicus, or potential cautery, is as follows:

Take lime made of burnt stones, that is quite fresh, very dry, solid, not affected by any moisture, nor as yet cleft asunder; of this put one part into a clean iron pot, and lay upon it two parts of the purest pot-ash, in such a manner, that the lime may be covered all over with this alcali. Let these be then left together in the pot, with a cloth flung over them, till the lime begins to crack and split asunder: when you observe this, add four times their weight of water, and boil them for the space of one or two hours. When the fæces are subsided, pour off the liquor, and let it be strained through Hippocrates's sleeve, made of thick linen cloth, till it at last passes through as limpid as pure water. Put this lixivium into a large iron ladle over the fire, and, taking care that it do not boil over, evaporate it till it becomes perfectly dry. Then increase your fire till the ladle grows red-hot, and, as soon as ever the salt has done smoaking, it will melt. When it is in this state, pour it out upon a hot brass plate; and, whilst the matter continues very soft, make it smooth, and cut it into such pieces as are fit for chirurgical uses. Let these be put into a very dry, hot, strong glass-bottle, by the fire-side, and instantly stop it with a choice dry cork: let the mouth of the bottle be then dipped in melted pitch, and be very accurately secured, that no moisture may possibly get through it, which is attracted by the alcali, prepared in this manner, with an incredible power, even through corks and bladders: but, if you observe these cautions, it may be kept for years. When you want to take a bit out for use, it must be done in a hot dry air, or near a good fire, and then the bottle must be immediately stopped again, as before.

Remarks.

1. This salt, from the truly igneous virtue of the lime attracted into the fixed igneous alcali, acquires a most acute and quick corroding power, which was neither in the alcali nor in the lime, when they were separate. The acrimony of it exceeds that of all other salts hitherto known; for, if you cut a round hole in a sticking plaister, and apply this to a human body, and then put a bit of this salt upon the skin in the vacuity, and cover it over with another plaister, that it may not fall off, it will, in a very short time, consume the skin, and the membrana adiposa; and hence it is valued by the surgeons, for what they call their potential cautery, above all others.

2. If almost any parts of animals are thrown into a fresh lixivium of this salt, whilst it is boiling, they will, in a short time, be converted into a liquid matter; at will likewise most vegetable substances, and the sulphurs of fossils. A poor man, unfortunately falling into a boiling copper of such a lixivium, had his cloths, and all the soft parts of his body, consumed, so that there was found nothing of him left, but his bones: hence this lixivium is of incomparable service, where the parts are gangrenous to a great depth, and almost sphacelated, at it disposes them to a happy separation; but it requires the prudent application of a skilful surgeon.

3. This salt melts with a pretty moderate fire, and then it runs like wax. By this easy fusion, therefore, it is capable, without the assistance of an intense fire, of dissolving a great many bodies, which, otherwise, are not dissolved without difficulty, as myrrh, gum sandarach, and others. The antient chymists wrote a great deal about the art of making alcali's melt in the fire like wax; and hence they called the operation *inceration*. Might they not mean the process we have just now described? Certainly the salt produced by it has this property.

4. If lime is first slaked, or extinguished, either in the air, or with water, as almost all old lime is, or is converted into a powder; then, if it is thus managed with a fixed alcali, it will not produce this acrid kind of salt. This salt, when it is once melted in the air, or is kept a good while, not carefully stopped, loses this singular virtue; and then it deposits a large quantity of inactive stony fæces, which did not appear before: hence, therefore, we learn, that fire communicates to inert stone, and shells of fish, an acrimony, that is not easily procurable in any other manner: when a native vegetable salt, therefore, from a natural, soft, saponacious one, is converted into a fixed alcali, does it not require this acrimony from the fire?

5. The salt, thus prepared, obtains this singular property, that it becomes vastly disposed to a union with the expressed and distilled oils, both of vegetables and animals, and thus to form a soap. And this seems to arise from its being rendered so exceedingly penetrating, that it becomes capable of intimately dividing these oils, and uniting with them, which, without the assistance of this sharp lime, can scarcely be effected conveniently: nor, without the lime, would the alcali run so easily in the fire; for that melts with a great deal of difficulty.

Lunar CAUSTIC, called also lapis causticus, is a preparation of silver, sometimes of copper, usually made by dissolving the metal with spirit of nitre, evaporating two thirds of the fluid, and boiling the rest to an oily consistence, which, when cold, grows hard.

CAU'STICUM *antimonial*, the name given in the late London Dispensatory to what was before called butter of antimony.

CAU'TIONARY *Towns*, places of strength, which one prince or power puts in the possession of another, as a security either for the payment of a debt, or performance of some other matter stipulated between them. Rochelle, Saumur, and some other cities in France, were allowed to the reformed, for their strength and security.

CA'XOU, in metallurgy, a word used to express a chest of ores of silver, or any other metal, that has been burnt, ground, and washed, and is ready to be refined.

CA'ZIMI, among the Arabian astronomers, denotes the center or middle of the sun. A planet is said to be in Cazimi, when it is not distant from the sun either in longitude or latitude above 17′, or the aggregate of the semi-diameter of the sun's disk and that of the planet.

CE'DAR, in botany, a large tree which pushes out branches at the distance of ten or twelve feet from the ground. They are large, and at a distance from each other. Its leaves are pretty much like those of rosemary. It is an ever-green, and lives very long, but dies as soon as its top is cut off. The leaves stand upright, and the fruit hangs down; that fruit is a small one, like that of the pine-tree, except that its rind is thinner, smoother, and more open. The seed is like that of the cypress-tree.

There are still some Cedars on mount Libanus, but in small number, above and to the east of Biblos and Tripoli. There are none to be seen any where else on those mountains. But it is very probable that there were a great many more formerly, since their timber was used in so many considerable works. There are some Cedars also growing in some parts of Africa, in the isle of Cyprus, and in that of Crete or Candia. Josephus, the Jewish historian, asserts, that Solomon planted so large a quantity of Cedars in Judea, that they were as numerous as the sycomore-trees, which are very common in that country.

They used that timber not only for beams, and for the boards which covered the buildings, and made up the cielings of the apartments, but they put it likewise into the body of the walls, so that there were, for instance, three rows of stone and one of Cedar-wood. They also made statues of it, when they would have them last a long time. It is used to make fine turners and inlaid work, and in some floors and cielings of royal palaces, and other stately edifices; but, in those places where it grows, it is employed in land and sea buildings, like common timber.

During the hottest season of the year, there runs naturally, and without any incision, from the trunk and large branches of this tree, a white, clear, and transparent resin, which is called Cedar-gum, or masticine-manna, which hardens and forms itself into grains like mastic. The largest trees hardly yield six ounces of it a day.

When the gum has done running of itself, they make incisions into the tree, from whence issues afterwards an unctuous liquor, which dries, as it runs along the trunk of the tree. This is the resin of Cedar, which is sold at the druggists shops; it is of a fine yellow colour, friable, lucid, transparent, and of a good smell.

Lastly, the Cedar furnishes also a third sort of drug, called turpentine, or resin of Cedar; it is a liquor clear, like water; of a strong penetrating scent, contained in small bladders or vesicles, which the excessive heat of the sun causes to rise on the trunk of the tree. These gums and resins of Cedar are to be met with in France.

Mr. Miller observes, that what we meet in the scripture of the lofty Cedars, can be no ways applicable to the stature of this tree; since, by the experience of those we have now growing in England, as also from the testimony of several travellers, who have visited those few remaining trees on mount Libânus, they are not inclined to grow very lofty, but, on the contrary, extend their branches very far: to which the allusion made by the Psalmist agrees very well, when he is describing the flourishing state of a nation: they shall spread their branches like the Cedar-trees.

The wood of this famous tree is accounted proof against all putrefaction of animal bodies. The saw-dust is thought to be one of the secrets used by those mountebanks, who pretend to have the embalming mystery. This wood is also said to yield an oil, which is famous for preserving books and writings; and the wood is thought, by lord Bacon, to continue above a thousand years sound. It is likewise recorded, that, in the temple of Apollo at Utica, there was found timber of near two thousand years old. And the statue of the goddess, in the famous Ephesian temple, was said to be of this material also, as was most of the timber work of that glorious structure.

This sort of timber is very dry, and subject to split; nor does it well endure to be fastened with nails; therefore pins of the same wood are much preferable.

The Cedar brought from Barbadoes and Jamaica is a spurious sort, of so porous a nature, that the wine will leak through it. That produced in New England is a lofty grower, and makes excellent planks, and flooring that is everlasting. They shingle their houses with it, and use it in all their buildings.

ings. This is the oxycedrus of Lycia, which Vitruvius describes as having its leaves resembling those of cypress.

The Cedar of Greece and Asia was no other than a smaller kind of juniper, which, having prickly leaves, was by some called oxycedrus; and the common juniper was at that time called also by the name of Cedar. The Lycian Cedar of the Greeks was this juniper kind; but the cedrium and cedrelæum, which were a kind of pitch and an oil separated from it by melting, were not prepared from this Cedar, but from the Syrian Cedar; which was a larger shrub, and resembled the cypress, and therefore was confounded with that tree, being called by some the wild cypress. The cedrium was always made from this species, but the oleum de coda, or code oil, was made from the fruit of the oxycedrus, or prickly-leaved juniper, called Cedar by the Greeks, and growing in their own country.

The shittim and the almug, mentioned in scripture, are usually supposed to have been kinds of Cedar.

Johnston, in his Dendrographia, is of opinion, that pitch was anciently made of Cedar, as well as of the pine and fir, grown old and oily.

CE'GINUS, in astronomy, a fixed star of the third magnitude, in the left shoulder of Bootes. Its longitude, according to Hevelius, for the year 1700, was 13° 26′ 4″, and its latitude northern 49° 35′ 47″.

Some also give this denomination to the star otherwise called Cepheu.

CEI'BA, in botany, the Indian name of the silk cotton tree. Dr. Linnæus calls it xylon, which is the old name applied to the common cotton; and he has given to that genus the modern title of gossypium. The characters are: it hath a rosaceous flower, consisting of several leaves placed in a circular order: from whose calyx arises the pointal, which afterwards becomes a fruit shaped like a bottle, divided into five parts from the top to the bottom; in which are contained several round seeds wrapped up in a soft down, and fastened to the five-cornered pyramidal placenta.

These trees grow very plentifully both in the East and West-Indies, where they arrive to a prodigious magnitude: the West-Indians hollow the trunks of those trees for making their canoes, for which they are chiefly valued.

It is reported, that in the island of Cuba, in Columbus's first voyage, was seen a canoe made of an hollowed trunk of one of those trees, which was ninety-five palms long, and capable of containing one hundred and fifty men.

And some modern writers have affirmed, that there are trees now growing in the West-Indies, so large as scarcely to be fathomed by sixteen men, and so high, that an arrow can scarcely be shot to their tops.

The wool of these trees is of a dark colour, and too short to spin; so that it is little valued: but sometimes the inhabitants stuff beds and pillows with it, though it is accounted unwholesome to lie upon. The inhabitants of the West-Indies call this silk-cotton; but, the ancient American name for this plant being Ceiba, father Plumier hath continued it under that name, and constituted a genus of it.

These plants are preserved in some curious gardens in Europe, where they thrive very well, if they are placed in a bark-stove; but, as they are trees of a large growth, it can hardly be expected to see either fruit or flowers from them in England; since they grow to a great magnitude before they produce either in their own country.

CE'LERI, a name given by our gardeners to some species of apium.

We have two sorts of this plant cultivated in our gardens, the Italian Celeri, and the celeriac.

The seeds of this plant should be sown at two different seasons, the better to continue it for use, through the whole season, without its running up to seed. The first sowing should be in the beginning of March, in an open spot of light earth; but the second sowing should be in April, in a moister soil. In about a month's time after sowing, the plants will come up; they must be kept clear of weeds, and, if the season is dry, they must be watered. When they have been a month or five weeks above ground, they will be fit to transplant. They must now be set at three inches distance, in beds of moist rich earth. In the middle of June some of the plants of the first sowing will be fit to transplant for branching; the soil in which it is now planted must be moist, rich, and light.

The manner of planting it at this time is this: you must dig a trench of ten inches wide, and eight or nine inches deep, loosening the earth at the bottom, and laying it level; and the earth which comes out of the trench, is to be equally laid on each side of the trench, to be ready to draw in again to earth the Celeri, as it advances in height. The trenches should be made at three feet asunder, and the plants set in them at six inches distance. The tops of their leaves, and ends of their roots, are to be cut off when planted; and they are to be watered, to fix the earth to their roots: after this, they require little care but the drawing up the earth to them, as they advance in height; it must be carefully observed, in doing this, never to bury the heart of the plant, nor ever to perform it but in dry weather; for, if done in wet, the plants will rot. The earth between the trenches is to be used, when that which was thrown out in the digging of them is all employed; and, soon after midsummer, some of the first sowing will be ready to cut, and the succeeding ones, if rightly managed, will continue it till April or May. Many plantations are indeed also made out of one sowing, by pulling up the strongest plants first, then some time after the strongest of the remaining, and, finally, the least of all, which will be got to a proper growth by that time. *Miller's Gardener's Dict.*

CE'LTIC *Philosophy.*— Under this denomination we are to comprehend not only the philosophers of Gaul, but all those who formerly flourished in Europe, either in the Britannic islands, among the Germans and Iberians, or in Italy. Burnet tells us, it is very probable that the Germans and Britons had their druids, who, if they were not so learned as those among the Gauls, and held in less esteem, yet professed the same principles and taught the same doctrine. It is not surprizing any account of their philosophy should be so obscure as it is, considering the interval of time wherein it flourished between us and even the ancient Romans. No writings or monuments are left to clear up the point; it is most probable they concealed their opinions from all who were not initiated in their mysteries, never wrote down, but conveyed their arcana by oral tradition. The fables of Solinus, Pliny, Pomponius Mela, Aul. Gellius, Herodotus, and Strabo, shew abundantly the weakness and ignorance of the Latin and Greek writers on this subject. Cæsar himself, the conqueror of the Gauls, though so nice an observer of the manners and customs of those he vanquished, says little of the Celtæ, and what he says is involved in a cloud of fables. What farther contributes to the obscurity of this history, is, the many different people who went by the general name of Celtæ; from hence an amazing variety of principles and customs must necessarily have been introduced. As, for example, in the time of Cæsar and Tacitus, the Gauls differed from the Germans very much, though they were of the same origin; the Germans were much heavier than the Gauls, who, according to Justin, had refined their manners by an intercourse with the Greeks, who had settled at Marseilles; and that the Gauls, from them, had contracted a politeness natural to their nation. The Greeks and Romans are both ignorant of the antiquity of the Celtæ in all respects.

The Celtæ were more addicted to war than study; they followed the chace in their vast forests with more ardour than they pursued metaphysical subtilties. But their moral philosophy was far more excellent than that of the Greeks and Romans, who had a dangerous way of rendering truth obscure by argumentation. But, notwithstanding the contempt they entertained for the polite sciences, they had among them sages and philosophers who kept their philosophy a secret, though in a different manner from that among the Greeks and Romans. These sages were called druids, a name famous in antiquity, though very obscure as to its original. The most probable opinion is, that they derive their name from the oak, because, by an invariable tradition, they are said to have assembled in groves of oaks, and held the oak sacred. The conformity of their doctrines with those of the Magi, among the Persians and Chaldeans of Babylon, argues them not unacquainted with those philosophers.

The druids had a great influence over the state; they in short left the prince only a power of commanding in time of war. The tyranny of these priests was no doubt destructive of the royal authority; for, if a prince pretended to take the reins of government into his own hands without consulting them, they at once interdicted him from being present at sacrifices, and at once launched out all the anathemas of religion against him, and, being followed with blind obedience by their disciples, subverted the government; they were, in short, impostors who subjected a weak people under the yoke of shameful ignorance. According to ancient writers, the druids wore collars of gold, dressed magnificently, and the pomp in which they lived, created the esteem and authority they had among the Gauls.

The druids were divided into several classes; according to Ammianus Marcellinus, there were among their body, bards, eubages, and those strictly called druids. The employment of the bards was to celebrate the actions of heroes in verse. The eubages applied themselves to the contemplation of nature, and discovering her secrets. Those which were called druids, by way of eminence, joined to the study of physics that of ethics and politics. They had two sorts of doctrine, one for the people, which was therefore public; another for their disciples, which they had kept so inviolably secret, that no part of it has transpired, except that of the immortality of the soul, which, Pomponius Mela says, they divulged with a design to animate the courage of their countrymen, and inspire them with a contempt of death.

The Celtæ, like other nations, sunk into idolatry. Their priests the druids, who certainly had clearer notions of the Deity than the people, encouraged them in this foolish superstition. This reproach may too justly be objected to all legislators. The gods they worshipped, were Theutates, Hesus, and Taranes; the Romans make Theutates Mercury, Hesus Mars, and Taranes Jupiter; but this is doubted by

men

men of learning among the moderns. It is however certain by the concurring testimony of antiquity, that they shed human blood on their altars, and the druids were the priests who slew the unhappy victims.

After the Gauls were conquered by the Romans, they, who before looked on God as the soul of the world, and worshipped him every-where, and in all places, though some were in a particular manner dedicated to him; followed the example of their masters, built temples and consecrated altars. The druids insensibly lost their credit, and were at last banished by a decree of the senate, either because it was apprehended they carried on some dangerous designs against the state, or continued human sacrifices.

The druids both among the Gauls and Germans preserved their authority by divination. But, what is more remarkable, these divinations were generally delivered by women, from whence grew the prodigious respect they had for them, which was sometimes carried to the pitch of adoration; for Tacitus tells us Velleda and Aurinia were reckoned among the goddesses.

We shall conclude this article by observing that the Celtæ, from a firm persuasion of the immortality of the soul and a future state, possessed true courage, had a just contempt of death, despised luxury, and refused to meet no danger, when virtue and honour called. It is indeed a pity such a nation had druids for their priests.

CE'MENT (*Dict.*)—We have various receipts for making Cement to mend broken china or glasses; one of the finest, and, at the same time, strongest Cements for this purpose is, the juice of garlick stamped in a stone mortar; this will leave little or no mark, if done with care.

Another Cement for broken glasses, china, and earthen ware, may be prepared by beating the white of an egg very clear, and mixing with it fine powdered quick-lime; or isinglass, powdered chalk, and a little lime may be mixed together, and dissolved in fair water, with which the glasses, &c. are to be cemented, and then set in the shade to dry; a precaution that should always be observed, which ever of the above Cements are used.

For the manner of preparing a Cement to bind together the various embellishments of grottoes. See the article GROTTO.

CEME'NTATORY *Water, aqua cementatoria.*—Those springs produce the water which passes under this name, that are strongly impregnated with vitriol of copper, which are met with at the bottom of several copper-mines, but especially in Hungary, near Neuvol, at the bottom of the Krapack mountains. The property of turning iron into copper is generally attributed to them; but, notwithstanding the knowledge of chemistry be so imperfect, it is easy to see there is no transmutation, but a simple precipitation, caused by the iron steeped in this water. This is the manner of the process to make this pretended transmutation:

The Cementatory water is very clear and limpid at the spring-head; reservoirs are made to catch it in considerable quantities. The water collected in these reservoirs is put into wooden troughs, about a foot wide, and of the same depth; as to their length, it is not determined; they are sometimes 100, sometimes 150 feet long. These troughs are filled with old iron as full as they can hold, then the Cementatory water is let in which covers the iron, dissolves and destroys it, and puts in its stead the copper with which it is impregnated. It has the same form as the iron, and in three months, or thereabouts, according to the strength of the vitriolic water, all the iron is consumed and destroyed, and the copper is entirely precipitated. The reason why the precipitated copper takes the same shape as the iron had before, is, because the vitriolic acid, having more affinity with the iron, leaves the copper which it held in a state of dissolution, to cleave to the iron: from whence it follows, that the quantity of copper which precipitates is exactly equal to the quantity of iron which dissolves.

By this method it is said a large quantity of copper is obtained, without much expence or trouble; and this copper, they tell you, is more ductile and malleable than what is procured from the mine after several meltings. This copper is soft, and like clay while under water, but it assumes a consistence and acquires a hardness on being brought into the air.

The two most famous springs of Cementatory water in Hungary, are those of Smolnitz and Heregrund: the first of these is said to furnish 600 quintals of such copper as we have described, such is the abundance of its water, and so strongly is it impregnated with vitriol of copper. Besides, it is remarkable that iron steeped in this water dissolves in three weeks entirely, and the copper succeeds in its place; whereas other springs take three months, sometimes a year, before the operation is completed.

Several other springs of the same quality are found in Hungary, Germany, Sweden, &c. Henckel, in his Pyritologia, page 764, explains the cause of these phænomena in this manner. The waters of these springs, says he, passing over the copper pyrites which are dissolved in the bowels of the earth, take off the vitriolic particles which are formed on the pyrites, and carry them along with them.

CE'NSUS, among the Romans, was an authentic declaration, made by the several subjects of the empire, of their respective names and places of abode, before proper magistrates, in the city of Rome, called censors; and in the provinces censitors, by whom the same were registered.

This declaration was accompanied with a catalogue, or enumeration in writing, of all the estates, lands, and inheritances they possessed; their quantity, quality, place, wives, children, tenants, domestics, slaves, &c.

The Census was instituted by king Servius, and was held every five years. It went through all the ranks of people, though under different names: that of the common people was called Census, or lustrum; that of the knights Census, recensio, recognitio; that of the senators, lectio, relectio.

Hence, also, Census came to signify a person who had made such a declaration: in which sense it was opposed to incensus, a person who had not given in his estate or name to be registered.

The Census among the old Romans was held, as is commonly thought, every five years; but this must not be taken to be precisely true: on the contrary, Dr. Middleton has shewn, that both the Census and lustrum were, for the most part, held irregularly and uncertainly, at very different and various intervals of time.

The Census was an excellent expedient for discovering the strength of the state: by it they learnt the number of the citizens, how many were fit for war, and who for offices of other kinds; how much each was able to pay of taxes towards the charge of the war.

The Census, according to Salmasius, was peculiar to the city of Rome. That in the provinces was properly called professio; but this distinction is not every-where observed by the ancients themselves.

CENT, signifies properly a hundred, being an abridgment of the word centum; but it is often used, in commerce, to express the profit or loss arising from the sale of any commodity: so that, when we say there is 10 per Cent. profit, or 10 per Cent. loss, upon any merchandize that has been sold, it is to be understood that the seller has either gained or lost ten pounds on every hundred pounds of the price at which he bought that merchandize, which is $\frac{1}{10}$ of profit, or $\frac{1}{10}$ of loss, upon the total of the sale.

To gain 100 per Cent. (or Cent. per Cent.) in trade, is the doubling of one's capital: to lose 50 per Cent. is to lose one half of it.

Cent, is also used in the trade of money, and signifies the benefit, profit, or interest of any sum of money, which is laid out for improvement.

Thus we say, money is worth 4 or 5 per Cent. upon exchange; that is to say, it brings 4 or 5 pounds profit for every hundred pounds laid or lent out.

Cent, is also used with regard to the draughts, or remittances of money, made from one place to another. Thus we say, it will cost $2\frac{1}{2}$ per Cent. to remit money to such a city.

When we say that a broker, or exchange-agent, takes one-eighth per Cent. fee or perquisite, for the contracts or bargains that are made by his means and interposition, it is to be understood, that there is to be paid to him the eighth part brokerage of a pound, which is 2 s. 6 d. for every hundred pounds he caused to be negociated. The one eighth per Cent. is commonly paid by both the contracting parties; that is to say, by him who gives, and by him who receives, the money; so that the brokers have $\frac{1}{4}$ or $\frac{1}{4}$ per Cent. for every bargain, which amount to 5 s. or $\frac{1}{4}$ of a pound for every 100 l. and 2 l. 10 s. for every 1000 l.

CE'NTAURS, in mythology, a kind of fabulous monsters, half men, half horses.

The poets feign that the Centaurs were the sons of Ixion and a cloud. The reason of this fancy is, that the castle to which they retired was called νεφέλη, which signifies a cloud. This fable is differently interpreted: some will have the Centaurs to have been a body of shepherds and herdsmen, rich in cattle, who inhabited the mountains of Arcadia, and to whom is attributed the invention of bucolic poetry.

The Centaurs in reality were a tribe of Lapithæ, who inhabited the city Pelethronium, adjoining to mount Pelion, and first invented the art of breaking horses, as is intimated by Virgil.

CENTENI'NUM *Ovum*, among naturalists, denotes a sort of hen's egg, much smaller than ordinary, vulgarly called a cock's egg; from which it has been fabulously held that the cockatrice or basilisk was produced. *Brown, Vulg. Err.*

The name is taken from an opinion, that these are the last eggs which hens lay, having laid an hundred before; whence Centeninum, q. d. the hundredth egg.

M. La Peyronie has carried the history of the ova Centenina to a greater length, as well as certainty; a hen was brought to him which for a considerable time laid no other eggs: the same hen was also observed to crow like a cock, and to render by the cloaca a thin yellow matter, much like the yolk of an egg diluted in water. Upon opening her, she was found hydropical; a bladder as big as the fist, full of water, was found contiguous to the oviduct, which it pressed and crowd-ed ed in such a manner, as not to leave the cavity thereof above five lines in diameter; so that a common egg, such as it is when it falls from the ovary into the tube, could not pass without bursting, by which the yolk was let out, and discharged another way. *Mem. Acad. Scienc. An.* 1710.

CE'NTER (*Dict.*)— CENTER *of the equant*, in the old astronomy, a point in the line of the aphelion; being so far distant from the center of the excentric, towards the aphelion, as the sun is from the excentric towards the perihelion.

CE'NTERING *of an optic glass*, the grinding it so as that the thickest part is exactly in the middle.

Method of CENTERING *an object-glass.*— A circular object-glass is said to be truly centered, when the center of its circumference is situated in the axis of the glass; and to be ill centered, when the center of its circumference lies besides the axis. Thus let *d* (*Plate* XV. *fig.* 1.) be the center of the circumference of an object-glass *a b c*, and suppose *e* to be the point where its axis cuts its upper surface. If the points *d* and *e* do not coincide, the glass is ill centered. Let *a f g* be the greatest circle that can be described about the center *e*, and, by grinding away all the margin without this circle, the glass will become truly centered. Now, the center *e* which lies in the axis of the glass, may be found by several methods, but I prefer this that follows:

Let a couple of short cylindrical tubes be turned in wood or brass, and let the convexity of the narrower be so exactly fitted to the concavity of the wider as just to turn round in it with ease, but without waddling; and let the planes of the bases of the tubes be exactly perpendicular to their sides. Place the base of the narrower tube upon a smooth brass plate, or a wooden board of an equal thickness, and, with any sharp-pointed tool, describe a true circle upon the board round the outward circumference of the base: and upon the center of this circle, to be found when the tube is removed, describe a larger circle upon the board. These two circles should be so proportioned, that the one may be somewhat greater, and the other somewhat smaller, than any of the glasses intended to be centered by them. Then, having cleared out all the wood within the inner circle, put the end of the tube into this hole, and there fasten it with glew, so that the base of the tube may lie in the surface of the board: then having fixed the wider tube very firmly in a hole made in the window-shutter, and having darkened the room, lay the glass to be centered upon the board fixed to the narrower tube; and having placed the center of it, as near as you can guess, over the center of the hole, fix it to the board with two or three lumps of pitch, or soft cement, placed at its circumference. Then put the narrower tube into the wider as far as it can go, and fix up a smooth screen of white paper to receive the pictures of objects that lie before the window, and, when they appear distinct upon the screen, let the inner tube be turned round upon its axis, and, if the center of the glass happens to be in this axis, the picture will be perfectly at rest upon the screen; if not, every point of it will describe a circle. With a pencil mark the highest and lowest places of any one circle, described by some remarkable point in that part of the picture which appears most distinct; and, when this point of the picture is brought to the highest mark, stop the circular motion of the tube, and, keeping it in that position, depress the object-glass, till the point aforesaid falls exactly in the middle between the two marks. Then turn the tube round again, and the point of the picture will either rest there or will describe a much smaller circle than before, which must be reduced to a quiescent point by repeating the same operation. Then, I say, the center (of refraction) of the glass will lie in the axis of the tube, and, by consequence, will be equidistant from the circumference of the large circle described upon the board fixed to it. Now, to describe a circle upon the glass *f g b* (*fig.* 2.) about its center of refraction, let a long slender brass plate *a c b* be bent square at each end, as represented in the figure, leaving a piece in the middle equal in length to the diameter of the large circle *a d b e* that was described upon the board; and let the square ends of the plate be filed away, so as to leave a little round pin in the middle of each. Then having laid it over the glass, along any diameter of the large circle *a d b e*, make two holes in the board to receive the pins *a b*, and find the center of this circle upon the long plate; and with this center *c* describe as large a circle as you can, upon the glass underneath, with a diamond-pointed compass; and grind away all the margin as far as this circle *f i k*, in a deep tool for grinding eye-glasses; and then the glass will be truly centered. If the pitch or cement be too soft to keep the glass from slipping, while the circle is describing, it may be fixed firmer with wax or harder cement.

To shew the reason of this practice, (*fig.* 3.) represents a section of the object-glass *k l m*, of the board *a b*, and of the tubes *c d* and *b i*, and of the window-shutter *n o*. Imagine the plane of this section, or of the scheme, to pass through *e*, a point in the glass, which keeps its place, while the rest are turning round it, by the motion of the tube; let it also pass through *l* the center of refraction in the glass, and cut an object in the line P Q R; then let a pencil of rays flowing from any Q be collected to the focus *q*, upon the screen S T; and the points Q, *l*, *q*, will be in a straight line described by the axis, or principal ray, of the pencil. Draw Q *e f*, cutting the screen in *f*; and, while the tube is turning round, the line Q *l q* will describe a conical surface, whose axis is the fixed line Q *e f*; and, therefore, the focus *q*, or image of the point Q, will describe a circle *q g x* about *f*, to be found upon the screen by bisecting the interval *g x* between the highest and lowest points of the circle. Now, as *f* is the center of this circle, so *e* is the center of another circle described by *l*; and, therefore, by depressing the glass *k l* along the surface of the board *a b*, till the image *q* falls upon the mark *f*, the point *l* will be depressed to *e* the center of motion, and then it will be in the axis of the tube, and consequently equidistant from the circumference of the circle described upon the board *a b*; and here it is plain that the image *q* will be at rest in the point *f*.

It is not necessary to the accuracy of the practice, that the point Q should be in the axis of the glass. For if the glass *k l m* be turned about its axis Q L *q*, the image *f* of any collateral point Q will remain at rest; because the points Q *l* are at rest, and the axis Q *e f* of the oblique pencil is a straight line.

The chief advantage of having a glass well centered is this, that the rays coming through any given hole or aperture, whose center coincides with the axis of the glass, will form a distincter image, than if that center lay beside the axis; because the aberrations of the rays from the geometrical focus of the pencil are as the distances of their points of incidence from the center of refractions in the glass.

If the picture be received upon the unpolished side of a piece of plane glass, instead of the paper S T, its motions may be discerned more accurately by viewing it from behind through a convex eye-glass; as in a telescope where cross-hairs are usually strained over a hole put into the place of the rough glass. Therefore, as object-glasses are commonly included in cells that skrew upon the end of the tube, one may examine whether they be pretty well centered, by fixing the tube, and by observing, while the cell is unskrewed, whether the hairs keep fixed upon the same lines of an object.

CENTRI'FUGAL *Wheel*. See *Centrifugal* WHEEL.

CE'NTRO-BARYC *Method* (*Dict.*)— The doctrine is comprised in the following theorem, with its corollaries.

Every figure, whether superficial or solid, generated by the motion of a line or a figure, is equal to the factum of the generating magnitude into the way of its center of gravity, or the line which its center of gravity describes.

Demonst. For suppose the weight of the whole generating magnitude collected in the center of gravity; the whole weight, produced by its motion, will be equal to the factum of the weight moved, into the center of gravity. But, when lines and figures are considered like homogeneous heavy bodies, their weights are as their bulks: and, therefore, the weight moved is the generating magnitude; and the weight produced, that generated. The figure generated, therefore, is equal to the factum of the magnitude, into the way of its center of gravity. Q. E. D.

Corol. 1. Since a parallelogram A B C D (*Plate* XV. *fig.* 7.) is described, if the right line A B proceed according to the direction of another A C, with a motion still parallel to itself; and the way of the center of gravity E is equal to the right line E F, perpendicular to C D, that is, to the altitude of the parallelogram: its area is equal to the factum of the base C D, or the describent line, into the altitude E F. See PARALLELOGRAM in the Dict.

Corol. 2. In the same manner it appears, that the solidity of all bodies, described by a plane descending according to the direction of any right line A C, is had by multiplying the describing plane by the altitude. See PRISM, and CYLINDER in the Dict.

Corol. 3. Since a circle is described, if the radius C L (*fig.* 5.) revolve round a center C, and the center of gravity of the radius C L be in the middle F; the way of the center of gravity is a periphery of a circle X, described by a subduple radius: consequently the area of the circle is equal to the factum of the radius C L, into the periphery described by the subduple radius C F.

Corol. 4. If a rectangle A B C D (*fig.* 5.) revolve about its axis A D, the rectangle will describe a cylinder, and the side B C the superficies of a cylinder. But the center of gravity of the right line B C is in the middle F; and the center of gravity of the generating plane in the middle G, of the right line E F. The way of this latter, therefore, is the periphery of a circle described by the radius E G; that of the former, the periphery of a circle described by the radius E F. Wherefore, the superficies of the cylinder is the factum of the altitude B C, into the periphery of a circle described by the radius E F, or the base. And the solidity of the cylinder is the factum of the generating rectangle A B C D, into the periphery of a circle described by the radius E G, which is subduple of E F, or of the semidiameter of the cylinder.

Suppose *v. gr.* the altitude of the describing plane, and therefore of the cylinder B C $= a$; the semidiameter of the

base

baſe D C $= r$; then will E G $= \frac{1}{2} r$; and, ſuppoſing the ratio of the ſemidiameter to the periphery $= 1 : m$, the periphery deſcribed by the radius $\frac{1}{2} r = \frac{1}{2} m a r$. Therefore, multiplying $\frac{1}{2} m r$ by the area of the rectangle A C $= a r$; the ſolidity of the cylinder will be $= \frac{1}{2} m a r$. But $\frac{1}{2} m a r = \frac{1}{2} r . m r . a$ the area of the circle deſcribed by the radius D G. It is evident, therefore, the cylinder is equal to the factum of the baſe into the altitude.

Corol. 5. In like manner, ſince the center of gravity of the right line A B (*fig.* 8.) is in the middle M, and the ſurface of a cone is deſcribed, if the triangle A B C revolve about its axis; if P M $= \frac{1}{2}$ C; the ſuperficies of the cone will be equal to the factum of its ſide A B, into the periphery deſcribed by the radius P M, on the ſubduple of the ſemidiameter of the baſe B C.

Suppoſe, *v. gr.* B C $= r$, A B $= a$; the ratio of the radius to the periphery $1 : m$; then will P M $= \frac{1}{2} r$, and the periphery deſcribed by this radius $= \frac{1}{2} m r$. Therefore, multiplying $\frac{1}{2} m r$ into the ſide of the cone A B, the product is the ſuperficies of $\frac{1}{2} a m r$. But $\frac{1}{2} a m r$ is alſo the factum of $\frac{1}{2} a$ and $m r$: therefore, the ſurface of the cone is the product of the periphery, into half the ſide.

Corol. 6. If the triangle A C B (*fig.* 6.) revolve about an axis, it deſcribes a cone; but if C B be biſected in D, and the right line A D be drawn, and A O $= \frac{2}{3}$ A D; the center of gravity will be in O. The ſolidity of the cone, therefore, is equal to the factum of the triangle C A B, into the periphery deſcribed by the radius P O; but A D : A O :: B D : O P; and A O $= \frac{2}{3}$ A D, and D B $= \frac{1}{2}$ C B. Therefore, O P $= \frac{2}{3}$ D B $= \frac{1}{3}$ C B.

Suppoſe, *v. gr.* C B $= r$, A B $= a$; the ratio of the radius to the periphery $= 1 : m$. Then will O P $= \frac{1}{3} r$ the periphery deſcribed by this radius $\frac{1}{3} m r$; the triangle A C B $= \frac{1}{2} r$; and, therefore, the ſolidity of the cone $\frac{1}{3} m r \frac{1}{2} a r = \frac{1}{6} a m r^2$. But $\frac{1}{6} a m r^2 = \frac{1}{2} r . m r \frac{1}{3} a$. Or, the factum of the baſe of the cone into the third part of the altitude.

This elegant theorem, which may be ranked among the chief inventions in geometry of the laſt age, was taken notice of long ago by Pappus; but the jeſuit Guldinus was the firſt who ſet it in its full light, and exhibited its uſe in a variety of examples. Several other geometers, after Guldinus and Pappus, alſo uſed it in meaſuring ſolids, and ſurfaces generated by a rotation round a fixed axis, eſpecially before the late invention of the integral calculus: and it may ſtill take place in ſome caſes, where the integral calculus would be more difficult. M. Leibnitz has obſerved, that the method will hold, though the axis or center be continually changed during the generative motion.

CE'PITES, in natural hiſtory, a name uſed by the ancients to expreſs a gem, which gave the repreſentation of ſeveral cluſters of plants and flowers in the beds of a garden, with naked veins, expreſſing the walks between.

CERA'STES, *the horned ſnake*, in zoology, the name of a ſpecies of ſerpent, which has on its forehead two protuberances, looking like ſhells, but of a more ſolid texture, and, from their reſemblance of horns, have given it its name: theſe are often no larger than grains of barley: its teeth are like thoſe of the viper, and are placed in the ſame order: it is of the number of viviparous ſerpents, and is remarkable among the ſerpent claſs for its long enduring thirſt. It is found in Lybia and Arabia, particularly about the town of Suez.

CERA'SUS, *the cherry-tree*, in botany, the name of a genus of trees, the characters of which are theſe: the flower is of the roſaceous kind, or compoſed of ſeveral petals arranged in a circular form: the piſtil ariſes from the cup, and finally becomes a roundiſh or heart-faſhioned fleſhy fruit, containing a ſtone of the ſame ſhape with its kernel.

The ſeveral ſorts of cherry-trees are propagated by binding, or grafting the ſeveral kinds into ſtocks of the black or wild red cherries, which are ſtrong ſhooters, and of a longer duration than any of the garden kinds. The ſtones of theſe two kinds are ſown in a bed of light ſandy earth in autumn, and the young ſtocks produced from them are to remain where they riſe till the ſecond autumn after their ſowing, when, in October they ſhould be planted out into a rich earth, at three feet diſtance from row to row, and at about ten inches diſtance in the rows. The ſecond year after the planting-out, they will be fit to bud, if they are intended for dwarfs; but, if they are intended for ſtandards, they will not be tall enough till the fourth year, for they ſhould be budded or grafted near ſix feet from the ground. The grafting is uſually performed in ſummer, and the head of the ſtock is to be cut off in the beginning of the March following, about ſix inches above the bud; and if the bud has ſhot well, and there is any fear of its being diſplaced by the winds, it muſt be gently tied up to the part of the ſtock left above it. The autumn afterwards, theſe trees will be fit to remove, and be ſet where they are to remain; or they may be left two years. Many, when they plant theſe trees in their places, lop off a great part of their heads, but this is an injury that often kills them; and, when they eſcape, they ſeldom get well over it for four or five years. If the trees are intended for walls, it is adviſeable to plant dwarfs between the ſtandards, that theſe may cover the lower part of the wall, while the others ſpread over the upper part; and, when the dwarfs riſe to fill the whole walls, the ſtandards ſhould be taken entirely away. When theſe trees are taken up from the nurſery, the dead fibres of the roots muſt be carefully taken off, and the upper part of the ſtock which is above the bud, muſt be cut off cloſe down to the back part of it: the bud muſt be placed directly from the wall. Cherry-trees thrive beſt on a dry hazley loam, and in a gravelly ſoil are very ſubject to blights, and ſeldom ſtand long good. They ſhould be placed at fourteen feet aſunder, with a ſtandard tree between each two. In pruning theſe trees, their ſhoots ſhould never be ſhortened, for they moſtly produce their fruit from their extreme part. All the foreright ſhoots are to be diſplaced, and the others trained horizontally; and, where there is a vacancy in the wall, the branches, being ſhortened, will throw up a ſhoot or two to fill it. *Miller's Gard. Dict.*

CERATO'NIA, *the carob-tree*, commonly called St. John's bread, in botany, a genus of plants whoſe characters are: it hath male and female flowers on diſtinct plants: the male flowers have an empalement of one leaf, which is cut into five parts: the female flowers conſiſt of one leaf, having a ſingle ſtyle, which afterwards turns to a fleſhy hard pod, including kidney-ſhaped ſeeds; each being divided by an iſthmus, in the pod.

We have but one ſpecies of this plant; viz. 1. Ceratonia. H. L. The carob-tree or St. John's bread.

This tree is very common in Spain, and in ſome parts of Italy, as alſo in the Levant, where it grows in the hedges, and produces a great quantity of long flat brown-coloured pods, which are thick, mealy, and of a ſweetiſh taſte. Theſe pods are many times eaten by the poorer ſort of inhabitants, when they have a ſcarcity of other food: but they are apt to looſen the belly, and cauſe gripings of the bowels. Theſe pods are directed by the College of Phyſicians to enter ſome medicinal preparations; for which purpoſe they are often brought from abroad.

In England the tree is preſerved by ſuch as delight in exotic plants, as a curioſity: the leaves always continue green; and, being different in ſhape from moſt other plants, afford an agreeable variety, when intermixed with oranges, myrtles, &c. in the green-houſe.

Theſe plants are propagated from ſeeds, which, when brought over freſh in the pods, will grow very well, if they are ſown in the ſpring upon a moderate hot-bed; and, when the plants are come up, they ſhould be carefully tranſplanted, each into a ſeparate ſmall pot filled with light rich earth, and plunged into another moderate hot-bed; obſerving to water and ſhade them until they have taken root; after which you muſt let them have air in proportion to the heat of the weather. In June you muſt inure them to the open air by degrees, and in July they ſhould be removed out of the hot-bed, and placed in a warm ſituation, where they may remain until the beginning of October, when they ſhould be removed into the green-houſe, placing them where they may have free air in mild weather: for they are pretty hardy, and require only to be ſheltered from hard froſts. When the plants have remained in the pots three or four years, and have gotten ſtrength, ſome of them may be turned out of the pots in the ſpring, and planted into the full ground, in a warm ſituation, where they will endure the cold of our ordinary winters very well, but muſt have ſome ſhelter in very hard weather.

CERA'TUM *epuloticum*, a name given in the late London Diſpenſatory to the compoſition commonly called Turner's cerate, and there ordered to be made in this manner: take oil of olive, a pound; yellow wax and prepared calamy, of each half a pound; melt the wax in the oil, and, when the mixture begins to congeal again, ſprinkle in the powder, and continue ſtirring it till the whole is cold. *Pemberton's Lond. Diſpenſ.*

Ceratum *mercuriale*, a form of medicine preſcribed in the late London Pharmacopœia, and ordered to be made in the following manner: take yellow wax and purified hogs lard, of each half a pound; quickſilver, three ounces; ſimple balſam of ſulphur, a drachm: melt the wax and lard, and then add to them gradually the quickſilver, firſt well divided by the balſam of ſulphur. *Pemberton's Lond. Diſpenſ.*

CERAU'NIA, Ceraunias, or Ceraunius *lapis*, in natural hiſtory, a ſort of flinty figured ſtone, of no certain colour, but of a pyramidal or wedge-like figure; popularly ſuppoſed to fall from the clouds in thunder ſtorms, and to be poſſeſſed of divers notable virtues, as of promoting ſleep, preſerving from lightning, &c.

The generality of naturaliſts take the Ceraunia for a native ſtone, formed among pyrites, of a ſaline, concrete, mineral juice. Mercatus and Dr. Woodward aſſert it to be artificial, and to have been faſhioned thus by tools.

CE'RUSE (*Dict.*)— The manner of preparing Ceruſe in quantities at Venice is deſcribed by Sir Philip Vernatti. The plates for this purpoſe are large, and about the thickneſs of a knife's back, and rolled up, but ſo as that the ſurfaces no where touch. Each roll is put into a ſeveral pot, wherein it is upheld by a little bar from the bottom, that it may not touch the vinegar, which is alſo put into the pot, to effect the

the converſion. The pots are then covered with a plate of lead, as cloſe as may be, and over this with a board; after which they are let down into a bed of horſe-dung, big enough to contain four hundred pots. After three weeks continuance, the pots are taken up, the plates unrolled, laid on a board, and beaten with battledores, till all the flakes come off, which, when they prove good, are hard, thick, and weighty; when otherwiſe, porous and light, and ſometimes black, or burned, if the dung proves not well ordered: ſometimes alſo there will be no flakes, or Ceruſe at all. From the beating-table it is carried to the mill, ground with water between two ſtones, to an almoſt impalpable fineneſs. Laſtly, it is molded into ſmall parcels, and expoſed to the ſun to dry, and harden for uſe. *Vernatti in Phil. Tranſ. N.* 138.

Ceruse, *in the manufacture of China.* The Chineſe make Ceruſe of this preparation of lead, which it is eaſier to ſee the advantages of, than to comprehend the manner in which they are brought about. The China veſſels, when they have been baked, and finiſhed, as to the matter, and even covered with their varniſh, will yet receive, into their very ſubſtance, the colours which thoſe people mix up, with an addition of Ceruſe, and, as ſome of the old accounts ſay, of copperas and ſaltpetre; but, though theſe latter ingredients had uſed to be added, the Ceruſe alone ſupplies their place at this time, at leaſt in very many things. It would be worth while to try an admixture of Ceruſe with the colours uſed in painting on glaſs; and this, after a ſecond baking, might, perhaps, be found to incorporate itſelf in the ſame manner that it does into China-ware, and to recover the long loſt ſecret of letting in the ſtrongeſt colours, without hurting the tranſparence. *Obſerv. ſur les coutum. de l' Aſie.*

Ceruse *of antimony*, a preparation of the regulus of that mineral, powdered, mixed with ſpirit of nitre, and diſtilled in a retort, till no more fumes will riſe. What remains at the bottom, being pulverized, and waſhed ſweet, makes the Ceruſa antimonii, a medicine preſcribed as a diuretic, and by ſome reckoned equal to the mineral bezoar. Some prepare the Ceruſe by fuſing and fulminating the regulus with nitre in ſubſtance; the produce of which is a fixed powder, called the Ceruſe of antimony.

CE'RVUS *volans*, in natural hiſtory, a name given by authors to the ſtag-fly, or ſtag-horned beetle, a very large ſpecies of beetle with horns ſloped, and ſomewhat like thoſe of a ſtag.

CE'SARE, *in logic*, a mode of ſyllogiſms in the ſecond figure, wherein the major propoſition, and concluſion, are univerſal negatives, and the minor an univerſal affirmative. Such is, CE, No man who betrays his country, deſerves praiſe. SA, Every virtuous man merits praiſe. RE. Therefore, no man who betrays his country is virtuous. *Walch. Lex. Phil.*

CETA'CEOUS, in a proper ſenſe, denotes only thoſe large fiſh which are viviparous, or breed their young within their own bodies, and have no gills, but lungs, with which they breathe, like quadrupeds, having but one pair of fins, and giving ſuck to their young.

Theſe ſcarce differ in any thing from quadrupeds, except the want of feet. They have no air-bladder, but are enabled, by the air they receive into the lungs in reſpiration, to render their bodies equiponderant to water.

Cetaceous, in the ordinary uſe, is alſo extended to all larger fiſh, called by the Latins belluæ marinæ, or ſea-beaſts.

In which view, Cetaceous fiſhes are divided into greater, including the whole kind properly ſo called; and leſſer, to which belong the porpoiſe, ſhark, dog-fiſh, &c.

CE'TUS, *the whale*, in zoology. See the article WHALE.

CHAFERCONNEE'S, printed linens, manufactured in the grand Mogul's dominions. They are imported by the way of Surat. They are of the number of thoſe linens, the trade of which is prohibited in France.

CHA'FERY, in the iron works, the name of one of the two principal forges. The other is called the finery. When the iron has been wrought at the finery, into what is called an ancony, or ſquare maſs, hammered into a bar in its middle, but with its two ends rough, the buſineſs to be done at the Chafery is the reducing the whole to the ſame ſhape, by hammering down theſe rough ends to the ſhape of the middle part. *Ray's Engliſh Words.*

CHAIN, in mechanic arts, a ſeries of ſeveral rings, or links, fitted into one another.

Chain alſo denotes a kind of ſtring, of twiſted wire, ſerving to hang watches, tweezer-caſes, and other valuable toys, worn by the ladies, upon.

The invention of this piece of curious work is owing to the Engliſh; whence, in foreign countries, it is denominated the Engliſh Chain. It is but of very late years that foreigners have undertook to imitate them, and hitherto with no extraordinary ſucceſs: thoſe of Paris have come neareſt. Theſe Chains are uſually either of ſilver or gold, ſome of gilt copper; the thread, or wire, of each kind to be very fine.

For the fabric, or making of theſe Chains.—A part of the wire is folded into little links of an oval form; the longeſt diameter about three inches; the ſhorteſt one. Theſe, after they have been exactly ſoldered, are again folded into two; and then bound together, or interwove, by means of ſeveral other little threads of the ſame thickneſs; ſome whereof, which paſs from one end to the other, imitate the warp of a ſtuff; and the others, which paſs tranſverſe, the woof. There are at leaſt four thouſand little links in a Chain of four pendants; which are, by this means, bound ſo equally, and withal ſo firmly together, that the eye is deceived, and takes the whole to conſiſt of one entire piece.

Chain-*pump*. See PUMP.

Chain-*ſhot*, in war, two bullets, or rather half-bullets, linked together by a Chain: their uſe at ſea is to ſhoot down yards, or maſts; or to cut the ſhrouds, or any other rigging of a ſhip.

Chain-*wales*, in a ſhip, are the broad timbers which are made jetting out of her ſides, to which, with Chains, the ſhrouds are faſtened, and by them ſpread out, the better to ſecure the maſts.

CHALCE'DONY. See Calcedony, in the Dictionary.

CHALDE'AN *philoſophy*. It is no eaſy matter to give a juſt idea of the Chaldean philoſophy; the monuments which remain of it are much leſs ancient than the ſect itſelf: what we can gather from the Greeks ſeems but of ſmall authority, and will give us but little inſight; for the Greeks had a turn of genius quite different from the Orientals. They altered every thing they received from other nations, whom, with an air of contempt, they called barbarous. Another reaſon which ſhould make us doubtful in determining what were the real opinions of the Chaldeans, is this, that they kept the dogmas of their ſect a ſecret among themſelves; none were admitted to the knowledge of them, but privileged diſciples; they never publiſhed them but under the veil of allegories, or ſymbols. Thus we can only form conjectures from what the Greeks and Arabians have tranſmitted to us. Hence that diverſity of opinions among the learned on this head, who, inſtead of explaining, have rendered it more obſcure and myſterious. Witneſs a ſect of philoſophers which appeared in Aſia much about the time of our Saviour's birth. Theſe men, to give weight to their dreams and idle doctrines, reſolved to colour them with the air of great antiquity, and made them paſs under the name of Chaldean and Perſian, the precious remains of the doctrines of thoſe philoſophers. In conſequence of which, they forged a great number of works in the name of the famous Zoroaſter, who was then looked on in Aſia as the chief and maſter of all the Magi in Perſia and Chaldea. Many men of eminent learning, both ancient and modern, have taken a great deal of pains to diſcover who this Zoroaſter was, ſo much boaſted of in the Eaſt, but, after all their diſquiſitions, have been forced to acknowledge themſelves in the dark.

Other philoſophers, not leſs ignorant of the ſacred myſteries in the ancient doctrine of the Chaldeans, choſe to ſhare the honour of ſetting up a ſeparate ſect with the former. Theſe therefore reſolved to give Ægypt the honour of Zoroaſter's birth, and were as bold as their antagoniſts, in forging works which they attributed to Zoroaſter. As Pythagoras and Plato went into Ægypt to ſtudy the ſciences, which this nation was ſaid to have carried to a very great perfection, they imagined the ſyſtems of theſe two Greek philoſophers a faithful extract of the doctrine of Zoroaſter. This boldneſs of forging books on both ſides ſufficiently ſhews what credit we ought to give to theſe two ſects of philoſophers. The Chaldeans were in great reputation among the Babylonians. They were the prieſts of the nation, and diſcharged the ſame offices as the Magi among the Perſians, as to inſtructing the people in all religious matters, ceremonies, and ſacrifices: from whence the Greek hiſtorians have often confounded one with the other; and this is a mark of their little nicety, in not diſtinguiſhing as they ought between the ſtate of philoſophy among the ancient Babylonians, and the ſtate of philoſophy after the Babylonians became ſubject to the Perſians.

It may not be amiſs juſt to remark, that among all ancient nations, namely, the Aſſyrians, Perſians, Ægyptians, Æthiopians, Gauls, Britons, Germans, Scythians, Hetrurians, the prieſts were always looked upon as ſages and philoſophers. They were, in general, men of addreſs and cunning, who made religion ſerve the political views and intereſts of princes. The Chaldeans acknowledged a ſupreme Being, author of all things, who eſtabliſhed that beautiful harmony which connects the univerſe. Though they thought matter eternal and pre-exiſtent to the operation of God, yet they did not ſuppoſe the world eternal; for their coſmogony repreſents our earth as an opaque chaos, wherein all the elements were confuſedly blended together, before it received that order and arrangement which rendered it habitable. They ſuppoſed, that monſtrous animals, of various forms, were born in the womb of this rude chaos, and were ſubject to a woman named Omerca. That the God Belus cut her in two; of one half he made the heavens, of the other the earth, and that the death of this woman deſtroyed all the monſtrous animals before-mentioned; that Belus, after having formed the world, and produced the living creatures in it, cauſed his own head to be cut off; that men and animals were produced out of the earth; that other Gods dipped men in the blood which flowed from the wound of the God Belus; and that this was the reaſon why men were endowed with intellectual faculties, becauſe they had received a part of the deity.

The fragments of Beroſus, preſerved by Syncellus, obſerve, that this coſmogony is nothing but a myſterious allegory, by which the Chaldeans expreſſed the creation of the world. This allegory indicates, that man owes his creation and birth immediately to God, and that the ſupreme Being made uſe

 of

of another God, for the creation of the world. This opinion was univerfally received all over the Eaft. They thought it beneath the majefty of the fupreme God to prefide immediately over the world; that all-perfect, as he was, he confined his contemplations to his own perfections, not concerning himfelf about poor mortals, but left the care to inferior local and tutelary deities. In honour of thefe only, incenfe fmoaked, and the blood of victims flowed upon the altars. But befides the good genii, who delighted in doing good to mankind, they admitted alfo of evil genii; thefe laft they fuppofed to be formed of groffer matter than the firft, and that a continual war fubfifted between them; the firft proceeded from the good principle, the latter from the bad. Hence it appears, that the doctrine of the two principles firft rofe in Chaldea, from whence it was propagated to the Perfians, and prevailed univerfally, almoft, among the Orientals. This doctrine feems to owe its rife to the facred hiftory of the fall of the firft man; for, according to them, thefe dæmons affumed all fhapes, at pleafure, to delude thofe who liftened to them. Such were the myfteries in which the Chaldeans initiated a fmall number of adepts, who were to fucceed them, and hand the tradition down from one age to another.

The doctrine they taught in public, according to Herodotus and Diodorus Siculus, was, that the fun, moon, and ftars, efpecially the planets, were deities which muft be adored. The ftars, principally in veneration among them, were the figns of the zodiac, without taking any thing from the dignity of the fun and moon, which they looked on as primary deities. They called the fun Belus, the moon Nebo, or Nergal. The common people, born to be dupes to thofe who have wit enough to gain the afcendant over them, thought a deity refided in every ftar, and, confequently, that fo many Gods deferved their adoration. As to the fages and philofophers of the country, they contented themfelves with placing their genii, or deities of a lower clafs, in them, as directors of their different motions.

This principle once eftablifhed, it was not difficult for them to perfuade the people, that the ftars had a great influence on the happinefs or mifery of mankind; and hence fprung judicial aftrology, in which the Chaldeans had the reputation of excelling, infomuch that all eminent in this fcience were called Chaldeans. Thefe quacks, like our fortune-tellers, pretended to read in the ftars human deftinies and future events: but the reality of this fcience depended upon the credulity of the people; for what connection can there be between the regular motion of the ftars and the free events of the will? The eager curiofity of prying into futurity is a diftemper as ancient as the world, but has exercifed its dominion moft among the Orientals, who are conftitutionally of a warm imagination. It is incredible to what extravagance this has prevailed, by the cunning artifices of the priefts: judicial aftrology was the ftrongeft rein by which they always ruled the people of the Eaft. Sextus Empiricus declaims, with much ftrength and eloquence, againft this trifling art, fo baneful to the happinefs of mankind, by the evils it neceffarily produces. The Chaldeans, in fhort, ruled the people with a rod of iron, which their own fuperftition impofed on themfelves; for nothing could be done without confulting the augures and aftrologers. Notwithftanding the credulity of the people, the impofture of judicial aftrology was too grofs not to betray itfelf. Under the confulate of M. Popilius and Cneius Calpurnius, it was decreed, by an edict of the Prætor Cor. Hifpallus, that the Chaldeans fhould depart from Rome, and all Italy, within the fpace of ten days; and the reafon affigned by the edict was, that they abufed weak and credulous minds, by their pretended knowledge of the ftars. Alexander himfelf, who was at firft very much prejudiced in favour of the Chaldeans, defpifed them after Anaxarchus fhewed him the vanity of judicial aftrology.

Though aftronomy was in very great efteem among the Chaldeans, and they cultivated it very much, yet they do not feem to have made any confiderable progrefs in it. What aftronomers muft they have been, to fuppofe the eclipfes of the moon to have proceeded from her turning her opaque fide towards the earth; and that the other was always luminous of itfelf, independent of the fun? Where had they learned that the terreftrial globe fhould be confumed by fire, on a conjunction in the fign Cancer, and be drowned on a conjunction in the fign Capricorn? Yet the Chaldeans have paffed for great aftronomers. Pretences to antiquity have been the foible of all nations, and a thoufand abfurdities are owing to it. The Chaldeans, in the time of Alexander the Great, pretended, that aftronomy had flourifhed in Chaldea four hundred and feventy thoufand years; but this is not probable, and only exifted in the warm imaginations of the Chaldeans. Callifthenes, who accompanied Alexander in his military expeditions, fent the account of the obfervations he had found at Babylon to Ariftotle: thefe obfervations went no farther back than one thoufand nine hundred and three years; which, if they are fuppofed to begin at the four thoufand three hundred and eighty-third year of the Julian period, when Babylon was taken, will go no higher than the two thoufand four hundred and eightieth year of the fame period. This falls very fhort of the chronological fyftem of Mofes, according to the verfion of the Septuagint, carried back no farther than the flood. If the Chaldeans had made more ancient obfervations, how came Ptolemy, who was fo exact an aftronomer, not to mention them, and fpeak of none till the firft year of Merodach, king of Babylon, which falls on the twenty-feventh year of the æra of Nabonaffar? The pretended antiquity of the Chaldean obfervations no more deferve our credit, therefore, than Porphyrius, who builds upon them. Epigenius affirms the aftronomical obfervations, found on the baked bricks at Babylon, go no farther back than feven hundred and twenty years; and, as even this is too long a fpace of time to be juftified by hiftory, Berofus and Critodemus have fhortened it to four hundred and eighty years.

After this, who would not laugh to fee the Chaldeans gravely prefenting us with their aftronomical obfervations, in fupport of their antiquity, when their own authors give them the lye? They certainly, as Lactantius fays, thought, by going fo far back as four hundred and feventy thoufand years, to give a fort of fanction to their antiquity, which make it lefs fufpected; but, in this, they were miftaken; for all chronology, not fupported by facts, is not hiftorical, and, confequently, proves nothing in favour of the antiquity of a nation. When we once know the courfe of the ftars, we can forefee, from their regular motion, the conjunctions, oppofitions, &c. which fhall happen at any future time, and may, confequently, by calculation, find out thefe phænomena, in any time paft, of the fame date; but thefe calculations, and a fyftem of fuch obfervations, purely arbitrary in point of time, no more prove the world to have exifted from eternity, than that it fhall laft to eternity. Such is the cafe of the ancient Chaldeans, with regard to their obfervations of four hundred and feventy thoufand years: if a fucceffion of hiftorical facts were annexed to thefe obfervations, credit ought to be given to them; but, as no fuch appear, they are only to be looked on as the dreams of a calculator.

CHALK, *(Dict.)*—The hard, dry, and fine Chalk is much the propereft for burning into lime; but the foft, unctuous Chalk is greatly the beft for lands; becaufe it diffolves with froft and rain, in the manner of marl. This fort of Chalk, ufed inftead of marl, by way of a manure, is a very fine improvement for fome forts of land, efpecially the firft time it is laid on. It changes the very nature of the foil, and makes it rich, for a time; but it foon exhaufts itfelf, and requires dunging, to keep it in heart afterwards. A fecond chalking will prove of very little benefit to thofe lands, which fucceeded ever fo well with the firft, unlefs they have lain a long time to recover themfelves after it. It is from hence, that the farmers have their trite faying, that "Chalk makes a rich tenant, but a poor landlord."

The beft method, therefore, of ufing Chalk, is to mix one load of it with two loads of dung, or mud; this will make it not only a temporary, but a lafting advantage to the ground. It is the beft improvement for fowre and cold lands, and is obferved always to do moft good to thofe lands that lie fartheft off from any natural beds of it; the ground near Chalk-beds partaking of their nature, though there is no Chalk diftinguifhable by the eye. The common method of chalking lands is to lay twelve or fourteen loads of Chalk upon every acre, and this will fometimes make the land bring very rich crops, for fourteen or fifteen years together.

It is beft to carry the Chalk upon a lay a year or two before it is plowed up; by this means it will fweeten the furface of the earth, and will not work fo much downwards, as it will, if plowed up at firft. It makes corn yield well; and, when laid upon grafs ground, it makes the grafs fweet and rich, and cattle that feed upon it grow fat foon. The cows alfo that feed in thefe paftures, are obferved to give better milk than ordinary.

They have a very eafy way of digging Chalk in Kent. It lies on hills, and the workmen undermine it as far as they think proper; then digging a trench at the top, as far diftant from the edge as the undermining goes at bottom, they fill this with water, and that foaks through in the fpace of one night, and the whole flake falls down at once.

In other parts of the kingdom, Chalk generally lies deeper, and they are often forced to dig for it confiderable depths, and draw it up in bafkets; yet, in thefe places, it fells cheap enough at the mouth of the pit to be worth buying, even to carry a great way, for manure. *Mortimer's Hufbandry.*

Black CHALK, a name given by the painters to a fpecies of ochreous earth, with which they draw on blue paper, and other fubftances. It is very improperly called Chalk, being more of the nature of the Cologn earth, than any other known fubftance, but containing much lefs vegetable matter than that.

Red CHALK, an earth much ufed by painters and artificers, and common in the colour-fhops of London, and elfewhere. It is properly an indurated clayey ochre, and is dug in Germany, Italy, Spain, and France, but, in the greateft quantity, in Flanders. Its characters, by which it is diftinguifhed from other earth, are thefe: it is of a fine, even, and firm texture; very heavy, and very hard; of a pale red on the outfide, but, when broken, of a deep dufky chocolate colour within. It adheres firmly to the tongue, is perfectly infipid to the tafte, and makes no effervefcence with acids. *Hill's Hift. of Foff.*

CHALK-*land.* Barley and wheat will fucceed very well on the better fort of chalky land, and oats generally do very well on any kind of it.

The natural produce of this sort of land, in weeds, is that sort of small vetch, called the tine-tare, with poppies, may-weed, &c. Saintfoin and hop-clover will generally succeed tolerably well on these lands; and, where they are of the better sort, the great clover will do. The best manure for these lands is dung, old rags, and the sheep-dung left after folding them upon it. If rain happens to fall on these lands, just after sowing, the earth will bind so hard after it, that the shoots from the seed cannot pierce through it, and the greater part of the crop will be, by this means, lost. In Hertfordshire they manure their Chalk-lands with pigeons dung, ashes, and soot, and with some horse-dung: and, in Oxfordshire, they use no other manure, than half-rotten dung, with which they mix sand; and this, they say, prevents the earth from binding. They generally sow these lands there with wheat, meslin, and barley, only, after wheat, they sow pease and vetches; in the sowing of these, they are particularly forced to wait for fair weather, because of the land's binding. *Mortimer's Husbandry.*

CHALK-*stones*, in medicine, are used for the concretions of calcareous matter in the hands and feet of people violently afflicted with the gout.

CHA'MA, in natural history, the name of a large genus of bivalve shells, the characters of which are these: it is usually smooth, though in some places a little rugose, and has in some few a number of spines. The valves of the shell are equal, elate, and convex, and the mouth gaping, not closing fast, and even in all parts, as in the oister.

The fish, contained in this genus of shells, have all a hot taste, like that of pepper, and inflame the mouth in a troublesome manner. The French have hence called them flames and flammets, and, in some parts of the same nation, they are called lavignons and pelourdes.

CHAMÆME'LUM, *camomile*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the radiated kind; the disk is composed of floscules, and the outer edge of semi-floscules, all standing upon embryo seeds, and all inclosed in one common squamose cup. The embryos finally ripen into seeds, and are affixed to the thalamus of the flower. To this it is to be added, that the leaves are finely divided, and the whole face and appearance of the plant has something peculiar, which readily distinguishes it from the other plants with radiated flowers.

M. Tournefort has enumerated nineteen species of Chamæmelum.

The common camomile is digestive, laxative, and emollient; it mitigates pain, and promotes the menses and urine; the leaves dried are said to answer these purposes better than any other part of the plant; for all others, the flowers are used. These are given in infusion, as a gentle emetic, very large quantities of the infusion being drank warm. They are also used in emollient decoctions, and are a general ingredient in clysters. The people who furnish the apothecaries with them, usually sell the double flowers, but the single ones have greatly more virtue. It is very remarkable of the flowers of this plant, that, like those of the common yarrow, they yield by distillation a fine sky-blue oil.

CHAMÆPI'TYS, *ground-pine*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, and is of the one-lipped kind; this lip is divided into three segments; the middle of these is bifid, and there are small jags, supplying, in some sort, the place of an upper lip. The pistil arises from the bottom of the flower, and is surrounded by four embryos, which finally become four oblong seeds, and are contained in an open capsule, which was the cup of the flower. To this also it is to be added, that the flowers of the ground-pines grow scatteredly in the alæ of the leaves, and are not placed verticulately.

The species of ground-pine, enumerated by M. Tournefort, are five.

Champæpitys, or ground-pine, though highly extolled as an aperient, cephalic, and nervous medicine, is, however, little used, except as an ingredient of the theriaca, and some other officinal compositions.

CHAME'LEON. (*Dict.*)—The structure and motion of this creature's eyes are very surprising; they are very large, and set in large cavities, appearing to be large spheres, of which one half stands out of the head, and is covered with a thin skin, perforated with a small hole at the top, through which is seen a very vivid and bright pupil, surrounded with a yellow iris; the whole is properly a longitudinal slit, which the creature opens more or less wide at pleasure; and the eye seems fixed to this eye-lid, so as to follow all its motions, not turning round within it, as in other creatures. The motion of the eyes of this creature is not less singular than their structure, since it can turn them so as to see what passes either far backward, on either side, or directly behind it, without at all moving the head, which is fixed to the shoulders; and the creature can give one eye all these motions, while the other is perfectly still. The trunk of the body is properly all breast, for the creature has no belly, its ribs being continued to the ilia; the feet have all five toes, two behind, and three before, the hind-ones being as large as the others. This creature moves as slow as the tortoise, which appears very singular; its legs are sufficiently long, and it has no great weight of body to carry; but it is said, that on trees, in its wild state, it moves very nimbly. Its tail, when inflated, is round as that of a rat or snake; when empty, it is very lank, and has three longitudinal ridges running along it, which are owing to the apophyses of the spine. This tail is a great safety to the creature on trees, as it twists it round the branches, when in any danger of falling. The account given by the ancients, and later writers, of the long hollow tongue of the Chameleon, which it can dart with such celerity to take flies, by means of a spongy nodule at the end, is found, on experience of those who have kept the creature alive, to be true. Those among the former, therefore, who supposed the Chameleon lived on the air only, were greatly mistaken; some, of late, have also favoured this opinion, because of the long time the creature will live without food; but this is the case with all the serpent kind also, which yet we know will eat solid food, when they can get at it. *Ray's Syn. Quad.*

CHA'MOS, or CHAMOSH, the idol or god of the Moabites.

The name of Chamos comes from a root, which, in Arabic, signifies to make haste, for which reason many believe Chamos to be the sun, whose precipitate course might well procure it the name of swift or speedy. Others have confounded Chamos with the god Hammon, adored not only in Lybia and Egypt, but also in Arabia, Ethiopia, and the Indies. *Lucan. Pharsal.*

CHA'OS (*Dict.*)—The ancient philosophers understood by this term a confused mixture of particles of every kind without form or regularity, to which they supposed motion essential, and consequently attributed the formation of the universe to it. This system among them is the corollary of an excellent axiom in itself, Ex nihilo nihil fit: but this they generalize too much; instead of restraining this principle to effects, they extend it to the efficient cause, and look on the creation as a chimerical and contradictory notion.

The philosophers, poets, and priests of antiquity, among the Heathens, embraced this opinion. Chaos, according to them, was the most ancient of all beings: the eternal Being, the first principle and cradle of the universe. The Barbarians, Ægyptians, and Persians, agree in this notion: Aristophanes, Euripides, &c. the Ionic and Platonic philosophers, even the Stoics, set out with a Chaos, and look on the successive periods and resolutions of this Chaos, to have continued according to the laws of motion, till, by different combinations, it at last formed the universe in that order we at present see it.

Among the Romans Ennius, Varro, Ovid, Lucretius, Statius, &c. held the same opinion. This took its rise among the Barbarians by whom it was transmitted to the Greeks, from them descended to the Romans, and was propagated to other nations: so that it seems doubtful to determine whether this doctrine be more ancient than universal.

Though the first notion of a Chaos be very ancient, it is very difficult to determine, whom we ought to ascribe its origin to. Moses, the most ancient of all writers, in his history of the creation, describes the world before to have been an undigested heap, wherein all the elements were confused: and from hence, probably, the Barbarian and Greek philosophers borrowed the notion of their Chaos. Moses tells us, this mass was covered with water; and several of the ancient philosophers have asserted the Chaos was a mass of water, not elementary water nor ocean, but a kind of mud, the fermentation of which, in time, produced this world.

Cudworth, Grotius, Schmid, Dickinson, and others, confirm this assertion, by insisting on the analogy there is between what Moses relates of the Spirit of God moving upon the face of the waters, and the fondness of the mythologists to separate the Chaos: they add farther in support of this, that a very ancient opinion prevailed, both among the philosophers and mythologists, that there is a spirit in the waters, aqua per spiritum movetur: from whence they conclude, that the ancient philosophers originally had their opinion and notion of a Chaos from the works of Moses, which they afterwards altered to their own convenience or pleasure.

Whatever was the opinion of the ancients, concerning the Chaos and its origin, it is certain, Moses included all things in the womb of his Chaos: and that their separation, conducted by an Almighty hand, soon brought forth all this variety of creatures which embellish the universe. To imagine, after the example of some system-writers, that God at first produced only a vague and undetermined matter, out of which motion, by intestine fermentations and attractions, formed a sun, an earth, and all the ornaments of the universe: to suppose with Whiston, that the ancient Chaos was the atmosphere of a comet; that there is a conformity between the earth and comets, which demonstrates that a planet is nothing but a comet, which has acquired and assumed a regular and durable form, has placed itself at a proper distance from the sun, and turns round it in an orbit nearly circular; and that a comet is nothing but a planet which begins to destroy or form itself again, that is, a Chaos, which in its primordial state moves in an orbit very excentric: to support these and many other extravagancies which have been advanced, the enumeration of them would take up time impertinently, and be substituting opinions that want verisimilitude, in the room of those truths, which God has attested by the mouth of Moses. According to the sacred account, water was already made; then he tells us the Spirit of God moved upon the face of the waters, the

stars

ſtars of the heaven as well as our earth were already made, becauſe the heaven which contains them was already created. This philoſophy of Moſes, which repreſents eternal wiſdom regulating nature, by an expreſs will and command, proceeds on certain uniform and general laws, is undoubtedly more rational than any whimſical ſyſtems that have been propoſed by the ancient materialiſts, who form the world from a fortuitous concourſe of atoms; or ſome modern philoſophers who would account for the exiſtence of all beings, on the principle of homogeneous particles aſſembling themſelves together. Thoſe latter ſeem not to reflect, that by attributing the formation of all particular beings, the harmony, connection, and dependence apparent between them, to the impetus of a blind motion, they rob the Almighty of his greateſt glory, the fabric of the univerſe, in favour of a cauſe they are ignorant of, both with regard to itſelf, and the manner of its operation. This doctrine borders cloſely on the errors and abſurdities of Strato and Spinoza.

From what we have ſaid, the little certainty of philoſophy both in its principles and progreſs is obvious: it has aſſerted at one time that motion and matter only were neceſſary beings; if it has perſiſted in maintaining matter to be uncreated, yet it has ſubmitted that matter to the direction of an intelligent being, to make it aſſume a thouſand different forms, and diſpoſe its parts in that fitneſs and order which was neceſſary to produce the univerſe. The preſent opinion is, that matter was created, and that God gave it motion; that this motion, firſt impreſſed by the hand of God, is ſufficient of itſelf to produce all the phænomena we obſerve in the viſible world. A philoſopher who ſhould be hardy enough to explain the mechaniſm, and even the firſt formation of things, barely by the laws of motion, and ſay, Give me matter and motion, and I will make a world, ought firſt to demonſtrate, that exiſtence and motion are not eſſential to matter; for, without this precaution, this philoſopher, ſeeing nothing in the wonderful works which nature has produced, but what motion only might have effected, will be apt to fall into atheiſm.

Let us open our eyes then on the dangerous enthuſiaſm of forming ſyſtems, and believe with Moſes, that, when God created matter, the heaven and the earth out of nothing, he determined, by ſo many particular acts of his will, all the different materials, which, in the courſe of the following operations, ſerved for the formation of the world. In the laſt five days of the creation, God only diſpoſed every being in the place he had diſtined for it, to form the ſplendid picture of the univerſe. That before the fiat was a confuſed maſs, and the ſcene of the world opened, as the almighty voice of its Creator ranged the different beings in that wonderful order which conſtitutes its preſent beauty.

Far from being of opinion, that this notion of a Chaos was particular to Moſes, all nations, barbarous or civilized, ſeem to have preſerved one common tradition of a ſtate of darkneſs and confuſion prior to the creation of the world; and it is probable they imbibed this notion from the ſame common ſource, notwithſtanding the ignorance of the people, and the fictions of the poets, have ſo much diſguiſed it.

CHA'PPE, in heraldry, the partition of an eſcutcheon, by lines drawn from the center of the upper edge to the three angles below, as repreſented in *plate* XXV. *fig.* 6. in the Dictionary.

CHARGE *(Dict.)*—The common allowance for the charge of powder of a piece of ordnance is half the weight of the ball. In the Britiſh navy, the allowance for thirty-two pounders is but ſeven ſixteenths of the weight of the bullet. But a late author is of opinion, that, if the powder in all ſhip cannon whatever was reduced to one third of the weight of the ball, or even leſs, it would be of conſiderable advantage, not only by ſaving ammunition, but by keeping the guns cooler and quieter, and at the ſame time more effectually injuring the veſſels of the enemy. With the preſent allowance of powder, the guns are heated, and their tackle and furniture ſtrained, and this only to render the bullets leſs efficacious. For a bullet which can but juſt paſs through a piece of timber, and loſes almoſt all its motion thereby, has a much better chance of rending and fracturing it, than, if it paſſes through with a much greater velocity. Vid. *Robins, Propoſ. for Increaſing the Strength of the Britiſh Navy.*

CHA'RLOCK, *rapiſtrum*, in huſbandry, a very troubleſome weed among corn, being more frequent than almoſt any other. There are two principal kinds of it; the one with a yellow flower, the other with a white. Some fields are particularly ſubject to be over-run with it, eſpecially thoſe which have been manured with cow-dung alone, that being a manure very favourable to the growth of it. The farmers in ſome places are ſo ſenſible of this, that they always mix horſe-dung with their cow-dung, when they uſe it for arable land.

When barley, as is often the caſe, is infeſted with this weed to ſuch a degree as to endanger the crop, it is a very good method to mow down the Charlock in May, when it is in flower, cutting it ſo low as juſt to take off the tops of the leaves of the barley with it: by this means the barley will get up above the weed; and people have got four quarters of grain from an acre of ſuch land, as would have yielded them ſcarce any thing without this expedient. Where any land is particularly ſubject to this weed, the beſt method is to ſow it with graſs ſeed, and make a paſture of it; for then this plant will not be troubleſome, it never growing where there is a coat of graſs upon the ground. *Mortimer's Huſbandry.*

CHA'RRE, an Engliſh name for a fiſh of the truttaceous kind, of which there are two ſpecies, diſtinguiſhed by the red Charre, and the gilt Charre; the former of which is called by the ichthyographiſts umbla minor, and the latter, the carpio lacus Benaci.

Red CHARRE, called by the Welſh torgoch, is a large fiſh, longer and ſlenderer in its general ſhape than the trout. The back is of a duſky yellow colour, and is ſpotted with obſcurely white ſpots: the belly is not carried to an edge, but is about a finger broad: this, in moſt of theſe fiſhes, is of an elegant red, ſometimes deeper, and ſometimes paler; but in ſome, particularly in the female, it is white. The ſcales are very ſmall, and the ſide lines running from the gills to the tail are perfectly ſtraight; the belly fins are red: the opening of the mouth is wide, and the jaws are nearly of the ſame length, the lower being only a very little longer than the other and more pointed: the teeth are ſmall and ſharp. It is caught in the lakes of Wales, and eſteemed a very fine fiſh; but its fleſh does not boil ſo red as that of the trout. *Willoughby, Hiſt. Piſc.*

Gilt CHARRE, is ſomething like the trout in figure, but it is broader, and its belly is prominent, eſpecially when the fiſh is large: the uſual ſize is about a foot in length, which it rarely exceeds. The ſcales are very ſmall, and the back is variegated with black ſpots. Its belly and the lower parts of its ſides are of a fine bright ſilver colour: the ſkull is pellucid, and the noſe bluiſh. This is very common in ſome of the lakes of Italy, but is not peculiar to that kingdom, as has by ſome been imagined, being frequent in ſome foreign, and in ſome of the northern lakes; and there is no doubt, but that the fiſh there caught, and called the gilt Charre, and the carpio lacus Benaci, are intirely the ſame fiſh. It is a very finely-flavoured fiſh, and much valued at great tables. *Willoughby, Hiſt. Piſc.*

CHA'TELET *of Paris*, the ſupreme court of judicature in Paris, the metropolis of France. Cauſes tried there are final, unleſs in ſome caſes where an appeal may be made to the parliament.

Juſtice is adminiſtered in this court by a provoſt (whoſe office in the Chatelet is of much more authority than in any other part of the kingdom) in whoſe name all acts of this court are diſpatched, two deputies for civil and criminal cauſes, two private deputies, fifty-ſix counſellors, one king's advocate and ſollicitor.

CHEEKS, a general name, among mechanics, for almoſt all thoſe pieces of their machines and inſtruments, that are double and perfectly alike.

The CHEEKS *of a printing-preſs*, are its two principal pieces: they are placed perpendicular, and parallel to each other; ſerving to ſuſtain the three ſommers, viz. the head, ſhelves, and winter, which bear the ſpindle, and other parts of the machine.

The CHEEKS *of a lathe*, are two long pieces of wood, between which are placed the puppets, which are either pointed, or otherwiſe; ſerving to ſupport the work, and the mandrils of the workman. Theſe two pieces are placed parallel to the horizon, ſeparated from one another by the thickneſs of the tail of the puppets, and joined with tenons to two other pieces of wood, placed perpendicularly, called the legs of the lathe. See LATHE.

CHEEKS *of the glaſier's vice*, are two pieces of iron, joined parallel at top and bottom; in which are the ais, or ſpindles, little wheel, cuſhions, &c. whereof the machine is compoſed.

CHEEKS, in ſhip-building, are two pieces of timber, fitted on each ſide of the maſt, at the top, ſerving to ſtrengthen the maſts there. The uppermoſt bail or piece of timber in the beak of a ſhip, is called the Cheek. The knees which faſten the beak-head to the bow of the ſhip, are called Cheeks; and the ſides of any block, or the ſides of the ſhip's carriage of a gun, are called Cheeks.

CHEEKS *of a mortar*, or *brackets*, in artillery, are made of ſtrong planks of wood, bound with thick plates of iron, and are fixed to the bed by four bolts; they riſe on each ſide of the mortar, and ſerve to keep her at what elevation is given her, by the help of ſtrong bolts of iron which go through both Cheeks, both under and behind the mortar, betwixt which are driven coins of wood; theſe bolts are called the bracket bolts, and the bolts which are put one in each end of the bed, are the traverſe bolts, becauſe with hand-ſpikes the mortar is by theſe traverſed to the right or left.

CHEKA'O, in natural hiſtory, the name of an earth found in many parts of the Eaſt-Indies, and ſometimes uſed by the Chineſe in their porcelain manufactures. It is a hard and ſtony earth, and the manner of uſing it is this: they firſt calcine it in an open furnace, and then beat it to a fine powder. This powder they mix with large quantities of water, and, ſtirring the whole together, they let the coarſer part ſubſide, and pouring off the reſt, yet thick as cream, they leave it to ſettle, and uſe the matter at the bottom, which is found in form of a ſoft paſte, and will retain that humidity a long time. This ſupplies the place of the earth called hoache, in the making that elegant ſort of China ware which is all white, and has flowers which ſeem formed by a mere vapour within its ſurface. The manner of their uſing it is this: they firſt make the

the veſſel of the common matter of the manufacture; when this is almoſt dry, they paint upon it the flowers, or whatever other figures they pleaſe, with a pencil dipped in this preparation of the Chekao; when this is thoroughly dry, they cover the whole veſſel with the varniſh, in the common way, and bake it as uſual. The conſequence is, that the whole is white, but, the body of the veſſel, the figures, and the varniſh being three different ſubſtances, each has its own particular white, and the flowers, being painted in the fineſt white of all, are diſtinctly ſeen through the varniſh upon the veſſel, and ſeem as if traced by a fine vapour only. The hoache does this as well as the Chekao, and has beſide this the quality of ſerving for the making the porcelain ware, either alone, or in the place of the kaolin: the Chekao has not this property, nor any other ſubſtance beſides this hoache, which appears to be the ſame with our ſteatetes or ſoap-rock. *Obſervat. ſur les Coutumes de l'Aſie.*

CHELIDO'NIUM, *celandine*, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts of four leaves, which are diſpoſed in form of a croſs: the piſtil ariſes from the cup of the flower, and finally becomes a unicapſular pod, containing roundiſh ſeeds.

The ſpecies of celandine enumerated by M. Tournefort are four; and by Mr. Miller three.

Bocconi has very ſtrongly recommended this plant as ſpecific in the cure of conſumptions: he propoſes the taking it in infuſion, or drinking its juice, and ſays enough in its praiſe to recommend it at leaſt to a fair trial, which would be eaſily made in a country where conſumptions are ſo common. *Boccon. de Plant.*

CHE'MISTRY (*Dict.*)—Rules to be obſerved in the practice of chemiſtry.

Let the firſt rule be, with care and diligence, to obſerve the proceſs uſed by nature, in the production of all thoſe things we would endeavour to imitate; for nature, as a moſt expert chemiſt, employs the very inſtruments which men alſo employ, viz. fire, water, air, and earth.

To illuſtrate this rule by an example; it appears, by numerous inſtances, that there is an acid or ſaline liquor naturally contained in the bowels of the earth; which acid, there mixing with various kinds of earthy matters, as a menſtruum, changes their natures, or makes them appear under different forms. Hence, common brimſtone, allum, the native vitriol, &c. ſeem to have their origin.

For by an exact ſcrutiny, and attentive conſideration, it appears, that, when this general acid diſſolves a certain bituminous earth, it makes brimſtone; when a chalky earth, allum; when iron or copper, vitriol, &c. And accordingly, by uſing the ſame kind of general acid (which may be procured by burning brimſtone under a glaſs-bell) in the ſame manner as nature ſeems to employ it, we can likewiſe, by art produce brimſtone, allum, or vitriol, when and where we pleaſe. And thus, if we could univerſally diſcover the proceſs and inſtruments which nature employs in the production of her effects, we ſhould have certain rules for imitating her.

Our ſecond rule is, to gain a habit of transferring, diverſifying, enlarging, and in proving an experiment, till it ends in ſome certain diſcovery, either of light to the underſtanding, or of uſe in life; one of which points all juſt experiments will end in, when duly proſecuted, and judiciouſly weighed and conſidered.

For unſucceſsful experiments are no leſs inſtructing than thoſe that ſucceed, which ought to be well remarked. The head muſt in all caſes co-operate with the hands: ſo that the mind ſhould be ever caſting about to diſcover the cauſe of failure, as well as of ſucceſs. This is a ſagacity which may be procured by uſe, and turned into a habit of invention and diſcovery: ſo that no ſingle experiment ſhall be performed, but ſome advantages will be immediately derived from it; nor no experiment be made, without ſome ſolid grounds of hope for ſucceſs.

The third rule to make this art turn to advantage, with regard to the improvement of any branch of trade that we may have in view, is, to proſecute experiments in an orderly ſeries; and to let the inquiry ſuit the genius and temper of the enquirer, ſo that it may be proſecuted by him with vigour and pleaſure. This hath been the practice of the greateſt maſters in this art.

Thus, if any one ſhould be averſe to fire and furnace, he may ſtill improve chemiſtry and arts, or perform many ſerviceable chemical operations, without much apparatus or expence, or without the utenſils and inſtruments commonly employed in that art: which may therefore be as conveniently practiſed within a ſtudy or a parlour, as in a laboratory. For there are many chemical enquiries, that may be proſecuted without the uſe of fires and furnaces: and even ſuch diſpoſitions as are more delighted with ſpeculation than practice, may greatly contribute to the improvement of chemiſtry, by ſorting, ranging, and digeſting experiments into tables; ſhewing what they prove, and how far they reach; how far they fall ſhort, and how they may be carried farther: others might, to advantage, employ themſelves upon drawing things of uſe in life, from the experiments already known and publiſhed: and, laſtly, others might, from a due conſideration of experiments, deduce new directions and rules of practice, for producing, in a ſure and

conſtant manner, much greater effects than are uſually hoped for. *Shaw's Lect.*

Commercial CHEMISTRY, is uſed to denote the application both of technical and philoſophical Chemiſtry, to the eſtabliſhing, ſupporting, or improving any branch of trade or commerce. *Shaw's Lectures.*

Oeconomical CHEMISTRY, the application of philoſophical, technical, or commercial Chemiſtry, to the ſervice and accommodation of the affairs of a family. *Shaw's Lectures.*

Philoſophical CHEMISTRY. Philoſophical Chemiſtry conſiſts of three parts, viz. invention, rationale, and experiment; whence we may define it to be a particular exerciſe of the rational and inventive faculties of the mind, leading to experiments, and thence to the diſcovery of cauſes, ſo as to form axioms that ſhall rationally account for phænomena, and diſcover rules of practice for producing uſeful effects. And thus philoſophical Chemiſtry is not only the key to all the other parts, but it diſcovers of itſelf the cauſes of many natural phænomena, as, particularly, earthquakes, volcanoes, vegetation, the growth of minerals, and the like.

This branch of Chemiſtry alſo explains the general forms and qualities of bodies, whereon their properties and effects depend; as volatility and fixedneſs, fluidity and firmneſs, colours, taſtes, odours, efferveſcences, fermentation, ſolution, precipitation, congelation, extraction, and the like.

To this part of Chemiſtry it alſo belongs to bring new inventions to the teſt, to diſcover their validity or inſufficiency. Thus when any hint is ſtarted for a new trade, or method invented for the improvement of an old one, before any attempt is made to ſupply it in the larger way, it ſhould be experimented in miniature; as the aſſay maſter tells the owner of an ore, whether it will be worth the erecting large works for it, or not. *Shaw's Lectures.*

Technical CHEMISTRY. By Technical Chemiſtry is meant the application of philoſophical Chemiſtry to the immediate ſervice of arts, ſo as by its means to invent, form, aſſiſt, promote, or perfect them in the large way of buſineſs. *Shaw's Lectures.*

CHE'RRY-*tree*. See CERASUS.

CHERT, in natural hiſtory, a name given by ſome of our miners to a peculiar fine kind of ſtone found in ſtrata, but of the hardneſs and ſmoothneſs of flint. It is called alſo in ſome places whern, and by ſome authors nicomia.

CHE'RVIL, *chærephyllum*, in botany, the name of a genus of umbelliferous plants, the characters of which are theſe: the flower is of the roſaceous kind, compoſed of ſeveral leaves irregular in ſize, and diſpoſed in a circular form on a cup, which afterwards becomes a fruit compoſed of two ſeeds, reſembling the beak of a bird, not ſtriated, but ſometimes rough, ſometimes ſmooth, and gibboſe on one ſide, and flat on the other.

The common garden Chervil flowers in May or June. Its leaves and ſeeds are uſed in medicine; the ſeed contains the principal virtue of the plant, and is eſteemed a great medicine in jaundices and dropſies. It is very certain that it is a very powerful diuretic, and a promoter of the menſes. It reſolves coagulated blood, and generally diſpoſes the perſon to ſleep. It is uſed alſo externally in fomentation, in cholicky pains and retention of urine.

The leaves of this plant are what the good women call ſweet fern, from which they diſtil a water, and eſteem it a very great remedy for cholicks.

CHE'SNUT-*tree*, See CASTANEA.

CHEVRE'TTE, in artillery, an engine to raiſe guns or mortars into their carriages; it is made of two pieces of wood of about four feet long, ſtanding upright upon a third, which is ſquare; they are about a foot aſunder and parallel, and are pierced with holes exactly oppoſite to one another, having a bolt of iron, which, being put through theſe holes, higher or lower at pleaſure, ſerves with a hand-ſpike, which takes its poiſe over this bolt, to raiſe any thing by force. *Guill. Gent. Dict.*

CHE'WING-*balls*, a ſort of balls contrived for horſes to chew, not ſwallow at once; not intended as a food, but as incentives to appetite, and on other medicinal occaſions very uſeful to the creature. The receipt now moſt eſteemed for theſe balls is this: take liver of antimony, and of aſſafœtida, of each one pound; wood of the bay-tree, and juniper-wood, of each half a pound; pellitory of Spain, two ounces: let all theſe be powdered together; then add as much fine grape verjuice as is neceſſary to make the whole into a paſte. This is to be formed into balls of about an ounce and an half in weight, which are to be dried in the ſun. Theſe are the Chewing-balls, and theſe are to be uſed one at a time in the following manner: the ball is to be wrapped up in a linen rag, and a thread is to be faſtened to this, in ſuch manner that it may be tied to the bit of the bridle, and kept in the mouth: when the bridle is taken off, the horſe will immediately eat, and, when one ball is conſumed, another is to be tied up, and put in its place, till the intent is anſwered.

CHIN-COUGH. In the Chin-cough, Dr. Huxham uſes the common evacuations, and propoſes to correct the lentor of the blood, and to ſtrengthen the nerves and ſtomach by mercurials,

curials, the cortex, and proper ſtomachics. *Obſ. de Aere & Morb. Epid.*

Dr. Burton declares againſt bleeding, vomiting, and purging in the Chin-cough, except in very urgent caſes; the medicine which he ſays has had great ſucceſs, is a ſcruple of fine powder of cantharides, and as much camphor, mixed with three drachms of the extract of jeſuits bark. Of this mixture he gives eight or nine grains to children every third or fourth hour, in a ſpoonful of ſome ſimple water, or ſome julep, in which a little balſam of capivi had been diſſolved. He ſays this method is not proper in ſuch Chin-coughs as proceed from thin ſharp rheum, but he believes, that, in the Chin-cough from a tough viſcid phlegm, it will ſcarce ever fail, at leaſt it has not failed yet. *Med. Eſſ. Edinb.*

CHINESE *Philoſophy.* The Chineſe are univerſally owned to have ſurpaſſed all other nations of India, in their antiquity, learning, politeneſs, the improvement of the ſciences, a taſte for philoſophy, and their political principles. And, according to ſome eminent authors, they may diſpute the pre-eminence, in theſe particulars, even with the politeſt nations in Europe.

If credit be given to theſe authors, the Chineſe had philoſophers in the firſt ages of the world. A plan of ſublime morality was current among them ſoon after the flood. Iſaac Voſſius, Spezelius, and a crowd of miſſionary jeſuits, who have travelled into China to propagate Chriſtianity, have given us this account of them: others, as Budæus, Thomaſius, &c. ſpeak leſs favourably of the Chineſe. The only method therefore of coming at the real truth is to take a ſhort review of the writings aſcribed to them; but unhappily it is a matter of doubt whether theſe are authentic, and the exactneſs of the tranſlation is very much diſputed.

The collection publiſhed at Paris in 1687, by the fathers Intorcetta, Hendric, Rougemont, and Couplet, preſents us with the Ta-hio or Scientia magna; a work of Confucius, publiſhed by his diſciple Cemcu. The Chineſe philoſopher in this work propoſes to teach princes the art of governing well; which he makes to conſiſt in that of knowing and acquiring all the qualities neceſſary for a ſovereign; ſuch as to command himſelf, to know how to form his council and court, and bring up his family in a proper manner.

The ſecond work in this collection is intitled Chumyum, or, de Mediocritate in rebus omnibus tenenda, the golden mean; but contains nothing more than may be met with in Seneca's Morals.

The third is a collection of dialogues and apophthegms concerning vices, virtues, moral duties, and good behaviour, intitled Lun-yu. At the concluſion of this article we ſhall give our readers the moſt ſtriking of theſe apophthegms, which are indeed the only valuable part of this book of Confucius.

The learned editors promiſed the public the works of Mencius, a Chineſe philoſopher, which Francis Noel, a miſſionary of the ſame company, performed in 1711, by publiſhing ſix Chineſe claſſics, in which are contained ſome fragments of Mencius. We ſhall not enter into the diſputes which theſe collections have raiſed among the literati, with regard to their authenticity.

The Chineſe chronology and philoſophy are not very conſiſtent. Fohi, the founder of the empire of China, reigned, according to them, in the 2954th year before Chriſt. The Chineſe cycle begins in the 2647th year before Chriſt, the eighth year of the reign of Hoangti. Hoangti's predeceſſors were Fohi who reigned 140 years, and Xinung who reigned 110 years. But, to follow the ſyſtem of Petavius, the birth of our Saviour falls in the year of the world 3889, the deluge in 1656; from whence it follows that Fohi reigned ſome ages before the flood: ſo that we muſt either give up the chronology of the ſacred writings, or that of the Chineſe. Neither a Chriſtian, nor a ſenſible European, will heſitate a moment which to prefer, when he reads in the Chineſe hiſtory, that Fohi's mother was impregnated by the rainbow, and a thouſand other ſuch extravagant ſtories, which make the epoch of his reign uncertain, notwithſtanding the unanimous teſtimony of a nation.

In whatever age Fohi reigned, he ſeems to have been rather an Orpheus or Hermes, than a great philoſopher or learned divine. For they tell us he invented the alphabet, two inſtruments of muſic, one of twenty-ſeven, the other of thirty-ſix ſtrings. They aſſert the book Ye-kim, attributed to him, contained the moſt profound ſecrets; that he taught the people, whom he had civilized, the exiſtence of a God, and the manner in which he ought to be worſhipped.

This Ye-kim is the third of the U-kim, or collection of the moſt ancient writings among the Chineſe: it is compoſed of whole lines and hemiſtichs, or rather lines ſtopped at different lengths, the combination of which exhibits ſixty-four different figures. The Chineſe looked on theſe as an emblematic hiſtory of nature, the cauſes of its phænomena, the ſecrets of divination, and of many other ſublime ſciences, till Leibnitz decyphered the ænigma, and demonſtrated that Fohi's two lines were only the elements of binary arithmetic.

The emperor Fohi tranſmitted his philoſophy to his ſucceſſors. They applied themſelves to improve what he had begun, to civilize the manners of the people, and accuſtom them to the uſeful bonds of ſociety. Xin-num went a ſtep farther; he taught agriculture, the virtues of plants, and the firſt attempts in the art of medicine. It is uncertain whether the Chineſe at that time were idolaters, atheiſts, or deiſts. Thoſe who pretend to prove they admitted the exiſtence of a God, from the ſacrifice Ching-tang made in the time of a famine, ſeem to want ſufficient grounds for the ſupport of their aſſertion.

The philoſophy of the kings of China ſeems to have been for a long time intirely political and moral, if we may form a judgment from the maxims of their kings Yao, Xum, and Yua. This collection is intitled U-kim, the firſt book of which, called Xu-kim, contains theſe maxims. The ſecond book, called Xy-kim, is a collection of moral poems and odes. The third is Fohi's lineary work already mentioned. The fourth is the Chum-cieu, or ſpring and autumn. This is an hiſtorical abridgment of the lives of ſeveral of their princes, wherein their vices are not concealed. The fifth is the Li-ki, which is a kind of ritual, to which was joined an explanation of what ought to be obſerved in ceremonies, profane and ſacred, and the duty of man in all ſtations of life, under the reign of the three imperial houſes, Hia, Xam, and Cheu. Confucius boaſted that he drew from the writings of the antient kings, Yao and Xum, the moſt ſublime ſcience and greateſt wiſdom.

The U-kim is the moſt ſacred, authentic, and moſt reſpected literary hiſtory in China. We may look on the reigns of their kings who were philoſophers, as the firſt age of the Chineſe philoſophy. The ſecond age which we are now entering upon, begins with Rooſi, or Li-lao-kiun, and ends with the death of Mencius. China had many philoſophers of note, long before the time of Confucius. Particular mention is made of Rooſi, Li-lao-kiun, or Lao-tan, who was born 346 years after Xekia, or 504 before Chriſt, at Sokoki in the province of Soo. They tell you he was an adept in the knowledge of the gods, of ſpirits, the immortality of ſouls, &c. Till this period the philoſophy of the Chineſe was only moral. But now metaphyſics, a number of ſects, and various opinions ſtarted up.

Confucius ſeems not to have greatly cultivated this philoſophy, but held that of the firſt kings in higher eſteem. He was born 451 years before Chriſt, at the village of Ceu-ye, in the kingdom of Xantung. His family was illuſtrious, and, according to the Chineſe, his birth miraculous, for they tell us that celeſtial muſic was heard round his cradle; that two dragons gave him pap; that at ſix years of age he arrived at the ſtature of manhood and gravity of old age. At the age of fifteen he applied himſelf to the ſtudy of literature and philoſophy. He was married at twenty, and his merit raiſed him to the higheſt preferment; but the luxury of a voluptuous and debauched court was diſagreeable to him, and he to the court. Being diſmiſſed from his employment, he retired into the kingdom of Sum, where he opened a ſchool of moral philoſophy, and had many diſciples, who were men of ability, and honeſt citizens. His philoſophy conſiſted more in deeds than words, in actions than expreſſions. His diſciples reverenced him when alive, regretted him when dead, and held him in ſo great veneration, that they inſtituted a kind of ſacrifices to his memory.

It is very difficult to determine whether Confucius was the Anaxagoras or Socrates of China, as the anſwer to this queſtion depends on a great knowledge of the language; but it is plain from the account we have given of his principal works, that he applied himſelf more to the ſtudy of humanity and morality than to the ſtudy of nature and its cauſes.

Mencius appeared in the next age. We ſpeak of this philoſopher next, becauſe Rooſi, among the Japaneſe, is the ſame with Li-lao-kiun among the Chineſe, whom we have mentioned before. Mencius has the reputation of having been ſuperior to Confucius in ſubtilty and eloquence; but at the ſame time is owned to be much his inferior, with regard to moral rectitude and ſimplicity of heart. All kinds of literature and philoſophy were almoſt extinguiſhed by Xi-hoam-ti who reigned about three ages after Confucius. This prince who was jealous of the glory of his predeceſſors, an enemy to men of learning, and an oppreſſor of his ſubjects, cauſed all the writings he could collect to be burned, except thoſe wrote on agriculture, medicine, and magic. Four hundred and ſixty ſages, who had retired to the mountains, with what part of their libraries they could carry along with them, were taken and expired in the flames, with the books they had preſerved: near as many who were confined in an iſland by the orders of this prince, fearing the ſame fate, choſe to throw themſelves from precipices into the ſea. The ſtudy of literature was prohibited by ſevere penalties, and the books that remained were diſregarded, and not looked into, till the princes of the race of Han ſet about the revival of learning, when it was with difficulty they recovered ſome of the works of Confucius and Mencius. They found a copy of Confucius buried in the ruins of a wall, but this copy was half rotten; and it is from this mutilated copy that his works now extant are taken.

The revival of learning may ſerve for a date of the third period of the antient Chineſe philoſophy.

The ſect of Foc then ſpread all over China, and, with it, idolatry,

dolatry, atheism, and superstition of all kinds; so that it is uncertain whether the ignorance, into which the brutality of Xi-hoam-ti had plunged these people, was not preferable to the false doctrines they were now infected with.

Three centuries after the birth of Christ, a sect prevailed throughout the empire of China, who imagined themselves more perfect by being inactive, and thought they resembled the aerial beings more, by their inert philosophy. These, as much as in them lay, forbad the natural use of the senses. But this sect grew into disrepute on the appearance of the Fan-chin. These Epicureans appeared in the fifth century, and maintained that virtue, vice, providence, immortality, &c. were only arbitrary terms, without a meaning. This philosophy is unhappily too palatable not to be received by the bulk of mankind, and is so much the more dangerous, as it becomes more universal.

The middle age of the Chinese philosophy commences about the tenth or eleventh century, under the two philosophers Cheu-cu and Chim-ci. These according to some were polytheists; according to others atheists. The sect of literati immediately followed those of Cheu-cu and Chim-ci. This sect, under the name of Ju-kiao, divides the whole empire with the sects Foe-kiao and Lao-kiao, which are in truth no other than three different combinations of superstition, idolatry, polytheism, and atheism.

At length the Europeans carried our sciences into the East; and this event is the epocha of the modern philosophy among the Chinese. The singular esteem with which they honoured the first Europeans who travelled into China, gives us no very high idea of their skill in mechanics, astronomy, and other parts of the mathematics. These Europeans were not men of any distinguished merit, but such whom zeal carried thither, to propagate the Christian religion at the hazard of their lives, in unknown regions, which indeed befel some of their successors. They were well received by the Chinese; superstition, apt to take offence and be alarmed, gave them no opposition; they opened schools, had many disciples, and their learning was admired. The emperor Cham-hy about the end of the last century admitted them at court, learned our philosophy and sciences of them, studied mathematics, anatomy, astronomy, mechanics, &c. but his son Yong-Tching banished all the virtuosi of Europe to Canton and Macao, except those which resided in Pekin, who continued there. Kien-Long the son of Yong-Tching was a little more indulgent to them; he however forbad the Christian religion, and even persecuted his soldiers who had embraced it; but permitted the jesuits to continue their instructions at Pekin.

We shall now give some account of the Chinese ethics; these depend, among them, on the study of what Confucius has wrote on this subject; we cannot therefore give a clearer idea of their morality than by exhibiting some of his maxims.

1st. Political ethics have two principal objects, the cultivation of the mind and the government of the people.

2d. The former requires the understanding to be adorned with all knowledge, to enable it to distinguish good from evil, truth from falsehood; to moderate the passions, to strengthen the love of truth and virtue in our hearts, to behave ourselves with decency and honesty towards other men.

3d. The latter object of ethics requires the citizen to know how to conduct himself, govern his family, and fill his own station of life properly.

4th. He merits the title of a philosopher, who has a profound knowledge of things and books, who weighs every thing wisely, submits to reason, and goes on boldly in the paths of truth and justice.

5th. When the intellectual faculty is brought to such a degree of perfection as to dive into the nature of things, the intentions and will purify themselves, bad affections depart from the soul, the body is preserved in health, domestic affairs are well managed, every duty of life discharged, private government is well administered, the empire well regulated, and enjoys peace.

6th. What has man from heaven? An intelligent nature, a conformity to which constitutes a rule of actions. The wise man exercises himself in keeping up to this rule.

7th. There is an unerring reason or celestial rectitude given to all; there is an human supplement to this gift, when it is lost. The celestial rectitude is in possession of the saint, the supplement is attained by the philosopher.

8th. There is only one principle of moral conduct, which is, to behave in all things with sincerity; to conform, with all our souls and all our strength, to this universal maxim, Do as you would be done unto.

9th. A man is known by examining his actions, considering their end, the passions in which he indulges himself, and the things with which he contents himself.

10th. We should immediately publish all things of universal benefit and utility; to conceal any part, to make any reserve is to despise virtue and drive her from us.

11th. Let the disciple learn the reasons of things, let him examine them, meditate on them, reason concerning them, consult the wise and learned, inform himself, banish confusion from his thoughts, and irregularity from his conduct.

12th. Virtue is not only constant in external appearances.

13th. Virtue, regardless of the partiality on earth, has not a thought which may not be avowed in the open face of heaven.

14th. We must not apply ourselves to virtue, but to be virtuous.

15th. The perfect man always keeps sight of himself.

16th. There are three degrees of wisdom, to know what virtue is, to love and to possess it.

17th. Uprightness of heart is the foundation of virtue.

18th. There are five rules to be observed for the conduct of the universe: justice between the prince and subject, affection between father and child, fidelity between man and wife, subordination among brothers, agreement between friends. There are three cardinal virtues, prudence to discern, universal benevolence which binds, and fortitude supports the whole. Uprightness of heart implies these.

19th. The motives of the mind are unknown to others; be wise therefore, and be particularly careful about those things which are known to yourself only.

20th. Virtue is placed between two extremes; he that has past the middle point, has done no better than he that has never attained it.

21st. One thing alone is valuable, that is, virtue.

22d. A nation is more powerful by virtue, than water and fire. I have never seen a people perish who have taken that for their support.

23d. Example is more necessary than precept for the people.

24th. A wise man is his own most severe censor, his own witness, accuser, and judge.

25th. To conquer ourselves, and recover the ancient and primary state of celestial rectitude, is to attain innocence and perfection.

26th. Slothful indolence and precipitate rashness are equally enemies to success.

27th. The upright man takes no by-path, but keeps on in the high road.

28th. The honest man is a citizen of the world.

29th. Charity is a certain and rational affection which sacrifices us to mankind, as if it made but one individual with us, and associated us to the adversity and prosperity of the whole human race.

30th. The honest man only has a right to love and hate.

31st. Repay injuries with aversion, and benefits with acknowledgment; for this is justice.

32d. To fall and not to rise again is properly to abandon virtue.

33d. It is a species of trouble of mind to wish to others what is not in our power to give them.

34th. The upright man acts according to his station, and covets nothing out of his reach.

35th. He who studies wisdom has nine visible qualities, clearness of eye, fineness of ear, serenity of countenance, gravity in deportment of body, veracity of intention, punctuality in performance, counsel in doubtful matters, consideration of consequences in vengeance and anger.

The morality of Confucius is vastly superior to his physics or metaphysics. We shall conclude this article with two or three remarks that may not perhaps be disagreeable to our readers.

Though the antiquity of the Chinese falls greatly short of their pretensions, yet the date of their empire certainly takes place soon after the flood; but, the greater antiquity we allow them, the more reason we shall have to reproach them with the little improvement they have made in their language and writings. It is inconceivable that a people to whom so much wit and sagacity is in general attributed, should have multiplied accents instead of words, and characters ad infinitum, instead of combining a small number of them to form a language. We have heard of no poets or orators among them; their dramatical performances are extremely imperfect, they contain all the actions of the person's life represented from the cradle to the grave, and the performance takes up several months. It is no wonder indeed they have neither had poets nor orators; for their language is neither capable of poetry nor eloquence.

CHIPPING, a phrase used by potters and China-men to express that common accident both of our own stone and earthen ware, and the porcelain of China, the flying off of small pieces, or breaking at the edges. Our earthen wares are particularly subject to this, and are always spoiled by it, before any other flaws appear in them. Our stone wares escape it better than these, but less than the porcelain of China, which is less subject to it than any other manufacture in the world. The method by which the Chinese defend their ware from this accident, is this: they carefully burn some small bambou canes to a sort of charcoal, which is very light, and very black; this they reduce to a fine powder, and then mix it into a thin paste, with some of the varnish which they use for their ware: they next take the vessels, when dried, and not yet baked, to the wheel, and, turning them softly round, they, with a pencil dipped in this paste, cover the whole circumference with a thin coat of it: after this, the vessel is again dried, and the border made with this paste appears of a pale greyish colour, when it is thoroughly dry. They work on it afterwards in the common way, covering both this edge and the rest of the vessel with the common varnish. When the whole is baked on, the colour given by the ashes disappears,

pears, and the edges are as white as any other part; only, when the baking has not been sufficient, or the edges have not been covered with the second varnishing, we sometimes find a dusky edge, as in some of the ordinary thick tea cups.

It may be a great advantage to our English manufactures to attempt something of this kind. The willow is known to make a very light and black charcoal, but the elder, though a thing seldom used, greatly exceeds it. The young green shoots of this shrub, which are almost all pith, make the lightest and blackest of all charcoal; this easily mixes with any liquid, and might be easily used in the same way that the Chinese use the bambou charcoal, which is a light hollow vegetable, more resembling the elder shoots than any other English plant. It is no wonder that the fixed salt and oil, contained in this charcoal, should be able to penetrate the yet raw edges of the ware, and to give them in the subsequent baking a somewhat different degree of vitrification from the other parts of the vessel, which, though, if given to the whole, it might take off from the true semi-vitrified state of that ware, yet at the edges it is not to be regarded, and only serves to defend them from common accidents, and to keep them entire.

The Chinese use two cautions in this application; the first in the preparation; the second in the laying it on. They prepare the bambou-cane for burning into charcoal, by peeling off the rind. This might easily be done with our elder shoots, which are so succulent, that the bark strips off with a touch. The Chinese say, that, if this is not done with their bambou, the edges touched with the paste would burst in the baking: this does not seem indeed very probable; but the charcoal will certainly be lighter made from the peeled sticks, and this is a known advantage. The other caution is, never to touch the vessel with hands that have any greasy or fatty substance about them; for, if this is done, they always find the vessel crack in that place. *Obs. sur les Cout. de l' Asie.*

CHIRU'RGERY (*Dict.*)—Chirurgery is divided into speculative and practical; the latter executes what the former directs. The theory of Surgery, as it is commonly called, should be distinguished into general and particular. The general theory of Chirurgery is the theory or science of medicine itself: the theory is inseparable; one part cannot be known thoroughly, or applied without knowing both. The only difference between medicine and Chirurgery seems to be with regard to their different objects, and the different classes of maladies in which each is employed. Chirurgery comprehends every science which teaches the art of healing, but applies them only in external cases. Medicine also requires this science equally, but has for its more immediate object internal cases; so that the science is the same; the application, not the science, making the difference.

By considering the objects of both these arts, their connection is very visible, and their theory the same. External disorders, the object of Chirurgery, are essentially the same, as internal maladies, the object of medicine; they differ only in their situation: they are of equal importance, offer the same indications, and equally require a cure.

Though the theory of medicine and Chirurgery be the same, yet we must distinguish between the physician and surgeon. A man acquainted only with the general theory in these arts will be neither the one nor the other. A physician, besides the knowledge of pharmacy, must have skill to apply the rules of his science to the cure of internal diseases; a surgeon, by practice, must acquire a readiness and ease in performing operations, and apply the same rules of science to the cure of external disorders.

Bare science, or knowledge alone, does not enable us to apply its rules, it only dictates them: practice only teaches to apply them properly, and that practice too under a master: study gives knowledge, but we cannot arrive at the art of applying that knowledge we have attained by study without experience; we gain readiness by often seeing the same objects, and custom only enables us to acquire a facility.

Anatomy, physiology, pathology, the doctrine symptoms, and the knowledge of the animal oeconomy, are in Chirurgery, as well as physic, the principia of universal knowledge. Anatomy displays the structure of the organs which compose the human body. Physiology explains their actions, mechanism, and uses. By this we know the human body in a state of health. Pathology teaches the nature and causes of diseases. The doctrine of symptoms acquaints us with the signs and complications of distempers, the particular indicia of which the surgeon ought to attend to. The knowledge of the animal oeconomy indicates a proper regimen with regard to air, diet, the passions of the mind, evacuation, exercise, rest. Therapeutics teach the surgeon the different methods of cure, to know the nature and property of his medicines, and in what manner they act.

All this kind of knowledge, however necessary, is yet insufficient; though it be the basis of physic and Chirurgery, yet it has not an essential connection with them; though these studies are the best preparations to initiate any one in these arts, ingenious men may chuse to improve their minds with a knowledge of anatomy, without ever attaining the art of physic or Chirurgery.

Beside the general praecognoscenda we have been speaking of, the surgeon must acquire the particular talent of manual operation; this can only be attained by a long course of practice and observation. He must first know what cases require an operation, the best manner of performing it, the difficulties which arise from the structure of the parts, and the proper remedies to be applied; he must also know the animal oeconomy, and attend to every motion of nature; for, without these precautions, a surgeon will make a blind operator, and be more apt to kill than cure.

To form the complete surgeon, something more is still wanted; operation which generally strikes the vulgar, is but one part of the cure in diseases which come within the sphere of Chirurgery; the accidents which may attend it, the various treatment these accidents may require, are all essential objects of Chirurgery. Let us suppose, for example, a fracture accompanied with a dangerous contusion; the reduction of the fracture, though often very difficult, is but a small part in the treatment of this disorder; the inflammation, gangrene, abscesses, suppurations, excessive discharges, fever, delirium, and convulsions, which frequently follow in such cases, require a more extensive knowledge than is necessary to reduce the bone; a small degree of knowledge, joined to practice and address, may perform the simple operation, but the accidents which may attend fractures are not to be cured or prevented, without understanding the animal oeconomy, the nature of the fluids and juices, and how medicines are to operate upon them. This can only be acquired by experience, the best source of certain knowledge after a due study of the theory.

Royal academy of CHIRURGERY.—This academy was first established at Paris, in the year 1731, and confirmed afterwards by letters patent, in 1748. It is under the direction of the secretary of the king's houshold, like other establishments of this kind: their meetings are held in the hall of the college of St. Come, every Thursday. On the Thursday after Low Sunday they annually have a public meeting, at which they declare what memoir has merited the prize left by the late M. de la Peyronie. This prize is a golden medal, value five hundred livres. The impression struck on this medal is the bust of Lewis the Well-beloved.

CHORD (*Dict.*) — To find the number of vibrations made by a musical Chord or string, in a given time, its weight, length, and tension being given. Let N represent the weight of the Chord; L its length; P the tension, or weight equivalent to it, by which the Chord is extended; and D the length of a given pendulum; p the circumference of a circle, the diameter of which is 1; then will the number of vibrations made by the given Chord, while the pendulum vibrates once, be expressed by $p \sqrt{\frac{DPa}{LN}}$. If we take L for the number of inches and decimals contained in the length of the Chord, and the proportion of the tension to the weight of the Chord, as n to 1, then will the number of vibrations of the Chord in one second be $\frac{355}{113} \sqrt{\frac{39.2n}{L}}$. Where $\frac{355}{113}$ denotes the proportion of the circumference to the diameter of the circle; and 39. 2 the length of a pendulum vibrating seconds, in inches and decimals of an inch, English measure. This last expression coincides with Mr. Euler's rule, only we here expressed in English what he gives in Rhinland measure. To illustrate this rule by an example; suppose the length of the Chord to be 18. 7 inches, its weight 6 $\frac{1}{5}$ grains, and the tension or weight extending this Chord to be 8 *lb* troy, or 46080 grains. Then $a =$ 18. 7, and $n = \frac{46080}{6.2} = 7432$. The number of vibrations therefore by the rule will be $\frac{355}{113} \sqrt{\frac{39.2 \times 7432}{18.7}} = 392$.

By logarithms, the rule may be thus expressed $\frac{L + W}{2} + C = V$. When L is the logarithm of the ratio of a pendulum, vibrating seconds, to the length of the given string; W the logarithm of the ratio of the tension to the weight of the string; C the logarithm of the ratio of the circumference of a circle to its diameter, or 0,4971500; and, lastly, V = logarithm of the required number of vibrations in one second.

In every Chord, the number of vibrations in a given time will be as $\sqrt{\frac{n}{a}}$, that is, as the square root of the extending weight, divided by the weight of the Chord, and its length. If therefore Chords be of the same length, their vibrations in a given time will be as the square roots of the extending weights, divided by the weight of the Chords. If Chords be equal in length and weight, their vibrations will be as the square roots of their extending weights or tensions; and if the tension be equal, and the Chords differ only in length, their vibrations will be as the square roots of their lengths, multiplied by their weight: that is, reciprocally as the lengths of the Chords, because the weights of the Chords will in this case be proportional to their length. *Euler.*

Mr. Euler informs us, that he found the Chord, making 392 vibrations

vibrations in a second, to beat unison with the key called *a* in instruments, that is, an octave and sixth major above the lowest C, being to *a* as 3 to 10, will make 118 vibrations in one second. And the highest C, or *c'''*, as Mr. Euler calls it, being four octaves above the lowest *c*, will vibrate 1888 times in one second of time. Mr. Euler supposes the limits of a human ear to be, with respect to gravity, two octaves lower than C; and, with respect to acuteness, two octaves higher than *c'''*.

CHOREʹGRAPHY, the art of writing down dances, like tunes, in characters and demonstrative figures.

This is an art which the ancients were ignorant of, or at least has never been transmitted to us. No author has mentioned it that we know of, before Furetiere, who in his Dictionary tells us of a curious treatise, wrote by Thoinet Arbeau, printed at Langres in 1588, intitled Orchesography. Arbeau was in all probability the first who thought of representing dances by characters, but he carried this art to no great perfection; he has however a just claim to the honour of having been the inventor of it. His method was to write down the tune on ruled paper, as usual, and over every bar to write in words what kind of step and figure was to be observed, throughout the whole tune. He never thought of describing the figure by lines, and dividing those lines into equal parts, corresponding to the measure, the time and notes, in every kind of time; or of expressing every different movement by a distinct character, and placing these characters over every division, corresponding to the lines of the figure, which has been done since with great exactness and perspicuity.

CHRIʹSTIANS *(Dict.)*—It has been the opinion of several, that the name Christian was derived originally from the Greek chrestos, good, useful: and Suetonius, speaking of Claudius, and of his expelling the Jews out of Rome, says that he banished them thence, because they were continually quarrelling about Christ: Judæos, impulsore Chresto, assidue tumultuantes Romà expulit. Tertullian says, the name Christian comes from the unction received by Jesus Christ; and that of Chrestianus, given by mistake, signifies that gentleness and benignity, whereof the Christians make profession.

When Christianity was first planted in the world, those who embraced it, were known among themselves by the names of disciples, believers, elect, saints, and brethren; nor did they assume the name of Christians, till the year of Christ 43, at Antioch, where St. Paul and Barnabas jointly preached the Christian religion. This was the name they afterwards so much gloried in, that, before the face of their enemies, they would acknowledge no other title, though hated, reviled, tormented, and martyred for it. Eusebius records a memorable story of one Sanctus, a deacon of the church of Vienna, who, being put to the rack, and examined by the magistrates, concerning his name, his country, his city, and his quality, made answer, I am a Christian; which, he said, was to him both name, and city, and kindred; nor could his persecutors extort any other answer from him.

The primitive Christians were known by several denominations. Epiphanius says, they were called Jesseans, either from Jesse, the father of David, or, which is more probable, from the name of Jesus, whose disciples they were. Eusebius says, they were likewise stiled Therapeutæ, i. e. worshippers of the true God, or spiritual physicians; and St. Jerom confirms it. And, because the Christian life took its original from the waters of baptism, because they were regenerated, or born again into Christ's religion, by water, the Christians were wont to please themselves with the name pisciculi. Sometimes the Christians stiled themselves Gnostics, i. e. men of understanding and knowledge; which name being afterwards abused by a perverse sort of heretics, they added the title of Christian to it, and gave themselves the title of Christian Gnostics. Another name which frequently occurs in the writings of the ancients, is that of Theophori, i. e. temples of God, and is as old as Ignatius. We sometimes meet with the name Christophori, used in the same sense. It is very observable, that the Christians, in all the names they chose, had a particular regard to Christ and God, abhorring all party names, and human appellations; insomuch that Epiphanius says, "The church was never called so much as by the name of any apostle: we never heard of Petrians, or Paulians, or Bartholomæans, but only Christians, from Christ." The Christians likewise took the name of catholic. The heathens used to confound the names of Jews and Christians together, often giving the name of Jews to Christians. Thus Dio, in the Life of Domitian, speaking of Acilius Glabrio, a man of consular dignity, says, he was accused of atheism, and put to death for turning to the Jews religion; which, as Baronius and others observe, must mean the Christian religion, because he was a martyr to it.

The Christians had also many names of reproach cast upon them by their enemies; such as Nazarenes, Galileans, Greeks, Impostors, Atheists, &c. which last name was common, upon account of their deriding the worship of the heathen gods. The reason why they called them Greeks was this; because many of the Christian philosophers wore the Grecian pallium, or cloak; and the Romans, taking offence to see them quit the Roman gown for that habit, took occasion from thence to deride them with the name of Greeks. The heathens also declaimed against the Christians, as magicians and sorcerers, because Christ and his disciples worked many miracles. St. Austin says, it was generally believed among the heathens, that our Saviour wrote some books of magic, which he delivered to Peter and Paul, for the use of his disciples. The new, the wicked, and unreasonable superstition, the barbarous, the new, and strange religion, were other names of reproach they call upon the Christian religion. These, with many other suchlike, may shew the inveteracy and malice of the heathens against the Christians.

The Jews were the first and most inveterate enemies the Christians had. They put them to death as often as they had it in their power; and, when they revolted against the Romans, in the time of the emperor Adrian, the most rigorous punishments were employed against them, to compel them to blaspheme and renounce Jesus Christ. And we find, that, even in the third century, they endeavoured to get into their hands Christian women, in order to scourge and stone them in their synagogues; where they cursed them solemnly, three times a day; and their rabbins would not suffer them to converse with Christians, upon any occasion: nor were they contented to hate and detest them, but they dispatched emissaries all over the world, to defame the Christians, and spread all sorts of calumnies against them. They accused them, among other things, of worshipping the sun, and the head of an ass. They reproached them with idleness, and being an useless race of people. They charged them with treason, and endeavouring to erect a new monarchy against that of the Romans. They affirmed, that, in celebrating their mysteries, they used to kill a child, and eat its flesh. They accused them of the most shocking incests, of impudence, avarice, and sometimes of prodigality, and of intemperance in their feasts of charity. But the lives and conduct of the first Christians were sufficient to refute all that was said against them, and evidently demonstrated, that these calumnies were merely the effect of the most inveterate hatred and malice.

We will now take a short view of the ten grand persecutions of the Christians.

The first who raised a general persecution against the Christians, was the emperor Nero, of whom Tertullian tells the Gentiles, and, for the confirmation thereof, appeals to their public records: "We glory, says he, in such an author of our persecution: any body who knows him, may understand, that nothing but what is eminently good, could be condemned by Nero." He was a prince of such brutish and extravagant manners, that their own writers scruple not to call him a brute in human shape; the very monster of mankind. He wanted, says Eusebius, this to be added to his other titles, to be called the first emperor who persecuted the Christian religion. He published laws for suppressing it, and put to death those who professed it; as appears by an inscription found in Spain, for he seems to have carried his persecution even to that country. This persecution continued a full year, even that after the burning of Rome, A. D. 66.

The second persecution was began by Domitian, a man eat up with pride and insolence; nay, so wickedly ambitious was he, as to affect divinity in all his public edicts, assuming to himself, and requiring others to give him the titles of Lord and God. This persecution began in the ninety-second year of the Christian æra, 26 years after that by Nero; and continued to Domitian's death, which happened about 3 years after.

The third persecution commenced under Trajan, a prince of excellent virtues, but sullied by his severe proceedings against the Christians. He looked upon the religion of the empire as undermined by this new way of worship; that the number of Christians grew formidable, and might endanger the tranquillity of the Roman state; and that there was no better way to secure himself the favour of the Gods, especially in the wars, than to vindicate himself against the Christians. Accordingly he issued out orders to proceed against them as illegal societies, erected and acting contrary to the laws. This persecution is placed by Eusebius, and by many after him, in the tenth year of Trajan, and the one hundred and eighth of the Christian æra; though Spanhemius thinks it began five years sooner.

The fourth persecution was set on foot by Hadrian, successor of Trajan. We do not find, indeed, that this emperor made any laws against the Christians, but only continued those of his predecessors. As to the duration of this persecution, Spanhemius reckons it commenced in the second year of Hadrian's reign, and was stopped in the tenth, which is A. D. vulg. 126.

The fifth persecution was in the reign of M. Aurelius Antoninus Philosophus. He ascribed the Christians resolute undergoing death to mere stubbornness and obstinacy; and accordingly made new laws and edicts against them, exposing them to all the malice of their enemies. The persecution commenced in the eastern parts, about the seventh year of his reign, A. D. 167, and continued for several years. It spread into the west, especially France, where it raged with great severity; and many received the crown of martyrdom. But the emperor at length greatly mitigated this severity, on account of a wonderful deliverance from his enemies, procured by the prayers of the Christians.

The sixth persecution was raised by Septimus Severus, who began to reign A. D. 195. The edicts which this prince gave out against the Christians, were executed with so much rigour and

and inhumanity, that they verily believed the time of antichrist was then come.

The seventh persecution was began by Maximinus, a man of base and obscure original, and of a mean and sordid education; having been first a shepherd, then a highwayman, and lastly a soldier. This persecution is placed A. D. 237.

The eighth persecution was raised by Decius, who was an implacable enemy to the Christians. This persecution was began A. D. 250; and, though it did not last two years, yet proved the hottest of any that had hitherto oppressed the church. The Christians were every-where driven from their houses, spoiled of their estates, and tormented in their bodies. Whips and prisons, fire and wild beasts, scalding pitch and melted wax, sharp stakes and burning pincers, were but some of the methods of their treatment; when the old ones were run over, new ones were daily invented. The laws of nature and humanity were broken down; friend betrayed friend, and the son his own father: every one was ambitious to promote the imperial edicts, and thought it meritorious to bring a Christian to the stake.

The ninth persecution commenced in the reign of Valerian, A. D. 257, and continued three years and a half: but, notwithstanding all the severity hitherto used, above one half of the vast Roman empire was become Christian.

The tenth persecution was begun, about the year 303, by Dioclesian. When he resigned the crown, Galerius Maximian carried on the persecution. It is, indeed, impossible to conceive, much more to express, the cruelties of that time. Eusebius, who was an eye-witness of them, tells us, that they were innumerable, and exceeded all relation. Monsieur Godeau reckons, that, in this persecution, there were no less than nine thousand martyrs killed in one month's time; and he observes, that, during the continuance of it, there were, in the bare province of Egypt, no less than one hundred and forty-four thousand persons massacred, and seven hundred thousand, who died through the fatigues of banishment, or of the public works to which they were condemned. This persecution seems to have been the first of the ten that affected the island of Great Britain. It lasted no less than ten years. The emperors thought they had finished their work, and told the world, as in some ancient inscriptions found in Spain, "That they had utterly destroyed the name and superstition of the Christians, and had restored and propagated the worship of the Gods." It seems they grant, that Paganism was at a low ebb before they attempted to restore it, and destroy Christianity: but they were far deceived in their vain boasting assertion; Christianity was not destroyed, but farther propagated; and, where they had done their utmost to ruin it, even there it had a glorious resurrection out of its grave, and Paganism hastened to its ruin.

Thus the Christian religion, in a most miraculous manner, expanded herself, growing up like a palm-tree, under the heavy weight of persecution; for, as we have shewn, no religion had more powerful oppositions, by various kinds of punishments, oppressions, and tortures, which have been said to have decked her with rubies, in her very cradle. Now, as the Christian religion hath the purest and most abstracted, the noblest and highest spiritual notions, so has it been most subject to differences of opinions, and distractions of conscience: the purer the wheat is, the more subject to tares, and the most precious gems to flaws. The several sects of the Christian religion are taken notice of in their proper places.

If we consider the Christian religion, with regard to its principles, it cannot be denied, but that they are very obscure and difficult to be understood; and that its mysteries are above the reach of human comprehension. The obscurity of them, no doubt, is owing in a great measure to the subtilties introduced by several philosophers, who became proselytes to Christianity in the first ages of the Church; and who, afterwards becoming doctors, endeavoured to explain the mysteries of the Christian religion, by arguments borrowed from the Platonic, and other Pagan systems of philosophy. Their successors likewise, by their laboured explanations, added new obscurities to those which they found before; and, the human passions insensibly blending with these symptoms, nothing more was wanting to render the Christian religion an impenetrable mystery. To this, no doubt, is owing that infinite number of sects and heresies, which have sprung up in the Church; each of which lays claim to a primitive purity of doctrine, the characteristic of divine inspiration, a right of superiority, and a perfect knowledge of the way to heaven; and there is not one which, indirectly at least, can forbear damning the rest who desist from it.

The excellency of its morals is a demonstration of the divine original of the Christian religion. It consists not in idle philosophical speculations, or perpetual grimace and affectation, but in a steady practice of the duties it requires, without the least view of recompence from men: it neither seeks their admiration, nor attempts to dazzle their eyes, and deceive them; and this practice, being grounded on God's positive commands, is entirely conformable to the conduct which its divine founder observed, whilst upon earth. There is no religion which excites men more to the love and practice of virtue, and hatred of vice; or that prescribes greater rewards for the one, and punishments for the other.

The Christian religion, in regard to the practice of it, consists in the most exact imitation, that possibly can be conceived, of the infinite perfections of the supreme Being. From hence we may derive that solid virtue, that power which it gives us to subdue our passions, and that satisfaction which we receive from the observance of those laws, to the utmost of our abilities, which God has prescribed mankind. The characters of Christianity are perfectly conformable to the attributes of the divine Majesty: the moral part never indulges men's passions; it has no other view than the preservation and happiness of mankind; nor have the most inveterate enemies of the Christian faith ever invented any thing but what was very much inferior to it, both in practice and speculation.

CHRONO'LOGY (*Dict.*)—The farther we go back into antiquity, the greater is the uncertainty of the æra's, or epocha's; wherefore, men of learning have applied themselves principally to the Chronology of the earliest times. M. Fontenelle, in his Panegyric on M. Bianchini, compares the first times to a vast ruinated palace, the materials of which lie all together in confusion, and a great part of them destroyed. The more these materials are deficient, so much the more room is there to form different plans, which have no correspondence, out of those which remain. Such is the state of ancient history. Besides, materials are not only wanting on account of the vast number of books which have been lost, but those which remain frequently contradict each other.

We must therefore either reconcile these, or resolve to make a choice of what we think probable; which, however, must always be suspected of being arbitrary. All the chronological enquiries, hitherto made, are more or less successful combinations of these indigested materials; and who can be assured the number of the combinations is exhausted? Are not new systems of Chronology published every day? Moreri, in his Dictionary, tells us, there are seventy different opinions concerning the Chronology from the beginning of the world to our Saviour: we shall content ourselves with mentioning the most celebrated authors. Julius Africanus, Dionysius the younger, Eusebius, St. Cyril, Bede, Scaliger, Petavius, Usher, Marsham, Vossius, Pagi, Pezron, M. Desvignoles, Mr. Freret, and Sir Isaac Newton: illustrious names! How difficult is the ancient Chronology, since, after the labours of so many eminent men, we seem rather to have seen, than cleared up, the obscurity of it. It is a kind of immense perspective, and out of sight; the bottom being interspersed with thick clouds, through the intervals of which some glimmerings of light appear.

If it only related to some particular events, we should not be surprized at the disagreement between these great men; but the points in question are concerning the most remarkable events in history, both sacred and profane; namely, the number of years since the creation; the distinction between the sacred and civil years among the Jews; the sojourning of the Israelites in Ægypt; the Chronology of the judges and kings of Juda and Israel; the beginning of the years of the captivity, and of Daniel's seventy weeks; the history of Judith and Esther; the birth, mission, and death of the Messiah, &c. the origin of the Chinese empire; the dynasties of Ægypt; the epocha of the reign of Sesostris; the beginning and end of the Assyrian empire; the Chronology of the kings of Babylon and Media; of the successors of Alexander, &c. not to mention the fabulous and heroic ages, wherein the difficulties are still more numerous, as the Abbé Artigni has well observed, in his Memoir concerning Literature and History. From whence the judicious author, last quoted, concludes it needless to set about reconciling the old systems, or devising new; it is sufficient, says he, to pitch upon one, and stick to it; and this opinion seems to coincide with that of other learned men, whom we have consulted on this occasion. As, for example, take Usher's system, which is at present in great repute, or that of Petavius, in his Rationarium Temporum. In writing ancient history, we are to mention whose Chronology we follow, for fear of leading our readers into an error; for, according to some authors, there are, from the beginning of the world to the Christian æra, but 3740 years; according to others, 6934; which makes a difference of 3194 years.

It seems a matter of no great importance to mention, at large, the various sentiments of chronologers, or enumerate the proofs they bring in support of their different opinions; the reader may apply to their different works. Besides, we design below to give an extensive view of the sacred Chronology, which is of the greatest moment. The following are the most famous opinions concerning the age of the world, from the creation to the birth of our Saviour.

According to the Vulgate,

			Years.
Usher	——	——	4004
Scaliger	——	——	3950
Petavius	——	——	3984
Riccioli	——	——	4184.

According to the Septuagint,

		Years.
Eusebius	—— ——	5200
The Alphonsine Tables	——	6934
Riccioli	—— ——	5634.

The

The birth of Christ is very much disputed: authors vary, even in this point, seven or eight years. But, since that time, Chronology begins to be much more certain, by the number of monuments we have left, and the differences we meet with in authors being much less considerable.

According to Sir Isaac Newton, the world is not so old by five hundred years as other chronologers have made it: the proofs he produces are of two kinds.

The first turn on the valuation of generations. The Ægyptians reckoned three hundred and forty-one generations from Menes to Sethos, and accounted three generations one hundred years. The ancient Greeks reckoned forty years a generation. In which Sir Isaac thinks them both mistaken. It is true, three ordinary generations may be computed at about one hundred and twenty years, but generations are longer than reigns; because it is evident, that men in general live longer than kings reign. According to Sir Isaac, every reign, one with another, is about twenty years: this he proves from considering the reigns of the kings of England, from William the Conqueror to George the First; from the reigns of the first twenty-four, the second twenty-four, and fifteen following kings of France; and from the whole sixty-three taken together. The ancients, therefore, erred in their calculation, by computing a generation at forty years.

The other kind of his arguments is yet more singular, and drawn from astronomy; which the reader will find in the Dictionary, under this article.

Upon the strength of these two arguments, taken together, Sir Isaac concludes, that the expedition of the Argonauts ought to be placed 909 years before Christ, and not 1400; which lessens the age of the world almost 500 years.

M. Freret, by comparing and considering the history of known times, apprehends Sir Isaac to lie under a mistake, in computing every generation of kings at twenty years. He finds, on the contrary, by different calculations, that they ought to be reckoned at least at thirty years, or, rather, between thirty and forty. He proves his assertion by the 24 generations, from Hugh Capet to Lewis XV. which make 770 years, or 32 years to a generation. It is very singular, that the calculations of Sir Isaac and M. Freret should both be right, and yet the result be different. The difference arises from hence, Sir Isaac counts by reigns; M. Freret by generations. As, for example, from Hugh Capet to Lewis XV. there are only 24 generations, but 32 reigns; and by allowing about twenty years for every reign, and above thirty for every generation, it follows, that, if Sir Isaac's calculation be too little, M. Freret's is too much. Reigns in general must not only be shorter than generations, but the generations of kings must be shorter than those of private persons, because kings are married younger.

With regard to the astronomical proofs, M. Freret observes, that the position of the stars and points of the equinox is by no means exact, in the writings of the ancients; that authors of the same age differ very much on this head. It is very probable, according to this learned chronologist, that Meton, by placing the summer solstice in the eighth degree of Cancer, rather conformed to the received opinion of his age, than the truth; it being the common custom among us to place the vernal equinox in the first degree of Aries, though its situation has long been far from it. M. Freret corroborates this conjecture, by many arguments, the principal of which are these: Achilles Tatius tells us, that several astronomers placed the summer solstice in the first degree of Cancer, others the 8th, others the 15th; Euctemon made an observation of the solstice with Meton, and Euctemon placed the autumnal equinox in the first degree of Libra; which is a proof, says M. Freret, that Meton, when he fixed the summer solstice in the 8th degree of Cancer, subscribed to the popular acceptation, not to truth. To follow the laws of the precession of the equinoctial points, the equinox must have been in the 8th degree of Aries 964 years before the Christian æra; and this is much about the time, that the calendar followed by Meton must have been published. Hipparchus places the equinoctial points at fifteen degrees distance from that of Eudoxus; from whence there would follow the difference of an interval of 1080 years between Hipparchus and Eudoxus, which is by no means to be maintained. M. Freret to these proofs adds several others, but too long for us to insert: and the reader would do well to read Sir Isaac's short answer to these remarks of M. Freret, published in 1726; in which are some articles that merit the greatest attention.

Chronology is not confined to past times, and fixing ancient epocha's; it extends itself to other uses, particularly in the church. By the help of this, we fix the moveable feasts; and, among others, that of Easter; and, by the means of the epacts, periods, and cycles, &c. we form the calendar. So that there are properly two kinds of Chronology; one purely historical, founded on facts transmitted to us by antiquity; the other mathematical and astronomical, which settles the different epocha's by calculations and observations, and serves to regulate the seasons of celebrating the feasts in the church.

Sacred CHRONOLOGY. By the Chronology of the first ages, is understood, in general, that order, in which all the events that preceded the flood, and immediately followed it, ought to be placed, with regard to time. But what course shall we take in settling this order? Shall we, with some of the ancients, look upon the world as eternal, and say, that the succession of beings was without beginning, and will be without end? Or, with some authors, admitting of a creation in time, shall we think its date to be carried so far back, that no thread of history or tradition remains to guide us in tracing up its high original? Or, rejecting the absurdity of these systems, and applying ourselves to the historical accounts given by some nations, shall we prefer those of the inhabitants of Bethica in Spain, who produce annals of 6000 years? Or, shall we reckon, with the Indians, 6461 years from Bacchus to Alexander the Great: or yet, more fond of antiquity, shall we subscribe to the Chronology of the Egyptians, who boast an history of twelve or fifteen thousand years, and, with them, ascribing to the reigns of gods and heroes 18,000 years more, make the world 30,000 years old? Or, asserting with the Chaldeans, that they had made astronomical observations above 400,000 years before Alexander's march into Asia, shall we grant them ten kings before the flood, from the beginning of their monarchy? Shall we reckon these reigns to have subsisted 120 sares? and, according to Eusebius, allowing 3600 years for the time of every sare, admit there were 432,000 years from their first king to the flood? Or, denying the truth of Eusebius's estimation of the sare, and willing to allow the Chaldeans all the antiquity they pretend to, shall we restore them the 410,000 years they seem to have lost by this calculation, and grant them the 473000 years in which they pretend to have made astronomical observations before Alexander's march, according to Diodorus Siculus?

Or, looking on all these Chronologies as fabulous, or reducible, by some light received from antiquity, to the Chronology of the sacred writings, abide by that? Both reason and religion direct us to embrace the latter opinion. Our first business is, therefore, to shew that these extravagant calculations of the Chaldeans and others may be reduced to some one of the systems of our authors in sacred Chronology; secondly, as these systems differ considerably, to reconcile them in order to fix some of the principal epocha's.

The Babylonian, Egyptian, or Chaldean annals reduced to our CHRONOLOGY. We are obliged to M. Gibert for our information in this important and difficult subject, in a letter he published at Amsterdam, in 1743, which the reader may consult. The ancients meant, by a year, the revolution of any planet in the heavens: see what Macrobius, Eudoxus, Varro, Diodorus Siculus, Pliny, Plutarch, St. Augustin, &c. have wrote on this subject. Thus the year consisted of two, three, four, six, or twelve months; and, according to Palæphatus and Suidas, sometimes of one day only. What sort of revolutions did the Chaldeans mean, by pretending to have made observations 473,000 years? Those of the solar day, answers M. Gibert; the solar day was their astronomical year; from whence it follows on this supposition, that the 473,000 years of the Chaldeans are reducible to so many days, or about 1297 years nine months of our solar annual revolutions. Now, this is exactly the number of years Eusebius reckons, from the first discoveries of Atlas in astronomy to Alexander's march into Asia: and he places these discoveries at the 384th year of Abraham: but the march of Alexander was in the year 1682; the interval, therefore, between the one and the other is exactly 1298 years, nearly the same as before.

This discovery is so much the more striking, as Atlas is accounted the inventor of astrology, and, consequently, his observations are those of the greatest antiquity. History furnishes sufficient conjectures to persuade us that the observations of Atlas and the Chaldeans were the same. But let us consider the consequence of this hypothesis of M. Gibert.

Berosus added 17,000 years to the observations of the Chaldeans. This author's history, dedicated to Antiochus, was, in all probability, brought down to the last years of Seleucus Nicanor, the predecessor of this Antiochus. This was much about the time that Babylon lost its name, and its inhabitants went into the new city built by Seleucus, that is, in the 293d year before Christ, or rather the 289th; for Eusebius tells us, that Seleucus then peopled the city he had built. Now, the 17,000 years of Berosus, according to the computation of M. Gibert, make 46 years and 6 or 7 months, or the exact interval between the march of Alexander and the first year of the 123d olympiad, that is, to the very time Berosus had carried his history.

The 720,000 years which Epigenius attributes to the observations preserved at Babylon, no longer make any difficulty; for, being reduced to Julian years, they make about 1971 years three months, which come very near to the 1903 years which Callisthenes allowed to these observations; the 68 years difference proceeds from this, that Callisthenes ends his calculation at the taking of Babylon by Alexander, as he ought; and Epigenius carried on his to the time of Ptolemy Philadelphus.

Another proof of the truth of M. Gibert's hypothesis and calculations may be deduced from what Alexander Polyhistor

hiſtor ſays, after Beroſus, that hiſtorical records of events were preſerved at Babylon for the ſpace of 150,000 years; but every one accuſes Beroſus of impoſture, who recollects that Nabonaſſar deſtroyed all hiſtorical monuments of preceding ages, and that Nabonaſſar lived only 410 or 411 years before Alexander: however, if we reduce this 150,000 years into days, the product is 410 years, 8 months, and 3 days, which time correſponds exactly to the interval between the 26th of February of the 747th year before Chriſt, when the æra of Nabonaſſar begins, to the firſt of November of the 337th year, that is, to the year and month from whence the Babylonians dated the reign of Alexander, after the death of his father. This computation carries us to the true epocha's; the 30,000 years which the Egyptians attribute to the reign of the ſun, the ſame with Joſeph, are reduced to 80 years, the time of ſervitude attributed to this patriarch by holy writ; the 1300 years, and more, as ſome reckon from Menes to Nitochris, are only years of ſix months, which make 668 Julian years, the ſame ſpace of time, which the canon of the Theban kings, by Eratoſthenes, puts between the ſame two reigns. The 2936 years which Dicæarchus reckons from Seſoſtris to the firſt olympiad, are only years of three months, which are reduced to 734 years, the time between Danaus, the brother of Seſoſtris, and the olympiads. According to M. Freret, in his Eſſays, the Chineſe date the epocha of Yao, one of their firſt emperors, about the year 2145 or 7 before Chriſt, and reckon their firſt aſtronomical obſervations, and the compoſition of a famous calendar, to have preceded Yao 150 years: now, in this caſe, the firſt aſtronomical obſervations of the Chineſe and Chaldeans will coincide; which is very ſingular. The Chineſe, as well as all other people, certainly came out of the plains of Shinar: the higher we trace the origin of all nations and people, the more reaſon we find to believe they have proceeded from hence: the more ſtrictly we examine their Chronology and clear up the errors we diſcover in it, ſo much the nearer it approaches to the ſacred Chronology; this Chronology is therefore true; they are the moſt ancient people who are in poſſeſſion of it, and, conſequently, what we ought to embrace.

We have three different copies which vary, with regard to the Chronology of the firſt ages of the world; the Hebrew text, which ſhortens the time, only reckoning about 4000 years from Adam to Chriſt; the Samaritan, which is thought leſs correct, makes this interval longer; the verſion of the Septuagint, which carries back the creation of the world to 6000 years before Chriſt. The Hebrew text reckons 1656 years from Adam to the flood; the Samaritan 1307. According to Euſebius and the Septuagint, this interval is reckoned at 2242 years; according to Joſephus and the Septuagint, 2256; according to Julius Africanus, Epiphanius, Petavius, and the Septuagint, it is reckoned at 2262 years.

If chronologers are divided, both with regard to which text they ought to follow, and the interval between the creation and the flood, they are not leſs divided in their opinions concerning the times ſince the deluge, as may be ſeen by comparing the ſyſtems of Marſham and Pezron.

Marſham's Syſtem.	years
From the flood to the call of Abraham ——	426
From the call of Abraham to the coming out of Egypt	430
From the coming out of Egypt to the building of the temple —— —— —— ——	480
The duration of the temple —— ——	400
The captivity —— —— ——	70

Pezron's Syſtem.	
From the flood to the calling of Abraham ——	1257
From the calling of Abraham to the coming out of Egypt —— —— —— ——	430
From the coming out of Egypt to the building of the temple —— —— ——	873
From the building of the temple to its deſtruction	470
The captivity —— —— ——	70

Other ſyſtems, to which we muſt refer our readers, have more or leſs the ſame difference. The diverſities, as well between the texts themſelves, as the commentators on them, ſuggeſted an opinion to the Abbé de Prades, which we ſhall examine, becauſe it has made a great noiſe in the world.

The Abbé ſets out with aſking this queſtion, How can it be, ſays he, that Moſes ſhould have wrote a Chronology, which is ſo different in the three different texts, that it is impoſſible to know which Moſes wrote, or whether he is the author of any one of them? He obſerves this contradiction in Chronology had given birth to innumerable various ſyſtems; that the authors of theſe ſyſtems had ſtuck at nothing to deſtroy the authority of the texts which did not favour their own particular ſyſtem; that the chronologers themſelves ſeem to have had no great opinion of the certainty of this Chronology, becauſe they have made ſo many additions, alterations, and corrections in it, ad libitum; that the Chineſe annals are not conſidered in any of theſe ſyſtems, and yet thoſe annals are not to be rejected without an hiſtorical ſcepticiſm; that this had furniſhed the infidels with arguments againſt the account of Moſes, who makes all men to have deſcended from Noah, whereas the chronicles of the kings of China go farther back than the flood. The Abbé is of opinion, on the whole, that Moſes was not the author of any one of theſe three Chronologies, and that whatever pains father Tournemine and others had taken to reconcile them, were to no purpoſe: that the three ſyſtems were of a more modern invention than Moſes; that the differences between them could not have proceeded from the careleſneſs of copyiſts; for, if the errors of copyiſts are ſuppoſed to have produced different Chronologies, there would in all probability have been many more than three; that the Chronologies would only differ as three copies of the ſame Chronology; that, if the Chronology of the Hebrew text, from which the Septuagint made their verſion, had paſſed for authentic, ſo reſpectable a body of men, as thoſe tranſlators were, would not have preſumed to alter it; that it cannot be ſuppoſed the Septuagint preſerved the Hebrew Chronology. That there is an error ſome where is plain; but is it in the Hebrew text, or the verſion of the Septuagint, or both? The anſwer to this queſtion is, ſays he, that neither Chronology is true. It is ſomewhat amazing, that the ignorance of the copyiſts ſhould never have been perceived, till after the Septuagint; that the interval between Ptolemy Philadelphus and the birth of Chriſt ſhould be the only ſpace of time expoſed to this uncertainty; that profane and ſacred hiſtory abſolutely diſagree in this point; that the ſuperſtitious carefulneſs of the Jews ſhould have been ſo groſsly deceived; that, the numbers being wrote in all the texts at length, not in cyphers, an alteration muſt have been extremely difficult; but, however eaſy it might have been, yet it will by no means follow that ſuch an alteration would have introduced different ſyſtems of Chronology. We cannot, ſays he, ſuppoſe the Chronology of Moſes to lie diſperſed in all the three texts, and therefore we ought to conſult them all on every fact, and uſe that which is moſt agreeable to truth, all circumſtances conſidered.

According to this ſyſtem of the Abbé's, the objection indeed of the infidels to the account of Moſes, drawn from the diverſity of the Chronologies, falls to the ground; but does not this ſyſtem greatly weaken the authority of the ſacred writings? Does it not greatly take away from the credit of the facts related in them, which is founded on the carefulneſs of the Jews in preſerving their writings? The Abbé aſſerts that theſe Chronologies are three different ſyſtems; but he only proves that their alteration is very extraordinary: how then are we to take theſe three Chronologies for connected and correſponding ſyſtems, when we ſee every epocha inſerted throughout the whole Hebrew text, but omitted, with regard to all the patriarchs, in the text of the Septuagint? A connection of facts is preſerved, becauſe they are leſs liable to error than chronological calculations; and however groſs the errors may be in theſe, they ought not to aſtoniſh us. Nothing, therefore, hinders us from admitting the three texts, and trying to reconcile them, becauſe they collectively contain what may clear up many difficulties. But how ſhall we reconcile them? By conſidering the Chronology and the events; ſometimes the Chronology alone is ſufficient; and, by comparing both together, will very often clear up many difficulties; and with regard to thoſe parts of hiſtory, where both theſe fail, we are of opinion they will always remain obſcure.

This ſyſtem is very different from that of the Abbé de Prades, but appears preferable, becauſe the Abbé denies Moſes to have been the author of the Chronology, and thereby invalidates the authenticity of ſcripture. The variation of the Chronology, with regard to the firſt ages of the world in the ſeveral texts, creates the uncertainty; but the Chriſtian neither imitates the puſillanimity of the Jew, nor the prejudice of the Muſſulman, in conſidering thoſe books which contain the fundamentals of his faith; but ſubmits them to the trial of reaſon, without fear of incurring the cenſure of impiety.

The Hebrew and Samaritan texts, as well as the verſion of the Septuagint, have each their ſeveral pretenſions; the Hebrew ſeems to be written in the ſame language as the firſt original; the Samaritan lays claim to the ſame advantage, and pleads, beſides, in its own behalf, the preſervation of the true ancient Hebraic characters. The verſion of the Septuagint was made from the Hebrew of the ancient Jews. The Chriſtian churches adopted it, the ſynagogue acknowledged it, and Joſephus in his Hiſtory has in general conformed to it. If ſome faults have crept into the verſion, may not ſome alſo have crept into the Hebrew text, and may we not entertain the ſame ſuſpicion of the Samaritan? Are not all copies ſubject to theſe, and many other accidents? Tranſcribers are not leſs incorrect in copying from the Hebrew, than in tranſcribing from the Greek. The purity and correctneſs of the text depends upon the ability, attention, and honeſty of the copier, not the language in which it is written.

As the authority of the three texts is ſupported on pretenſions nearly equal, it ſeems our buſineſs to enquire what reaſons there may be for preferring one to the other in places where they contradict each other, without partially adhering to either. We ought, in juſtice, to think the three texts copies of one original; and conſequently ought not to be prejudiced in favour of any one, but try to reconcile them. Theſe principles being premiſed, we proceed to propoſe ſome rational conjectures concerning the Chronology of the three texts, with

with regard to the lives of the old patriarchs, and the time of their birth: we mean, since the flood, for the distribution of the people, the establishment of empires, and succession of princes, depend on that period; and in doing this we shall keep our eye on Josephus, whose authority is considerable; and either follow him, or correct him, when his sentiments of Chronology vary from that of holy writ.

As neither the texts themselves nor this historian agree in point of Chronology, there must necessarily be a fault somewhere; let us therefore examine where it lies.

First, the Samaritan text and version of the Septuagint seem right in giving the patriarchs 100 years more than the Hebrew text; partly, because two of them agree, and partly, because Josephus strengthens this opinion by his consent. By reckoning the lives of each patriarch separate, it may be objected the sum total agrees with the Hebrew; but this is a fault in the addition. The Hebrew text, in the first ages after the flood, speaks of wars and tributes imposed on conquered people; this time, compared with the number of events it contains, appears very short. Noah's three sons beget an immense posterity, forget their common origin, treat each other as enemies, and this in the interval of 367 years, which is all the time the Hebrew text allows from the flood to Abraham's going out of Mesopotamia; and Shem, according to the same text, lived 502 years after the flood. The life of man in the ages immediately succeeding the flood was 400 years. Noah himself survived the flood 350 years. Thus Abraham must have lived in the time of Noah, Shem have seen Isaac, and children of the same father must have been ignorant their father was alive; which seems almost incredible. But the objections drawn from the preceding facts are not the only reasons for enlarging the space of the second age. In Genesis we have an account of current coin as a thing common, and of ancient original, on occasion of the tomb which Abraham bought of the sons of Heth. Whoever reflects, must think that a long series of time must have passed from the discovery of the mine to the use of metal for this purpose. It must be acknowledged these are things very hard to be accounted for; however, let us not abandon reason and experience, like some who have done no true honour to the cause of religion, by getting over every thing with miracles; but let us apply reason and experience to the discovery of truth. What will be the result? These suggest, that, according to the authority of scripture, men after the flood lived together in one society, till they grew numerous enough to separate; when God said to the children of Noah, People the earth and divide it, he did not order them to disperse themselves solitarily here and there, and leave the patriarch Noah alone; when he blesses them to increase and multiply, his will was, that they spread themselves over the face of the earth in proportion as they increased. Wherefore, those who before the confusion of languages send Shem into Syria or Chaldea, Cain into Egypt, and Japhet we know not whither, and from thence date the Chronology of kingdoms, give us the history of their own imaginations, not of the times. Men after the flood chose a convenient and proper place to dwell in; this was the plain of Shinar. Here they settled; as they grew numerous, they extended themselves; at last they became so numerous as to be able to divide into large colonies, and, as they saw themselves under a necessity of separation, said to one another, Let us, before we part, erect a common work, which may transmit the memory of our union to posterity; let us build a tower whose top may reach to heaven. The extravagance of the design was like the success of it; scarce had they began their work, when God confounded their language, and forced them to forsake this monument of pride. They formed colonies, went into different countries, and by degrees overspread the face of the earth: thus far good sense, experience, and scripture concur to carry us. These events seem naturally to require a longer time than the Hebrew text allows. Shall we, to lessen the force of the objections made on account of the number of the people, the wars, arts, religions, languages, &c. as some have done, to account for the prodigious increase, reply, that the women regularly brought forth twins, a male and a female, every nine months? Or, shall we rather, to remove the difficulty, adhere to the Samaritan text and version of the Septuagint, against the Hebrew text, and allow 100 years more to the patriarchs? If the foregoing reasons are not sufficient to make us declare on this side the question, the dynasties of Egypt, the kings of China, and other Chronologies which are not to be looked on as fabulous, and go higher than the flood, according to the Hebrew text, leave us no room to doubt. The birth of Terah, the father of Abraham, should have been placed at the 129th year of Nahor the grandfather of Abraham, though the Samaritan text places it in the 79th, the Septuagint in the 179th, the Hebrew in the 29th, and Josephus in the 120th. This great diversity gives us reason to presume there is a fault in the whole. The Samaritan may have omitted the hundred, which fault is to be corrected by the Septuagint and Josephus, who have retained it; as to the figures that follow the hundred, the Hebrew may be most exact; Josephus comes nearest to it; a view of them together may set this in a clearer light.

	years.
The Samaritan text ——— ———	79
The Septuagint ——— ——— ———	179
Josephus ——— ——— ——— ———	120
The Hebrew text ——— ——— ——— ———	29
A new conjecture ——— ——— ———	129

The Septuagint makes Cainan the third patriarch from Shem, or fourth from Noah; but this is a mistake according to the Hebrew text, the Samaritan text, and Josephus; and he is omitted in the first chapter of the first book of the Paralipomena in the Septuagint itself, where the succession of the patriarchs mentioned in Genesis is repeated. Origen had not admitted it into his Hexapla, which seems to prove that it was not in the best copies of the Septuagint. Origen, in his twentieth Homily on St. John, makes Abraham the twentieth from Adam and tenth from Noah, which agrees with the account in the Antiquities of Josephus. Theophilus of Antioch, Julius Africanus, and Eusebius are of the same opinion. A passage of the third chapter of St. Luke's gospel, which mentions Cainan, seems to make against this; but the passage is omitted in the Cambridge MS. and may have proceeded from a mistake of the transcriber, both in the Septuagint and St. Luke; it is highly probable this Cainan is the same with him before the flood, and has by some mistake been inserted in both genealogies, exactly in the same rank; that is, the fourth from Adam, and the fourth from Noah.

The sum total of the lives of the patriarchs in the Hebrew and Samaritan texts seems right; they only differ about Heber and Terah. The Hebrew makes Heber live 464 years, the Samaritan 60 years less; but this is not very material; for we want to fix the time of his birth, not the duration of his life. The Septuagint agrees with the Samaritan text, and we are inclined to think that more correct than the Hebrew, partly for this reason, and partly, because it is observed, men's lives shortened, as they lived more distant from the flood; but Heber's life, according to the Hebrew text, is longer than either that of his father or his uncle; as to the difference between the Hebrew and Samaritan texts concerning the time Terah lived, as it makes a more essential difficulty, and relates to the birth of Abraham, we shall consider it more at large.

It appears from what we have said, that, of the three texts, the Samaritan is the most correct, with respect to the parts of Chronology we have considered; it is only defective, with respect to the time when Nahor begat Terah; and there the hundred has been omitted. We must now enquire the time of the birth of Abraham, and the death of Terah. Though Josephus and all the texts agree to place the birth of Abraham at the 70th year of Terah, yet several chronologers fix the birth of Abraham at the 130th year of Terah.

According to the book of Genesis, say they, Abraham went out of Haran at the age of 75 years; and, according to St. Stephen, in the seventh chapter of the Acts, he did not go out of Haran till after the death of his father. Now Terah, according to the Hebrew text and Septuagint, lived 205 years, wherefore Abraham must have been born when his father was 130 years old; for, if we subtract 75 from 205, we shall have 130 years remaining.

When you object to them that it is said in Genesis chap. xi. v. 26, 'Terah lived seventy years and begat Abraham, Nahor, and Haran', they reply, this means no more than in general, that Terah had lived seventy years, had three sons at different times, and by mentioning them all together, say they, the author of Genesis had plainly no design of determining the exact time of their birth; if Abraham is named first, it is out of honour, not as being the oldest.

These considerations appeared sufficient reasons to Marsham, Pezron, and others, for fixing the nativity of Abraham at the 170th year of the age of his father Terah; but Petavius, Calvisius, and others, persist in fixing the birth of Abraham at the 70th year of Terah: the latter insist upon it, as contrary to all probability, that Moses should have neglected to set down the exact time of Abraham's nativity, who seems to have wrote the Chronology of the ancient patriarchs, principally with a view of coming down to the father of the faithful; and, in other respects, is so exact with regard to the years of this patriarch. They say it is more likely that St. Stephen was less exact in points of Chronology and geography, which were not important in the first martyr, but would be unpardonable negligences in Moses, who wrote as an historian. The geographical error of St. Stephen they say is this, that God appeared unto Abraham in Mesopotamia before he dwelt in Charran, whereas Charran is in Mesopotamia; the geographical error will be rectified by a very small transposition in the text, which runs thus: Deus gloriæ apparuit patri nostro Abrahæ, cum esset in Mesopotamia, priusquam moraretur in Charran, & dixit ad illum Exi, &c. only put the et, which is before dixit, before priusquam, and the sense will be that Abraham was in Mesopotamia before he dwelt at Charran; this difficulty may even be got over without correcting the text, by saying that St. Stephen thought Abraham dwelt in some other part of Mesopotamia before he dwelt in Charran. Petavius, in his Rationarium Temporum, to reconcile St. Stephen and Moses's account, supposes a twofold going forth of Abraham from the city of Charran;

Charran; the first, in his 75th year, by the command of God into the land of Canaan, that he a long time afterwards returned to Charran; and carried with him those of his family he had left behind and all his effects; but Moses expresly says, speaking of this going out off Charran, which Petavius acknowledges for the first, that Abraham took with him his wife Sarah and Lot his nephew, and all the substance that they had gathered, and all the souls that they had gotten in Haran. Wherefore, we must leave the dreams of Petavius, and reconcile Moses with St. Stephen some other way. To solve the difficulty, we propose the following conjectures.

First, Abraham never returned into his own country after leaving it, and departed not from Haran till after the death of his father Terah. St. Stephen expresly says so, and Genesis plainly insinuates it. In the book of Genesis we read concerning the going forth of Chaldea, that Terah carried with him Abraham, Lot, and Sarah, to go and dwell in Canaan; that they came as far as Haran, where they stopped, and Terah died there; which proves that the design of Terah was to have gone into Canaan, though he was prevented by death at Haran. Immediately after Moses relates the departure of Abraham out of this city with Lot his nephew and all their substance.

Secondly, The authority of St. Stephen does not determinately fix the year of Abraham's nativity, but obliges us to place the death of Terah before the 75th year of Abraham's age; but, as Terah might have died long before his son arrived at that age, St. Stephen's speech gives no light to the Chronology.

Thirdly, Moses has exactly pointed out the time of Abraham's nativity, which was the design and end of this Chronology: Abraham is the hero of his history, and he begins from him to distinguish the Hebrews from all other nations.

Fourthly, We might conjecture that Terah did not beget children till he was 170 years old, and that the 100 years which are reckoned in the lives of all his ancestors, are omitted in his; but this conjecture is weak, for it is said of Sarah, even before she went out of Chaldea, that she was barren, though she could not then be above twenty-five years old, and Abraham at most five and thirty; it is said also of Abraham that he looked on it as a thing impossible to beget children at an 100 years old, which he never could have thought, if he had not been born before his father was 170 years old.

Fifthly, It appears that Abraham was born at the 70th year of the age of Terah. The Hebrew and Samaritan texts, the Septuagint and Josephus, agree in rescinding the hundred. Now, as the birth of this patriarch is carried no farther back, it is evident, the only means of reconciling Moses with St. Stephen will be to shorten the life of Terah; the Hebrew text and Septuagint agree this patriarch lived 205 years. The Samaritan text says he lived but 145 years. And the latter seems more correct than the other two. The clearing up the difficulty before us is, we apprehend, a sufficient proof of it. The 70 years which Terah lived before he begat Abraham, and the 75 years which Abraham lived before he went out of Haran, make up the 145 years of the Samaritan text; and thus Abraham's departure out of this city will be after the death of his father according to St. Stephen's account, and his nativity at the 70th year of Terah according to Moses.

Some critics suspect a corruption in the Samaritan text, and ground their suspicions on its consonance with the events, which must certainly be a proof of the contrary: for the criterion of truth in history is clearness. The Samaritan text is more ancient than that which Eusebius has inserted in his Chronological Canons. Before Eusebius who would have changed it? The Christians? They only made use of the Septuagint or common Hebrew. The Samaritans? What interest of theirs was it to allow 145 years for the life of Terah rather than 205? Wherefore it follows the error is not in the Samaritan text. All the texts agree that the ages of the patriarchs shortened successively after the flood; the father of Terah lived no more than 148 years, and it is by no means probable, therefore, that Terah lived 205 years: besides, God had promised Abraham a long life; this promise, at least, should have extended to the days of his father Terah, which were 205 years, according to the Hebrew text and Septuagint, whereas Abraham lived no more than 175 years, as we read in Genesis. It is therefore more probable, that God prolonged the life of Abraham 30 years more than the life of Terah: that the Samaritan text is right; that Moses is exact in his history and Chronology; that St. Stephen spoke according to the truth of some Hebrew text which was more correct than any that have been handed down to us.

Thus we have endeavoured to remove this grand difficulty in the sacred Chronology; and, with regard to the rest, must refer our readers to the authors already mentioned, who have wrote very largely on this subject.

CHRONO'METER, a machine contrived by the late ingenious Mr. George Graham, and made so exact as to measure a small part of time very nicely, even to the 16th part of a second. To one end of an horizontal axis is fixed a contrate wheel of 120 teeth, and, at the other end, there is a little barrel which on its outside receives the string of a little weight to turn the wheel round; the wheel with its teeth moves an horizontal pinion of 15 leaves (or teeth) fixed to the bottom of a vertical axis on whose top is the balance wheel, which is a contrate wheel of 15 teeth cut askew; that is, one side of every tooth is perpendicular to the plane of the wheel, and the other cut obliquely with a curve. Just over this last wheel, there is a little axis or rod of steel placed horizontally, which has two little pallets at right-angles to each other, so placed as to be alternately struck by the upright part of the skew teeth on the opposite sides of the balance wheel, in such manner that not one of the teeth of that wheel can pass by without a stroke be made against each pallet to give a quarter of a turn to the axis above-mentioned. At the other end of this axis is fixed a wire, at whose end is a brass bob, whose center of gravity is distant from the horizontal axis 2,45 inches, that is, near two inches and a half, or the 16th part of the length of a pendulum vibrating seconds. Therefore, as the weight carries the wheel-work round, the skew teeth of the balance wheel must strike the pallets fixed to the horizontal axis about which the little pendulum moves; and as that pendulum, on account of its length, vibrates four times in a second, and there must be two strokes against the pallets for every tooth that passes by in the balance wheel, so there must be two swings of the pendulum, or half a second in time, for every tooth of the great wheel that is brought forward by the piviot (whose number of teeth is equal to that of the balance wheel) and, as the great wheel has 120 teeth, there will be performed 240 vibrations of the pendulum, whilst the great wheel goes round; therefore, an hand or index fixed to the great wheel will go round in one minute pointing to 60 large divisions for seconds on the dial plate, which divisions are again subdivided into four to shew the quarters of seconds. But then, besides this, there is a quadrant of a circle of a radius equal to the length of the pendulum, which is divided into four parts by five little brass pins, fixed to an horizontal axis; which quadrant serves not only as a detent to set the machine a going in a sixth part of a second, but also to stop it in the same time, the pins stopping the pendulum in any fourth part of its vibration; for, in fixing the pins, regard was had to the time of every fourth part of the vibration, the two spaces between the pins next to the lowest part of the quarter of the circle, which the pendulum vibrates in $\frac{1}{4}$ of a second, being so much greater, as the pendulum moves swifter in that part of its vibration.

This Chronometer is of great use for measuring small parts of time in astronomical observations, the time of the fall of bodies, the velocity of running waters, and fit for many other purposes, where a small space of time is to be measured nicely, as from three or four seconds to a minute or two; but it is not adapted to measure long spaces of time very exactly; because, though it seems to vibrate exactly a quarter of a circle every vibration, yet it does not really do so, and the difference of the lengths of the vibrations in such large arcs makes a difference in time; and, however small that difference is, yet a great many of them create a sensible error. In this machine, there is sometimes an error of $\frac{1}{4}$ of a second in fourteen seconds. This is a fault which all clocks are liable to, that have short pendulums which swing large arcs of a circle.

CHRYSA'ETOS, *the golden eagle*, a large and beautiful bird of prey. Its weight is usually twelve pounds; his general colour a chesnut brown, with a number of white spots; there are but few of them on the back, but a larger number on the belly; his feet are feathered to the toes, and yellow. He is extremely bold and fierce, and will seize upon almost any thing for prey; his voice is clear and shrill, and often makes a moaning noise.

That species of eagle which we call simply the eagle, without any addition, is of this kind, and is properly charactered by the name of Chrysaetos cauda annulo albo cincta; a transverse white line on its tail being its most obvious distinction. *Willughby's Ornithol.*

CHUBB, the English name for the fish called the capito and cephalus by authors, and by some of the ancient Romans squalus.

The resorts of this fish are easily found, for they are generally holes overshaded by trees, and the fish will be seen floating in such, almost on the surface of the water, in a hot day in great numbers. They are but a poor fish for the table, and are very full of bones; but they entertain the angler very much, and are of the number of those that are easily taken. The best manner of fishing for him is thus: prepare a very strong rod of a sufficient length; fix to the hook a grasshopper; place yourself so as to be perfectly out of sight of the fish, and drop in the bait about two feet from the place where a large Chubb lies; if he does not see the angler, he very seldom fails biting, and is immediately taken; but he is so strong a fish that he should be taken out carefully, after a great deal of playing, otherwise the tackle will be in danger; a beetle, or any large fly, will answer the purpose in the place of a grasshopper, and, if there are none of them to be had, the method of fishing must be altered, and the line be long enough for fishing at the bottom. In March and April this fish is to be caught with large red worms: in June and July with flies, snails, and cherries; but in August and September the proper bait is good cheese, pounded in a mortar, with some saffron, and a little butter; some make a paste of cheese and Venice turpentine for the Chubb in winter; at which season this fish is better than at any other; the bones are less troublesome in this

this season, and the fish is more firm and better tasted; the roe is also well flavoured in general. The angler must keep his bait for this fish at the bottom in cold weather, and near the top in hot, and the fish will bite eagerly.

CICATRIX *(Dict.)*—In large wounds, where there has been a loss of substance, an even Cicatrix is not to be expected without great care in the surgeon. When an even, thick, and white matter appears in the wound, it is to be dressed either every day, or every other day, as occasion shall require: the superfluous matter must at every dressing be wiped away with a very light hand; and it is indeed much better to leave some of it in the wound, than to treat that roughly in the taking it away; for wiping the wound too roughly hinders the growth of a new flesh; but a little matter, being left, only performs the office of oil or balsam, in keeping the parts moist. These rules being observed, new flesh will presently spring up, and the wound unite: but, that an even Cicatrix may be procured, the surgeon must endeavour, by degrees, to harden the new flesh, by the application of a dry lint, covered with a light bandage. When this does not prove sufficient, it may be proper to use some of the drying balsams, or drying powder, such as tutty, lapis calaminaris, mastich, colophony, &c. Rectified spirit of wine is frequently used for this purpose also, with great success, for it carries a very great astringent and drying virtue with it. *Heist. Sur.*

CICHORIUM, *succory*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the semi-flosculous kind, being composed of a great many semi-floscules, which stand upon the embryo fruits, and are contained in a common cup, which afterwards contracts itself so as to form a sort of capsule, containing a number of angular, umbilicated, and somewhat wedge-like or cuneiform seeds.

The species of succory enumerated by M. Tournefort are fourteen, and by Mr. Miller, five.

The common succory stands recommended by most of the medical writers, as one of the best known aperients and detergents: it is prescribed in all diseases of the liver, and is a powerful diuretic. Schroder tells us, that it has also great virtues attributed to it against hæmorrhages; but it is not much regarded at present in that light.

CIMEX, in natural history, the name of a genus of insects, the characters of which are these: the head is small: the back towards the shoulders is broad, and is covered with a crustaceous substance: its shoulders are of an angular make, and its wings partly crustaceous, partly membranaceous, and are so formed, that they exhibit the figure of a cross, where they meet at the middle of the back; and they have a long proboscis, which is bent under the belly, and always lies straight, not in a spiral form.

Mr. Ray divides the Cimices into two kinds, those of a shorter, and those of a longer and narrower make. Of the first kind he describes eight species.

Besides these, there are two species of water Cimices: the first has a long body, and its shoulders are black; the wings and the triangle under the shoulders are of a shining brown, and the hinder pair of legs are very long, and serve as oars. The other is smaller, and is of a rounded, but depressed figure. Its colours are black and a shining yellow: the antennæ are very short, and the legs do not seem made for swimming.

Beside all these, which are properly of the Cimex kind, there is another set of insects mentioned by Mr. Ray, as nearly approaching to them, and described under the name of cimiformes muscæ. *Ray's Hist. Insect.*

CIMOLIA *alba*, the officinal name of the earth of which we now make tobacco pipes. Its distinguishing characters are, that it is a dense, compact, heavy earth, of a dull white colour, and very close texture; it will not easily break between the fingers, and slightly stains the skin in handling. It adheres firmly to the tongue; melts very slowly in the mouth, and is not readily diffusible in water. It is found in many places. That of the isle of Wight is much esteemed for its colour. We have vast plenty of it also near Poole in Dorsetshire, and near Weddensbury in Staffordshire. *Hill's Hist. of Foss.*

CIRCULATION. *(Dict.)*—Dr. Nichols has contradicted the received doctrine of the motion of the heart, and of the Circulation of the blood, both in adults and fœtus's. The Circulation of the blood, according to him, depends on six motions: 1°, of the right auricle. 2°, right ventricle. 3°, pulmonary artery. 4°, left auricle. 5°, left ventricle; and 6°, of the aorta. Of these, the first, third, and fifth are synchronous, as are likewise the second, fourth, and sixth; but the first, third, and fifth are a syncronous to the rest: and, therefore,

The two auricles The two ventricles The two arteries	are alternately	relaxed contracted.

See *Nichols, Compend. Anat. & Prælect.* 15. *ap. Med. Ess. Edinb.* vol. III.

CISTERN. If the farmers of England would fall into the method used in Spain, and at Amsterdam, Venice, and other places, of saving the rain water of the whole year, or at least so much of it as would be necessary, in cisterns, they would have always water for their cattle in the summer droughts, and many thousand acres of land, now left useless, might be turned to profit.

The best way of preserving the water, for the service of the house, is in Cisterns in the cellars. These may be made with brick or stone, joined with plaister of Paris, which will keep out the wet very well; or with a kind of mortar made of slaked lime, with linseed oil, and tow or cotton. A bed of good sound clay may be laid at the bottom, and on this the bricks for the floor, and then the walls may be raised in the same manner, only leaving spaces behind them, into which clay is to be rammed in the like manner. Thus it will be a clay Cistern, faced with brick; and the bricks will keep the clay moist, and prevent it from cracking, though it be not full of water. This will do in any shady place, as well as in cellars: and thus may a Cistern be made in a garden, in some shady place, and covered over, which may receive the water running from the walks, and will retain it for the service of the garden, all the year.

Where there is want of water for the cattle in the fields, the way is to dig a pond in some place into which there is a descent; then to cover the bottom and sides with a double coat of tough clay, each six inches thick, and each very well rammed: then to cover the bottom with large stones, which will keep the clay moist, and prevent its cracking, when not covered with water. But this is a troublesome thing; for, if there happen to be a crack in any part, it is often found necessary to go over the whole work again, before the pond will hold a drop of water.

Another method of making a pond hold water, is to daub it over with clay and mortar mixed together, and then with mortar alone. This has an advantage over the other way, in that, if any crack happens, it may be mended by a cement of clean hair and tallow, mixed with slaked lime, and the yolks of eggs, well beat together. This, applied to the crack, will close it safely, without the necessity of undoing the whole work, as in the other case.

In chalky countries it is common to find a low place on the downs, and, digging a hole by way of a pit there, they cover the bottom evenly with the chalk rubbish, and, when it is wetted by the rain, they ram it well, and afterwards drive cattle into it, and fold sheep in it: the consequence of all which trampling is, that the bottom at length becomes so firm, that it holds the water perfectly well. By one or other of these means, Cisterns or reservoirs may be made in all countries: and our farmers, if they would carefully try one or the other of them, as their land most required, would not have so much to complain of from droughts. *Mortimer's Husbandry.*

CISTUS, in botany, the name of a genus of plants, the characters of which are these: the flower is of the rosaceous kind, composed of several petals, arranged in a circular form. The pistil arises from the cup of the flower, and, finally, becomes a roundish or pointed multicapsular fruit, which, when ripe, opens at the top, and generally contains a number of small seeds. See *plate* IX. *fig.* 3, which represents a branch of the sweet Cistus of candy, *i* the flower, *k* the seed vessel, *l* the seed vessel open, *m* the seed.

The species of Cistus, enumerated by M. Tournefort, are twenty, and by Mr. Miller, seventeen.

The several species of this beautiful shrub are to be propagated by sowing their seeds on a gentle hot bed, or on a warm border of common rich earth in March. When the plants are grown to be three inches high, they should be transplanted either into small pots, or into a border of rich earth, placed at ten inches distance. They will require some screening from hard weather for the first winter, and must be watered at times. In the spring following, they must be carefully removed, with as much as possible of their own earth about them, and be placed where they are to remain. They are very bad plants to remove, when old.

They may also be propagated by cuttings, planting them in a rich bed, and shading them with matts, and watering them carefully for two months: they will by that time have taken root, and may be treated as the seedling plants of the same age. *Miller's Gard. Dict.*

CITREÆ *Mensæ*, in antiquity, tables made of the wood of the citron-tree, very beautiful, and greatly esteemed by the ancient Romans.

CITRINUS, in natural history, the name of a peculiar species of sprig crystal, which is of a beautiful yellow.

It is very plentiful in the West-Indies, and is found in some parts of Bohemia. Our jewellers have learned from the French and Italians, who are very fond of it, to call it citrine, and often cut stones for rings out of it, particularly out of the pyramid, which is always finer than the column; and these, after they have passed through two or three hands, are generally mistaken for topazes. *Hill's Hist. of Foss.*

CITRON *(Dict.)*—The several sorts of Citrons are cultivated much in the same manner as the orange-tree; to which we shall refer the reader to avoid repetition: but shall only remark, that these are somewhat tenderer than the orange, and should therefore have a warmer situation in winter, otherwise they are very subject to cast their fruit. They should also continue a little longer in the house in the spring, and be carried in again sooner in the autumn; as also have a warmer and better defended situation in the summer, though not so much exposed to the heat of the sun, in the heat of the day.

And

And as their leaves are larger, and their ſhoots ſtronger, than thoſe of the orange, they require a greater plenty of water in the ſummer; and in winter they ſhould have but little water at each time, which muſt be oftener repeated. The ſoil ought to be much the ſame as for the orange-tree, but not quite ſo ſtrong.

The common Citron is much the beſt ſtalk to bud any of the orange or lemon kinds upon, it being the ſtraighteſt and freeſt growing tree: the rind is ſmoother, and the wood leſs knotty, than either the orange or lemon, and will take either ſort full as well as its own kind; which is what none of the other ſorts will do: and theſe ſtocks, if rightly managed, will be very ſtrong, the ſecond year after ſowing, capable to receive any buds, and will have ſtrength to force them out vigorouſly; whereas it often happens, when theſe buds are inoculated into weak ſtocks, they frequently die, or remain till the ſecond year before they put out: and thoſe that ſhoot the next ſpring after budding, are often times ſo weak as hardly to be fit to remain, being incapable to make a ſtraight handſome ſtem, which is the great beauty of theſe trees. *Miller's Gard. Dict.*

CITRON-*wood*, ſo named by the Europeans, on account of its ſcent and colour; and what the Americans call candle-wood. What is uſually brought in billets of more than a thouſand pounds weight, is the trunk of a great tree, which grows commonly in the American iſles, and to a very great height. Its leaves, which reſemble thoſe of the laurel in ſhape, are very large, and of a bright green. Its flowers have the ſcent of jaſmine, and are like orange-flowers. Its fruit is black, and the bigneſs of pepper. It is this wood which ſome authors take for the true citrine ſantal, which is an inſufferable fraud, the difference, both in price and quality, of theſe two woods being very great.

The cheat is diſcoverable, not only in that the billets of the true ſantal weigh not more than a hundred pounds, whereas thoſe of the Citron-wood, as we have ſaid, weigh upwards of a thouſand pounds: but alſo, becauſe the ſantal is of a ſoft and agreeable taſte and flavour, reſinous, and moderately heavy; and, on the contrary, the Citron-wood is weighty, compact, oily, and of a ſtrong ſmell, inclining to that of the fruit from whence it takes its name. This wood is fit for turners and in-laid work, it taking an excellent poliſh.

CI'TRUL, *the water melon*. This plant hath trailing branches, as the cucumber, or melon, and is chiefly diſtinguiſhed from the other cucurbitaceous plants, by its leaf, which is deeply cut, and jagged, and by its producing an eatable fruit. See *plate* XIII. *fig.* 1. where *a* is the flower, *b* the fruit, *c* the ſeed.

You muſt, in order to cultivate this plant, firſt provide yourſelf with ſome ſeeds, which ſhould be two or three years old; for new ſeeds are apt to produce vigorous plants, which are ſeldom ſo fruitful as thoſe of a moderate ſtrength. Having provided yourſelf with good ſeed, you ſhould prepare an heap of new dung the beginning of February, which ſhould be thrown in a heap, for about twelve days, to heat; then you ſhould make a hot bed for one ſingle light, for which one good load of dung will be ſufficient; this dung ſhould be well wrought in making of the bed, and muſt be beaten down pretty cloſe with a dung fork, that the heat may not be too violent, and of longer continuance. When the dung is thus laid, you ſhould cover it about four inches thick, with good light earth; and, having ſpread it very even, you ſhould put the frame and glaſs over it, leaving it to warm four or five days, before you put the ſeeds into it; obſerving, if the ſteam riſes pretty much, to raiſe up the graſs with a ſtone, to let it paſs off. Then, if you find your bed in proper temper, you may ſow your ſeeds therein in drills, covering them over with earth, about half an inch. After this, if you find your bed very warm, you muſt give it air in the day-time, by raiſing the glaſſes; but, if the bed is cool, you muſt cover it well with matts every night, as alſo in bad weather. In four or five days after, you muſt prepare another hot bed, to receive theſe plants, which will be fit to tranſplant in ten days, or a fortnight, at moſt, after the ſeeds are ſown. This bed need not be very large; for a few of theſe plants will fill a large quantity of frames, when they are planted out for good: and, while the plants are young, there may be a great quantity kept in one light; ſo that thoſe perſons who raiſe early cucumbers and muſk-melons, may alſo raiſe their plants in the ſame bed; for two or three lights will be ſufficient to raiſe plants of all three kinds, to ſupply the largeſt families, until they are planted out for good. In the management of theſe plants, while young, the chief thing to be obſerved is, to let them have a large ſhare of air, whenever the weather will permit, otherwiſe the plants will draw up weak, and be good for little. As theſe plants require two or three hot beds, to bring them to perfection, it will be the better way to put the plants into baſkets, as ſome do in raiſing of early cucumbers; but you ſhould not plant more than two plants in each baſket; for, if one of them lives, it will be ſufficient: therefore, when both the plants ſucceed, you ſhould draw out the weakeſt and moſt unpromiſing of them, before they begin to put out their ſide-ſhoots, otherwiſe they will entangle, and render it difficult to be performed, without greatly injuring the remaining plant.

The baſkets in which theſe plants are to be planted, need not be more than a foot diameter; ſo that one light will contain eight of them, which will be ſufficient for twenty-four lights, when they are planted out for good; for, where the plants are vigorous, one ſingle plant will ſpread ſo far as to fill three lights; and, if they have not room, they ſeldom ſet their fruit well. Theſe baſkets may remain in the nurſery beds until the plants have ſpread, and put out many runners; for, when the heat of this bed declines, it is ſoon revived, by adding a proper lining of warm dung to the ſides of the bed, quite round; ſo that when they are taken out of this bed, and placed in the ridges where they are to remain, the heat of the beds will laſt ſo long as to ſet their fruit, which is of great conſequence; for, when the plants are ridged out very young, the beds are generally made of a great thickneſs in dung, in order to continue their heat; ſo that, for ſome time after they are made, they are ſo extreme hot, as to endanger the ſcalding of the plants; and, by the time the fruit begins to appear, there is little heat left in the beds, which often occaſions the fruit to drop off, and come to nothing.

After theſe plants are placed in the beds where they are to remain, you muſt carefully lead the ſhoots as they are produced, ſo as to fill each part of the frame, but not to croud each other; and be careful to keep them clear from weeds, as alſo to admit freſh air, whenever the weather will admit: they muſt alſo be frequently watered, but do not give it them in great quantities. *Miller's Gard. Dict.*

CI'TRUM. The ancient Romans had a ſort of tables made of an elegant wood, and called Citrum; theſe have been ſuppoſed, by ſome, to be made of the wood of the citron-tree, and by others, of the cedar; but it appears plainly, that they were made of neither, but of a wood peculiar for its fineneſs, and very different from both.

The more modern writers of the Mooriſh hiſtory tell us, that about mount Atlas, and in ſome of the iſlands on the coaſts of Africa, there grow cedars, which much reſemble the cypreſs-tree; and of the wood of their trunk they at this time make very beautiful tables, and of a large price. The name cedar is become very uncertain in its ſignification, and we at preſent call the junipers of the Weſt-Indies the Virginia and Bermudas cedars. It is poſſible that this cedar of the Africans, which grows like the cypreſs, may be the Citrum of the Latins, and thya of the Greeks; and that the citreæ and thyinæ menſæ may have been made of its wood. Vitruvius alſo tells us, of trees reſembling the cedar in their growth, and the cypreſs in the leaves. Theſe muſt be different from both, and muſt have a peculiar name, and might probably have been the trees called thya by the Greeks, and Citra by the Latins, of which theſe famous tables were made.

CI'TY. It has been obſerved that large Cities are more liable than other places to peſtilential and putrid diſorders, which is owing to the ſtagnation and corruption of the air. This is always the caſe in thoſe which are low and unprovided with common ſewers; where the ſtreets are narrow and foul, the houſes dirty, water ſcarce, and jails and hoſpitals crowded: alſo, when in ſickly times, the burials are within the walls, or when dead animals and offals are left to rot in the kennels or on dunghils; when drains are not provided to carry off any large body of ſtagnating water in the neighbourhood; when fleſh meats make the greateſt part of the diet, without a proper mixture of greens, bread, wine, or fermented liquors; from the uſe of old mouldy grain. In proportion to the number of theſe and the like cauſes concurring, a City will be more or leſs ſubject to peſtilential diſeaſes, or to receive the leaven of the true plague brought into it by any merchandize. *Pringle, Obſerv. on the Diſeaſes of the Army.*

CI'VES, in botany, a very ſmall ſpecies of onion, which never produces any bulbs, and ſeldom grows above ſix inches high in the blade, which is very ſmall and ſlender, and grows in tufts and bunches. This uſed to be in great requeſt for ſallads in ſpring, as being milder than other onions which had ſtood the winter, but at preſent it is not much regarded. The way of propagating it is by parting the roots in autumn, and planting them, at ſmall diſtances, three or four in a hole; they will ſtand the winter very well, and be fit for uſe early in the ſpring.

CLA'NGULA, in zoology, the name of a ſpecies of duck found about the ſea-coaſts, and called in Engliſh the golden eye. Its body is ſhort and thick; its head large, and its neck ſhort; its beak is ſhort and broad, and is all over black; its head is of a very obſcure and duſky green, yet gloſſy, and there is a large white ſpot at each angle of the beak; the iris of the eyes is of a beautiful yellow; the neck, ſhoulders, breaſt, and belly are white, and the back black; the wings are black and white, and the tail is wholly black; the legs are very ſhort, and the feet very broad, and both are of a ſaffron colour; the hinder toe is ſmall, but is edged on each ſide by a membrane, which adds much to its breadth.

CLAP-*net*, among ſportſmen, a ſort of net contrived for the taking of larks with a looking-glaſs, by the method called daring, or doring. The nets are ſpread over an even piece of ground, and the larks are invited into the place by other larks faſtened down, and by a looking-glaſs compoſed of five pieces, and fixed in a frame, ſo that it is turned round very ſwiftly, back-wards

wards and forwards, by a cord pulled by a person at a considerable distance behind a hedge.

CLAR, or CLAER, in metallurgy, bone-ashes perfectly calcined, and finely powdered, kept purposely for the covering the inside of coppels.

CLARIGA'TIO, in Roman antiquity, a ceremony that always preceded a formal declaration of war. It was performed in this manner; first four heralds crowned with vervain were sent to demand satisfaction for the injuries done the Roman state. These heralds, taking the gods to witness that their demands were just, one of them, with a clear voice, demanded restitutions within a limited time, commonly thirty-three days; which being expired, without any restitution made, then the pater patratus, or prince of the heralds, proceeded to the enemies frontiers, and declared war.

CLATTE' in heraldry, a term borrowed from the French, to express such lines as are sometimes found in the old paintings, and engravings of arms. These lines are of an irregular kind, and not reducible to any other proper lines of heraldry, as the engrailed, indented, embattled, or the like. *Nesbit's Heraldry.*

CLAVA'RIA, in botany, the name given by Vaillant, and continued by Linnæus, to a genus of fungus's, the characters of which are, that they grow perpendicularly, and have a simple and uniform surface; these have been called also, by the same Vaillant, under some small varieties in the species, corallo-fungus, and by Tournefort coralloides.

CLA'VICLE (*Dict.*)—*Fracture of the* CLAVICLE. The Clavicle is extremely subject to be fractured, both from its transverse position, and from its smallness. Whether it happens to be broken near the humerus, or near the sternum, its end that is next the humerus always descends lower than the other, from the weight of the arm which was before sustained by the Clavicle and head of the sternum; and, notwithstanding that part of it next the sternum remains immoveable by the descent of its other end, it can scarce happen, but they will in some degree collapse over one another.

The reduction of a fractured Clavicle is not very difficult, especially when the fracture is transverse; nor is it usual for the humerus, with the fragment of the Clavicle, to be so far distorted as not to be easily reduced by the fingers. The difficulty, however, is much greater to keep the bone in its place when the fracture has been reduced, and that most of all when the bone has been broken obliquely. For this there are two reasons; for the circular bandages, with which the bones of the arms and other extremities are usually held very firm, cannot be applied here, by reason of the form and disorder of the part, and then the weight of the depending arm soon pulls to pieces what the surgeon has been replacing.

This fracture is to be reduced in the following manner: the patient must be placed on a low seat, and an assistant is to thrust his knee against the middle of the patient's back, between his two shoulders; then laying hold of both the patient's arms with his hands, he must pull them gently and gradually backwards, by which means the Clavicles will be properly extended: while this is doing, the surgeon must stand before, and endeavour to replace the bone with both his hands, ordering the assistant to hold the bone in that position; he is then to apply a narrow and thick compress, so as to fill up the cavities above and below the Clavicle; upon these he is to lay two more narrow compresses made in the form of an X; over all these he is to apply a piece of paste-board, accommodated to the shoulders and neck, and first steeped in spirit of wine, or oxycrate; then he must place a ball under the arm, or else bind it several times with a thick roller, to prevent the humerus from subsiding; and lastly the whole is to be properly bound up, and the arms suspended by a sash or sling hung across the shoulder, about the neck. The plaisters that have been used to be employed on this occasion, have, of late years, been found to be wholly useless. When ever there are any loose splinters of the bone that are entirely separated, which, though they should not wound, or hurt the flesh, yet will obstruct the meeting of the Clavicle, it seems altogether requisite to open the skin, and remove them before the reduction of the bone, treating the wound as usual: but, if there be any splinters which still adhere to the bone, and prick the adjacent parts, and impede the reduction, they must be also either taken off with the forceps, or else forced back into their places, by which they may be again united to the bone. But to divide the parts, and remove the fragments, requires great caution, lest some of the large subclavian veins, or arteries, be wounded in the operation, and thereby a fatal hæmorrhage be produced. *Heister, Surg.*

CLA'VUS *hystericus*, in medicine, a name given to a peculiar species of a head-ach, more frequently attacking women than men, and with them usually owing its original to a suppression of the menstrual discharges. In some cases, the pain is less violent, and only attends people during the three or four first days of the menstrual discharge. In others, the pain is more violent, and almost continual; and when to the common causes of it there is added a venereal taint, which is no uncommon case, it becomes then the most terrible of all pains in the head.

Signs of it. These are a piercing pain about the fore head or temples, resembling that of a nail driven into the head: this pain sometimes also extends itself over the whole head: with this there generally is a sensation of pain about the sagittal suture in particular, and a remarkable coldness there: often there is an inflation and redness of the face, with a noise and ringing in the ears. To these there are not unfrequently added a slight fever, a chilness of the extremity, a remarkable lassitude, and want of appetite, with frequent eructations and nauseas, and costiveness of the bowels. It generally returns about the time of the menses; or, in cases where it is continual, it rages with more than ordinary violence at that time. Among the women, those are most subject to it who lead sedentary lives, and feed high, and who are naturally passionate, and of a hasty temper.

Method of cure. The first care in this respect is to keep the bowels lax, for they are almost always naturally costive in this disease: emollient clysters are the most proper means of this; and, where purges are required besides, they must always be of the most gentle and least vellicating kind. After these, the violent emotions of the blood are to be quieted by powders of nitre, antimony diaphoretic, crabs eyes, and cinnabar; and, if there be a spissitude in it, the natural and diuretic salts are to be given, in a scruple at a time, every day. Tartarum vitriolatum alone, given in this manner, frequently has a very great effect. If it be found necessary, besides this a gentle opiate may be sometimes given, such as a small dose of the storax pill: and, externally, spirit of wine and camphor is not a little serviceable. By way of prevention, it is extremely proper to bleed at spring and autumn every year: and, above all things, to keep regular in regard to the menstrual discharges. Gentle purges are to be given at times, and necessary exercise above all things to be advised; and this should always be the more insisted upon, the more averse the patients are to it, and the more they love to indulge in a sedentary course. *Junker's Consp. Med.*

CLEAT, in ship-building, a piece of wood fastened to the yard arm of a ship, to keep the ropes from slipping off the yard. *Manœuvring.*

CLEW, of the sail of a ship, is the lower corner of it which reaches down to that earing where the tackles and sheets are fastened; so that when a sail is made going, or sloping by degrees, she is said to have a great Clew: and a ship is said to have a great Clew, when she has a very long yard, and so has much canvas in her sails.

CLEW-*garnet*, among seamen, a rope fastened to the Clew of the sail, and from thence running in a block seized to the middle of the main and fore-yard. Its use is to hail up the Clew of the sail close to the middle of the yard, in order to its being furled.

CLEW-*line*, is the same to the top-sails, top-gallant sails, and sprit-sails, that the Clew-garnet is to the main-sail and fore-sail, and has the very same use. In a gust of wind, when a top-sail is to be handed, they first hale home the lee Clew-line, and by that means the sail is handed much easier.

CLINCH *of a cable*, is that part of it which is bent about the ring of the anchor, and then seized or made fast.

CLINCH-*bolts*, in a ship, are such as are clinched with a riveting hammer at those ends which come through.

CLI'NCHING, in the sea language, a kind of slight caulking used about the ports on a prospect of foul weather: it is done by driving a little oakum into their seams, that the water may not come in at them.

CLOCK (*Dict.*)— To adjust the period of a Clock, it is not necessary that the line of sight through the telescope should describe the meridian. If it always describes the same vertical circle at every transit of a star, it is sufficient. For the intervals of time between the successive appulses of a fixed star to the same vertical, are equal to the intervals between its appulses to the meridian. But, lest the uncertainty of the air's refraction should cause any difference in the times, it is better to have the vertical circle near the meridian; and to observe a star near the equator, because its transit is quicker. Now, the line of sight may be kept in the same vertical circle at every observation, by examining the level of the transverse axis every time; and by observing also, whether the cross hairs always cover the same mark upon a distant object, which in the night time must be illuminated by a lanthorn. For then the line of sight will describe the same vertical, notwithstanding any warping of the materials or even of the building to which it is fixed. Now, we learn from astronomy, that the period of the Clock will be exactly equal to a solar day of a mean length, if the same fixed star come to the cross hairs 3 minutes 56 seconds sooner every subsequent night than the night before it. For the interval of time between the apparent appulses of a fixed star to the same point of the heavens, is the same as the period of the earth's motion about its axis, which is called a sidereal day, and is 3′. 56″. shorter than a solar day of a mean length; I say of a mean length, because solar days, or the interval between the sun's appulses to the meridian, are unequal. But the error in the Clock's period will be discovered more exactly, by comparing two remote observations rather than two successive ones. For example, suppose a star comes to the cross hairs at 9 h. 30′. 18″. by by the Clock, and seven days after at 8 h. 50′. 24″. by the Clock; the difference of these times is 39′. 54″. and a seventh part of it is 5′. 42″; which shews that the diurnal period of the Clock is 5′. 42″. longer than a sidereal day; whereas a solar day of a mean length is but 3′. 56″. longer: and by consequence the diurnal period of the Clock is 1′. 42″. too long.

CLOSE-*fights*, aboard a ship, are such bulkheads as are in a fight put up fore and aft in the ship, that the men may stand behind them secure, and fire upon the enemy; and, if the ship is boarded, scour or clear the decks.

CLOTH (*Dict.*)—The goodness of Cloth, according to M. Savary, consists in the following particulars: 1. That the wool be of a good quality and well dressed. 2. It must be equally spun, carefully observing that the thread of the warp be finer and better twisted than that of the woof. 3. The Cloth must be well wrought, and beaten on the loom, so as to be every-where equally compact. 4. The wool must not be finer at one end of the piece than in the rest. 5. The lists must be sufficiently strong, of the same length with the stuff, and consist of good wool, hair, or ostrich feathers, or, which is still better, of Danish dog's hair. 6. The Cloth must be free from knots and other imperfections. 7. It must be scowered with fuller's earth, well fulled with the best white soap, and afterwards washed in clear water. 8. The hair or nap must be well drawn out with the teazel, without being too much opened. 9. It must be shorn close, without making it threadbare. 10. It must be well dried. 11. It must not be tenter-stretched, to force it to its just dimensions. 12. It must be pressed cold, not hot pressed, the latter being very injurious to woollen cloth.

CLOVER, a species of the trifolium. See the article TRIFOLIUM.

Clover is greatly cultivated in England for feeding of cattle, and is esteemed very profitable, because the great quantity of cattle which this grass will maintain, does very much enrich all clayey lands, and prepare them for corn in two or three years, which is the length of time that this crop will continue good.

In the choice of this seed, that which is of a bright yellowish colour, a little inclining to brown, should be preferred; but the black rejected as good for little.

Ten pounds of this seed will be sufficient for an acre of ground; for if the plants do not come up pretty thick, it will not be worth standing. The land in which this is sown should be well plowed, and harrowed very fine, otherwise the seeds will be buried too deep, and thereby lost.

The best time to sow it is about the beginning of August, at which season the autumnal rains will bring up the plants in a short time; whereas, when the seeds are sown in the spring, if it be done very early, they are many times burst with wet and cold; and, if it be done late, they are in danger of miscarrying from drought: whereas in autumn, when the ground has been warmed by the summer's heat, the rains then falling greatly promote the vegetation of seeds and plants.

The seeds should be harrowed in with bushes; for, if it be done with a common harrow, they will be buried too deep.

Most people have recommended the sowing of this seed with several sorts of corn; but if it be seasoned, as before directed, it will be much better, if sown alone; for the corn prevents the growth of the plants until it is reaped, and taken off the ground; so that one whole season is lost; and many times, if there be a great crop of corn upon the ground, it spoils the Clover, so that it is hardly worth standing; whereas, in the way before directed, the plants will have good roots before winter; and in the spring will come on much faster than that which was sown the spring before under corn.

About the middle of May this grass will be fit to cut, and there should be great care taken in making it; for it will require a great deal more labour and time to dry than common grass, and will shrink into less compass; but, if it be not too rank, it will make extraordinary rich food for cattle. The time for cutting it is when it begins to flower; for, if it stands much longer, the lower part of the stems will begin to dry, whereby it will make a less quantity of hay, and that not so well flavoured.

Some people cut three crops in one year of this grass; but the best way is but to cut one in the spring, and feed it the remaining part of the year, whereby the land will be enriched, and the plants will grow much stronger.

One acre of this grass will feed as many cattle as four or five acres of common grass: but great care should be taken of the cattle when they are first put into it, lest it burst them. To prevent which, some turn them in for a few hours only at first, and so stint them as to quantity; and this by degrees, letting them at first be only one hour in the middle of the day, when there is no moisture upon the grass, and so every day suffering them to remain a longer time, until they are fully seasoned to it: but great care should be had never to turn them into this food in wet weather; or, if they have been for some time accustomed to this food, it will be proper to turn them out at night in wet weather, and let them have hay, which will prevent the ill consequences of this food: but there are some who give straw to their cattle, while they are feeding upon this grass, to prevent the ill effects of it; which must not be given them in the field, because they will not eat it where there is plenty of better food. There are others who sow rye grass amongst their Clover, which they let grow together, in order to prevent the ill consequences of the cattle feeding wholly on Clover: but this is not a commendable way, because the rye grass will greatly injure the Clover in its growth.

Where the seeds are designed to be saved, the first crop in the spring should be permitted to stand until the seeds are ripe, which may be known by the stalks and heads changing to a brown colour; then it should be cut in a dry time: and, when it is well dried, it may be housed until winter, when the seeds should be threshed out; but, if the seeds are wanted for immediate sowing, it may be threshed out before it be housed or stocked; but then it must be well dried, otherwise the seeds will not quit their husks.

It has been a great complaint amongst the farmers, that they could not thresh out these seeds without great labour and difficulty; which I take to be chiefly owing to their cutting the spring crop when it begins to flower, and to leave the second crop for seed, which ripens so late in autumn, that there is not heat enough to dry the husks sufficiently: whereby they are tough, and the seeds rendered difficult to get out; which may be intirely remedied by leaving the first crop for seed, as hath been directed.

When the cattle are fed with this hay, the best way is to put it in racks, otherwise they will tread a great quantity of it down with their feet. This feed is much better for most other cattle than milch cows, so that these should rarely have any of it, lest it prove hurtful to them: though, when it is dry, it is not near so injurious to any sort of cattle, as when green.

COAL (*Dict.*)—There are various kinds of Coal, as the hard dusky black Coal.—This is one of the species of Coal in common use in London, and many other parts of the kingdom, and is called Scotch coal, though that name is not strictly applied to this species alone; but the following kind, more distinctly called Welch Coal, is often sold under the same denomination. It is a considerably firm and compact substance, of a moderately close texture, and pretty heavy: it is naturally of a rough, rugged, and a dusty surface, and is usually seen in flat masses, though it naturally constitutes large and continued strata; but, being of a laminated structure in these, it naturally breaks into masses of this shape in digging, and these more readily split, or break horizontally, than in any other direction, though by no means regularly or evenly in that. It is rough and harsh to the touch, and of a rude and rough surface; it is of a very strong and deep black, but not at all glossy; and, when broken, is much less so than any other Coal. Examined by the microscope, it appears of a tolerably close and compact texture, of an irregular laminated structure, and considerably bright.

It is very readily inflammable, and burns briskly, giving a bright white flame, and burning away very quick into ashes, not into cinders, in the manner of the common Coal. This is owing to its being more purely bituminous, and regularly inflammable; the masses of the common Coal becoming extinct before they are half consumed, these never going out till they are wholly burned away.

It is dug in great quantities in many parts of the kingdom; about Limington there is so much of it, and such quantities sent from thence, that in every place it is called Limington Coal.

The hard glossy COAL.—This is a species of coal sometimes sold in London under the name of Scotch Coal, but known in many parts of this kingdom under the name of Welch Coal; and is much esteemed for its burning with less smoke than any other kind.

It is a very firm and compact body, of a close, even, and regular texture, and considerably heavy; it is of a tolerably smooth surface, and soft to the touch, and is usually brought to us in moderately large and irregular flat lumps. In the earth it composes very large and thick strata, which being of a laminated structure, it naturally falls into masses of this shape in breaking. It is the hardest of all the species of Coal, but is not nearly so hard as the ampelites: it breaks more easily horizontally than in any other direction, though not regularly or evenly in that, and, when fresh broken, is very bright and glossy, and of a very fine deep black.

Examined by the microscope, it appears of a very remarkable even texture, and of a laminated structure, being composed of numerous small and thin plates, or flakes, laid closely on one another, and each of these of many other, much thinner and finer; the microscope shews, however, some part of these thinner flakes to be much purer, blacker, and more glossy than the rest.

It is dug in vast quantities in Wales, and in many parts of England; it is very readily inflammable, and burns with a bright, vivid, white flame, and almost wholly without smoke, but does not consume so fast as the former species, or burn away at once to ashes, but make cinders, like the common.

It is so remarkable for its burning without smoke, that, in some parts of this kingdom, and in general in Wales, they make malt with it without previous burning.

The

The friable glossy Coal.— This is a substance extremely well known, being the common firing of London, and of the greatest part of the kingdom. It is dug in different degrees of purity and goodness in different places; and the finest of this kind is known, among the dealers in Coal, by the name of Tanfield moor Coal, the place where it is dug.

It is a friable substance, of a smooth and even texture, and but moderately heavy, being much lighter than either of the former species, though heavier than the cannel, or ampelites: it is of an irregular and uneven surface, and usually comes to us in large thick masses, in various shapes, but not remarkably flat. It constitutes immense strata in the earth, and is in those of an irregularly laminated structure, and thence is naturally raised in broad and flat, rather than any other shaped pieces; but these are so brittle, that they are easily broken transversly, and, therefore, seldom retain long their original flat form. It is smooth on the surface, and somewhat soft to the touch, and is of less hardness than any other coal; it breaks with a tolerably even, and very remarkably bright, surface, and is of a fine deep shining black.

Viewed by the microscope, it appears of an irregular laminated structure, and close texture, and of a very remarkable brightness.

It is very readily inflammable, and does not burn soon to ashes.

It is dug about Newcastle in England, whence it has its name of Newcastle Coal, and in vast plenty in a great many other parts of the kingdom.

Coal-*balls*.— In the country of Liege, they use a kind of balls made of Coal and clay, for firing. These balls are made with one third of clay, without sand or gravel, and two thirds of Coal-dust, well mixed, and formed either into round balls, or into bricks. This Coal dust, being the refuse of the mine, makes this sort of firing cheap. See *Philos. Trans.* N°. 460. *Sect.* 3.

COA'MINGS, in ship-building, are those planks, or that frame, which raise up the hatches higher than the rest of the deck. Loopholes, for muskets to shoot out at, are often made in the Coamings, in order to clear the deck of the enemy, when a ship is boarded.

CO'BALT (*Dict.*)— Cobalt put into a coated retort, and set over a strong fire, yields thick fumes, which by degrees assemble themselves in the neck, and upper part of the vessel, in form of a solid substance. This is white arsenic, or ratsbane, but the ore is seldom so pure as to yield these flowers white and perfect from the beginning; they are often blackish at first, and, after this, red, which shews that there is some portion of common sulphur in the Cobalt, which, mixing with the arsenic, turns it red, as it will common white arsenic, especially if a little scoriæ of copper be added, or in the first case, if a little copper be contained in the Cobalt.

These red flowers form themselves into a solid substance of a laminated structure, and have much the appearance of a regulus of some kind; but they alter on being exposed to the air, and, though very bright and glossy at first, they become opake and dull afterwards. When roasted, as the miners term it, in a reverberatory oven, in which the flame of the wood is beat back upon the ore, it yields a white dusty substance like meal, which sticks to the top of the oven, and is collected for the making of common white arsenic, and the other kinds. The remaining substance, after all these white flowers are raised, is only the fixed earth which turns into that blue glass called smalt.

Bismuth ores, treated in the same manner, yield their metal for the common uses, as the Cobalt yields its arsenic; and the remainder, like that of the Cobalt, is an earth easily fusible into the same blue glass.

CO'CCUS *Polonicus*, an insect which may properly enough be called the cochineal of the northern part of the world. As the cochineal loves only the hot climates, this creature affects only the cold ones. It is collected for the use of dyers, but the crops of it are much smaller, more difficultly made, and the drug itself greatly inferior to the true cochineal. It is commonly known by the name of Coccus polonicus, or the scarlet grain of Poland. Poland is indeed the place where it is gathered in the greatest abundance, but it is not the only one; it is found in many other of the northern countries, and may very possibly be produced in some of the more temperate ones, where it is not known, as it is very much hid by nature from the eyes of common observers.

This kermes of Poland, if it may be so called, is found affixed to the root of a very small plant, and usually to the same plant, which has been thence called the polygonum cocciferum. Authors have informed us of the same berry, as it is often called, also growing at the roots of the mouse-ear, rupture wort, pimpernel, and pellitory of the wall; that it is in no other than dry sandy places, and that it is found at the roots of these plants. Breynius, in 1731, printed, at Dantzick, a very curious account of this production, which proves it incontestably to be an animal, and gives us many reasons for knowing it to be of the progall-insect class. *Reaumur, Hist. Ins.*

Toward the end of June, the Coccus polonicus is found in a state to be gathered. Every one of the creatures is then nearly of a spherical form, and of a fine violet colour; some of them, however, are not larger than poppy seeds, and others of the size of a pepper-corn; and each of them is lodged either in part, or intirely in a sort of cup, like that of an acorn. More than half the surface of the body of the animal is usually covered by this cup. The outside of this covering is rough, and of a blackish brown; but the inside is smooth, polished, and shining. On some plants they find only one or two of these, and on others more than forty; and they are sometimes placed near the origin of the stalks of the plant.

CO'D-FISH, is the largest of the genus of the aselli, called asellus maximus by authors, and, sometimes, asellus varius, sive striatus. The characters by which this is distinguished from other fishes of the same genus are these: its colour on the back and sides is a dusky olive, variegated with yellow spots; its belly is white; its sides have a long white line running their whole length, from the gills to the tail, which, at the abdomen, is curved, but elsewhere straight; its scales are very small, and adhere firmly to the skin; its eyes are large; at the angle of the lower jaws there hangs a single beard, which is short, seldom exceeding a finger's length; its tongue is broad; it has several rows of teeth, one of which is much longer than all the others. Among these there are some moveable teeth, as in the pike; and in the palate, near the orifice of the stomach, and near the gills, it has small clusters of teeth. It has three back fins, two at the gills, and two at the breast, and two others behind the anus; and the tail is plain. *Willughby's Hist. Pisc.*

COIN (*Dict.*)—*Flemish* Coins.— Those of gold are imperials, rides, or philips, alberts, and crowns.

Those of silver are phillips, rixdollars, patagons, scalines, and gulden: and those of copper, patards.

Patard, or penny.

								l. s. d.

by reason of the base alloy, no more than		½

For the other Coins of Europe; see the article Exchange, in the Dictionary.

Coins *of the coasts of Barbary*.— The current Coins struck here are rubies, medians, ziams, and metecals; all of gold: the last of which are struck at Morocco, the rest at Fez, Algiers, and Tunis; which beside have doublas of silver, and burbas of copper.— Tunis, has its nasaras of silver, its blanquilles likewise of silver, and felours of copper.

Other Coins of Africa, are the merigal of gold, current in Sofala, and the kingdom of Monopotapa; and the pardo of silver, current in Mosambica.

	s.	d. Sterl.
Rubie, equal to 35 aspres, or ——	1	9
Menian, 50 aspres, or ——	2	7

Persian Coins.— These are either silver, or copper; gold they have none: of the first kind are the abassi, mamodi, shahee, and bisti: of the second the kabesqui, and half kabesqui; the tela, or cherasis, indeed is gold; but it is less a money than a medal, though it has some course in commerce.

	s.	d. Sterl.
Abassi, equal to —— ——	1	4½
Mamodi, ½ the abassi — —	0	8¼
Shahee, ½ the mamodi, ——	0	4 and ⅛

Bisti, some relations make this a Coin worth about one penny half-penny; but others only a term of accompt, signifying 10 dimars, or $\frac{1}{1000}$ part of a toman.

Casbequi, or cabesqui, equals $\frac{1}{4}$ of a penny sterling.—Tela, or cherasis, usually struck at the accession of a new king, and at the beginning of each new year; its weight and worth various.

Chinese Coins.—Throughout the kingdom of China and Tonquin, there are not properly any Coins struck; instead of these, they cut their gold and silver into little pieces of different weights; those of gold, the Dutch, from their figure, which resembles a boat, called golchuts: those of silver, the natives call leam; the Portugueze, taels.— Their small money is of copper; ten of these make their shilling, and ten of those their crown, or leam.

Beside these, they have a small money of lead, mixed with the scum of copper, having holes in the middle to string them on for the ease of numbering: this species is called caxa, cas, and pitis; and the string, which usually holds 200, is called santa. They are so very brittle, that they never fall without breaking into a great number of pieces; and, if left all night in salt water, stick so close together that they cannot be separated.

There are two kinds of golchuts, great and small.—Golchut, an ingot, which, at 3l. 3s. per ounce, usually amounts to 101l. 5s. sterling.—Other golchuts only weigh half as much; their value in proportion.

Tael, or leam, equal to 6s. 8d. sterling.

Copper money $\frac{1}{1000}$ part of the teal, or somewhat more than ½ of a farthing.

Caxa, cases, or pitis, ⅓ of a farthing sterling, 300,000 of these are nearly equal to 56 Dutch livres.

Caxa larger, $\frac{1}{1000}$ of a piastre, or piece of eight.

Coins *of Japan*—The Japonese strike coupants, both of gold and silver, and copper pieces with holes in the middle, like those of China; six hundred of these make the tael. Their other monies, or quasi monies, are ingots, which they cut like the Chinese of different weights, chiefly three; the largest of the weight of six rials, viz. forty-eight taels, the tael equivalent to seventy-five Dutch styvers. The second equal to six taels and an half; and the third to ⅛ of a rial, or one tael $\frac{1}{10}$.

Besides these, they have a small silver money, in form of round beans, of no determinate weight, usually weighed by maises; the common payment being by ten maises, which make one tael.

	l.	s.	d. Sterl.
Coupant of gold, weighing one ounce six drachms; its figure a long oval, the longest diameter about four inches, and the shortest half an inch.	6	12	6
Other coupants of gold, near ⅓ of the former, amounting to about —	2	4	2
Coupant of silver, current at —	0	4	6
Copper money — — — —			$\frac{1}{12}$ of a farthing.

Coins *of Siam*.—In the dominions of Siam are struck gold pieces five or six grains heavier than the half pistole of Spain; but these are rather pieces of curiosity, than of use in commerce.

Their silver Coin is the tical, or baat; the dimensions whereof are the mayon, or seling, foang, and sompaye. These pieces are all strangely struck: in form they resemble nuts, a little flatted at the extremities; and are some of them cloven like horse-shoes; on two of the sides are some Siamese letters.—Their copper money, called bia, is round and thick: beneath this is the cauris.

Copper Coin, or farthing of Siam, -	0	$0\frac{3}{16}$

Coins *of the coasts and islands of the Indies*.—The principal, and those most generally current, are pagodos, rupees, larins, fanos, or fanons, and coupans, each whereof are struck both of gold and silver.

Besides these general Coins, are particular ones, viz. at Goa, St. Thomas's of gold.—Along the Persian gulf, about Mecca, and throughout Arabia, the larin.—Along the coasts of Malabar, and at Goa, the pardao and xeraphin of silver.—At Bantam, the fardos; at Malabar, the tare; at Siam the tayl, with its diminutions the mayam, foang, sompaye, and demi-foang; all of silver.— At Surate, Agra, and the rest of Indostan, the pecha, or pessa, and doudous, all of copper.—The basarucos and chedas, of tin.

	l.	s.	d. Sterl.

The other round — — — — — 0 : $0\frac{1}{4}$

Mogul COINS.—In the dominions of the great Mogul, are roupies, mamoudas, and pechas; the first both of gold and silver; the second of silver alone, and the third of copper.

There are others struck by the princes tributary to him, and the powers bordering on him, scarce current beyond their respective territories: particularly a small silver Coin struck by the king of Matoucha, whose territories lie to the north of Agra, of the value of the pecha of Mogul, but half as heavy again.—The raja of Parta-jajamoula, to the north of Patua, likewise strikes some little pieces, both of silver and copper, of small value.—The raja of Ogden, who commands between Brampour, Seronge, and Amadabath, a small silver Coin, equal to six-pence sterling; and another of copper, equal to an halfpenny sterling. The king of Cheda and Pera, a tin-money called cheda.—The king of Achem, little slight gold pieces, worth about fifteen-pence sterling.—And tin pieces, eighty of which are equal to the English penny, current in the isles of Sumatra.—The gold Coin of the king of Macassar and Celebes is taken by the Dutch for a florin.—The king of Camboya strikes only pieces of silver and copper: his gold, wherein he abounds, is negotiated by weight.—The kings of Java and Bantam, in the same island, and those of the Molucca islands, strike only copper Coins: they allow foreign silver species to be current in their territories, but coin none.

Roupia, see COINS *of the coasts, &c. of India*.

Mamouda, or mamotha, its value is not fixed: in the kingdom of Mazarate, the great mamouda is equal to — — — } s. d. Ster. 0 : 11

The small, half the great one — — — 0 : $5\frac{1}{2}$

Pecha, see COINS *of the isles of India*.

Silver piece of Matoucha — — — 0 : $0\frac{1}{2}$

Silver piece of the king of Ogden — — 0 : 6

Copper piece of the same — — — — 0 : $0\frac{1}{2}$

Cheda, see COINS *of the isles, &c. of India*.

Gold piece of the king of Achem — — 1 : 3

Tin piece of the same — — — — 0 : $0\frac{1}{80}$

Gold piece of the king of Macassar, taken by the Dutch for a guilder, — — — } 1 : $10\frac{1}{2}$

To the number of current Coins which have distinct names to specify them, may be added many more, both in Europe and Asia, only denominated and known from their value; such are those called simply pieces, with the addition of their price; as in Spain, the piece of eight rial, in England the piece of twenty-one shillings, or guinea; in France the piece of four francs, piece of ten sols, or shillings; piece of four sols; piece of two sols; of six blanks; of 30, 15, 6, 4, &c. deniers, or pence.

Shells current for COINS.—These serve in many places for money; and are brought from the Maldives, and called in the Indies cowries: on the coasts of Africa they change their name, and are called bouges.

In America they take a third name, viz. porcelains. Indeed these last do not come from the Maldives; there being shells found in the West-Indies much like those of the East.

In the kingdom of Congo is another kind of shells, called zimbi; though some will have them the same with the cowries.

Cowries, coris, or bouges, are white shells, current particularly in the estates of the great Mogul; dug out of the ground by the Maldivians: sixty-five are usually reckoned equivalent to the pone, a small copper Coin, worth about an halfpenny sterling; which brings each cowry to $\frac{1}{130}$ of a penny sterling. Porcelains are nearly on the same footing with the cowries.

Zimbi, current particularly in the kingdoms of Angola and Congo. Two thousand zimbis make what the negroes call a macoute; which is no real money, whereof there is none in this part of Africa, but a manner of reckoning: thus, two Flemish knives they esteem a macoute; a copper bason, two pounds weight, and twelve inches diameter, three macoutes; a fusy ten, &c.

Fruits current for COINS.—There are three kinds of fruits used for Coins; two in America, particularly among the Mexicans; which are the cacao and maise: the other in the East-Indies, viz. almonds; brought thither from Lar, and growing in the desarts of Arabia.

Cacao, fifteen of these are esteemed equivalent to a Spanish rial, or seven pence sterling.

Maise has ceased to be a common money since the discovery of America by the Europeans.

Almonds are chiefly used where the cauris are not current. As the year proves more or less favourable to this fruit, the value of the money is higher or lower: in a common year, forty almonds are set against a pescha, or halfpenny sterling; which brings each almond to $\frac{1}{20}$ of a farthing.

Ancient COINS are those chiefly which have been current among the Greeks, Jews, and Romans.

For Jewish Coins, their Values and proportion stand thus:

						l.	s.	d. Sterl.
					Gerah — — — — — — —	00	00	$1\frac{17}{100}$

COI'NING, in the tin works, is the marking the tin, when cast into blocks, or slabs, with the figure of the lion rampant. This is done by the king's officer. The king's custom is four shillings for every hundred weight. *Ray's Engl. Words.*

COLD (*Dict.*)—Cold is the destroyer of all vegetable life, when increased to an excessive degree; and it is hard to say how much increase of it the hardier of them are, or are not able to bear. We find many of our garden plants and flowers, which seem to be very stout and hardy, go off at a little increase of Cold beyond the ordinary standard. In the severe winter, in 1683, Mr. Bobart tells us, that the artichoaks and colliflowers all perished; and that the odoriferous suffrutices, such as thyme, sage, lavender, hyssop, and the like, were generally killed, very few escaping, except such as had been planted the preceding year, and were therefore so low as to have the advantage of a covering of snow over them; which is the defence nature has given to the natives of the coldest countries, and proves superior to any thing that can be invented by art for their preservation. In the corn fields, such parts of them as had remained covered with snow, had escaped very well, the corn all looking fresh and vigorous, after the melting of it in the spring: but, when the lands had lain so exposed that the snow had melted off, the crop was generally destroyed, and the farmer obliged to new sow the place. *Phil. Transf.* Numb. 165.

COLE-*seed*, the seed of the naphew or napus, propagated in many parts of England to great advantage, for the oil expressed from the seed. It is much sowed in the moory lands in the fen countries. The freshest mould is found best for it, or what the farmers call a lusty soil, which is newly broken up, and has been long at rest. They commonly give two tilths to the ground they sow with Cole-seed; but, if they manure it, then only one. They lay on the manure, a little before they begin to plow; and, plowing in the morning, sow that very day. The time of sowing is in June, July, and August: July is the best month. They sow the seed over furrows, a peck to an acre, and bush-harrow it; they then have a crop that time twelvemonth, which they shear or reap as they do wheat, disposing it into little heaps. When it has lain about a fortnight upon the ground, they thresh it upon a sail-cloth, with common flails; then winnow it, and afterwards send it to the mills. *Morton's Northampt.*

The land where this has grown, is very well prepared by it for wheat; though some sow oats upon it, as wheat succeeds best of all after it. When the oil is pressed out of the seeds, they use the remaining cakes in some places as firing; but in others they give them to their cows and other cattle in winter, when other food is scarce. In some places, they mix the powder of these cakes with water, and give it to their calves till they are three or four days old, instead of milk, and it does as well for them, till they are able to eat grass or hay. It is a good method to burn the stubble on the Cole-seed lands, for it is so stumpy that it is of no use to plow it in. *Mortimer's Husb.*

CO'LLAR, in ship-building, a rope fastened about her beak-head, into which the dead man's eye is seized that holds the main-stay. There is also a collar, or garland, about the main-mast head, which is a rope wound about there, to save the shrouds from galling.

COLLAR *of a plough*, a term used by our farmers to express a ring of iron, which is fixed to the middle of the beam, and serves to receive the end of two chains, the lower one called the tow chain, and the upper one called the bridle chain. The lower chain is fixed at its other end to the box, and the upper, or bridle chain, to the stake which runs parallel with the left-hand crow-staff. These chains, by means of this collar, and their other insertions, serve to join the head and tail of the plough together. In some places the bridle chain is not fixed to the collar, but to the beam itself, by means of a pin; and this is the better way on many accounts. *Tull's Husbandry.*

CO'LOGNE *Earth*, a substance used in painting, much approaching to amber in its structure, and of a deep brown. It has generally been esteemed a genuine earth, but has been discovered to contain a great deal of vegetable matter, and, indeed, is a very singular substance.

It is dug in Germany and France: the quantities consumed in painting, in London, are brought from Cologne, where it is found very plentifully; but our own kingdom is not without it, it being found near Birmingham, and on Mendip hills, in Somersetshire; but what has been yet found there is not so pure or fine, as that imported from Cologne. *Hill's Hist. of Foss.*

CO'LONY (*Dict.*) — In order to give a clear account of the causes and effects of these settlements, it will be proper to distinguish them into six separate classes.

1. About 350 years after the flood the whole human race were but one family; at the death of Noah his descendants, being too numerous to live together, separated. The posterity of each of the sons of this patriarch, Japhet, Sem, and Ham, divided into different tribes, set out from the plains of Shinar in quest of new habitations, and every tribe became a distinct people: thus, they gradually peopled the different countries of the earth, in proportion as the respective countries they went into could support and maintain them.

Such was the first kind of Colonies; necessity was the cause, and the effect was the subdivision of the tribes or nations.

2. Though men were thus scattered over the face of the whole earth, yet every different country was not so completely occupied by its antient inhabitants, but that new ones might share it with them.

In proportion as countries were at a greater distance from the common center, from which all nations set out, every separate family wandered at pleasure, without making any fixed abode; but in those countries where a larger body of men staid, nature and mutual convenience uniting them, they formed societies. Ambition, dissension, war, and even their increase, in a course of time, drove some parts of these societies to seek new habitations.

Thus Inachus, a Phœnician, came and founded the kingdom of Argos in Greece, whose posterity was driven out by Danaus, another adventurer, who came out of Ægypt. Cadmus, not daring to return to his father Agenor, king of Tyre, landed on the confines of Phocis, and there laid the foundation of the city of Thebes. Cecrops at the head of an Ægyptian Colony built the city, which afterwards, under the name of Athens, became the seat of arts and sciences. Africa with unconcern saw the walls of Carthage rise, which soon after made it tributary. Italy received the Trojans who had escaped from the ruin of their country. These new inhabitants introduced their laws and sciences into those countries, whither chance had conducted them; but they only formed little societies, and almost all erected themselves into republics.

A multiplicity of citizens, in a territory either of narrow limits or little fertility, has given an alarm to liberty; and policy has removed this inconvenience by establishing Colonies. Nay, even the loss of liberty has sometimes engaged a part of the people to quit their own country, in order to form a new society, more agreeable to their own minds.

This, among others, gave birth to most of the Greek Colonies in Asia, in Sicily, Italy, and Gaul. The views of conquest and ambition did not enter into their scheme. Although, in general, every Colony preserved the laws, the language, and religion of the metropolis, yet it was free, and depended only on its founders.

This second kind of Colonies had different motives, but the effect which distinguishes them, was to multiply independent societies among nations; to promote commerce between them, and polish their manners.

3. As soon as the earth had such a number of inhabitants, that a distinction of property became necessary, this property occasioned differences between them. These differences were decided by the laws among the members of a society, but could not be so determined among independent associations; power decided, the vanquished yielded to the victor, and the spirit of conquest invaded the minds of men.

The conqueror, to secure his frontiers, dispersed the conquered in countries under his allegiance, and gave their territories to his own subjects, or contented himself with building and fortifying new towns in them, which he caused to be inhabited by his soldiers, and the citizens of his own state.

Such was the third kind of Colonies, examples of which may be found in almost all ancient histories.

By means of these Colonies, Alexander took in such a multitude of conquered people with such rapidity. The Romans, in the infancy of their republic, made use of them to increase it; and, at the time when their vast empire extended itself in every part of the world, these were the barriers, which, for a long time, defended it against the Parthians, and people of the North. This kind of Colony was a consequence of conquest, and, indeed, its defence.

4. The excursions of the Gauls into Italy, of the Goths and Vandals into all Europe and Africa, and of the Tartars into China, form a fourth kind of Colonies. These people, driven out of their country, by more powerful people or distress, or perhaps attracted by the knowledge of a milder climate and more fruitful country, conquered to share the kindlier soil with those they had subdued, and only to make one nation with them. Quite different from other conquerors, who seem to have set out only in pursuit of enemies, as the Scythians in Asia, and the founders of the four great empires.

The effect of these Colonies of Barbarians, was to exterminate polite arts, and spread ignorance throughout the countries wherein they settled, at the same time that they increased the number of people, and founded powerful monarchies.

5. The fifth kind of Colonies is such as have been founded by a spirit of commerce to enrich their mother people, or metropolis.

Tyre, Carthage, and Marseilles are the only cities of antiquity, which laid the foundation of their power on their trade; and they only followed this plan in some of their Colonies. Utica, built by the Tyrians, near 200 years before the flight of Eliza, more known by the name of Dido, never pretended to any sovereignty in the realms of Africa, but only served as a port a port for the Tyrian ſhips to put into, in the ſame manner as the Colonies eſtabliſhed at Malta, and along the coaſts frequented by the Phœnicians. Cadiz, one of their moſt ancient and famous Colonies, only pretended to the trade of Spain, without intermeddling with the adminiſtration of its government, much leſs giving it laws. The founding Lilybæum in Sicily gave the Tyrians no notion of conquering that iſland. Commerce alone was not the object of the eſtabliſhment of the Carthaginian ſtate, though the city ſought to aggrandize itſelf by commerce. Carthage made war to extend or preſerve that trade to itſelf only, and therefore diſputed with Rome a right to Sicily, Sardinia, Spain, and Italy, even at the walls of that city. The Carthaginian Colonies along the coaſts of Africa, on both ſides the ſea to Cerne, rather augmented the riches of the ſtate than ſtrengthened the power of its dominion. Marſeilles, a Colony of Phocæans, driven out of their own country, and afterwards out of the iſle of Corſica by the Tyrians, as they inhabited a barren country, attended to nothing but their fiſhery, trade, and independence. Their Colonies in Spain, and the ſouthern coaſts of Gaul, were planted with the ſame view.

Such ſort of ſettlements were doubly neceſſary to people who applied themſelves to commerce. They who knew not the uſe of the compaſs, were afraid to venture too far from the ſhore; they made coaſting voyages, and their navigation was ſo timorous, that it made frequent ports neceſſary: the generality of the people they traded with, ſet a certain value on the commodities they intended to part with, and came down out of the inland countries, at the time of the arrival of the ſhips, to exchange them for what they wanted.

The form of theſe Colonies has a great affinity with thoſe of the European nations trading to Africa and the Indies, which have ſtore-houſes and forts for the ſecurity and convenience of their trade. Our own nation therefore make a more conſiderable figure as merchants in thoſe countries, than any other in Europe, becauſe they do not endeavour to conquer the inhabitants, and acquire the poſſeſſion of large dominions.

6. The diſcovery of America, about the end of the fifteenth century, has increaſed the European Colonies, and preſents us with a ſixth kind of them.

All theſe have had commerce and culture both at once for the object of their ſettlement. It was neceſſary for them, firſt, to conquer that part of the country they intended to poſſeſs, drive out the ancient inhabitants, and introduce new.

As theſe Colonies were only eſtabliſhed for the benefit of the mother country, it follows:

1. That theſe Colonies muſt immediately depend upon it, and conſequently be under its protection.

2. That the trade ought to be excluſive to the founders. A Colony of this nature anſwers its end ſo much the better, in proportion as it promotes the manufactures, employs a greater number of hands, and gives the balance of trade to its mother country in her commerce with other nations. Theſe three benefits may unite in ſome particular circumſtances, and one of the three may in ſome meaſure compenſate for the whole; but, if the Colony is deficient in this reſpect, it is plainly pernicious to its mother country, and weakens it.

Thus the profit of the trade and culture of our Colonies reſults from, 1. The larger product which their conſumption occaſions to the proprietors of our own lands, the expence of culture deducted. 2. What our mechanics and mariners receive, who work for them, and on their account. 3. What neceſſaries they ſupply us with. 4. What ſuperfluities they furniſh for exportation.

From theſe premiſſes many concluſions may be drawn.

Every Colony ought to be confined to ſuch arts and objects as may be uſeful to its mother country. If a Colony deals at foreign markets, and conſumes foreign commodities, the mother country is a ſufferer in proportion to ſuch dealings, and ſuch conſumption; therefore, a reſtraint in this caſe is no attempt on the liberty of the Colony, but is ſtrictly juſt. Colonies become more uſeful, by how much they are rendered more populous, and their lands are better cultivated.

The ſtate ſhould be at the firſt expence of eſtabliſhing Colonies; children ſhould inherit equally, at the death of their fathers, in order to fix a greater number of inhabitants on the ſpot. The firſt expence of the ſtate is not all; till the Colony has acquired ſtrength to ſupport itſelf, and ſettled a trade to maintain itſelf, it will continually ſtand in need of the protection and aid of its mother country. The Colonies of America having eſtabliſhed a new form of connection and commerce, it has been neceſſary to make new laws in them. Able legiſlators have principally had in view the protection and cultivation of the Colony; but, when theſe are come to ſome perfection, it may ſo happen, that ſuch laws may become contrary to the deſign of inſtituting Colonies, which was to promote trade. When a ſtate has ſeveral Colonies which may carry on a mutual trade, the way to augment their ſtrength and riches is to encourage it.

Upon the whole, it appears the liberty of Colonies ſhould be reſtrained by the mother country. But all monopolies, impoſitions, particular privileges, or exemptions, are extremely pernicious; and, though their effect may not be felt immediately, will certainly end in the deſtruction of the Colony; for whatever contributes to raiſe the price of commodities, without increaſing their real value, muſt ruin the trade of the Colony.

COLOUR (*Dict.*)—Tranſparency, whiteneſs, blackneſs, and Colours, as conſidered in bodies, depend upon certain particular ſtructures, textures, or arrangements of the parts of bodies, as the following inſtances will abundantly demonſtrate.

Glaſs, cryſtal, diamond, nitre, borax, and other tranſparent ſolid bodies, loſe their tranſparency, and appear white upon their being reduced to powder; that is, by a bare alteration of their groſs texture, or a ſimple reduction to ſmaller parts; ſo as to reflect many of the rays of light, which they before tranſmitted. And the ſame holds of the white of eggs whiſked up to a froth, frothy water, &c.

Black talc, by being made red-hot in the fire, is turned of a gold Colour; ſyrup of violets, by boiling heat, loſes its beautiful violet-Colour, ſo as at length to become pale, or colourleſs; white loaf-ſugar, being barely melted over the fire, without water, immediately changes its whiteneſs, and becomes brown; or, by a longer continuance, black; ſo that a ſingle grain of this black ſubſtance will tinge a pint or a quart of fair water, or colourleſs brandy, of a beautiful yellow, brown, or ſtraw Colour; for which purpoſe it is uſed by diſtillers, and others.

All the finer, coloured flowers, as violets, carnations, roſes, &c. loſe of their Colour, barely by being expoſed to the open air for any long time; ſo as at laſt to appear perfectly diſcharged, or white, as if they had been expoſed to that particular diſcharger of Colour in ſilks, &c. the fume of burning brimſtone. And the ſame is remarkable of the finer or lighter kinds of Colours in ſilks, or the light blues, yellows, and reds, particularly the light grain-coloured ſilks; all which Colours are gradually changed, diſcharged, or aboliſhed, in wearing, or by the ſilks being long expoſed to the action of the air. But the ſcarlet Colour is more fixed and durable. And, in general, the deeper any Colours are, the more fixed and durable they prove; as being thus not ſhades, as the pinks, light blues, &c. are, but true Colours, correſponding to the original Colours of light. Add to this, that dyers conſtantly find their Colours prove brighteſt, or ſtruck to the beſt advantage, when the air is clear. Laſtly, the blue eſſential oil of camomile-flowers loſes its Colour, and changes to a dirty green, by being expoſed to the air.

Different waters ſtrike different Colours with the ſame tinging ingredients. Thus irony waters turn black, or inky, with galls, green tea, &c. And dyers find ſome certain waters more proper for their purpoſes than others. And, in general, the pureſt and lighteſt waters ſtrike the beſt Colours with dying-ſtuffs. And hence it is that ſuch waters as have, by long ſtanding, putrified, or fermented, and purged themſelves, being not filtred through the common filtring-ſtone or ſand, are found to extract and communicate Colours to the greateſt advantage.

Salts, having a power to alter the textures of vegetables, conſequently produce changes of Colours therein. Thus moſt flowers, whether blue or red, as violets, roſes, &c. turn green with alkalies: But violets turn red, and roſes have their native redneſs greatly heightened by acids; ſo again, the yellow roots of rhubarb, turmeric, &c. are heightened, or made redder, by alkaline ſalts.

As metals have a ſtrong texture in their metalline form; ſo they preſerve their natural Colours durably, unleſs corroded or diſſolved by their particular menſtruums: after which, their ſolutions ſtrike particular durable Colours, or afford the ſtrongeſt ſtains.

Iron, diſſolved in ſtale ſmall-beer, gives the beautiful yellow uſed in callico-printing; when ſublimed with ſal armoniac, it alſo affords a yellow. And the common iron-moulds made by ink are owing to the iron diſſolved in copperas, whereof the common black writing ink is made.

Copper, melted with zink, appears of a gold-Colour; diſſolved in aqua-fortis, it affords a beautiful green; and, in any urinous ſpirit, a beautiful blue; and the ſolutions may be reduced to dry Colours by cryſtallization, or evaporation. The ſame metal precipitated with common ſalt, out of aqua-fortis, gives the turquoiſe Colour to white glaſs, when melted therewith.

Tin, a white, or colourleſs metal, affords a light blue Colour, by being fluxed with antimony and nitre. The ſame metal is neceſſary in ſtriking the ſcarlet-dye, with aqua-fortis and cochineal: its calx, by ſtrong fuſion, turns a glaſs of the opal Colour.

Lead, being corroded by the fumes of vinegar, makes the fine white called ceruſe, and the white fucus called the magiſtery of lead; by being coloured in a ſtrong naked fire, it becomes minium, or red-lead; and this, melted into glaſs with ſand, is the foundation of the art of imitating all the coloured gems: for this glaſs itſelf will reſemble the hyacinth; and, by the addition of prepared gold and tin, the ruby; the ſapphire with cobalt, the emerald with iron and copper, the amethyſt with gold, and the granat with iron, &c.

Silver, another white, or colourleſs metal, being diſſolved in aqua-fortis, if chalk is put to the ſolution, turns of a beautiful purple, or amethyſt Colour: and its own ſolution, though pale as water, durably ſtains the nails, the ſkin, the hair, and other animal ſubſtances, brown or black.

Quickſilver, mixed with brimſtone, makes a black maſs; and this, by ſublimation, affords the beautiful red pigment called cinnabar, or vermilion: and the ſolution of quickſilver, being precipitated with common ſalt, yields a ſnow-white powder; which alſo turns black, by being mixed with ſulphur.

Gold, diſſolved in aqua-regia, affords a fine yellow liquor, which ſtains animal ſubſtances beautifully purple: and, if the ſolution be ſufficiently weakened with water, and mixed with a ſolution of tin, a fine red or purple powder may be thus obtained for ſtaining glaſs moſt beautifully red.

Many mineral ſubjects are natural pigments; as native cinnabar, ochre, black-lead, &c. but particularly the yellow earth called light ochre, found in Shattover-hills, which is uſed native, as a light yellow, and by calcination makes a light red. This Colour England ſupplies Italy with; and Le Gar would frequently ſay he had been no painter without it.

Colours may alſo be produced, deſtroyed, and regenerated upon ſimple mixture: for,

Put dry red roſe-leaves into ſpirit of wine; and, by ſtanding a little therein, the roſe-leaves will loſe their red Colour, without manifeſtly tinging or altering the liquor; then add a little oil, or ſpirit of vitriol, thereto, and the liquor will appear of a red Colour. But, if a little alkaline or urinous ſpirit be poured to the mixture, the red Colour preſently changes to a green; which, by the addition of a little more ſpirit of vitriol, turns to a red Colour again.

Make a ſlight infuſion of bruiſed galls in water, ſo as not to diſcolour the water; filtre the infuſion; make alſo a weak ſolution of green vitriol in water, and filtre the liquor, ſo that they may both appear pellucid: theſe liquors being now mixed together, an inky blackneſs will immediately ariſe; but, if a little oil of vitriol be added to the mixture, the blackneſs will, by degrees, totally vaniſh, and the liquor appear pellucid again; though the blackneſs may be recalled by the addition of a little ſalt of tartar.

If a little bruiſed camphire, which is a very white ſubſtance, be put into pellucid oil of vitriol, and the containing glaſs be ſhook for ſome time, the camphire will diſſolve, and gradually change the mixture to a brown, and at length to a full black. But, upon the addition of fair water, the blackneſs entirely vaniſhes, and the camphire riſes to the top in its priſtine form, and native whiteneſs.

If the ſhavings of lignum nephriticum be infuſed for ſome time in cold water, and the clear liquor be decanted into a clean glaſs, and viewed from the light, the liquor will appear of a beautiful blue; but, if viewed towards the light, of a yellow. If a little ſpirit of nitre be put to this liquor, it loſes its power of reflecting the blue rays; but the addition of a little oil of tartar, per deliquium, recovers that power again.

If logwood be infuſed in water, it gives a red Colour; which, upon the addition of a little ſpirit of urine, turns to a fine purple: but this may be changed to a bright red, by dropping in a little ſpirit of common ſalt.

An infuſion of braſil-wood, or cochineal, in water, is much heightened, in its red Colour, by the addition of ſpirit of urine, and lowered or turned paler by the ſpirit of ſalt.

If ſpirit of wine be digeſted upon recent camomile-flowers, and diſtilled over from them in a glaſs retort, the ſpirit will thus acquire a beautiful blue Colour; which may be made deeper by being drawn over again from freſh flowers.

A beautiful blue tincture being made by digeſting ſpirit of urine upon filings of copper, the addition of a little oil of vitriol intirely deſtroys the blue Colour, as a little ſpirit of ſalt turns it to a green.

Pellucid oil of vitriol being mixed with pellucid oil of turpentine, or the eſſential oil of aniſeeds; or more particularly with oil of cloves; they thus turn into a thick, red balſam.

And ſo again, if a pellucid common oil be, by means of a little wax, and continued triture, gradually mixed with fair water; they thus unite into a very thick, white ſubſtance, balſam, or cold cream.

Oil of vitriol, being diſtilled over from quickſilver, leaves a white powder behind; to which, if water be poured, the powder preſently becomes of a beautiful yellow.

To a ſolution of quickſilver, in ſpirit of nitre, add ſpirit of urine, and a white powder will be precipitated; to another parcel of the ſame ſolution add oil of tartar per deliquium, and a yellow powder will fall to the bottom: to a third parcel of the ſame ſolution add ſpirit of urine, and the precipitate obtained will be of a fleſh-Colour.

If a clean new pen be dipped in ſpirit of vitriol, and the common deep blue paper be wrote upon therewith, the letters appear of a very bright and beautiful red: and, in the ſame manner, pellucid ſpirit of ſalt ſtains a black hat red.

A pellucid ſolution of ſaccharum ſaturni in water, being wrote with, becomes inviſible upon the paper, when dried: but the bare fumes of another tranſparent liquor, viz. an infuſion of quicklime and orpiment in water, will ſoon render the inviſible writing black and legible. And thus thoſe commonly called inviſible or ſympathetic inks are made.

The volatile ſalt of ſal armoniac, a white body, and the cryſtals of copper, a green one, will, by mixture, become purple. Salt of ſteel, a green body, and ſugar of lead, a white one, being mixed together, the ſurface of the mixed powder will appear red, whilſt the internal parts are of a dirty white.

That original and ſimple, as well as compound Colours, are producible by mixture, appears from many experiments.

If the ſun's rays paſs through two pieces of differently coloured glaſs, for inſtance, a blue and a yellow piece, laid upon each other, and theſe rays be received from the glaſſes upon white paper, they then appear of a beautiful green.

It is common, with the dyers, to dye the cloth firſt blue with woad, and turn that blue into a green by the yellow called dyers weed, or luteola.

To a fine yellow ſolution of pure gold, in aqua-regia, add a deep blue ſolution of copper in ſpirit of urine, and the mixture will appear green.

Blue and yellow ammel, being melted together, conſtitute a green one.

The painters make a great variety of compound Colours, by mixing two, three, or more different Colours together, either on their pallat, or the canvas.

A mixture of the ſeven, or even five, original Colours, will make a white; and the more perfectly, the finer and more perfect the coloured bodies are. Thus, if a large top be painted on its upper ſurface, one part red, another yellow, another green, another blue, and another violet; this ſurface whilſt the top is ſpinning briſkly (ſo that the motion ſhall confound the ſeveral Colours, or make them appear mixed to the eye) will exhibit a dirty kind of whiteneſs. And in like manner, by mixing together powders of different Colours, as vermilion, orpiment, indigo, verdigreaſe, &c. in proper proportions, the compound powder will, in a ſtrong light, appear to be white. And, if differently coloured flames could be brought to mix, this experiment might be made in greater perfection.

Flames are of different Colours, according to the bodies that produce them. Thus the flame of burning camphire is white, like the focus of a burning-glaſs; the flames of ſpirit of wine, and ſulphur, are blue; the flame of white wax is white, inclining to blue; that of tallow white, but rather inclining to yellow, &c. Whence proceeds the difference of the Colours of bodies, as viewed by day-light, candle-light, fire-light, ſulphureous light, &c. And, for making experiments to this purpoſe, oil might be impregnated with certain metals, as particularly copper and iron, by triture and digeſtion, ſo as to exhibit their particular flames.

The priſmatic or original Colours may be imitated to conſiderable perfection in liquors, where the parts of the tinging ſubſtances are rendered extremely minute or fine. Thus a ſolution of cochineal in ſpirit of urine, viewed in a ſtrong light, affords a moſt vivid and beautiful red; a ſolution of copper in ſpirit of urine yields a glorious blue; a ſolution of verdigreaſe in diſtilled vinegar is an excellent green; a ſolution of gold in aqua-regia makes a fine yellow; an infuſion of violets in hot water affords an excellent violet-Colour, &c. And, from a thorough acquaintance with theſe liquors, and the methods of varying, mixing, and heightening their Colours, many improvements in the arts depending upon Colours, dyes, and ſtains, might be rationally expected.

CO'LTIE, among the timber merchants, a word uſed to expreſs a tree which has a defect in ſome one of its annual circles, which renders it unfit for many of the uſes it might otherwiſe have been fit for. In this caſe ſome one of the annual circles, near the center, is perceived by the eye to be thicker than the reſt, and its ſap veſſels larger. It has an appearance much different from that of the others, and is ſo looſly connected both to its inveſtient and inveſted circles, that, on ſawing a tranſverſe piece of the trunk off, it will ſlip out from the others, and ſo leave the heart looſe, and the reſt hollow, ſeeming to have been only fitted, not connected, to the others. In ſplitting the wood for the other uſes, it yet more readily drops out, and the timber of ſuch a tree is therefore much leſs fit for general uſe than that of others. It is not eaſy to ſay to what accident, in the growth of the tree, this is owing: but it ſeems probable that it expoſes the tree to other accidents; in particular, Bobart ſeems to think, that among the trees which were ſplit by the hard froſt, in the year 1683, while other trees of the like ſizes and kinds eſcaped, this coltineſs might be the occaſion of the miſchief, as well as their being wind-ſhaken, or lagged. *Phil. Tranſ.* N°. 165.

CO'LUMBINES, *aquilegia*, in botany, a genus of plants much cultivated in gardens.

The manner of propagating Columbines is either by ſowing, or parting the old roots; but, the old roots being very apt to degenerate, the ſowing them is much the beſt method.

The ſeeds muſt be ſown in a nurſery bed in Auguſt or September, and, in the March following, the plants will appear above the ground, at which time they muſt be carefully cleared of weeds, and watered gently at times, if the dryneſs of the ſeaſon requires it. In the beginning of May, they will be ſtrong enough to tranſplant, and muſt then be placed at eight inches diſtance, in beds of good, freſh, undunged earth, and they muſt here be alſo kept cleaned from weeds, and watered as they may require it; at Michaelmas they may be removed into the borders of the flower-garden, and in the May following they will flower. *Miller's Gard. Dict.*

CO'LURE (*Dict.*)— It is diſputable over what part of the back of Aries the equinoctial colour paſſed in the time of Hipparchus. Sir Iſaac Newton, in his Chronology, takes it to have been over the middle of the conſtellation. Father Souciet inſiſts fifts on its having paffed over the dodecatemorion of Aries, or midway between the rim and firft of the tail. We have fome obfervations, in the Philofophical Tranfactions, N° 466, concerning the pofition of this Colure in the antient fphere, from a draught of the conftellation Aries, in the Aratæa publifhed at Leyden and Amfterdam 1652, which feem to confirm Sir Ifaac's opinion; but the antiquity and authority of the original draught may ftill remain in queftion.

COMBINA'TION (*Dict.*)—The ingenious Mr. John Smeaton has given us, in the Philofophical Tranfactions, Vol. XLVII, the following new Combination of pullies. See *Plate fig.* VX. 9.

The axis in peritrochio, and the compound pulley, are the only mechanic powers, which can with convenience be applied to the moving large weights, when the height, to which they are intended to be raifed, is confiderable. The excellence of the former is, their working with little friction; that of the latter, in their being eafy to be moved from place to place, and applied extempore, as occafion requires.

The prefent method of arranging pullies in their blocks may be reduced to two. The firft confifts in placing them one by the fide of another, upon the fame pin; the other in placing them directly under one another, upon feparate pins. But in each of thefe methods an inconvenience arifes, if above three pullies are framed in one block. For, according to the firft method, if above fix pullies are placed by the fide of one another, as the laft line, by which the draught is made (or, as it is commonly called, the fall of the tackle) muft neceffarily be on the outfide pulley or fhieve, the difference of their friction will give it fo great a tendency to pull the block away, that as much will be loft by the rubbing of the fhieves againft the block, on account of its obliquity, as will be got by increafing the number of lines.

The fecond method is free from this objection; but, as the length of the two blocks, taken together, muft be equal to the fum of the diameters of the fix pullies, befides the fpaces between for the ropes, and the neceffary appendages of the framing, were there more than three pullies in each block, they would run out into fuch an inconvenient length, as to deduct very confiderably from the height, to which the weight might otherwife have been raifed: fo that, upon thofe accounts, no very great purchafe can be made by the common tackles of pullies alone.

In order therefore to increafe its power, fometimes a fecond tackle is fixed upon the fall of the firft; but here it is obvious, that, whatever be the power of the fecond tackle, the height to which the weight might otherwife have been raifed by the firft, will be lefs in the fame proportion as the purchafe is increafed by the fecond.

Again, very frequently the fall of the firft tackle is applied to an axis in peritrochio, which increafes the purchafe very commodioufly without the inconveniencies laft mentioned; but then the machine is rendered cumberfome, and, confequently, lefs fit for a moveable apparatus.

All thofe impediments I have avoided, by combining the two methods, above defcribed, in one. The pullies are here placed in each block in two tier; feveral being upon the fame pin as in the firft method, and every one having another under it, as in the fecond; as alfo that, when the tackle is in ufe, the two tier, that are the remoteft from one another, are fo much larger in diameter than thofe that are neareft, as to allow the lines of the former to go over the lines of the latter without rubbing.

From this conftruction arifes a new method of reeving the line upon the fhieves: for here, let the number of fhieves be what it will, the fall of the tackle will always be upon the middle fhieve, or on that next the middle, according as the number of pullies on each pin is odd or even.

To do this, the line is fixed to fome convenient part of the upper block, and brought round the middle fhieve of the larger tier of the under block; from thence round one of the fame fort, next the center one of the upper block; and fo on till the line comes to the outfide fhieve, where the laft line of the larger tier falls upon the firft fhieve of the fmaller, and, being reeved round thofe, till it comes at the oppofite fide, the line from the laft fhieve of the fmaller tier again rifes to the firft of the larger, where it is conducted round, till it ends on the middle fhieve of the upper block on the larger tier, as will appear more plain, by infpection of the figure annexed.

In this method all the lines are clear of one another, and the blocks are kept parallel. The model which I had the honour to fhew the Society, and from which I made the draught, is a compofition of twenty fhieves, five on each pin. With this model, which may eafily be carried in the pocket, I have raifed 600 weight. But with a tackle of this fort, properly executed in large, one man will eafily raife a ton, and a greater number in proportion.

I have tried feveral numbers of fhieves as far as 36; but 20 feems to be the largeft number, that will anfwer well in practice.

A very commodious tackle of twelve might be executed in wood, in the fame manner that common blocks are made.

COMEDO'NES, a name given to a fpecies of worm, with which the children of Mifnia, and fome other countries, are terribly afflicted; and of which Hoffman, in his treatife of Endemial Difeafes, gives this account: children in the country are frequently feized with a fort of tabes, which fo deftroys their flefh, that they appear merely like fhadows: the common people generally fuppofe thofe children to be under the influence of witchcraft, but fuch as have enquired more narrowly into the diftempers, have found that it is owing to certain worms, refembling black hairs, or cords, lodged under the fkin. When the fkin is rubbed with honey, in a bath, or any warm place, they will appear and come out; but, when it is contracted by cold, they keep concealed within.

CO'MMA *of Pythagoras*, is the difference between fix tones major, and the octave; or between 19 octaves, and 12 twelfths. It will therefore be expreffed by the proportions $\frac{531441}{524288} = \frac{9^6}{8^6} : \frac{2}{1} = \frac{3^{12}}{2^{19}}$. The fmall figures, written above the larger, fignify the exponents of their powers.

C'OMMERCE (*Dict.*)—Commerce owes its original to our wants, real or imaginary. Nature is contented with little, but luxury and ambition have extended Commerce to fupply their wants; and the rich fupport induftrious numbers to furnifh fplendor and magnificence. Convenience introduced it; and its progrefs has been principally owing to the increafe of mankind, who have found it neceffary to extend trade for their mutual fupport. The hiftory of Commerce (fee the article in the Dictionary) affords us three important reflections.

1ft. People by induftry may fupply the defects of their native country, and poffefs more riches than thofe who are the natural proprietors of them. Gold and filver are agreed on to pay the value of commodities, but are of no more ufe than as they make us able to procure them. Induftry fupplies every country with what it wants, and by that means enriches itfelf: without induftry no people ever can be rich.

2d. The people infenfibly lofe their trade, who do not carry it to the greateft extent. Every branch of trade fuppofes a want of what is exported, and the profits arifing from merchandize enable us to extend Commerce. Nothing is more dangerous to a trading nation than to force the people they trade with to fupply their own wants, or procure them elfewhere. Wonders of induftry have come to maturity, in the womb of neceffity. The efforts of induftry are like the courfe of an impetuous torrent, whofe waters ftruggle with violence againft the banks which confine it, till at laft it overflows them, and diffufes itfelf all over the plains.

3d. Whatever nation carries on a great trade, muft be proportionally populous and opulent. The conveniences and comforts of life are the moft powerful attractions that act upon men: could we fuppofe a trading people to fubfift in a country where the neighbouring people did not apply themfelves to trade, what would be the confequence? The trading people would foon have all the foreigners, becaufe their Commerce would employ and pay them.

Thefe three reflections point out the principles of Commerce, in a body politic. Agriculture and induftry are the effence of them; they have fo neceffary a connection, that, if either has the balance againft the other, the public fuffers. Without induftry the fruits of the earth will be of no value; if agriculture be neglected, the fource of Commerce is dried up.

The object of trade in a ftate, is to employ as many hands as poffible. Agriculture and induftry are the only means of fubfifting; if thefe are both profitable to the ftate that employs them, the ftate will never want hands.

The effect of trade is to ftrengthen the ftate, which ftrength confifts in the number of people its political riches draw to it; that is, its real and relative wealth taken together.

The real riches of a nation confift in the degree of independence it has on any other to fupply its own wants, and the fuperfluity it is capable of exporting to fupply the wants of other nations. The relative riches of a nation confift in the quantity of money or value its Commerce draws to it, compared with that of other neighbouring nations. A combination of thefe real and relative riches conftitutes the art and fcience of adminiftering political Commerce.

Every proceeding in trade, contrary to thefe principles, is pernicious to trade itfelf.

Thus, Commerce may be beneficial or detrimental: to convince us of which, we muft diftinguifh between the profit of the merchant and the profit of the ftate. If the merchant imports foreign commodities which impede the confumption of domeftic manufactures, the merchant will enrich himfelf by the fale of them; but the public will be a lofer, more ways than one. 1ft. By the value paid to foreigners. 2d. By the wages paid to the different artificers employed in the different manufactures. 3d. By the value that the growth of the materials in the country or colony would have produced to the country or colony into which they are imported. 4th. By the profit which would arife from the circulation of all thefe feveral fums.

If the materials are of the growth of the colonies, the ftate will befides lofe the benefit of navigation. If the materials are

are foreign, this disadvantage subsists equally; and, instead of the loss of our own product, it will be by the exchange of the national commodities in return for these materials. The gain of a state is, therefore, exactly what we have mentioned; and the state must be a loser in case of the preceding suppositions. The gain of the merchant consists in the excess of the price of the sale above the price of the purchase.

The merchant may in some cases be a loser, and the state a gainer: if a merchant imprudently sends the manufactures of his own country abroad into countries where they are not wanted, he will lose by the sale of them; but the state will have gained by the growth of the materials, and the employment of artificers in the manufacture of them.

Commerce seems most rationally established on the nine following maxims.

1st. The exportation of superfluities is the most clear gain.

2d. The most advantageous manner of exporting superfluities of our own produce is to manufacture them first.

3d. The importation of foreign materials to be manufactured at home, instead of taking them ready manufactured, is a great saving to a state.

4th. Bartering one commodity for another is in general advantageous, except in cases where it is contrary to the foregoing principles.

5th. The importation of commodities which hinder the consumption of those of our own product, which interfere with our own manufactures, or put a stop to the culture of our lands, is pernicious.

6th. The importation of foreign goods, merely for the use of luxury, is a real loss to the state.

7th. The importation of such foreign goods as are wanted, of absolute necessity, cannot be accounted an evil, though a nation is impoverished by such importation.

8th. Importation of foreign goods, to re-export them, procures a certain benefit.

9th. To let our ships out for freight to other nations is a beneficial branch of trade.

Every operation of Commerce ought to be regulated by these principles, and formed upon this plan.

COMPA'RTMENTS, in gardening, are beds, plats, borders, and walks, laid out according to the form of the ground, and depend more on a good fancy, than on any set of rules, for their construction. They are also sometimes merely diversities of knots of flower gardens or parterres, of which there are an infinite variety, according to the fancy of the designer.

Plain Compartments, are pieces of ground divided into equal squares and flower beds, marked out by line, and made of regularly equal length and breadth. Some allow to these squares borders of two feet broad, if the plot of ground be small, and, if larger, of three feet, and edge the borders with box, or with upright hardy thyme: the alleys up between are to be laid with sand or gravel, and kept clean weeded.

CO'MPASS (*Dict.*)— Before the invention of the Compass, which is between 300 and 400 years ago, the navigating of ships was a very tedious and precarious operation: but the Compass enables the mariner to hold his course over the seas in as direct and true a tract, as the land-carrier directs his carriage in a well beaten road. Hence it might be reasonably imagined, that no necessary expence or care should ever be wanting in the construction of this most useful instrument: but it has so happened, that scarce one sea Compass in ten is fit for the use for which it is made; and this has arose from their being fabricated by unskilful and ignorant workmen, for the wholesale dealers in the shipping way; who generally pay no more regard to the construction of this instrument, whereon the success of the voyage and the lives of the men in a great measure depend, than they do to any indifferent thing of the same price.

There are, however, Compasses used in the royal navy, and some few trading ships, which are constructed with more care, and on better principles; and are therefore vastly preferable to those commonly used in the merchants service, which, from their composition, seem as though they had been contrived purposely to vary from what was to be expected of them: such as joining the outside box together with iron nails; making the needle of soft wire, and disposing it in form of a rhombus, in expectation that the magnetical forces of the sides would conspire to act in the diagonal: making the pin and socket so badly, as to prevent the traversing of the card, &c. &c.

But it must be observed, that it is only within a few years that sea Compasses have been made free from the multitude of inconveniencies to which the best constructed of them were liable to before: such as, 1. Needles having several poles, occasioned by their irregular shape, the best kind being straight bars with flat ends. 2. The needles being made of such a temper as was neither susceptible of receiving, or retaining half the virtue it was possible to give them; and, consequently, they were not with due strength and perseverance directed towards the poles of the world. 3. The want of proper means to restore their loss of magnetism, while on a voyage. 4. The troublesome and inaccurate methods of rectifying a damaged pin on which the card turned, together with the expence attending the use of agate caps or sockets, than which none are so proper. 5. The want of proper contrivances to hinder the card from being affected by the various motions of the ship. These, and several other imperfections, have been happily removed by the labours of the truly celebrated Dr. Gowen, knight, F.R.S. whose admirable invention of giving magnetism to steel bars, greatly superior to any power they could derive from the natural loadstones, joined to a multitude of experiments which he has made for the marine service, have produced the means of constructing sea Compasses so perfect, that there seems nothing farther to be wished for, as necessary to this instrument. It may be reasonably expected, that such correct Compasses will readily come into general use, as there have been several trials made of them both in men of war, and merchantmen: but, like several other useful improvements, it must wait till time has removed old prejudices. See *Magnetical* NEEDLES in the Dictionary, and AZIMUTH *Compass*, in the Supplement. *Robertson's Navigation.*

The Compass has been sometimes observed to be disturbed by the electricity of its glass cover, and this from so slight an application of the finger, as was barely necessary to wipe off a little dust. The same glass, rubbed a little more with the finger, a bit of muslin, or of paper, would attract either end of the needle, so as to hold it to the glass for several minutes, far out of the due direction, according to what part of the glass was most excited. And, when the needle, after adhering to the glass, has dropped loose, and made vibrations, those would not be bisected, as usual, by that point where the needle should rest, but either be made all on one side, or be very unequally divided, by means of some remains of electrical virtue in that part of the glass which had attracted the needle, until at length, after fifteen minutes or more, all the electricity being evaporated, the magnetical power took place. The cure for this inconvenience, is to moisten the surface of the glass: a wet finger will do it immediately and effectually. *Phil. Transf.* N°. 480.

CO'MPOSITE *Capital.—Plate* IV. *fig.* 14, in the Dictionary, represents, in a side view, a Composite capital, and *fig.* 15. a plan of the same capital inverted.

CO'MPOSTS (*Dict.*)— Composts are various, and ought to be different, according to the different nature or quality of the soil, which they are designed to meliorate; and according as the land is either light, sandy, loose, heavy, clayey, or cloddy.

A light loose land requires a Compost of an heavy nature, as the scouring of deep ditches, ponds, &c.

So, on the other hand, a land that is heavy, clayey, or cloddy, requires a Compost of a more sprightly and fiery nature, that will insinuate itself into the lumpish clods, which, if they were not thus managed, would very much obstruct the work of vegetation.

The great use of Composts is for such plants as are preserved in pots or tubs; or sometimes it is used for small beds or borders of flower gardens; but it is too expensive to make Composts for large gardens, where great quantities of soil are required: in such cases the only composition that can be made with moderate expence, is, where the land is too light and sandy, to lay marl, clay, or any other heavy dressing upon the land: the best season for this work is in autumn, when it should be spread abroad, and exposed all the winter, that the frost and rain may dissolve and separate the clods, whereby it will be rendered fine by the spring of the year, when it may be dug into the ground; and if, before this is done, there is some rotten stable dung, or neat's dung, added to it, the land will be greatly mended by it.

But where the land is heavy, and of a clayey or loamy nature, then light sharp dressings are the best Composts; such as sand, ashes, or near London, where it can be had, the soil of the streets is an excellent dressing, because these will separate the parts of the clay and loam, and prevent its binding hard in dry weather; so that all sorts of plants will thrive much better in it than they would, before this composition was added.

In the making a Compost for such plants as are kept in pots or tubs, the same thing is to be observed; for, where the natural soil of the place is stiff and heavy, there should be a sufficient quantity of sand and rotten dung added, so as to render it light, especially for all plants which do not delight in a stiff soil; and, on the other hand, where the soil is naturally too light or sandy, there should be a proper quantity of loam and rotten neat's dung mixed with it, to give it a firmer texture; and these should be proportioned to the several qualities of the plants which the Compost is designed for; this is to be understood, where large quantities of earth are wanted, in places where it may be difficult to get the sorts of earth proper for the plants it may be designed for; which, in some countries, cannot be had, unless it is fetched from a great distance; therefore, where that is the case, there will require some skill in making a Compost of such materials as can be more easily procured, which may answer the purpose as nearly as possible; but, where a small quantity only is wanted, there can be no great difficulty, at proper seasons, to procure what may be wanted of the proper soils to make such a Compost as is necessary for the plants.

In making of any Compost, great care should be had, that the several parts are properly mixed together, and not to have too much of any one sort thrown together; therefore, when three or four several sorts are to be mixed together, there should be a man or two placed to each sort, in proportion to the quantity of each; for if two parts of any one sort are requisite to be added, there should be two men put to that, and but one to each of the other: and these men must be careful to spread each sort in such a manner over each other, as that they may be exactly mixed together. Another thing which should be observed is, never to lay these Composts in too large heaps, but rather continue them in length, laying them up in ridges, so that the air and sun may more easily penetrate through it; and, as these composts should, if possible, be made a year before they are used, that they may enjoy a summer's sun and winter's frost, they should be frequently turned over, which will prevent the growth of weeds, and expose every part of the heaps equally to the sun and air, which is of great advantage to all sorts of Composts; for the more they are exposed to the influence of these, the better will the earth be prepared for vegetation; which is evinced by the fallowing of land, which, when rightly managed, is equivalent to a dressing. *Miller's Gard. Dict.*

COMPRESS (*Dict.*)— It is frequently the custom among surgeons, after the plaister and other dressings are applied, to cover all with a Compress, which is made of the softest old linen, four, six, or eight times doubled. These are of service, not only by preserving the parts from the injuries of the external air, but also for the securing and fixing the plaisters and other dressings. Compresses are also frequently applied where no plaister is made use of, and that sometimes dry, sometimes wetted with certain liquors, which are supposed to be strengthening, emollient, resolving, lenient, cooling, &c. They are frequently dipped in the decoctions of certain herbs, into wine, spirits of wine, vinegar, or oxycrate, and sometimes into lime-water, and are administered either cold or hot, as the nature of the case requires. Compresses are of various forms; some are square, others oblong, others triangular, and others in form of a cross, according to the part they are to be applied to, and according to the occasion and situation. Some are called straight, others oblique, others transverse, and others annular, as those that surround the arm or foot. There are some also necessarily made in the form of an asterism; some are divided either on one or both sides, as far as the middle; sometimes they form a hexagon, and sometimes are round or globular, resembling a ball: these are used in luxations of the os humeri, and are placed under the axillæ. Sometimes Compresses of a much smaller size are required, which are either square for the wounds of the blood vessels, to restrain hæmorrhages; or taper, for sectures of wounds, or in ligatures of the arteries.

Compresses of all kinds are intended for these purposes: 1. to preserve and cherish the natural heat of the body. 2. To secure the dressings that are laid under them. 3. To convey liquid remedies to parts wounded or otherwise disordered, and to prolong the use of them. 4. To fill up any cavities or depressions of the parts, that the dressings, especially in fractures, may be applied with greater security: and, lastly, to prevent bandages from bringing a troublesome itching, or other pain or uneasiness on the skin. *Heister's Surg.*

CONCHÆ *anomiæ*, in natural history, the name of a fossile shell-fish, found in great abundance, and in great variety of species, but not known in any of them living, on the shores or in the seas of our own or other countries. In Gloucestershire, and some other of our counties, these are found as common as pebbles on the ploughed lands in other places. They are a sort of bivalve shells, the valves of which are of unequal extent, both of them convex, and the head or beak of the longer valve crooked, and falling over the head of the other. See *Plate* XV. *fig.* 10.

CONCLAVE (*Dict.*)— It depends on the members of the Conclave themselves to pitch upon a place, for the Conclave has no determined one; but, for some time, the palace of St. Peter, otherwise called the Vatican, has been always made use of, both for the greatness of the place, and other conveniencies; so that the cardinals never stand to deliberate now, but only for form's sake. They build then in a great apartment of this palace as many deal cellulæ as there are cardinals, with lodges and places for the conclavists that shut themselves in to wait and serve the cardinals. These little chambers have their numero or number, and are drawn at hazard; so that it happens very often, that cardinals of different factions lodge near one another. These are made up during the nine days of the ceremony of the pope's funeral, all which time, any body may go into the Conclave, and see the cellulæ, which are hung on the outside with green serge or camblet; only those that belong to the deceased's favourites, or to them promoted by him, who have theirs covered with deep violet-coloured cloth, and over each is the cardinal's arms that lives in it. Between the cellulæ and the windows of the palace is a long gallery for the conveniency of the Conclave, and it is from this the cellulæ receive their light. The next day after the pope's burial, that is, the 10th after his death, the cardinals having heard a mass, they call the holy Ghost's, go in procession two by two to the Conclave, where they all meet in the chapel every day, morning and evening for a scrutiny, which is done by writing their suffrages in little billets, and putting them in a chalice that stands upon the altar; when all are put in, two cardinals are chosen by the rest to read openly them that are named, and keep an account of the number for each; and this is done till two thirds join for the same person, but a pope is seldom chosen after this manner; whence it happens, that after the scrutiny they come to what they call an accez, that is, a trial, whether he that has most voices in the scrutiny could come to two thirds; but it is observable, that they cannot give their suffrages, in the accez or access, to those they have appeared for in the scrutiny. If this does not succeed, they have recourse to the way of inspiration, which is an open declaration, or, rather, a conspiracy of many cardinals to cry together, such a cardinal is pope; as, for example, Altieri papa is begun by one or two, chief of a party, when they find suffrages enough to assure them that this method will not fail; and then the rest of the cardinals are forced to join, that they may not incur the pope's displeasure, who would be chosen in spite of them. As for the scrutiny, it is done thus: each cardinal prepares his billet, wherein he writes his own and his name he is for, and another word of device. The cardinal's name is writ under a fold of the paper, and sealed with a seal for that purpose. The name of the chosen is writ by a conclavist under another fold without seal, and the word by which the cardinal knows it is his name that is read, is writ on the outside, as, Deo volente, or some such-like. The fold that covers the cardinal's name is never opened until the pope is chosen, who, to know those that helped towards his promotion unfolds all. The motto serves in the accez, that it may appear, that each cardinal has given another beside that they gave in the scrutiny, seeing two billets with different persons under the same name; and at the end of the scrutiny and accez, if the suffrages be not sufficient for the election, they burn all the billettings, that the chusers names may be kept secret. During the Conclave, each cardinal is allowed but two servants, or three at most; and this only to princes, or for some particular privilege. Several press for this employment, because the new chosen pope gives each conclavist three or four hundred livres, and they have the pleasure of seeing all that passes; yet the place is troublesome enough, because they must take in the meat and drink from a certain place common to all that live in the same part, and must wait at table, and be as streightly confined as their masters. *Histoire du Conclave.*

CONCORD, *Concordia*, in mythology, a goddess much esteemed amongst the ancient Romans. Julius Cæsar, and Tiberius, built her a temple. She was generally represented under the shape of a young girl clad in the old fashion, crowned with a garland of flowers, holding a bason with a heart in her right hand, and in the left a bundle of rods. There is an old medal of the emperor Nerva, wherein union is represented by a woman who bears a lance in her left arm, and a buckler in the other, and by a ship's stern and colours with these words, Concordia exercitum, S. C. Angeloni mentions this last in the History of the Cæsars, p. 102. In other medals they represent union with two horns of plenty in one hand, and a vessel of fire in the other. When Concord is invincible, she is represented by an armed Geryon, a golden crown on his head, with six arms and as many feet; in three of his hands he holds a lance, a scepter, and a sphere, and lays the other three on a shield. *Tit. Liv.*

CONFECTIO *cardiaca*, a name given, in the late London Dispensatory, to the so much esteemed medicine, commonly known by the name of the Confectio Raleighana, or Sir Walter Raleigh's cordial. The composition is also altered, as well as the name, and is ordered now to be made in the following manner: take fresh tops of rosemary and juniper berries, of each a pound; the lesser cardamum seeds, freed from their husks, zedoary, and saffron, of each half a pound. Draw a tincture from these, with a gallon and a half of proof spirit; reduce this tincture, when filtred, to the weight of about two pounds and an half, by a gentle evaporation; then finish the electuary by adding the following species finely powdered; viz. of compound powder of crab's claws, sixteen ounces; cinnamon and nutmeg, of each two ounces; cloves, an ounce; double refined sugar, two pounds. *Pemberton's London Dispensatory.*

CONFECTIO *Paulina*, a name given in the late London Dispensatory, to the composition which used to be called Confectio Archigenis. It is now ordered to be made in the following manner: take costus or zedoary, cinnamon, long-pepper, black-pepper, strained storax, galbanum, opium, and Russia castor, of each two ounces; of simple syrup, boiled to the consistence of honey, an equal weight to thrice the species. *Pemberton's London Dispensatory.*

CONGER, in zoology, the name of the sea eel, a very voracious and extremely large fish of the eel kind.

It grows to an enormous size, four or five cubits being a common length with it, and its thickness that of a man's thigh. It is of a pale grey on the back, and a fine milk-white on the belly, and has on each side a straight white line,

line, somewhat broad, made as is were of a double row of dots, and running from the head to the tail; the top of its back fin is black all the way; and in the end of his upper jaw, just at the nose, he has two short tubular horns, out of which a mucous liquor may be squeesed. Their flesh is very agreeable, but is not easy of digestion. *Willughby's Hist. Pisc.*

CONICHTHYODO'NTES, in natural history, a name given by Dr. Hill to a genus of fossile bodies, called by other authors plectronitæ, from their supposed resemblance to the spur of a fighting cock.

CONSTI'TUENT *Parts*, in chemistry. The Constituent parts of bodies are their dissimilar parts, into which they may be resolved, by the rules of that art. They are thus called in distinction from the integrant parts of bodies, which are parts of the same nature and properties with the bodies themselves. Thus quicksilver, dissolved by aqua-fortis, may be separated from the diluted menstruum, by means of a copper-plate, in its own form; this therefore was only divided into its integrant parts: but cinnabar, resolved by chemistry into sulphur and mercury, is divided into its Constituent parts, neither of these, nor any particle of them, being cinnabar, or having its properties. *Shaw's Lectures.*

CONSTRU'CTION *of equations* (*Dict.*)—The learned Baker, in his Clavis Geometrica, has given us the following elegant method of constructing cubic and biquadratic equations.

Let the parameter, or latus rectum, be called $1 = L$ (*Plate* XV. *fig.* 11.) and its vertex *a*; then, at right angles to the axis, inscribe $RA = \frac{1}{2}p$, for half the second term in the equation; then shall its point A be the vertex of the diameter A D, to be drawn parallel to the axis; so that the distance of this diameter from the axis is always $\frac{1}{2}$ of p, or $\frac{1}{2}$ of pL, for L is equal to 1; and consequently when $p = o$, or when the second term is wanting, A D will be in the axis, and the points R, *a*, A, all coincident. Next, in this diameter he determines the point D by the length of A D, and then erects in D a perpendicular to D A, as D H, whose length he also determines, and by that means finds H, the center of the circle which is to intersect or touch the parabola: and this he performs by what he calls his central rule, viz.

1. $\frac{L}{4} + \frac{pp}{8L} \pm \frac{q}{2L} = b = AD$; And,

2. $\frac{p}{2} \pm \frac{ppp}{6LL} + \frac{pq}{4LL} + \frac{r}{2LL} = d = DH$.

Which two rules, because $L = 1$, may be contracted thus,

1. $\frac{1}{4} + \frac{pp}{8} \pm \frac{q}{2} = B = AD$.

2. $\frac{p}{2} + \frac{ppp}{6} \pm \frac{qp}{4} \pm \frac{1}{2}r = d = DH$.

And you must observe, that in the former of these rules + signifies downwards from the point A, and — upwards from it; and in the latter rule + signifies towards the left-hand, as — doth towards the right; so, according as the affirmative or negative roots prevail, H will be on the left or right-hand of D.

And in both parts, if p, q or r be $= o$, the member where it is found will vanish and become also $= o$.

As to the signs of the quantities in his rule, he makes p always retain the sign it hath in the equation, but q always puts on a contrary one to what it had there; r is always with a positive sign, except when pr have contrary signs in the equation, and then r will always have a negative sign in the rule.

Having thus, by his central rule, found H the center of the circle, the next work is to determine the radius; and, if the equation be no higher than a cubic, H A is always the radius; but, if it be a biquadratic, then supposing — S, or that the fifth term, or absolute number, be a negative quantity, take in the line A H, produced both ways, if there be occasion, $AI = L$ above, and $AK = S$; and, making I K a diameter, describe the semicircle K L I, and erect at the point A the line A L perpendicularly; which therefore will be a mean proportional between A K and A I: I say, the circle must pass through L, and H L will be the radius.

But, if it be + S, you must draw another diameter H A, and therein fit in or apply $AZ =$ to L A before found; for now the square of A L is to be taken from H A, as in the former case it was to be added to it; which will find the point Z through which the circle must pass, and the radius will be H Z, which circle being drawn, it will cut the parabola in 4, 3, 2, or 1, or in no point; and, according to the number of such intersections, will the real roots of the equation be found, which will be always so many perpendiculars from those points to A D, as, *e. gr.* N O on the left-hand, M *o* on the right, &c. Of which, if there be no p or second term, and also it be $-r$, then on the left-hand are the positive roots, and the negatives ones on the right-hand: but if the second term be there, and with a negative sign, as $-p$, then N *o* on the left-hand are affirmative, and the others M *o* on the right negative; but, if it be $+p$, it is, on the contrary, N *o* negative, and M *o* positive.

CONSTRUCTION, *in grammar* (*Dict.*)—The Construction is generally more simple, easy, and direct in the modern tongues than in the ancient: we have very few of those inversions which occasion so much embarrasment and obscurity in the Latin; our thoughts are usually delivered in the same order wherein the imagination conceives them: the nominative case, for instance, always precedes the verb, and the verb goes before the oblique cases it governs.

The Greeks and Latins, M. St. Evremont observes, usually end their periods, where, in good sense and reason, they should have begun; and the elegance of their language consists, in some measure, in this capricious arrangement, or rather in this transposal and disorder of the words.

CONSTRUCTION, is either simple or figurative.—Simple, is that wherein all the terms, or parts of the discourse, are placed in their natural order.

Figurative CONSTRUCTION, is that wherein we recede from this simplicity, and use certain expressions, shorter and more elegant than nature affords.

The syntax, or Construction of words, are distinguished into two parts, concord, and regimen or government.

CONTA'GION (*Dict.*)—In times of pestilential Contagion, the physician, and others who attend upon the sick, are in the most imminent danger of falling into the same condition; nor have any of the so much boasted preservatives against this been found of any consequence; on the contrary, the very remedies, many of them at least, which have been contrived on this occasion, are very dangerous, when lodged in imprudent hands, as well as useless and improper in all. The best methods of safety are, first, never to visit a patient in any infectious disorder, when one is fasting, but some generous wine ought always to be drank first. Some are of opinion that it is proper to eat first a piece of bread and butter, soaked in vinegar, either simple, or with rue first stamped in it. When one is in the patient's apartment, great care is to be taken never to eat or drink there, nor to swallow one's spittle; and it is no idle custom in those who are continually in the infected room to chew zedoary, myrrh, angelica, cinnamon, or the like warm and aromatic drugs; for all these things promote a plentiful discharge of saliva from the mouth, which it is certain, when swallowed, cannot but often carry pestilential particles down with it into the stomach, whence they will easily find their way into the blood. It may be added as a good rule, that we never stay too long in an infected room; for a constitution that could have resisted the Contagion for a small time, may easily be overpowered by too long a continuance in the way of it.

After one is returned home from a visit of this kind, it is always proper to wash one's hands and mouth with vinegar and water; to change cloaths, hanging the former in the air, and then to drink some warm liquor, as tea of scordium, sage, or other herbs of that kind, or, in their place, coffee; for this opens the pores, and, if any small quantity of the pestilential virus should have mixed itself with the blood, expels it by a gentle perspiration. It may be also of great assistance to all about the sick, from preventing them from being infected, to hold frequently sponges dipped in vinegar to their noses, and frequently to sprinkle vinegar on a red-hot iron, in the room, to correct and mend the air. *Heister's Surgery.*

CONTI'NUOUS *Fevers*, a term used by the medical writers to express such fevers as have no intermissions, but have some sort of regular remissions from the violence of their symptoms every day. They are thus called by way of distinction from the continent fevers, which never have the least remissions.

Of the number of Continuous fevers, are the quotidiana continua, and the catarrhal fevers, which are more violent every day towards evening, and are much more mild in the middle of the day. *Junker's Consp. Med.*

CO'NTOR, or CUNTOR, a bird of Peru, said to be the largest in the world. With its wings expanded, it measures fixteen feet from the tip of the one to the other; a single feather of it is four feet two inches long; its beak is strong enough to tear off the hide, and rip up the bowels of an ox. Two of them will attempt a bull, and devour him. *Phil. Trans.* N°. 208.

CONTRA'RY *Propositions*, in logic, universal propositions, one of which affirms, and the other denies, the same predicate of the same subject; as every square is a parallelogram, and no square is a parallelogram. These propositions differ in quality, but not in quantity, and therefore are distinguished from contradictory propositions, which differ in quantity and quality.

Contrary propositions cannot be both true, but may both be false: whereas, in contradictory propositions, one is necessarily true, and the other false.

CONTU'SIONS *of the cranium*. When the cranium is violently contused, it will be discovered by the tumor and softness of the part, by the separation of the integuments from the cranium, and by the collection of stagnating blood which appears to be confined under the skin. In this case you are to endeavour to divide the confined fluids, by attenuating medicines externally applied, or to discharge them by making an opening with a knife, or, lastly, to bring them to suppuration. When the extravasation of fluids is very considerable, it is best to discharge the greatest part of them instantly by incisions, and

and what remains will then easily be dispersed. Fomentations, and medicated bags of the warm herbs, rue, wormwood, savin, scordium, &c. quilted into bags, and boiled in wine, or in water, with a mixture of spirit of wine, or malt, or mellasses spirit. But, where it is found impracticable to divide and attenuate the stagnating fluids, the suppuration of them must be attempted, and, if the contusion have been but small, after the suppuration is formed, and the matter discharged, the wound will easily heal, by the application of a vulnerary balsam.

In violent contusions, where there is no opening, or but a very small one, the wound must be inlarged with the knife, to prevent the neighbouring parts from being corroded, and by this means the wound will be easily cleaned, and the cure performed by the method before laid down. When the pericranium is wounded, but not in so great a degree as to lay the cranium bare, the wound is to be dressed with warm balsamic medicines. But, where the cranium is exposed and laid bare, its external lamella being robbed of its nourishment, by the destruction of the vessels, by which it was constantly supplied, it will lose its natural colour, and become yellow, livid, black, and, by degrees, separate from the neighbouring parts, and exfoliate, which will greatly protract the cure of the wound. To hasten this exfoliation, the surgeon ought to bore several holes through the denudated part, as deep as the diploe, with an awl, or such like instrument. This operation not only forwards the exfoliation of the part, but makes way also for the sprouting up of new vessels. The dressing, which ought to be repeated each time with great expedition, is to be applied in the following manner: when the wound is well cleaned, pledgits thoroughly saturated with the mild balsamics, with the addition of a small quantity of honey of roses, are to be laid upon the injured part of the cranium; over these a sticking plaister is to be applied; and over that the proper bolster and bandage. These applications should be continued till the cranium appears sound, and the wound is in a condition to heal. *Heister's Surg.*

CONVO'LVULUS, *bind-weed*, in botany, the name of a very large genus of plants, which some have also made much larger than it really is, by making every climbing plant belong to it. The characters, however, of the Convolvulus, properly so called, are these: they have flowers consisting only of one leaf each, formed into the shape of a bell, and usually very wide at the mouth. From the cup of the flower arises a pistil fixed to the lower part of the flower, in the manner of a nail; this ripens into a roundish membranaceous fruit, which is usually surrounded by the cup, and in some species is unicapsular, in others tricapsular, and contains seeds usually of an angular figure.

Tournefort has enumerated fifty-six species of Convolvulus.

COO'PERAGE, in mechanic arts, the art of making all kinds of casks, &c.

COO'PERS. This is a necessary and extensive business, in all its branches, which are,

Those which make casks, not tight, chiefly for dry goods, package, and soap.

Others that make all sorts of tight casks, for holding liquids. Both these are smart work, but the latter by much the nicer part; and they take with an apprentice generally the sum of 10 or 20l. whose working hours are from six to eight, in which time some good hands will earn 3s. or 3s. 6 d. but the common wages are 15 s. a week.

And to set up a master in the dry way will require from 200 to 500 l. except they keep to soap casks only, as some do, which is easier work, and does not require so much money. One who keeps to the making of butts, hogsheads, &c. for brewers, vinegar merchants, shipping, &c. requires a good stock of the best staves, and of course more money to carry on their business: But there are those also who work mostly on the lesser sort of tight casks, which is much lighter work, and takes less money.

Lastly, the wine Coopers, whose province is not only to look after the casks, but the liquor itself, in which many of them are also great dealers. These will not take an apprentice with less than 20 l. and, if importers, perhaps, not less than 50 or 60 l. had need have 1000 or 2000 l. stock: and a journeyman in this part has seldom more than the others, unless they are extraordinary cellar-men, who have sometimes 40, 50, or 60 l. a year and their board.

They were incorporated into a company in the year 1501, in the reign of Henry VII, and, by an act in the 20th year of Henry VIII, they were authorized to gauge all beer, ale, and soap vessels for a farthing each: livery fine 15 l.

Their hall is in Basing-hall-street, and their court-day on the first Tuesday in the month.

They have also an handsome barge, in which they attend the lord mayor to Westminster, on the day of his installation.

Arms. Girony of eight sable and gules, on a cheveron between three annulets, or, a croze between two axes sable, on a chief vert three lillies argent. Motto. Love as brethren.

CO'PPEL (*Dict.*) — The matter of which Coppels are to be made, must be such as can resist the strongest fire, such as will not run easily into glass with vitrifiable bodies, as glass of lead, &c. and such as may be reduced into a well coherent,

though porous mass. The best earth for this purpose is found to be that which is made of calcined bones of all animals, a very few excepted, especially swines bones; for a Coppel made of the bones of this creature is found to receive something metallic into it, at the same time that it absorbs the glass. The best bones for this purpose are those of calves, horses, sheep, and oxen; and, of these, the smallest bones are always to be preferred, as they are the more easily calcined, especially such as have been long exposed to the air.

The calcination of these bones is to be made in an open fire, for a few hours or more, according to their size, and such should be chosen as have the least fat about them. The calcination is known to be perfect, when there is not a black spot remaining, either on the outside of the bone, or within it, when broken. When the bones are perfectly calcined, they must be reduced to a very fine powder, either by the grinding on a porphyry, or sifting through a fine sieve, after beating. This powder must be also carefully washed in warm water; for, during the calcination, the bones are almost always impregnated with the salt of the ashes of the fuel.

This powder is called by some clar, and is an excellent substance for Coppels. The bones of fishes, when small, are yet more easily calcined than those of other animals: this may be done with ease in an open earthen vessel, and the powder of these is preferable even to the former.

Parget, or plaister of Paris, made of various kinds of spar, tho' all kinds will not do for this purpose, is also excellent: but, as there are some sorts of spar which will not afford a proper plaister, it is proper to try in a small quantity first. The calcination is to be made in an earthen vessel, covered with a tile, in an open fire. The spar crackles a little with the heat, and, when this noise is over, the calcination is perfect.

As the preparation of bone ashes for this use, however, is tedious, and the proper sorts of spar not always or every-where to be had, the want of them may be supplied with the ashes of vegetables, properly prepared: but, lest the Coppels should vitrify, by reason of the alkaline salt in these ashes, the following method must be observed in their preparation: Wash off the lightest and finest part of the ashes from hot wood embers, with warm water, through a sieve, that the finest part of the ashes may not fly away, nor any of the embers be mixed with them; pour upon this dust pure boiling water; and stir it with a stick; when the ashes have subsided, decant off the water, and pour in fresh boiling water, stirring all together, as before: when this has settled, decant it off again; and repeat this operation with fresh water every time, till the water have not the least taste of the salt, but is perfectly insipid. When this last water is decanted off, add a fresh quantity; stir the ashes thoroughly up, and, after eight, ten, or twelve seconds, pour off the liquor, as yet thick with the ashes, into a clean vessel: part of the ashes will now remain in the former vessel; on these pour more water, stir them, and, after a short rest, pour off as before into the other vessel. Repeat this, till in the first vessel there remains only a little sandy matter, or a few coarser particles. Let the washed ashes now stand, till the water is perfectly clear above them; then decant this carefully off, and you will find these ashes now become a good earth for this use, and free from redundant salt and oil, and immutable in the fire. These, however, if made into a paste, and rolled into small balls, and burnt again in a potter's oven, and then washed anew, become purer and better still.

Finally, put a small quantity of the ashes of beast or fish bones into a very clean earthen vessel, and calcine them a second time, for a few hours, in a most violent fire; afterwards wash them with water, and grind them to a perfectly fine powder on a pophyry, and keep this preparation, as also each of the others, separate, for the more or less nice uses. This last preparation is properly called clar, or caer, by the German metallurgists.

For the hollow of the Coppels, which is to contain the metal, must be a spherical segment, and not very deep: first, that the surface of the melted mass, be it ever so small, be distinctly visible to the artificer's eye; and, secondly, that the metal, left in that cavity, may melt together in one globule. But the outside of the Coppel must be only a small matter convergent towards the basis, like a truncated cone, that it may stand firmly on its base: and, that this figure may be regularly given to these vessels, it is convenient to have copper or brass moulds for the making them.

Now, to make Coppels from these preparations, take bone ashes of beasts or fishes, either alone, or take two parts of wood ashes to one part of these, and mix them perfectly in a marble mortar, or on a porphyry or levigating stone; then add to the mixture, by several quantities, just so much either of pure water, or of the whites of eggs diluted with water, as will be necessary to make the matter stick together, when strongly pressed between the fingers: and great caution must be used, not to exceed or fall short of this proportion of the fluid. If you use the calcined spar, it must be made up with a solution of vitriol.

Put a sufficient quantity of this matter, thus wetted, into a small mortar, supported on a firm prop, and press down the matter closely with your fingers, that the capacity of the mortar may be quite full: lay the rest aside.

Then

Then put the peſtle, made for a mould to make the Coppels, perpendicularly on the ſurface of the matter in the mortar, and with a mallet drive it down with three or four blows, according to the different diameter of the Coppel that is to be made: thus make the maſs conſiderably compact; but take great care that the peſtle do not rub againſt the ſides of the mortar. When this is done, remove the peſtle, and ſtrew the cavity it has made in the maſs with aſhes of dry bones of the preparation called claer, ground extremely fine, and ſifted through a fine ſieve: after this, wipe the peſtle with a clean cloth, and put it into the cavity again, driving it in with one or two more blows. Then having at hand a ſmaller wooden plank, ſtrewed a quarter of an inch thick with dry aſhes, put upon it the mortar containing the Coppel already prepared; the Coppel will eaſily quit its mould, and, its inequalities at the upper edge and bottom being taken evenly off with a knife, let it be inverted, and laid aſide in a dry place.

The dry fine aſhes are applied to the inſide of the Coppel, that the little inequalities commonly remaining there may be filled, and it may make a ſort of fine ſieve, admitting through it vitrified bodies, but retaining gold and ſilver. The cavity, being regularly covered with this perfectly fine ſubſtance, prevents any harm from the common matter of the Coppels being a little defiled with ſand, or other powder, eaſy to be vitrified; which is a fault indeed hardly poſſible to be avoided, eſpecially when wood aſhes are uſed. Hence it is plain, that this powder muſt needs be prepared with very great caution, and even the levigating it muſt be done on a very hard ſtone, leſt, if on a ſoft one, ſome particles might perhaps be abraded from its ſurface, and ſpoil the powder.

Coppels had better be too compact than too looſe in their texture, ſince the latter is always a miſchievous accident, whereas the former, by abſorbing the glaſs more ſlowly, is of no other hurt than the retarding the operation a little.

Coppels made of bone aſhes, or of calcined ſpar, are more valuable than thoſe of wood aſhes, as they require not ſo much caution and regularity in the management of the fire; but, if wood aſhes enter the compoſition, the Coppel muſt be made pretty hot before the metal is put into it, otherwiſe the aqueous vapours, forcing their way out, will cauſe the metal to be thrown out in drops; for Coppels of this kind can never be perfectly dried by the air alone, there being always ſomething of an alkaline ſalt yet remaining in wood aſhes, which makes them attract the water out of the air, as the dark colour of theſe aſhes, and the ſolution of ſal armoniac poured on them, alſo ſhew; for this reaſon, theſe aſhes are alſo more diſpoſed to vitrification than thoſe of bones, the latter approaching much nearer to the nature of the incombuſtible ſtones.

As to the moiſtening the matter of the Coppels, great care muſt be taken not to uſe a fluid too mucilaginous and fat; for this makes the Coppels ſo compact, that they not only either abſolutely reject vitrified bodies, which they are intended to receive, or yield them but a very ſlow or difficult paſſage; but alſo are apt to ſplit, when made very hot, and diveſted of their oily part.

Neither muſt ſuch mucilaginous fluids by any means be uſed, as may produce a great deal of fixed alkaline ſalt in the heating of the Coppel, as the tartareous dregs of fermented bodies do. Nor muſt the aſhes be moiſtened too much; for, if they are, the ſurface of the veſſel will never be perfectly neat.

Some artificers mix about a tenth part of fine waſhed clay to to their aſhes, for the making their Coppels: when this is done, the matter muſt be moiſtened with water only, the clay making the whole ſtick ſufficiently together. Great care, however, muſt be taken, that too much clay is not added, and the different degree of the fatneſs of the clay be attentively conſidered.

The aſhes of bones uſed alone, and ground to a ſufficient fineneſs, require no clay or mucilaginous fluid to increaſe their coheſion, but do very well with pure water alone: and Coppels of this kind, and ſuch as are made of the calcined ſpars, need hardly be made at all hot before the metal is put into them.

The operation, however, when performed in a Coppel made of bone aſhes, or of calcined ſpar alone, takes up a little more time, but it is more ſecurely performed than in Coppels where wood aſhes make a part of the matter of them: for, as the bone or ſpar veſſels receive the vitrified metal more ſlowly, on account of their compact ſtructure, ſo it is leſs to be feared that any of the perfect metals ſhould be abſorbed alſo, even though the management of the fire be not ſo critically minded. *Cramer, Art of Aſſ.*

COPELLING. Silver may be precipitated out of its ore by Copelling alone, in the following manner: roaſt a centner of the ſilver ore in the common way; when roaſted, powder and ſift it very fine, and, if it melts with difficulty, mix with it one centner of litharge: when it is an ore that melts eaſily, this may be omitted. Divide the powder into five or ſix parts, and wrap every one of them ſeparately in ſmall pieces of paper. Put a large Coppel under a muffle in the furnace; ſift it thoroughly; then put into it ſixteen centners of lead. When the lead begins to ſmoak and boil, put upon it one of the ſmall parcels of powdered ore, in its paper; then diminiſh the fire a little. The paper will be immediately conſumed, and the ore caſt to the ſide of the coppel, in form of ſcoriæ. When this is done, increaſe the fire again, and add a ſecond parcel of the ore; and continue this method till all the ore is put in; after which, ſcorify the lead in a ſtronger fire. The ſilver contained in the ore, with that contained in the lead, will now be found in form of a bead in the coppel; and, ſubtracting the known quantity yielded by the lead, the remainder of the weight gives the quantity of ſilver in that centner of ore.

Silver is not the only ore that can be thus worked; many others may be aſſayed in the ſame manner, by Coppelling alone: thoſe are indeed to be excepted from this proceſs, which ſplit, or which corrode the coppels. *Cramer's Art of Aſſ.*

COPPER (*Dict.*)—*The general method of ſeparating* COPPER *from its ore.*—After a proper aſſay, the ore is treated according to the ſubſtances with which it is mixed. If it abounds with ſilver, it is firſt gently warmed or calcined, till a great part of the ſulphur goes off in fume. At Goſlaw in Germany, they firſt break the ore in pretty large lumps, then burn it in an open fire of wood and charcoal; after which they beat it ſmaller, and warm it twice again: and thus make it fit for the firſt furnace, where it is melted into a ſtony red matter, called Copper-ſtone; which, being again roaſted and melted, becomes black Copper; this they roaſt again, in order ſtill more to free it from its ſulphur, and now it is in a fit ſtate to be nealed for its ſilver; which they extract, by adding four parts of lead to one of the black Copper, then melting them together in a ſtrong fire, and caſting the maſs into moulds, where it hardens into blocks. Theſe are carried to another furnace, and buried in charcoal; giving only a gentle heat, till the lead and ſilver melt and run away together into the receiver, leaving the Copper blocks unmelted behind, which are thus honeycombed and drained of their ſilver; but left capable of being brought to tough and malleable Copper, by repeated fuſion. In the Hungarian mines the learned Dr. Brown tells us, that they ſometimes burn the ore, and ſometimes melt it; and this ſometimes by itſelf, and ſometimes mixed with other minerals and its own droſs.

The purification of Copper chiefly depends upon totally freeing it from its ſulphur, which may be done, for the more curious uſes, by melting it ſeveral times with fixed alkali's, nitre, or borax.

After the heterogenous parts have been thrown off, as before directed, from the proper earth of the ore, the pure metal then remains to be ſeparated from this earth by fuſion.

But there are two difficulties, at leaſt one or other of them, always found in this affair. For (1.) This proper mineral earth, how fluxible ſoever it may prove in gold and ſilver, yet ſcarce comes up to the fuſibility of the pure metal, but is apt rather to flow thick and ſluggiſh, unleſs the fire be very intenſe indeed: but it is plain, that, if this ſubſtance remains viſcous, the moleculæ of the metal cannot ſink through it, in order to form a metalline maſs at the bottom. (2.) Sometimes only a very ſmall quantity of pure metal lies concealed in a vaſt body of ſuch adhering earth, or wrapped up with the matter of other metals; whence one of theſe two inconveniences muſt ariſe, viz. either that the ſmall quantity of metal cannot well, under ſo great a load of recrement, come into a little maſs; or elſe, if it could, it muſt of neceſſity be ſo violently agitated and toſſed about by the ſtrong fire required to keep ſo large a bulk of ſlag in fuſion, as in the ebullition to be again involved, as it were, in little drops or bubbles among the pappy maſs of the ſcoria.

Theſe two inconveniences have their remedies. (1.) The firſt is, to add ſuch ſubſtances as promote vitrification, and, at the ſame time, cauſe a thin flux of the vitrified body. Such ſubſtances are, for the large work, ſand, fluxile mud, alkaline ſalts, tartar, nitre, &c. and, for the ſmall, glaſs of lead, a little borax, or any compound flux-ſalt, the baſis whereof are commonly tartar and nitre. (2.) The ſecond is, to add a metal itſelf. This is a common way, and ſeems greatly improveable, if it can be brought to anſwer the expence. In this caſe, as a greater maſs of metal cannot, by the ſame fire, be ſo much agitated and toſſed about as a leſs, or, if it could be agitated as much, yet all its particles would cohere more firmly on a large maſs than in a ſmaller one; hence, by ſuch an addition of metal, the little maſs that would otherwiſe be with difficulty collected from the ſeveral falling particles of the melted matter, is artificially inlarged, ſo as to cover the whole bottom of the melting-pot; in conſequence whereof, all the ſingle metallic particles that fall afterwards, are eaſily catched and detained below, by the large metalline maſs, which there lies ready to receive them.

Copper, being itſelf of difficult fuſion, requires ſuch a fire as is able to melt its glaſſy ſcoria ſufficiently thin, at the ſame time that it is melted itſelf; and this it does, unleſs the flints ſhould prove very obſtinate indeed. Hence bare fuſion, ſometimes, without any other aſſiſtants, will bring out the metal from its ore, and throw it down into a maſs, the ſcoria here flowing ſo thin, as readily to ſuffer the metalline particles to ſink through it; but, when the ore is more ſtubborn, its ſeparation may be promoted by metalline, or other additions, as above-mentioned.

In short, the difficulty of thus separating the metal from its proper earth is principally found in the ores of silver, gold, and Copper; but lead and tin, being very fusible bodies, are much easier melted from their adhering mineral matter.

CO'RAL (*Dict.*)— It had been long the received opinion, that Coral was soft in the sea, and was hardened by the air upon taking it out of the water; and our learned Mr. Boyle was not willing to quit this opinion. But, as experiments are the only way of assuring ourselves of the truth, Boccone, for this purpose, went to sea in one of the Coral-fishers vessels, and, by plunging his arm into the water, had an opportunity of examining the Coral, as they were fishing it up, before it came into the air. He invariably found it hard, except at its extremities; where, upon pressing it between the nails of the fingers, it furnished a small quantity of a milky fluid, resembling in some degree the juice of spurge or sow-thistle. Boccone observes farther, that he saw several furrows under the bark of the Coral, which terminate at the extremities of the branches, about which one might clearly see several small holes of the form of a star, which he imagines are destined for the production of branches. Venette's account of Coral, in his treatise of Stones, is much the same as Boccone's.

The count de Marsigli, in a letter to the Abbé Bignon, in the year 1706, takes notice, that, in order to give the best account of the production of Coral, he wanted to be assured, whether the milky juice before-mentioned was found therein both in winter and summer, which was a matter of dispute even among the Coral-fishers. For this purpose he went in winter a few days to sea with the Coral-fishers, and made several important discoveries into the nature of Coral. He sent the Abbé Bignon an account of some branches of Coral, which he found covered with flowers, and which was a thing unknown even to the Coral-fishers themselves. These flowers were about a line and a half in length, and of the same distance one from another, and formed a star-like appearance. These bodies, which the count de Marsigli imagined were flowers, M. Peyssonnel afterwards discovered to be the insects inhabiting the Coral. As to the fact, whether the Coral furnished a milky juice in winter as well as in summer, count de Marsigli observed, that he did in December find the milky juice between the bark of Coral and its substance, in the same manner as he did in the month of June preceding.

M. de Peyssonnel was unwilling, that the idea, which the ingenious discovery of the count de Marsigli had given, in relation to the flowers of Coral, should be lost; and therefore, being at Marseilles in the year 1723, he went to sea with the Coral-fishers. Being well apprised of what Marsigli had observed, and the manner of his making these observations, as soon as the net, with which they bring up the Coral, was near the level of the water, he plunged a glass vessel therein, into which he conveyed some branches of Coral. Some hours after, he observed, that there appeared a number of white points upon every side of this bark. These points answered to the holes, which pierced the bark, and formed a circumscribed figure with yellow and white rays, the center of which appeared hollow, but afterwards expanded itself, and exhibited several rays resembling the flower of the olive-tree; and these are the flowers of Coral described by Marsigli.

Having taken this Coral out of the water, the flowers entered into the bark, and disappeared; but, being again put into the water, some hours after they were perceptible again. He thought them not so large as the count de Marsigli mentions, scarce exceeding in diameter a large pin's head. They were soft, and their petals disappeared, when they were touched in the water, forming irregular figures. Having put some of these flowers upon white paper, they lost their transparency, and became red, as they dried.

Our author observed, that these flowers grew from the branches in every direction, from broken ones, as well as from those which were whole; but their number lessened towards the root; and, after many observations, he determines, that what Marsigli took for flowers were truly insects.

Coral is equally red in the sea as out of it; and this redness is more shining, when just taken out of the water, than even when it is polished. The bark of Coral, by being dried, becomes somewhat pale. The extremities of its branches are soft, to the length of five or six lines; they are filled with a whitish juice tending to yellow. The Coral-fishers said, that in the month of May this juice sometimes appeared upon the surface of the bark; but this, notwithstanding great attention, our author could not observe.

The body of Coral, although hard, seems to give way a little, when pressed between the fingers; and, being broken at different distances, when just taken from the water, there always came therefrom a small quantity of milky juice through certain tubes, which appeared to be destined towards the bark.

Having enquired of the fishers in what direction the Coral grew in the sea, they acquainted him, where the depth of the sea permitted them to dive, that they had found it growing sometimes perpendicularly downwards, sometimes horizontally, and sometimes upwards.

Having verified these observations during the eight days he staid with the fishermen, he adds, that he had never found any pores perceptible in the substance of the Coral; that there issued less milk from the large branches than from the smaller ones; and that the first were harder, and less compressible.

The bark of Coral covers the whole plant from the root to the extremities of the smallest branches. It will peel off; but this is only, when just taken out of the water. After it has been exposed for a short time to the air, you cannot detach it from the body of the Coral, without rubbing it to powder. This bark appears pierced with little holes, and these answer to small cavities upon the substance of the Coral. When you take off a piece of this bark, you observe an infinite quantity of little tubes, which connect the bark to the plant, and a great number of little glands adhering to these tubes; but both one and the other do not distinctly appear, except when they are full of juice. It is from these tubes and glands that the milky juice of Coral issues forth. Besides these, you see in variety of places the bark push itself outwards, where the substance of the Coral is hollowed, and formed into the little cells, taken notice of by Boccone and Marsigli. In these you see little yellowish bodies, of the length of half a line, which terminate at the holes in the bark; and it is from these that the flowers appear.

Our author has found branches of Coral, which, having been broken, have fallen upon other branches, have fastened themselves thereto, and have thus continued to grow. He has found, when a piece of stone, shells, or other hard bodies, have offered themselves between the ramifications of Coral, that it has expanded itself over them, and inveloped them in its substance. He has seen pieces of Coral growing upon detached pieces of rock, glass bottles, broken pots, and other substances, from which the plant could receive no nourishment. It has been said by great authority, that Coral grows from the rocks perpendicularly downwards; but our author has seen some growing to a round flint, which must necessarily have vegetated upwards, like most other plants.

M. de Peyssonnel proceeds to examine, whether or no Coral is a plant, according to the general opinion, or a petrification or congelation, according to some; and, after having exhibited the various arguments delivered in support of these, he concludes, that Coral, as well as all other stony sea-plants, and even sponges, are the work of different insects, particular to each species of these marine bodies, which act uniformly according to their nature, and as the supreme Being has ordered and determined. The Coral insect, which is here called a little urtica, purpura, or polype, and which M. Marsigli took for its flower, expands itself in water, and contracts itself in air, or when you touch it in water with your hand, or pour acid liquors to it. This is usual to fishes or insects of the vermicular kind.

When our author was upon the coasts of Barbary in 1725, he had the pleasure of seeing the Coral insect move its claws or legs; and, having placed a vessel of sea-water with Coral therein near the fire, these little insects expanded themselves. He increased the fire, and made the water boil, and by these means kept them in their expanded state out of the Coral, as happens in boiling shell-animals, whether of land or sea. Repeating his observations upon other branches, he clearly saw, that the little holes, perceptible upon the bark of the Coral, were the openings through which these insects went forth. These holes correspond with those little cavities or cells, which are partly in the bark, and partly upon the substance of the Coral; and these cavities are the niches, which the insects inhabit. In the tubes, which he had perceived, are contained the organs of the animal; the glandules are the extremities of his feet, and the whole contains the liquor or milk of Coral, which is the blood and juices of the animal. When he pressed this little elevation with his nails, the intestines and whole body of the insect came out mixed together, and resembled the thick juice furnished by the sebaceous glands of the skin. He saw, when the animal wanted to come forth from its nich, he forced the sphincter at its entrance, and gave it an appearance like a star with white, yellow, or red rays. When the insect comes out of its hole without expanding itself, the feet and body of it form the white appearance, observed by Marsigli; but, being come forth, and expanded, it forms what that gentleman and our author took for the petals of the flowers of Coral, the calyx of this supposed flower being the body of the animal protruded from its cell. The milk before-mentioned is the blood and natural juice of the insect, and is more or less abundant, in proportion to its health and vigour. When these insects are dead, they corrupt, and communicate to the water the smell of putrid fish.

The substance of Coral, by a chemical analysis, scarce furnishes either oil, salt, or phlegm: live Coral with its bark furnishes about a fortieth part of its weight in these; but the bark of Coral alone, in which are contained these animals, affords a sixth part. These principles resemble those drawn from a human scull, hartshorn, and other parts of animals.

After the accounts here laid down, we are able to assign the reasons of all the particular facts we observe in Coral. We see, why a branch thereof, broken off and detached from its stem, may flourish. It is because the Coral insects, which are contained

contained in its cells, not having been injured, continue their operations; and, drawing no nourishment from the stem of the Coral, are able to increase, detached and separate. How they live and are nourished, is proposed to be explained in treating of the urtica of the madrepora, in which these animals are vastly larger, and appear very distinctly.

In each hole or star of the madrepora, on which our author lays the evident proof of his new system, the urtica, placed in the center of each pore,' causes it to increase in every direction, by lifting itself further and further from the center of the stone. And in Coral, and in the lithophyton, the urtica, being niched in their crusts or barks, deposits a juice or liquor, which runs along the furrows perceived upon the proper substance or body of Coral, and, stopping by little and little, becomes fixed and hard, and is changed into stone; and this liquor, being stopped by the bark, causes the Coral to increase proportionably, and in every direction. In forming Coral, and other marine productions of this class, the animals labour like those of the testaceous kind, each according to its species, and their productions vary according to their several forms, magnitudes, and colours.

If, after what has been here laid down, some will still consider these marine productions as plants, they are truly zoophytes, formed by the labour of the animals, which inhabit them, and to which they are the stay and support.

By what is exhibited in this work, the author conceives, that he has explained the nature of these several marine productions, which have hitherto been so enigmatical. It is true indeed, that no reasons can be assigned, why the œconomy of these animals is directed in such or such particular forms, We can no more account for the admirable structure and colour of several species of shell-fish: we must in this, as in most of the other operations of nature, cry out, O altitudo divitiarum! *Phil. Transf.* Vol. XLVII. p. 449.

To these observations on this curious subject, we shall add the following of the learned and ingenious Dr. James Parsons, inserted in the same volume of the Philosophical Transactions.

The several ingenious opinions of some of this learned society, upon what M. Peyssonnel has advanced, concerning the formation of some of the submarine bodies by animals, have occasioned the following conjectures; which I lay before you, not at all presuming absolutely to decide a question of so difficult a nature, but only endeavour at throwing a little more light upon the subject, in general, by such further observations, as I thought would be most conducive, at least, to come to a little more certainty about it.

I believe it may be said, that there can be no ocular demonstration of the fabrication of any of these bodies, whether by animals, or by vegetation; because this happens under the water, far enough from any human observation. Therefore, when at any time such of these, as are said to be the work of animals, have been taken up, there is no doubt but that those soft gelatinous weakly animals may have been seen upon them, and thence have been concluded to be the makers of them. Certainly there is nothing impossible to divine providence, in the order and disposition of every thing to the best advantage. Among the animals, from the largest to the most minute, none are destitute of proper habitations; and we see, amongst them, prodigious variety in the modes and designs of such dwelling-places. Some are capable of erecting for themselves commodious apartments to live in, as shell-fish, even out of their own constituent parts, as they grow. Others lodge their young in the very skins of animals; and, where there are any, who have neither sagacity nor strength enough to provide places for themselves, they are at least taught by their Maker to find them ready made.

Such are the bounds set to our intellectual powers here, that we can have no means of judging of objects which do not fall immediately under our inspection, but by comparing them to something else, as near them as may be; or by considering their proportions and effects; what is probable, what is not, in the phænomena that belong to them; and what absurdities may arise from the uses and actions ascribed to them, for certainly they may be easily seen, by considering the objects themselves.

I would neither conclude, with M. Peyssonnel, that, because I found animals upon such bodies as he mentions, they were the makers of such bodies; nor that, if one or more kinds of those bodies were actually the work of such creatures, all others, that had any relation to them, must also be their work; any more than I would, on the other hand, conclude, that, because one or more of these submarine substances were not made by them, none at all were produced by them. I would rather examine the parts of those bodies in as nice and scrutinous a manner as possible, and compare their characteristics with those of other bodies in both the animal and vegetable kingdoms; and, by finding out some of their properties only, be, in a great measure, able to range them in the rank, which they were designed to hold by divine providence.

In order to this, let us see first what are those animals, which we are acquainted with, who certainly fabricate their dwelling-places, as they grow, for themselves; and what the common or usual advantages are, which they are in general observed to be endowed with; which will be best done by taking a nearer view of them. All the testaceous tribe, whether of land or water, and whatever their forms be, may be said to produce their own habitations, but not to fabricate them. For we must observe, there are but two modes, by which these kinds of animals are furnished with them; the one by secretion from themselves, and these necessarily grow with them: the other by a designed apposition of parts of the animals themselves. Now, in the first case, there is a necessity for a just proportion between the animal itself, and the shelly matter secreted from it. It must be large enough, and have stability and strength in proportion to the matter which it secretes, and is to move about with; and it will appear, that this is the general rule through nature: or, if it be an immoveable body, the creature ought certainly to be allowed so much significancy and strength, as would, on the one hand, seem necessary for the secretion of so much matter as was sufficient to constitute that body, or, on the other, to be capable, by its own proper action, of gathering together the matter, and building up the structure. Where this is wanting, I, for my own part, would be far from hastily concluding such work to be the fabrication of such seemingly weakly insignificant animals; more especially if, upon these very bodies, there were appearances of other characteristics, that, at the same time, were likely to lead me into another arrangement of them.

I have produced here before you such of the shell animals, as are unquestionably the makers of their own houses, that are furnished with these requisites mentioned; and others I shall now offer you, being somewhat nearer those said to form the Coral, &c. than other testaceous kinds.

The dentalia are tubular shells, formed from their inhabitant animal, as much as a cockle, or an oyster: and we must observe, that each of these has a sufficient cavity for its habitation, and in itself has the proportional size and strength necessary for the purpose.

The vermiculi marini enjoy the same privileges, and are always attached to their shells at their posterior extremities, as well as the others, of whatsoever kind. They are found in groups, adhering together by a natural cement, blended, and, as it were, confounded together; and yet every one has its own cell, and is sufficient to produce it in those requisites before-mentioned. All the kinds of these have one extremity small, and increase in diameter to the anterior extremity; which is indeed the case of all the turbinated fish of whatsoever kind. To these we may add, that the crusts of crustaceous animals, and those of insects in their chrysalis state, will always shew, how necessarily an animal must have power and sufficiency to form his habitation, either by secretion, or actual operation.

The syringoides, so called from their forms, carry the same testimonies of their strength and power; many species of which we find fossil, of which I have the honour to shew several specimens: and I have no doubt, but it will be hard to find any creatures so deficient, or, in other words, more abandoned to destruction by the Creator, than these, in any part of nature.

Whatever is constructed by an animal, that is, among those that we know with any certainty, it is surely to dwell in themselves, or to deposit eggs or young in. There was really no need to build a fabric to dwell upon; because all those creatures, such as the polypi of every kind, which attach themselves to bodies, have innumerable sorts of matter, to which they can adhere, every-where, near them: and if these of the sea have, in their nature and properties, any analogy with our fresh-water polypi, as to their propagation, and the detachment of their young from themselves; with the several kinds of the same genus, the polypes à panache, polypes à bouquet, the bell-like polypi, and every other kind, by our ingenious observer Mr. Trembley, all which detach their young from them nearly in the same manner; one would almost be persuaded, that they were never intended to dwell in cavities, but upon nidus's convenient for their attachment only, with full liberty, at proper times, to detach their young in like manner; who immediately meet some one or other of these submarine bodies for their security also; for indeed there is hardly room to suppose any other way of propagation for these, than for those of M. Trembley, since they are much of the same substance and consistency every way. And it must be remarked, that few or no animals that have shells of any kind, can ever quit them, but must remain in them till they die.

We are now, secondly, to consider some of the most obvious marks, that distinguish vegetable from other substances.

Whatever body is fixed by its root, no matter, whether it be flat or fibrose, increasing upwards, and ramifying into smaller and smaller branches, till they become more and more pointed to their extremities; having fibres either apparently tubular, or only porous or woody; would incline one, who had at all made the works of nature his study, rather to favour the idea of a vegetable in such a body, than that of any other production. If these characteristics are common to any of the species of Corals, corallines, madrepores, &c. it would be no wonder they owed their increase to a kind of vegetation; nor would their hardness weigh at all against it, because every one knows, that water is the universal vehicle of all matter into bodies of this kind. It is by water, that the testaceous matter is carried into the juices of shell-fish, and from it detached into the order we see it in the shells. It is from water that sparry incrustations upon vegetables are made: it is a deposit from water which lines our common tea-kettles with a sparry crust; and it is also this fluid that conveys the particles of tartar into the grape, which is afterwards deposited on the sides of the wine-vessel; and, no doubt, it is water which carries up into those hard bodies their stony matter; for there can be no doubt of their being organized bodies. Besides, though the organization, in its origin, is probably flexible enough, yet the arrangement of these petrific particles, in so exact a manner, would inevitably render the whole hard enough, in the course of its growth. Is not the shell of a common egg hard enough? And yet its membrane, into the cellules of which the testaceous particles were secreted and ranged, in order to produce that hardness, was soft enough before. If we were to make transverse sections of the generality of these bodies, we should see a regular radiated order of pores from their central medullary pipes, some foliated, others more tubular, others barely porous, all differing from one another only according to their own natures. What more is there in the order of the fibres of trees or plants? Transverse sections of any of these will shew you the most beautiful figures, in such orders, that can be conceived; which, long ago, that accurate and learned naturalist, Dr. Grew has ingeniously observed, in his Anatomy of Plants, where he has given elegant figures of such sections in a variety of examples. And although some of these bodies have their pipes and pores quite stopped up, as they grow, yet their external appearance will shew them fibrose.

In like manner some trees are so very hard, from the strong connection of their parts, that, in a transverse section, neither pores nor fibres can be distinguished: and they are as susceptible of a fine polish as any stone. And indeed it would seem to me much more difficult to conceive, that so fine an arrangement of parts, such masses as these bodies consist of, and such regular ramifications in some, and such well contrived organs to serve for vegetation in others, should be the operations of little, poor, helpless, jelly-like animals, rather than the work of more sure vegetation, which carries on the growth of the tallest and largest trees with the same natural ease and influence, as the minutest plant, in a manner, which I have elsewhere explained.

Is it not also somewhat particular, that, if Corals are the work of these insects, there should be no cavity left behind them, as they raise it into branches; but that they should leave it solid within? And would it not be very surprizing, that such cellular passages, as we see diversified into many kinds, should be made by these creatures from the basis, to be left behind them, as they carry up the building, without any further purpose, in brain-stones, &c. If this was the case, and that these little creatures could be supposed to build them, these would be a deviation from the general uniformity and purpose, that is observed every-where else: for certainly cells are built by every animal to deposit something, eggs, young, or other matter, in them; neither of which can be said of the insects in question.

It has been said, that flies, wasps, and bees, build themselves cells, in order to make a comparison between them and these polypi. They do so; but is there no distinction to be made? I can find several. Bees, wasps, &c. are in themselves compact strong animals, well made for the work allotted them, very able to bring and put together the materials of their nests; and, when they have done their work, that proportion between the fabric, and the creatures which raised it, is apparent, which all nature points out, and the purpose is fulfilled soon, in their filling them with what nature had destined they should hold. But can this be said of our polypi? Where is that proportion between a little configurated-jelly, and the mass of matter said to be their work? What is deposited in the cells they form? What makes others solid? And how do these jellies so wonderfully dispose the fine arrangement of pores, fibres, nodes, branches, &c. And to what purpose, if they could be capable of it? In a word, I humbly propose to sum up this essay in two general sentiments; and these will be the rule, by which I, for my own part, shall always judge of things of this nature; viz.

1. Whatever bodies shall be found to carry the appearances and characteristic marks of vegetables, even though animals are found upon them, they certainly will pass with me for such, till stronger evidence shall evince the contrary.

And 2. I shall ever expect to see, at least, a seeming power, proportion, and stability, in animals to render them capable of performing what they may be thought to have done.

Red Coral. The effect of vegetable distilled oils on Coral, by the help of a long digestion, is such as could not have been imagined, till the experiments of Dr. Langelot shewed that they were a sort of solvent for that refractory substance. This gentleman had put fragments of red Coral into some distilled vegetable oil, and let them stand many months, in hopes of drawing a tincture from them; but without success. At length having a digesting furnace at work, he placed the glass in which the Coral and oil were, in the furnace among the other things; the consequence was, that, after about a month's digestion, the pieces of Coral were found to be swelled, and higher coloured than before, and, with a few days longer continuance with the same heat, the whole quantity of Coral had lost its original figure, and was blended together into a red mucilage, the oil still swimming above it in its pristine form, and not at all altered in colour: the most violent agitation of the vessel could not cause these two substances to mix together, and all the artifice that could be used, proved vain toward the tinging the oil with a red colour. After long trial in the same, and an advanced heat, the oil was poured off as clear as before, and very little altered in smell, or other qualities; and, tartarised spirit of wine being poured on the remainder, with a very short digestion took a very high red tincture. This process is a great proof of the power of digestion.

The common red Coral yields, by distillation in a retort, a volatile vitreous spirit, in no inconsiderable quantity; this turns syrup of violets green, and makes an effervescence with acids, and renders a solution of corrosive sublimate white and milky. And the fixed salt drawn from the residuum produces a white coagulum in the same solution; from which it is evident that it is not a mere alkali, but a sal salsum, in some degree. Red Coral calcined, even in a very gentle fire, becomes white; the same change also happens to it, when infused a long time in some oily substances, as the oils of anise, fennel, or in white wax kept in fusion. The menstrua in this case acquire a red colour, in proportion as the Coral loses it. It appears from these and several other experiments, that Coral is not, as some suppose, a mere terrestrial absorbent, but that it contains a volatile urinous salt, and a bituminous oil, combined with its earthy matter; and on these its virtues in medicine principally depend. The red colour of Coral is evidently owing to its bituminous oil, which it is found not difficult to separate, and wholly divest it of. It is observed, that Coral, newly taken up out of the sea, contains both the salt and oil in greater abundance than that which has been long kept; and it is suspected by many, that its external cortical substance contains more of it than the interior, harder, and more stony matter.

The antients used Coral in many external medicines for distemperatures of the eyes; and internally as an astringent and refrigerating medicine. We use it only internally, and that principally in diarrhœas, and bleedings in too great evacuations of the menses, in the fluor albus. The vulgar attribute to it, besides these virtues, many others, which we have not sufficient warrant for; such as its strengthening the heart, curing malignant fevers, and resisting poison; and they tell us, that it will do all this as well, if worn externally, as if taken inwardly; which may very possibly be true. *Geoffrey, Mat. Med.*

White Coral. There is no part of the world where white Coral is produced in such abundance, as on the shores of the island of Ceylon, and others of the neighbouring Indian coasts. The lime used in that part of the world, for building houses, fortifications, &c. is all made by burning this Coral. It lies in vast banks which are uncovered at low water, and it is spongy and porous. While young, it grows erect, in form of little shrubs, and is then firm and solid, and smooth on the surface, but the branches continually shoot out more, and these other new ones, till the whole is one confused bush. These branches are all covered with a white viscous matter, which, in time, hardens upon them, and becomes Coral; and, this filling up all the interstices between the branches, when they become so numerous, and hardening between and over them, the whole becomes one coarse rock, and the adjoining masses of this kind, uniting to one another, form at last a continued bank, which has the appearance of a great white rock. In the places where the Coral grows in this manner, there are like banks formed of oyster-shells; the oysters here grow often to a foot in diameter, and a foot in thickness; and it is said, that they continue to increase in bulk, after the animal is dead. *Phil. Transf.* Numb. 282.

CO'RALLO-*Achates*, in the natural history of the antients, the name of a very beautiful species of agate, found at this time in the East Indies, but not in any plenty, and called, by Dr. Hill, achates miniaceus flavo variegatus, or the red lead-coloured agate, variegated with yellow. Its basis, or ground colour, is a pale, but very bright red, in which there are discovered, on a close inspection, in most of the pieces, multitudes of veins of a dark red, drawn in very fine and close concentric circles, round one or more points, the whole giving a mixt red, not unlike that of our red lead, or that of the common red Coral in its rough state, when first drawn out of the sea. It is always variegated also with a number of small and beautiful blotches of a fair yellow, which are ranged with great irregularity in the mass, but never interfect, or are interfected, by the veins; they are all small, and either round or oblong. It is very hard, and capable of a fine polish, and, when wrought, is an extremely elegant stone. *Hill's Hist. of Foss.*

CORALLODE'NDRON, *coral-wood*, in botany, the name of a genus of trees, the characters of which are these; the flower is of the papilionaceous kind, but of a very singular make; its vexillum is remarkably long, and of the shape of a sword; its alæ and carina short; from the cup of the flower there is a cylindric pistil, surrounded by a fimbriated membrane, which finally becomes a sort of knotty pod, composed of two valves, and containing a number of kidney-shaped seeds.

CORALLOI'DES, in botany, a term used by M. Tournefort to express a genus of mushrooms; the distinguishing characters of which are, that they are of a fleshy fungose texture, and are branched in the manner of coral.

CO'RDIA, the sebesten, in botany, a genus of plants, whose characters are:

The flower is of one leaf, which is funnel-shaped, and is expanded at the brim, where it is slightly cut into five or six parts: the pointal, which is situated in the middle of the empalement, afterwards becomes a globular fruit, pointed at one end; which is divided into two cells, in each of which is included one oblong seed.

These plants, being natives of warm countries, are too tender to live through the winter in this country, unless they are preserved in a stove. They are propagated by seeds, which must be procured from the countries of their natural growth; for they never produce any in England. These seeds must be sown in small pots, which must be plunged into a good hot bed of tanners bark in the spring; and, if the seeds are fresh and good, the plants will begin to appear in five or six weeks after. These must be brought forward in the hot bed, by being treated as other tender exotic plants; observing frequently to water them, as they are aquatic plants; and in July, if the plants have made much advance, they should be gradually hardened; otherwise they will grow so weak, as not to be easily preserved through the winter. As these plants obtain strength, they will become more hardy; but, during the two first winters, it will be proper to plunge them into the tan-bed in the stove; but, when they begin to have woody stems, they may be placed on shelves in a dry stove, where if they are kept in a moderate degree of heat, they may be preserved very well. They may also be placed abroad in a warm situation, in the beginning of July; where the plants may remain till the middle of September, provided the season continues warm; otherwise they must be removed into the stove sooner. *Miller's Gard. Dict.*

CO'RDIAL or *compound waters*, in chemistry.—*The best method of making* CORDIAL *or compound waters.*

Infuse a pound of fresh citron-peel in two gallons of good melasses spirits, commit the whole to the still, draw off the spirit gently, with care to avoid the faints: then make up, as they call it, with soft water, so as to leave the liquor proof, and add half a pound of fine sugar; and thus you will procure a genuine citron water.

This experiment is general, and shews the usual methods of making all the compound or cordial waters, by those distillers who are called compounders, and also by the apothecaries; though apothecaries seldom make distilled waters so good as the compounders.

The perfection of this branch of Distillation depends upon the observance of a few rules, which might be easily complied with: and these rules we shall here lay down, as judging them of consequence to the improvement not only of the art of the compounder, but also of a branch of pharmacy and medicine.

The first rule is, to use a well-cleansed spirit, that is freed from its own essential oil. For, as the design of compound distillation is to impregnate the spirit employed with the essential oil of the ingredients, it ought first to have deposited its own.

The second rule is, to suit the time of previous digestion to the tenacity of the ingredients, or the ponderosity of their oil. Thus rhodium-wood and cinnamon require to be longer digested before they are distilled, than calamus aromaticus, or lemon-peel. Sometimes also cohobation (that is, the pouring of the spirit, once drawn off, upon the same ingredients) proves necessary; as particularly in making strong cinnamon water; where the essential oil is extremely ponderous, and difficultly rises along with the spirit, without one cohobation more.

The third rule, is, to suit the fire or strength of the distillation to the ponderosity of the oil intended to be raised with the spirit. Thus strong cinnamon water should be distilled off brisker than the spirit of mint or baulm.

The fourth rule is, that a due proportion of only the finer essential oil of the ingredients be thoroughly united or incorporated with the spirit, so as to keep the grosser and less fragrant oil. And this may be chiefly effected by leaving out the faints, and making up to strong proof with fine soft water in their stead. And upon the observance of these four easy rules the perfection of the art of compound distillation seems to depend.

The addition of fine sugar to Cordial waters is a thing of less moment, and may be used or omitted occasionally. And, if these directions be observed, there will be no need of fining down Cordial-waters with allum, white of eggs, ising-glass, or the like; for they will be presently bright, sweet, and pleasant-tasted, without any further trouble.

CORIA'RIA, myrtle-leaved sumach in botany, a genus of plants whose characters are:

It is male and female in different plants; the male flower has five leaves, which are joined to the empalement; these have ten slender stamina: the female flowers have the like empalement, and the same number of petals; and in the center are placed five pointals, which turn to a berry, inclosing five kidney-shaped seeds.

The sort with male flowers is most common in England, the other being very rarely seen in any of the gardens. These grow wild in great plenty about Montpelier in France, where it is used for tanning of leather; and, from this use, has been titled by the botanists, rhus coriariorum; i. e. tanners sumach.

These shrubs seldom grow more than three or four feet high, and, as they creep at the root, they send forth many stems, whereby they form a thicket; so may be planted to fill up vacancies in wilderness quarters; but they are improper for small gardens, where they will take up too much room: and, as there is no great beauty in the flowers, they are only admitted for variety.

It may be propagated plentifully from the suckers, which are produced from the creeping roots in great abundance: these should be taken off in March, and planted into a nursery, to form good roots; where they may continue one or two years, and then must be removed to the places where they are to remain.

This plant delights in a loamy soil, which is not too stiff; and should be placed where it may have shelter from the north and east winds; where it will endure the cold of our ordinary winters very well, and will flower better than if it is preserved in pots, and sheltered in the winter, as hath been by some practised.

CORI'NDUM, *heart-peas*, in botany, a genus of plants whose characters are these:

It hath a trailing stalk, emitting claspers, whereby it fastens itself to whatever plant it stands near: the calyx (or flower cup) consists of three leaves: the flowers consist of eight leaves, and are of an anomalous figure: the ovary becomes a fruit which is like a bladder, and divided into three cells; in which are contained round seeds, in form of peas, of a black colour; having the figure of an heart of a white colour upon each.

These plants are very common in Jamaica, Barbadoes, and most of the other warm islands in the West-Indies; where their seeds are scattered, and become weeds all over the country.

They may be cultivated in England, by sowing their seeds on an hot bed in March; and, when the plants come up, they must be transplanted into a fresh hot bed, where they may remain until the middle of May; at which time they may be transplanted into pots or borders, and exposed to the open air. These plants will require sticks to support them, otherwise their branches will trail upon the ground, and be apt to rot, especially in a wet season. There is no great beauty in this plant; it is chiefly preserved as a rarity in the gardens of the curious. It produces its flowers in June, and the seeds are perfected in August.

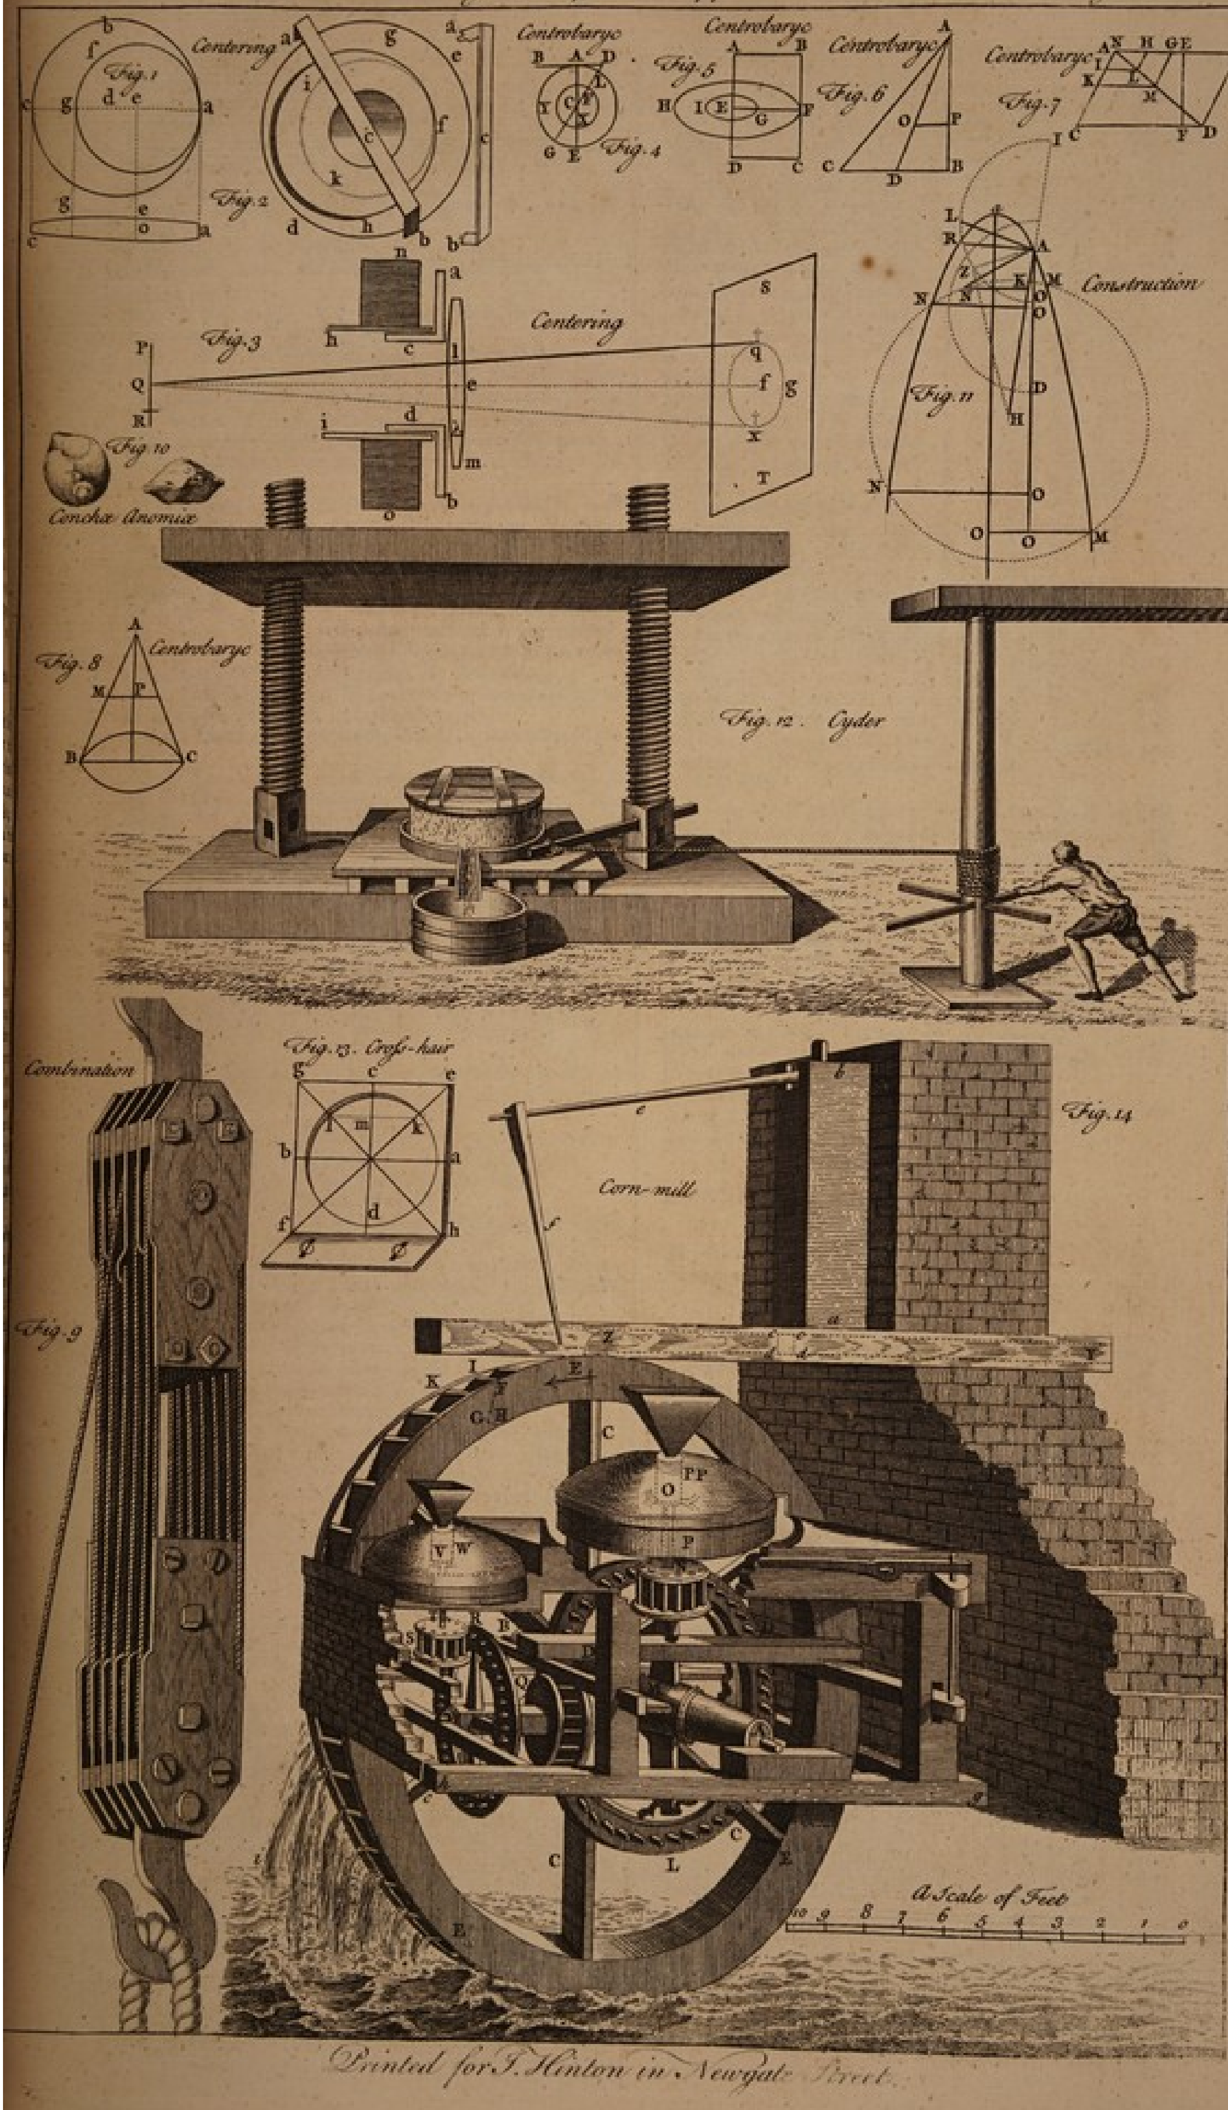
CO'RN-MILL—AB (*Plate* XIV. *fig.* 14.) is an under shot wheel, upon whose shaft D is fixed a spur or cog-wheel (here called a face-wheel) E, whose cogs take the rounds of the trundle or lantern G, which carries round the mill-stone in the hurst, or round from I, containing the nether mill-stone at V V, and the upper at N N; the axis fixed to the upper mill-stone being the iron bar F.

They commonly make these sort of wheels from 12 to 18 feet in diameter, the float boards about 2½, or three feet broad in their length, with an height of 10 or 12 inches. The shaft is 15 or 18 inches diameter.

The cog-wheel is generally eight feet diameter, measuring from the middle of the sole (that is, where the cogs are put in to take the rounds of the trundle) on one side, to the same on the other. The sole or rim of this wheel must be made of two pieces eight inches thick, crossed one over the other, so as to have a breadth of eight inches. This wheel has 48 cogs four inches high, and 3⅓ inches wide, 2 inches thick at the end, and 2⅓ inches at bottom, because of the heel. Their root is twelve inches long, and 2½ thick, square at top, and reduced to an inch and ½ at bottom.

The lantern or trundle is made of two round pieces or flat heads of 22 inches diameter, and four inches thick, in which are set nine rounds of two inches and an half diameter, and 18 inches high; the center of these rounds is placed upon the circumference of a circle of nine inches radius, which must be taken for the diameter of the trundle. The rounds must be made of hard wood, as wild pear-tree, or crab-tree. Through the trundle goes an iron axis 2½ inches square, and of an height proportionable to the situation of the mill-stones, in respect to the position of the cog-wheel; it must be well fastened to the upper mill-stone, and its bottom must be reduced to a pivot of about half an inch diameter, which turns in a socket let into the thickness of the horizontal supporting piece H. The same dimensions are given to the parts of a wind-mill.

Here follow the names and the measures of all the parts of such a mill, necessary when we would calculate its effect, which may be easily done by those who understand algebra.



Printed for T. Hinton in Newgate Street.

a = 8 feet, radius of the water-wheel.
b = 4 feet, radius of the cog-wheel.
c = 9 inches, radius of the trundle.
d = 2 feet, mean radius of the mill-ſtone.
f = $\frac{3}{4}$ of an inch, radius of the gudgeons of the wheel.
h = $\frac{1}{2}$ of an inch, mean radius of the end of the pivot of the mill-ſtone, or of the trundle.
p = 200 pounds, the force of the power that turns the wheel.
q = 1305 pounds, the friction of the centers.
r = 4348 pounds, the weight of the mill-ſtone, and the trundle and its axis.
x = the weight equivalent to the reſiſtance that the mill-ſtone meets with in grinding the corn.

Such a mill as this having its upper mill-ſtone of 6 feet diameter, and of about 4348 pounds weight, and which goes round about 53 times in an hour, may grind in 24 hours about 120 ſeptiers of corn, each weighing 75 pounds, when the ſtone is newly chipped or pecked, and is of a good quality; the hard and ſpongy ones being the beſt, &c. *Belidor's Hydraul.*

The following is a curious over-ſhot mill for grinding corn, at the Bar Pool, by the abbey in Nuneaton, in Warwickſhire.

In the perſpective drawing all care has been taken, to ſee as much as is neceſſary to ſhew the whole ſtructure of all the uſeful or moving parts of the mill; for which it is laid open or cut in ſuch ſections, as I judged beſt ſuited the purpoſe. The ſcale fits the orthography or fore right ſide of the frame or building; the other parts perpetually diminiſhing.

A B, (*Plate* XV. *fig.* 14.) The axle-tree or ſhaft of the water-wheel 13 feet long, and 17 inches diameter.

C C C. Having ſix arms fixed in it at D, 9 inches broad and 3 thick.

E E E. The ſole of the wheel is fixed, being 18 inches broad, and the ſhrouds 14 inches deep; having 30 buckets. Their breadth F I 17½ inches. F G, depth 19. G H, the elbow to the ſide 4 inches.

I K. Their diſtance from one to another 17 inches and an half. The whole height or diameter of the wheel 16 feet.

L L. A cog-wheel placed on the ſame ſhaft by 4 arms at M, 7 feet diameter, having 48 cogs or teeth, which turns,

N. A wallower, pinion, or trundle 19 inches diameter, of 9 rounds or leaves, in which is fixed an iron ſpindle

N O. Going through the middle of the lower mill-ſtone P, moving in a collar, to which is fixed the rind O laid into the upper ſtone P P, which it bears up and turns about. That upper ſtone

P P. Whoſe diam. is 5. 8. } And between the edge and the
Thickneſs at the edge 0. 5. } middle the convexity is about
Middle 1. 4. } 1 inch ½.

Q. A wallower 2. 4 diam. of 15 rounds, which is at pleaſure applied to the cog-wheel L L. On the ſame axis is

R. A cog wheel 5. 4 diam. of 40 cogs, turning

S. A wallower of 9 rounds, whoſe axis

T. Has a rind V at its top bearing and turning the upper mill-ſtone,

W. Which ſtones are uſed for grinding wheat for fine flower. They are 4 feet diam. 5½ thick at the edge, 15 in the middle, with the convexity between 1½.

X. The ſurface of the water in the pool lying 7½ feet above the level or the top of the wheel.

Y Z. A trough or lander conveying the water from the pool at Y, and delivering it into the buckets of the wheel at Z. This trough is 12 inches ſquare within, having

a b. A penſtock upon it, whoſe cavity is the ſame, and

c d. An orifice 10½ broad and 12 high, with a ſhuttle or ſluice to open and ſhut it, which lets the water upon the wheel, and is (generally) raiſed about two inches, by means of

e. A lever or balance fixed to its ſhank, by the handle *f.*

This mill will grind 30 buſhels in 12 hours.

The velocity of the { wheel 8 / large ſtone 40 } per minute.

But as its force, power, action, &c. that are moſt wanting to be known, have, as yet, been but little conſidered: I ſhall here ſubjoin the calculus in ſuch a plain manner, as may be underſtood by any who are a little verſed in numbers; though to have done the ſame in an algebraic, or (ſome parts) in a fluxionary proceſs, would have been more elegant, but not ſo generally underſtood and examined.

For the velocity of the water and the wheel.

The water falls 7, 5 feet = 90 inches, which ſpace a heavy body falls in 41‴, and a double column of water iſſues forth, viz. 15 feet. Then in one minute there will be expended at the orifice 1350 feet = 16200 inches; and, the opening of that ſluice being 10. 5 × 2 = 21 inches area, there will be 1206 ale gallons fall on the wheel in a minute = 19 hogſheads 9 gallons, or 1148 hogſheads per hour.

2. The diameter of the wheel being 16 feet, the circumference is . 50,3 feet;
Which multiplied by the revolution it makes in a minute — — — — — — — } = 8
The wheel goes in a minute, or its velocity 402,4 feet.

Then as 402 : 1350 :: 1 : 3,35; ſo the velocity of the water to the velocity of the wheel is as 3,35 is to 1.

3. The adjutage, as above, gives 1206 gallons, which, divided by 8, gives 150,7 ale gallons, which ÷ by 30, the number of buckets, gives 5,02 gallons to each bucket, that is, nearly 50lb. wt. of water in each bucket.

4. But, as only one bucket, viz. that horizontal with the axis, can act by a force of 50lb. on the longer end of the lever, the radius of the wheel E E (the ſhorter end being the radius of the cog-wheel L L) their forces in proportion to their centers of gravity will be different; which calculated, and from thence their ſtatical weights (as I call them) their forces will be (in a leſs number than half the buckets) as in the margin. The ſum of the weights in the laſt column will be 3 hundred and 66 pounds.

Buck	lb.	hun. lb.	Stat. Wt. lb.
1	50	1.0	6.8
2	50	2.6	17.6
3	40	4.3	29.2
4	50	5.6	38.
5	50	6.3	42.8
6	50	6.8	46.2
7	50	7.3	50.
8	50	7.2	49.5
9	42	6.8	38.
10	40	6.3	33
11	36	4.4	27
12	31	4.0	17
13	22	2.5	7

402,1 = 3 hund. 66lb.

5. But as a cubic inch of water weighs 58 ounces, and there are always falling 3780 cubic inches, the force impreſſed, were it on the tangent of the wheel, will amount to 137 lb. but the diſtance of the penſtock from the pool 6 feet. The force is in it and by the ſhuttle, as alſo its ſtriking obliquely on the paddles or buckets nearly to an angle of 45 degrees; from which conſiderations (and experiments I have made) its velocity, and conſequently force, is leſſened about one half: therefore I add only 60lb. to the ſum of ſtatical weights, and it makes 4 hund. 0q. 14lb. = 462 pounds.

6. Rad. wheel 8
Rad. cog-wheel 35)3696(1056 force at the cogs or trundle of the ſtone equal to 9 hund. 48lb. for the reſiſtance of the ſtones, the grinding, and the great friction of the ſtones and corn.
Or 1056
× by rad. wall ,75
Rad. of the ſtone 2.8) 729(282,8lb. force at the periphery of the ſtone = 2 hund. 2q. 2lb.

7. The force on the wallower rounds (Q) 1056
The rad. of that wallower × 1.2
The rad. of the next cog-wheel 2.4)1261,2(526lb. force on the trundle (S) that carries the wheat mill, and 526 × rad. wall. 7 is = 3682 ÷ 24 rad. of the ſtone gives 153lb. force at the periphery thereof.

8. The great ſtone makes 5, 33 revolutions for the wheels 1, and 42, 4 times per minute.
Rounds, cogs (3.2
15 48(× 8 times the wheel.
25,6
9)40(4,4 × 4,4
112,6 per min.

The velocity of the periphery of the great ſtone.
Its circumference 3136
× 42.4
754,72 feet in a minute.

Alſo the velocity of the ſmaller is 1407,5 feet per minute.

9. The weight of the mill-ſtones.
The great one contains 22,5 cubic feet = 1912 lb. = 17 hund. 0 q. 4 lb.

This water-mill is by moſt people accounted as good a one, as any the country affords, for diſpatching as much buſineſs in the time, and doing it well, though perhaps among the curious there may be ſome objections againſt its train (as the movement-makers call it) for they generally ſay that the pinion ſhould divide the wheel exactly, or be ſome aliquot part of it, which here it is not; for 9)4.8(5.33. but, had it been
4.5
40
9)54(6, it then had been ſuch. 27
0

However, this goes well, it is a very agreeable height 16 feet, the fall conſiderable 7½ feet; for, the wheel being made 20 feet higher in the place it ſtands, it could not have been capable of doing ſo much buſineſs: of ſo much more ſervice is the impulſe, ſtroke, or momentum of the water, than is its bare ſtatical weight.

N. B. Our buſhel here generally holds $\frac{1}{12}$ parts more than the Wincheſter. *Beighton.*

M. Belidor, by the particular account he ſeems to give of under-ſhot mills, and their ſeveral parts; and the calculations concerning the operations of the parts ſingly, and the whole together; ſhewed that he had well examined thoſe mills: but he knew very little of over-ſhot mills, which he ſpeaks very ſlightly of, ſaying, that the millers value them very little; but it muſt be ſuch millers as live in a flat country, and are only uſed to mills upon rivers and large brooks; for, in hilly countries, the over-ſhot mills are of vaſt ſervice, and uſe of little water, as often to do good work by the water of ponds ſupplied

ſupplied by ſprings. As in this Nuneaton mill, with the expence of only 1148 hogſheads, or 287 tons per hour, thirty buſhels or 1800 pounds of corn are ground in twelve hours. The under-ſhot mill deſcribed by M. Belidor does indeed grind about twice and an half more corn, viz. 4500 pounds, in twelve hours; but it is with the expence of twenty-four times more water. For, if the ladle-boards of this under-ſhot mill be three feet long, and go twelve inches in water, and the adjutage, or paſſage of the water againſt them, be in the ſame proportion with an height of water ſeven feet and an half above the center of the adjutage, as in the over-ſhot mill; the expence of water will be 6820 tons per hour in the under-ſhot mill: whereas the expence of water in the over-ſhot, through an adjutage ten inches and an half wide, and two inches deep, is only 287 tons per hour.

I have had occaſion to examine many under-ſhot and over-ſhot mills, and generally found, that a well made over-ſhot mill ground as much corn in the ſame time as an under-ſhot mill, with ten times leſs water: ſuppoſing the fall of water at the over-ſhot to be twenty feet, and at the under-ſhot to be about ſix or ſeven feet. I generally obſerved, that the wheel of the over-ſhot mill was of fifteen or ſixteen feet diameter, with an head of water of four or five feet, to drive the water into the buckets with ſome momentum.

It is a difficult thing, and requires ſome experiments to determine, whether there ſhould be any impulſe given in an over-ſhot mill; or rather a wheel made of ſuch a large diameter as to receive the water without any percuſſion, by which means it may go with leſs water; and thoſe who are for this method alledge, that, beſides the obliquity of the impulſe when a fall is made uſe of, there is only the firſt beginning of the jet that can do any thing, the ſpouting water daſhing in the water that is already in the bucket, and making a froth. For my part, I can determine nothing certain in this for want of ſufficient experiments; but I think, that there might be ſome fall allowed, that the momentum might be uſeful at firſt, while the water ſtrikes againſt the wood of the bucket, before the bucket is ſo full that the water daſhes againſt water. The determining this, to know what part of the height of the fall muſt be taken for the diameter of an over-ſhot wheel, would be a uſeful maximum. Too great an impulſe might make the wheel go ſo faſt, that it might, as it were, withdraw itſelf from the action of the ſtatical weight.

The velocity that M. Parent determines, in his maximum, for the under-ſhot wheel, may perhaps be the beſt here; though it has not been demonſtrated to be ſo. But here it is ſo, the velocity of the wheel is the third of that of the water; and the goodneſs of this mill ſhews it to be right.

The objection which Mr. Brighton thinks may be made, as to the train, is of no force here; for though, in clock work, the number of the pinion ſhould equally divide the wheel, leſt a leaf of the pinion ſhould fall foul upon the edge of a tooth; it is an excellency in mill work, not to have the number of the trundle to be an aliquot part of the number of the ſpur wheel, becauſe, that way, the rounds are worn out too faſt, when the ſame cogs too often take the ſame rounds: and very likely this was done on purpoſe.

CORNUS, *the cornelian cherry*, in botany, a genus of plants, whoſe characters are:

The calyx, or flower cup, conſiſts of four ſmall rigid leaves, which are expanded in form of a croſs: from the center of which are produced many ſmall flowers, each conſiſting of four leaves, which are diſpoſed almoſt in form of an umbrella: theſe flowers are ſucceeded by fruit, which are oblong, or of a cylindrical form, ſomewhat like an olive, containing an hard ſtone, which is divided into two cells, each containing a ſingle ſeed. See *Plate* XVI. *fig.* 1. where *a* is the flower, *b* the flower ſeparate, *c* the fruit.

All the ſorts of Cornus may be propagated by their ſeeds, which, if ſown in the autumn ſoon after they are ripe, will moſt of them come up the following ſpring; but, if the ſeeds are not ſown in autumn, they will lie a year in the ground before the plants will appear; and, when the year proves dry, they will ſometimes remain two years in the ground; therefore, the place ſhould not be diſturbed, where theſe ſeeds are ſown, under two years, if the plants ſhould not come up ſooner: when the plants are come up, they ſhould be duly watered in dry weather, and kept clean from weeds; and, the autumn following, they may be removed, and planted in beds in the nurſery, where they may remain two years; by which time they will be fit to tranſplant, where they are to remain for good.

They are alſo propagated by ſuckers, and laying down of the branches; moſt of the ſorts produce plenty of ſuckers, eſpecially when they are planted on a moiſt light ſoil, which may be taken off from the old plants in autumn, and planted into a nurſery for a year or two, and then may be tranſplanted into the places where they are to remain; but thoſe plants which are propagated by ſuckers, rarely have ſo good roots as thoſe which are propagated by layers, and, being much more inclinable to ſhoot out ſuckers, whereby they will fill the ground round them with their ſpawn, they are not near ſo valuable as thoſe plants which are raiſed from layers.

COROLLA, among botaniſts, is the moſt conſpicuous part of a flower. It expreſſes the coloured tender part which ſurrounds the organs of generation. The parts it is compoſed of are called petals; if it conſiſt only of one piece, it is called monopetalous; if of more, it is ſaid to be dipetalous, tripetalous, and ſo on, as it conſiſts of two, three, four, or more parts.

COROLLARY, or CONSECTARY, in mathematics, is uſed for a conſequence drawn from one propoſition already advanced or demonſtrated: as if from this theorem, That a triangle, which has two equal ſides, has alſo two equal angles, this conſequence ſhould be drawn, that a triangle, which hath the three ſides equal, has alſo its three angles equal. *Ozanam, Dict. Math.*

CORONA, in anatomy, is that edge of the glans of the penis where the preputium begins.

CORONA, among botaniſts, expreſſes any thing growing on the head of the ſeed. The Coronæ of ſeeds are of various kinds; ſometimes ſimple, conſiſting only of a dentated membrane; ſometimes pappoſe, conſiſting of downy matter, which in ſome caſes is immediately fixed to the ſeeds; in others, its has a pedicle growing from it. Sometimes the Coronæ are compoſed of ſimple filaments, and ſometimes they are ramoſe.

CORONA *imperialis*, crown imperial, in botany, the name of a genus of plants, the characters of which are theſe: the flowers are collected into a ſort of crown near the top of the ſtalk, and have over them a large tuft of leaves. The flowers are of the liliaceous kind, being each compoſed of ſix petals. This piſtil ſtands in the center of the flower, and finally becomes an oblong fruit, edged with a ſort of membranaceous wings. This is divided into three cells, which contain a large number of ſeeds, of a flatted ſhape, lying cloſely upon one another. To this it is to be added, that the root is tunicated, and has a number of fibres iſſuing from its baſe.

There are ſeveral diſtinct ſpecies of this plant preſerved in the gardens of the curious, all which make a very elegant appearance; there are alſo a great number of varieties which are propagated from the ſeeds of one or other of the ſpecies, in the ſame manner with thoſe of the tulip.

When they are thus raiſed, the beſt time for tranſplanting them is in July or Auguſt, before they puſh forth new fibres; or they may be taken up out of the ground in June, after their green leaves are decayed, and kept till Auguſt, and then planted out into beds of rich earth, with ſome rotten dung buried deep in them. The moſt pleaſing method of planting them is at eight or ten feet diſtance, in the middle of long flower beds; a hole of ſix inches deep ſhould be opened with a ſpade, and the root put into it, and the earth put in with the hand upon it, and all the ſtones picked out, and the lumps broke. They now require no farther care, but in February will ſhoot up, and grow ſo quick, if the weather be mild, as to flower in March. As this is uſually a windy ſeaſon, it is proper to plant ſtakes in the earth, to tie theſe plants to, to prevent their being blown down; and it is a good caution never to gather the flowers, which much weakens the roots; they ſhould, therefore, always be ſuffered to die upon the ſtalks. The roots ſhould be removed once in three years, and their off-ſets ſeparated, and planted in beds. *Miller's Gard. Dict.*

CORONA *imperialis*, in conchyliology, a name given by authors to a kind of voluta, differing from the other ſhells of that family, by having its head ornamented with a number of points, forming a ſort of crown.

CORONILLA, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the papilionaceous kind, and the piſtil which ariſes from the cup, finally becomes a pod compoſed of many parts joined together by a ſort of articulation, each containing an oblong ſeed.

There have been pieces of amber found, with the pennated leaves of Coronilla included in them, and as elegantly expanded as the moſt curious botaniſt could have expected it, for preſerving them in his Hortus ſiccus. Breynius gives us an account of one of theſe pieces of amber, in which the middle part of one of theſe leaves was thus elegantly preſerved; he examined the ſpecimen with the greateſt accuracy, but could not find the leaſt fraud or deceit in it, and is very particular in the deſcription of the piece, and in the diſpoſition of the leaf in it.

CORPUS *Chriſti-day*, a feaſt held always on the next Thurſday after Trinity Sunday. It was inſtituted in the year 1264, in honour of the bleſſed ſacrament, to which alſo a college in Oxford is dedicated. We find it mentioned in 32 Hen. VIII, c. 21. By which ſtatute Trinity term is appointed for ever to begin the morrow after this feaſt.

CORTEX, the rind or bark of trees. The wounds of the bark, and its ſeparation from this wood, whether natural, or experimentally made, are eaſily cured, and made to unite again, by proper care. If ſections be made in the rinds of the aſh and ſycamore, of a ſquare figure, three ſides cut, and the fourth uncut, and the whole be afterwards bound round with a packthread, it will all unite again, only leaving a ſcar in each of the ſides where it was cut. If ſeveral parts of the bark of either of theſe trees be cut off, and intirely ſeparated from the tree, ſome ſhallower, leaving a part of the bark on, and others deeper, to the wood itſelf; theſe pieces being again put

put into their places, and bound on with packthread, will not indeed unite, but a fresh bark will grow in their places, and thrust them away; but, if they be first carefully laid on in the exact direction, in which they originally grew, and then the whole part beyond the wound on every side covered with a large plaister of diachylon, or the like, and this bound over with packthread to keep all firmly in their places, the pieces of bark, whether cut off shallower, or deep down to the very wood of the tree, will firmly unite themselves to the places where they originally grew. This cure will be performed in the space of about three weeks; but the outer rind of the separated pieces will not be plump, but somewhat shrivelled; the edges also will recede somewhat from their original place, so that there remains a sort of scar all round. These experiments are best made in the spring season, for, in the autumn and winter, the sap arising but weakly, the parts that should unite wither before that is brought about. The success of these experiments has made some think, that the whole branch of a tree, separated and bound on again, might grow on again; but the experiments that have been made in the most favourable manner for such a trial, have all proved vain, the branch cut off withering always in a few days, however well united, and carefully kept on. *Phil. Transf.* N°. 25.

CO'TINUS, *Venice sumach*, in botany, a genus of plants, whose characters are:

It hath round leaves, with long foot-stalks: the flowers are small, consisting of five leaves, which expand in form of a rose; are disposed in capillary branches of very slender and stiff filaments or hairs, which are widely diffused after the manner of plumes, and spring out of the top branches: in the center of the flower is situated the pointal, attended by five minute stamina: the pointal afterwards turns to an oval berry, inclosing one triangular seed.

The wood of this shrub is greatly used in the southern parts of France, where it grows in great plenty, to dye their woollen cloths of a yellow colour, or feuillemorte; and the tanners use the leaves to prepare their skins; from whence it was called Coti coriaria.

CO'RVUS, *the raven*, is particularly used for a large bird of the crow kind, well known throughout the world, as being found in all climates, and all regions. The ravens build in high trees, or upon the ruins of old lofty buildings; they lay four, five, or six eggs, of a bluish green, variegated with spots and streaks of black. There are many fabulous stories of the longævity of the raven, but birds are in general long-lived, and the crow kind not less so than the rest. *Ray's Ornithol.*

CORVUS, in antiquity, a machine, invented by the Romans, at the time of their wars in Sicily, when they first engaged the Carthaginian fleet. According to Polybius, the Corvus was framed after this manner: On the prow of their ships they erected a round piece of timber about one foot and a half diameter, and twelve feet in length, on the top of which was a block, or pulley; round this piece of timber was a platform of boards four feet in breadth, which was about eighteen feet long, and well framed and fastened with iron; the entrance was longways, and it was moveable round the aforesaid upright piece of timber, and could also be hoisted up and down within six feet of the top: about this frame was a sort of parapet knee high, which was defended with upright bars of iron, sharp at the ends, and towards the top there was a rising, by the help of which, and a pulley, or tackle, it was hoisted and lowered at pleasure; with this moveable gallery, they boarded the enemy's ships, when they did not lie side by side, sometimes on their bow, and sometimes in the after part of the ship; the soldiers, keeping the boss of their bucklers level with the top of the parapet, &c. and by means of this new engine, got a victory over the Carthaginians in their first sea fight with them, though the enemy were long before well skilled in naval affairs, and the Romans raw and ignorant.

CORVUS *aquaticus*, in zoology, the name given by authors to the bird commonly known by the name of the cormorant. It is of the size of a goose, and is of a very deep dusky brown on the back, with some admixture of a greyish gloss, and white on the belly and breast; its long wing feathers are greyish; its tail is a hand's-breadth and a half long, and when expanded, looks roundish at the end; its beak is between three and four fingers-breadths long, and is a little hooked at the end; its legs are very short, but very thick and strong, and, which is a very peculiar thing, are flat, or compressed, especially while the creature is young; and another singularity is, that the base of the lower chap is covered by a naked yellow membrane, in the manner of the wild swan's beak; its legs are black, and covered with a series of cancellated scales; the toes are all joined by one membrane. It builds not only among the rocks, but often also on trees. *Ray's Ornithol.*

CORY'ZA (*Dict.*)— This is a disease which few people trouble a physician about, being usually left to nature; but it is, however, in the power of medicine to do great service, and, usually, wholly to remove the complaint; which, even where it is not attended with danger, is so far troublesome, as that any one would wish to be rid of it. In cases of a gravedo, a just and necessary excretion of the congested matter must be provided for; and this may easily be contrived to be made, by less troublesome evacuations than those to which nature seems to point, and by more convenient outlets; and, by continuing this method, the future distempers of this kind may be anticipated and prevented. For the ready discharge of the matter, according to the intent of nature, errhines are to be used; the powders of the cephalic herbs, as thyme, betony, lavender, and the like, may be snuffed up the nose, and, by the volatile pungent salts, may be smelled to: by these means the mucid humour, which caused the infarction, will be rendered thin, and fitted to discharge itself. After this, it will be proper to give a gentle purge. And, when the cure is perfected, the return may be prevented by bleeding and purging in spring and autumn. When the defluxion is very violent, Stahl recommends the use of gentle diaphoretics, and of a powder composed of cinnabar, and a gentle opiate. In cases where the matter of a Coryza is very acrid, and there is a violent pain in the head, the external use of camphor is of great service; it is in this case to be applied to the temples; and the patient should at the same time take, internally, powders composed of nitre and the common absorbents, and diaphoretic antimony, and afterwards should take some gentle purges, and frequently bathe the feet in warm water. *Junker's Consp. Med.*

COSMO'LOGY, the science of the world in general. This Wolfius calls general, or transcendental Cosmology, and has written a treatise on the subject, wherein he endeavours to explain how the world arises from simple substances; and treats of the general principles of the modifications of material things, of the elements of bodies, of the laws of motion, of the perfection of the world, and of the order and course of nature.

CO'STAR's *Engine*, an invention for raising water from mines. Devonshire and Cornwall, where there are a great many mines of copper and tin, is a very mountainous country, which gives an opportunity in many places to make adits, as they call them, or subterraneous channels, or sought from the bottom of the mine where the miners are at work, to some valley at a distance, a little lower at the bottom of the mountain, to carry off the water from the mine, which otherwise would drown them out from getting the ore. These adits are sometimes carried a mile or two, and dug at a vast expence, as of two, three, or four thousand pounds, especially where the ground is rocky. And yet they find this much cheaper than to draw up the water out of the mine quite to the top, when the water runs in plenty, and the mine is deep. Sometimes they cannot find a level near enough proper to carry to it an adit from the bottom: suppose the mine be 50 yards deep, and they can only find a level 25 yards above the bottom; yet they find it worth while to make an adit to save half the height to which the water is to be raised, thereby saving half the expence, and delivering the water into the trough L Z (*Plate* XIV. *fig.* 13.) where it runs off under ground without bringing it up to the grass.

The late Mr. Costar, considering that sometimes from a small stream, and sometimes from little streams or collections of rain water, one might have a pretty deal of water above ground, though not a sufficient quantity to turn an over-shot wheel; thought that, if a sufficient fall might be had, that water might be made useful in raising the water from the bottom of the mine to the adit, and thereby save the expence of men and horses used for that purpose: the fall to be had appeared to him to be C L; that is, from the grass or mouth of the pit down to the adit, which here we will suppose 25 yards. Then he contrived to place a rag-wheel R R, with its chain or bucket pump at the mouth of the pit at C *c*, much after the manner of Francini, receiving the superior waters brought into a collective cistern W, through a pipe A, leading it into the buckets B, making them go the reverse way, because in the common chain-pump the rag-wheel carries the buckets, but here the buckets carry the rag-wheel, down as far as the adit, into which they discharge themselves at *b b*; and there turning another rag-wheel *r r*, whose axis works an engine bringing the water from the bottom, which is also delivered into the adit which carries away both the waters to the delivery at the bottom of the mountain at Z, which we suppose at a great distance from the mine. Any kind of engine may be worked by this lower rag-wheel, whose axis is H I; as, for example, a common chain pump, by making the rag-wheel sufficiently deep; or cranks, as I have represented it at G *g* in the figure, working two pump-rods K K moving in the barrels M M, and delivering their water into the trough leading to the adit.

N. B. There must be a wheel fixed to the axis of the upper rag-wheel at C, to carry a pinion or smaller wheel D, having a fly E F, in order to regulate the motion of the whole machine, and prevent jerks.

CO'STUS *dulcis*, in the materia medica, the name of a root, which, being apt to contract a bitterness in growing old, is called in that state, by many authors, bitter Costus, and supposed a different drug.

It is the root of the Costus Indicus violæ martis odore, called by the Indians tsianocua. It grows to six or seven feet high; the leaves are of a lively green, but something paler on the upper side than the lower; the flowers are four-leaved, white, and

and ſhaped like a bell; the fruit is three-cornered, and divided into three cells, containing a number of triangular ſeeds. The root always contracts a bitterneſs, and grows darker-coloured in keeping, though, when freſh, it was pale and ſweet; and hence the ſuppoſed difference, the deſcriptions of authors agreeing alike to each, in all but theſe accidents.

The leaves of the common garden coſtmary are ſtomachic and detergent. They are given with ſucceſs againſt crudities of the ſtomach, belchings and vomitings after meals. They have alſo great reputation in curing an offenſive breath, heart-burns, and many of the moſt obſtinate and inveterate head-aches, the cauſes of which lie in the ſtomach.

COTESIAN *Theorem*, in geometry, an appellation uſed for an elegant property of the circle diſcovered by Mr. Cotes. The theorem is:

If the factors of the binomial $a^{\lambda} \pm x^{\lambda}$ be required, the index λ being an integer: let the circumference A B C D (*Plate* XVII. *fig.* 1.) the center of which is O, be divided into as many equal parts as there are units in 2λ; and from all the diviſions let there be drawn to any point P in the radius O A, produced if neceſſary, the right-lines A P, B P, C P, D P, E P, F P, &c. then ſuppoſing $OA = a$, $OP = x$, the product of all the lines A P, C P, E P, &c. taken from the alternate diviſions throughout the whole circumference, will be equal to $a^{\lambda} - x^{\lambda}$, or $x^{\lambda} - a^{\lambda}$, according as the point P is within or without the circle; and the product of the reſt of the lines B P, D P, F P, in the remaining alternate places, will be equal to $a^{\lambda} + x^{\lambda}$.

For inſtance, if $\lambda = 5$, let the circumference be divided into ten equal parts, and the point P be within the circle; then will $AP \times CP \times EP \times GP \times IP$ be equal to $\overline{OA}^5 - \overline{OP}^5$, and $BP \times DP \times FP \times HP \times KP = \overline{OA}^5 + \overline{OP}^5$. In like manner if λ be $= 6$, having divided the circumference into twelve equal parts, $AP \times CP \times EP \times GP \times IP \times LP$ will be equal to $\overline{OA}^6 - \overline{OP}^6$, and $BP \times DP \times FP \times HP \times KP \times MP = \overline{OA}^6 + \overline{OP}^6$.

The demonſtration of this theorem may be ſeen in Dr. Pemberton's Epiſt. de Coteſii Inventis.

By means of this theorem, the acute and elegant author was enabled to make a farther progreſs in the inverſe method of fluxions, than had been done before. But in the application of his diſcovery there ſtill remained a limitation, which was removed by Mr. de Moivre. See *Dr. Smith's Theoremata logometrica & trigonometrica, added to Cotes's Harmonia Menſurarum, p.* 114, 115. *De Moivre, Miſcel. Analyt. p.* 17, *& ſeq.*

COTESIAN *Theorem*, in dioptrics, a beautiful theorem invented by Mr. Cotes.

Prop. To find the apparent magnitude, ſituation, apparent place and degree of diſtinctneſs with which an object is ſeen through any number of glaſſes of any ſort, at any diſtances from each other, and from the eye and object.

Let P M (*Plate* XVII. *fig.* 2.) be an object viewed by the eye at O through any number of glaſſes at A, B, C, whoſe focal diſtances are the lines a, b, c. The diſtance O P may be conſidered as divided by the glaſſes A, B, C, into two parts, ſuch as P A, A O; P B, B O; P C, C O; or into three parts, ſuch as P A, A B, B O; P A, A C, C O; P B, B C, C O; or into four parts, ſuch as P A, A B, B C, C O; and ſo on as far as the number of glaſſes permits. All the ſeveral products of ſuch correſponding parts, applied reſpectively to the focal diſtance, or to the product of the focal diſtances of the glaſſes which are placed at the point or points of diviſion, will give ſo many ſeveral lines, which muſt be looked upon as negative, if there be an odd number of convex glaſſes at the points of diviſion, otherwiſe as affirmative. Let P Ω be the ſum of P O and thoſe ſeveral lines according to their ſigns, and let P Ω and P O lie the ſame way, if the ſum be affirmative, but contrary ways, if the ſum be negative; and Ω will be the point, at which the naked eye being placed, ſhall ſee the object under the ſame magnitude with which it appears through all the glaſſes, the eye being at O; and, therefore, the apparent magnitude of the object will bear the ſame proportion to the true magnitude, as the diſtance P O bears to the diſtance P Ω.

The apparent ſituation of the object is alſo determined by the point Ω. For, if Ω and O be placed on the ſame ſide of the object, it will appear erect, otherwiſe inverted.

Imagine, now, the eye to be removed from O to C, ſo that its diſtance from the laſt glaſs may vaniſh; at the ſame time the point Ω will move to another place ω, which may be found as above. Let O γ bear the ſame proportion to O C, which Ω P bears to Ω ω, and let the order of the points O, C, γ, be the ſame as the order of the points Ω, ω, P; then will γ be the apparent place of the object viewed at O, through all the glaſſes.

And, from the ſituation of this point γ, a judgment may be formed of the degree of diſtinctneſs with which the object appears. For the rays flowing from the point P, by paſſing through the glaſſes, are diſpoſed to fall upon the eye in the ſame manner, as if, the glaſſes being removed, they tended from the point γ when it is before the eye, or towards the point γ when it is behind the eye.

For let α r (*Plate* XVII. *fig.* 3.) be the firſt image of the object made by the glaſs A; β s its ſecond image made by the glaſs B; γ t its third image made by the glaſs C. It is evident that the object P M and its image α r will be terminated by the ſame lines P A α, M A r; that the image α r and its image β s will be terminated by the ſame lines α B β, r B s; that the image β s and its image γ t will be terminated by the ſame lines β C γ, s C t. Now, if the eye be placed at O, and γ t be the laſt image, it is manifeſt, that the object ſeen through all the glaſſes will appear under the ſame angle which is really ſubtended by the image γ t. Draw therefore M Ω parallel to t O, making the angle P Ω M equal to γ O t, and the naked eye, being placed at Ω, ſhall ſee the object P M under the ſame magnitude with which it appears through all the glaſſes, the eye being at O. And, conſequently, the apparent magnitude ſhall be to the true magnitude, as the angle P Ω M to the angle P O M, or as the diſtance P O to the diſtance P Ω. Let us at firſt ſuppoſe all the glaſſes to be concaves. The diſtance P Ω will be to P A, as the angle P A M to the angle P Ω M, or, as α A r to γ O t; or in the compound ratio of α A r to α B r, β B s to β C s, γ C t to γ O t, that is, in the compounded ratio of α A + A B to α A, β B + B C to β B, γ C + C O to γ C. Therefore $P\Omega = PA \times \frac{\alpha A + AB}{\alpha A} \times \frac{\beta B + BC}{\beta B} \times \frac{\gamma C + CO}{\gamma C}$ &c. by which theorem the diſtance P Ω is given ſo ſoon as α A, β B, γ C, can be found. Theſe are found as follows, $\alpha A = \frac{PA \times a}{PA + a}$, $\beta B = \frac{\overline{\alpha A + AB} \times b}{\alpha A + AB + b}$, $\gamma C = \frac{\overline{\beta B + BC} \times c}{\beta B + BC + c}$.

Whence it is eaſy to conclude, that, if the eye at B views the object P M through one glaſs at A, P Ω will be equal to $PB + \frac{PAB}{a}$; that, if the eye at C views the object P M through two glaſſes A and B, P Ω will be equal to $PC + \frac{PAC}{a} + \frac{PBC}{b} + \frac{PABC}{ab}$; that, if the eye at O views the object P M through three glaſſes A, B, and C, P Ω will be equal to $PO + \frac{PAO}{a} + \frac{PBO}{b} + \frac{PCO}{c} + \frac{PABO}{ab} + \frac{PACO}{ac} + \frac{PBCO}{bc} + \frac{PABCO}{abc}$; and ſo forwards continually as the ſolution of the problem directs. Now, if any of the glaſſes be convex, the focal diſtances of ſuch glaſſes muſt be looked upon as negative, ſince they are contrary to thoſe of concave glaſſes; and, therefore, the terms which involve an odd number of convex glaſſes at the points of diviſion, muſt be taken as negative. Q. E. D. 1°.

The point M is ſeen immediately through the glaſſes by the ray t O, which enters the eye at O in a direction parallel to M Ω by conſtruction. If therefore Ω fall on the ſame ſide of the object as O, the ray t O muſt advance towards the eye, from the ſame ſide of the common axis O P as the point M; and, conſequently, the object will appear through the glaſſes erect. But, if Ω falls on the contrary ſide of the object to the point O, the ray t O which advances towards the eye in a direction parallel to Ω M, muſt appear to come from the contrary ſide of the axis to the point M; and, conſequently, the object will appear through the glaſſes inverted. Q. E. D. 2°.

By conſtruction the lines M Ω, M ω, M P, P Ω, are reſpectively parallel to the lines t O, t C, t γ, γ O; and, therefore, the figure M Ω ω P is ſimilar to the figure t O C γ. Hence it follows, that O γ the diſtance of the laſt image from the eye, or the diſtance of the apparent place of the object from the eye, is to O C as Ω P is to Ω ω; and that the order of the point O, C, γ, will be the ſame as the order of the points Ω, ω, P. Q. E D. 3°.

The point γ being the laſt image of the point P, the rays which flow from P, after they have paſſed through all the glaſſes, will flow from or towards the point γ. Q. E. D.

COUCH, in heraldry, a term uſed to expreſs the ſhield of a coat of arms, when it does not ſtand erect, but hangs downward. The origin of this poſition of ſhield ſeems to have been, that the perſons who were to fight in tournaments were compelled, from the time that proclamation was made till the day of fighting, to hang up their ſhields, by one corner, from the windows or balconies of the neighbouring houſes, or on the trees or barriers of the ground, if the exerciſe was performed in the field. The horſe combatants hung up their ſhields by the left corner, and the foot combatants by the right. Hence the left corner, hanging, became the moſt honourable, and we ſee, in all the ſons of the royal blood of England and Scotland, that the ſhields with their arms all hang that way. Some writers on heraldry expreſs this diſpoſition by the word pendant. *Niſbet's Heraldry.*

COULTER, in heraldry, that part of the plough which forms the edge, ſtanding before the ſhare of the plough, and cutting the clods, as the ſhare tears them up. The Coulter is an inſtrument of two feet eight inches in length, of near two inches breadth, and near one inch thick. It is driven through the beam

beam of the plough, and fixed in its proper direction by a wedge. See PLOUGH.

The modern improvement of the plough by Mr. Tull gives it four Coulters; the consequence of which is, that the earth, ploughed up, is cut four times as small as by the common plough, which has only one.

In all Coulters, the length and direction are to be nicely regulated. The cutting the hole and driving the wedge, regulate the direction, and its length is altered from the beam by the driving it farther down, as its point wears away. The first Coulter in all ploughs ought to be laid in the beam, in the following manner: its back is to bear against the back of the Coulter-hole, its right side above, to bear against the upper edge of the Coulter hole, and its left side to bear against its lower edge; so that there should always be at least three wedges to hold the Coulter; the pole wedge before it, another on the left side of it above, and a third on the right side underneath; and the hole must be so made, that, the Coulter standing thus across the hole, its point may incline so much towards the left, as to be about two inches and a half farther to the left than the point of the share, if it were driven down so low as it. But it never ought to be so low in any plough. As to its bearing forward, the point of the Coulter should never be before the middle of the point of the share; but, if it be set too obliquely, it will, in the working, have greater power to move up the pole wedge and get loose.

In the four-coultered plough, the three additional Coulters must all stand in the same position with this, in regard to the inclination of their points one to another. This is a vast advantage to them; for by this means, when the fin of the plough is raised up, by turning the handles towards the left, their points do not rise out of the ground, as they would do, were it not for this inclination. In regard to their pointing forward, experience shews, that it is best that every one of the three should be a little more perpendicular than that next behind it; by this means there is a greater space left between them above than below, and the roots of weeds can never clog them up as they otherwise would do, and by that means raise the plough out of the ground, if not picked clean by a man at times.

None of these Coulters ought to descend so low as the share, except when the land is to be ploughed very shallow; it is always sufficient for them to cut through the turf, let the plough go as deep as it will; in ploughing shallow, the fin of the share must also be broad enough to cut off the fourth piece or furrow; else that, lying very fast, will be apt to raise up the groundwrist, and throw out the plough; but, when the land is plowed deeper, the groundwrist will break off this fourth furrow, though the fin be not broad enough to reach it. *Tull's Husbandry.*

COUNCIL *(Dict.)*—The first general Council ever since the time of our Saviour was the Nicene, so called from the place where it was held, viz. Nice, a city of Bithynia, a province in Asia Minor, formerly called Bebrycia and Mygdonia, and now, by some, Bursia, by others, Bescangial, and, by the Turks, Osmanili.

But, though the place in which this most renowned Council was convened is universally agreed upon, the precise time of its celebration is not so certainly determined. That it was held in the reign of Constantine the Great, the first Christian emperor, as it had been summoned by his honourable letters, is very evident from Eusebius, an eye-witness, and a very significant party in it; from Socrates, and other historians; besides the concurring testimony of the whole Council itself to attest it. But then, about the time, authors are not so unanimous. For, whereas some place it under the year of our Lord 324, others make it in 325; some again in 328, and others in 330. But our modern writers, in general, place it in the year 325: which seems to be the truer account, especially if we follow the authority of the forenamed Eusebius; who says that Constantine made a royal entertainment at the conclusion of that Council, for the fathers of it, in the 20th year of his reign; which began immediately upon the demise of his father Constantius, in the year 306.

However, what gave occasion for calling this holy and oecumenical or general Council, we have more certain knowledge of, viz. The heresy of Arius, a presbyter of the church of Alexandria; who began to vent his pernicious doctrines against the divinity of our blessed Saviour, about the year of our Lord 317.

The place appointed for the meeting of this Council being the city of Nice, all necessary preparations were made for the reception of so venerable a body; and indeed, not only venerable, but numerous; for there came to this assembly, besides a very great appearance of bishops from all parts, of presbyters, deacons, acolyths, &c. an innumerable company: all whose expences were liberally supplied out of the emperor's treasure. But, besides those of the clergy, there were many others, disputants and orators, who likewise attended.

After having determined the differences which troubled the church, they proceeded to make some rules for the discipline of it, which were called canons. Of these there were only twenty, according to Theodoret, though Ruffinus makes twenty-two; but that is by dividing two of them to make up that number; so that, in truth, he owned no more than twenty; of which the reader may see an account in *Du Pin's Ecclesiastical History.*

The second general Council, since the times of Christianity, was held at Constantinople, under the reign, and by the command of Theodosius the Great, though, the year is not certainly agreed among historians; some asserting that it was in the year 313, while others place it in 385: but Mr. Du Pin differs from them all; for he seems to make it a year earlier than the earliest of them, viz. 312: but this admits of some doubt.

The occasion of calling this Council was much the same with that for calling the Nicene, viz. to curb the insolence of the Arians, by a ratification of the Nicene confession, and to ordain a bishop into the see of Constantinople from whence Gregory of Nazianzen was resolved to depart.

In this Council Prosper says there were 180 bishops present, though Socrates and some others mention but 150. But, when Prosper reckons 180, it is not improbable that he includes the Macedonian bishops in that number, because they were summoned as well as the Catholics, and thirty-six of them appeared. And what very much favours this conjecture is this, that we find afterwards, that 150 bishops were present at the election of Nectarius, when the Macedonian bishops were departed from Constantinople.

The canons which Mr. Du Pin ascribes to this general Council, are seven.

The third general Council was that of Ephesus, convened by Theodosius junior, at the suit of Nestorius himself; and promoted by pope Celestine, the first of that name, about the year of our Lord 434, according to Prosper's computation; though some others make it a year later: but the difference is not very material.

That this Council also was assembled by the imperial mandate, besides the authority of Evagrius, we have the words of the Council itself, in an epistle to the emperors: 'The holy Council, which was gathered together by the grace of God, and by the authority of your dominion, in the chief city of the Ephesians, &c.'

There are, as bishop Prideaux observes, two copies of this Council; the first containing eight, the second thirteen canons; all which are comprehended in the anathema's of St. Cyril, to which we refer the reader.

The fourth general Council was the general Council of Chalcedon, a city in Bithynia, lying directly over-against Constantinople. This Council also, as the former, was convened by the authority of the emperor.

The precise year in which this Council was celebrated, is no more certain than any of the former: some placing it in 454, others in 455, and Mr. Du Pin, according to custom, three or four years before the rest, viz. in 451: though, if it be true, that this Council was convened in the third year of Martianus, which Mr. Sympson asserts, and Martianus came to the throne in the year 450, as bishop Prideaux says he did, it is evident that neither of the former computations are to be depended upon. However that be, this Council was held in the great church of St. Euphemia in the city of Chalcedon, in the presence of the commissioners, officers of the emperor, and counsellors of State, who regulated every motion of it, and were seated in the middle of the assembly. Some writers say, that the emperor himself was there in person, and that he intreated all the fathers not to attribute it to ostentation of his power that he sat there, but to his earnest desire that the true faith should be confirmed and established.

Concerning the president of this Council there is no certainty, unless perhaps the emperor himself presided: neither is the number of bishops, &c. any better determined; for some say there were about 600, others 630; but Mr. Du Pin says, there are but 350 in the subscriptions: however, it is most generally received, that the number was 600 or upwards, and that this was the most numerous Council that had ever been.

Several very great men were present at this Council, and even some who had been instrumental in the condemnation of Nestorius. Notwithstanding, by some strange infatuation, the wicked opinion of Eutyches was approved by this Council; Eutyches himself, with 300 monks, all involved in this heresy, and excommunicated by Flavianus, were absolved, and the tables were turned upon Flavianus, for they excommunicated him; and not only so, but the faction of Eutyches most barbarously treated him, trod him under foot, and so wounded him, that he died in three days time. In this synod also were condemned several pious and learned men, Ibas of Edessa, and Theodoret of Cyrus in particular, besides Eusebius of Doryleum, &c.

During the whole time of the sitting of this Council, the place was environed with very strong guards, which Chrysaphius brought with him, to compel those bishops who would not comply to favour the Eutychian heresy: from hence this second Council of Ephesus was by the antients called [illegible], as if it had been nothing else but a convention of robbers.

The transactions of this Council are set down at large in Mr. Du Pin's Ecclesiastical History, Cent. 5. to which we refer the curious reader.

Besides

Besides this, there are thirty canons ascribed to the Council of Chalcedon; though Mr. Du Pin is of opinion, that the collection of them was not made in any session of the Council; but that they were composed since, and taken out of the several actions: however, he set them down in order. The first of them commands, that the canons made by preceding Councils be observed. The sixth forbids the ordination of any clergyman, absolutely, and without a church title. The eighth enjoins the clergy that belong to monasteries and chapels of martyrs, to be subject to their bishop. And the twenty-eighth grants to the church of the city of Constantinople, which is called new Rome, the same privileges with old Rome, because this city is the second city in the world. It also adjudges to it, besides this, the jurisdiction over the dioceses of Pontus, Asia, and Thrace, and over the churches which are out of the bounds of the emperor, and a right to ordain metropolitans in the provinces of their dioceses. These are the most material canons of this Council: the rest, which principally concern only clerks and monks, are of lesser moment, and for that reason we shall not trouble the reader with them.

The fifth general Council was held again at Constantinople, and is therefore called the second of that place. It was gathered by the emperor Justinian: for Evagrius says thus: Eustachius being bishop of Jerusalem, Justinian gathered together the fifth Council. And so Nicephorus: The emperor Justinian gathered together the fifth holy general Council, the bishops of all churches being called together.

The time in which this Council was held is as uncertain as the rest, some placing it in the year 551, others in 552, and Mr. Du Pin in 553.

The number of bishops assembled at this Council was 165, according to some; though Mr. Du Pin says, there were but 147, besides the eastern patriarchs; and that all the bishops present at it belonged to their patriarchates.

In the meetings of this Council, what they did, principally was, they condemned the three chapters; having first discussed that great question, whether it was lawful to anathematize the dead? and passed it in the affirmative. Mr. Du Pin says, When the extracts taken out of the books of Theodorus of Mopsuestia, and the creed attributed to him, were read, the bishops, without any further examination, cried out anathema against the writings, against the creed, and against the person of Theodosius; an anathema to those who did not anathemize him.

Mr. Du Pin seems to think, that this business of the three chapters was the whole employment, and took up all the time of this Council. But some other authors tell us, that the several errors of Origen about the trinity, the plurality of worlds, and the pre-existence of souls, were condemned by it: and that his whimsical opinions, that the heavens and the stars are animated; that the glorified bodies shall be of a round figure; and that the torments of the damned shall have an end, were utterly exploded.

There are extant eight collations of this Council, and fourteen canons, which are all contained in their anathema's, according to bishop Prideaux; though Mr. Collier says, that neither this nor the following Councils made any canons, and that the Quinisex Council, or the Council in Trullo, was called afterwards to supply the defect.

The sixth general Council, being the third of Constantinople, was held in that city, by the command of Constantinus Pogonatus the emperor, so called from his bringing home with him a long beard from the wars, whereas he went forth without one. This Council was assembled in the twelfth year of that emperor, and of our Lord 781, according to some; though Mr. Du Pin says it was a year sooner, and yet makes it the thirteenth of that emperor, notwithstanding he began his reign in 769.

The most remarkable transactions of this Council were these: the patriarchs of Constantinople and Antioch were accused of teaching that there was but one will in Jesus Christ; which Macarius of Antioch publicly and strenuously maintained in the Council; but the patriarch of Constantinople retracted, with all the bishops of his patriarchate, except Theodoret of Meletinum.

In the seventeenth session they also received the definitions of the five first general Councils, and particularly that of the fifth general Council against Origen, against Theodorus of Mopsuestia, &c. They recited the creeds of Nice and Constantinople, and approved the definition of the Council held at Rome by Agatho, against the Monothelites.

As for the canons of this Council, the reader is to expect no more from it, than were made by the former, according to Mr. Collier, i. e. just none: though there are who make the subsequent Council in Trullo, as it were, an appendix to it; and, if so, there are more canons of this Council, than of all the general Councils before it.

But, before we dismiss this sixth general Council, it will be necessary to observe, that, though this Council under Constantinus Pogonatus is commonly reckoned one of the Councils acknowledged by the ancients to be general, there are some writers of great authority, who rather give that title to the next succeeding Council, held at Constantinople, under the reign of Justinian the Second: and this, they say, was the sixth general Council, not that in the reign of Pogonatus. Among the writers who are of this opinion, is the right reverend and judicious bishop Beveridge; for he says thus: 'The sixth general Council is that which is commonly called the Tertullian Council, gathered together by Justinian, the son of Constantinus Pogonatus.'

In this Council 102 canons of discipline were ratified according to Mr. Du Pin and others; several of which are in direct opposition to the practice of the modern Latin church, tho' they were so agreeable to the sentiments of the ancients, that Gratian says this synod was received by the fathers of the second Nicene Council.

The second Nicene Council is generally allowed to be the seventh general Council; though Mr. Sympson reckons another before it, viz. a fourth Council held at Constantinople, under Constantinus Copronymus, or Constantine the fourth of that name: and this Council, consisting of 338 bishops, he says, was assembled by the command of that prince, in the year 755 (Mr. Du Pin says in 750) in order to abolish the worship of images, which for some time before had prevailed mightily in the East. What Copronymus designed he also effected by the means of this Council; for in it several defenders and champions of image-worship were condemned, and a decree made against the use and worship of them. However, as Mr. Sympson observes, though they abolished one, they introduced another superstition, not less dangerous in the consequence than the former; for in the fifteenth and seventeenth canons of this Council, which are nineteen in number, they allow of the invocation of saints. But this Council was not received in the church of Rome, though a great part of the Eastern churches received it, by the emperor's authority, and put the decree against images in execution; till at last the reins of the government came into the hands of Irene the empress, widow to Leo III; she assembled another Council, to disannul the decree against images, in the reign of Copronymus. To this Council she invited pope Adrian, who sent two priests, as his deputies, to Constantinople, where this Council was designed to meet; and did meet in the year 786, according to Mr. Du Pin, others say in 788, till the soldiers besieged the bishops, and required with threatenings, that no Council should be held. Hereupon they were forced to separate for that time: but in the latter part of the next year they were assembled again at Nice, by the same authority, when the pope's legates held the first place, the patriarch of Constantinople held the second, the deputies of the eastern bishops the third, and after them the bishops of Cæsarea, Ephesus, and Cyprus, with 250 archbishops or bishops, and above 100 priests or monks.

There are twenty-two canons of this Council yet extant.

We come now to speak something of the eighth general Council, which, properly speaking, was the fourth of Constantinople: bishop Beveridge says, the eighth general Council was gathered together at Constantinople by the emperor Basil; and he cites the authority of the acts of that Council to prove it. And, if this be sufficient to prove this one of the famous general Councils of the Greeks (and we are giving an account of those Councils only) this was one of those famous Councils. But bishop Prideaux, though he says this fourth Council at Constantinople was assembled under Basil; he also says it was assembled under Basil, the murderer of the Greek emperors, and Adrian the Second, usurping the Roman see, notwithstanding the opposition of the Roman emperor. And for this reason it is, as may be conceived, that he places this Council in the number of the controverted general Councils.

However, as the learned bishop Beveridge, and some others, give this Council a place among the œcumenical or general Councils, and hold none to have been general after this; it cannot be a fault to enlist this Council, upon that great authority, in the number of the more famous general Councils.

This eighth general Council assembled at Constantinople in the year 869, as Mr. Du Pin says, though others say in 871, when Lewis II. (the Western empire being now entirely divided from the Eastern) was emperor of the West.

The regulations made by this Council are contained in 27 canons, the heads of which are set down by Mr. Du Pin in his account of this Council; to which the reader is referred.

These, as bishop Beveridge observes, are all the Councils allowed by the Greek church, or any other, except the papists. The famous Bullinger, in his treatise De Conciliis, it must be owned, allows but the six first of these Councils to be properly called œcumenical, or general: but Dr. Prideaux reckons the seventh among them; and bishop Beveridge has increased their number to eight, which he says are all the general Councils which have ever been held since the time of the first Christian emperor.

COUNTER-GUARD *(Dict.)* — *To construct a* COUNTER-GUARD. — Having described the ravelins and drawn their fosses, then in the counter-scarp of the ravelin take *a b (plate* VI. *fig.* 21.) equal to about twenty-four yards, and draw the face *b c* parallel to the counter-scarp of the foss before the bastion; and the out-line of the Counter-guard will be determined, the inner boundary being the counter-scarp of the grand foss.

In this work put a rampart of about sixteen or eighteen yards broad, with a parapet of six yards, and annex the ramps and a barbet, a barbet, if necessary: also make a foss of twenty-four yards broad, the counter-scarp being parallel to the faces.

The Counter-guard seems to be, next to the ravelin, one of the most useful outworks; for it occupies but little ground, is of no great expence, covers the faces of the bastion so effectually, that they cannot be battered in breach until the enemy has made himself master of this work; and, when he has it, he will meet with difficulties enough in finding earth to cover himself and erect batterries; and must, therefore, be at a considerable trouble in bringing it from beyond the foss, while he is exposed to the fire of the faces of the neighbouring ravelins; which, with the flanks of the bastions, are the defences of the Counter-guard.

COUNTER-*drawing*, in painting, &c. the copying a design or painting, by means of a fine linen cloth, an oiled paper, or other transparent matter; whereon the strokes, appearing thro', are followed and traced with a pencil, with or without colour.

COUNTER-*mark*, a second or third mark, put on any thing marked before.

The word is applied, in commerce, to the several marks put on a bale of goods belonging to merchants, that it may not be opened but in the presence of them all, or their agents.

In goldsmiths works, &c. the Counter-mark is the mark or punchion of the hall, or company, to shew the metal is standard, added to that of the artificer who made it.

COUNTER-mark of a horse, is an artificial cavity, which the jockies make in the teeth of horses that have outgrown the natural mark, to disguise their age, and make them appear as if they were not above eight years old.

COUNTER-mark of a medal, is a mark added to a medal, a long time after its being struck.

Counter-marks appear to be faults or flaws in medals, disfiguring the ground, sometimes on the side of the head, and sometimes on the reverse; particularly in the large and middle-sized brass: yet are they esteemed as beauties among the curious, who set a particular value upon such medals, in regard they know the several changes in value they have undergone; which are expressed by those Counter-marks.

Antiquaries, however, are not well agreed about the signification of the characters they find on them. On some, N. P R O B. on others, N. C A P R. on others, C A S R. R M. N T. A V G. S C. Some have, for their Counter-mark, an emperor's head; some several; some a cornucopia.

Care must be taken not to confound the monograms with the Counter-marks; the method of distinguishing them is easy. The Counter-marks, being struck after the medal, are dented or sunk in; whereas the monograms, being struck at the same time, with the medals, have rather a little relievo.

COURIER (*Dict.*)—The ancients also had their Couriers: we meet with two kinds, viz. those who ran on foot, called by the Greeks hemerodromi, q. d. Couriers of a day. Pliny, Corn. Nepos, and Cæsar, mention some of these, who would run 20, 30, 36, and, in the circus, even forty leagues per day.—And riding Couriers, cursores equitantes, who changed horses, as the modern Couriers do.

Xenophon attributes the first Couriers to Cyrus. Herodotus says, they were very common among the Persians, and that there was nothing in the world more swift than these kind of messengers. 'That prince, says Xenophon, examined how far a horse would go in a day; and built stables, at such distances from each other, where he lodged horses, and persons to take care of them; and at each place kept a person always ready to take the packet, mount a fresh horse, and forward it to the next stage: and this quite through his empire.'

But it does not appear, that either the Greeks or Romans had any regular fixed Couriers, till the time of Augustus: under that prince they travelled in cars; though it appears from Socrates, they afterwards went on horseback.

Under the Western empire, they were called viatores; and, under that of Constantinople, cursores: whence the modern name.

COURSING.—There are three several courses with greyhounds. 1. At the hare, 2. At the fox, and 3. At the deer. For the deer there are two sorts of Courses, the one in the paddock, the other either in the forest or purlieu. For the paddock Course, there must be the greyhound and the terrier, and the mungril greyhound, whose business it is to drive away the deer before the greyhounds are slipped; a brace, or a leash, are the usual number slipped at a time, seldom at the utmost more than two brace.

In the Coursing the deer in the forest or purlieu, there are two ways in use; the one is Coursing from wood to wood, and the other upon the lawns by the keeper's lodge. In the Coursing from wood to wood, the way is to throw in some young hounds into the wood, to bring out the deer; and, if any deer come out that is not weighty, or a deer or antler, which is buck, sore, or sorrel, then you are not to slip your greyhounds, which are held at the end of the wood, where the keepers, who can guess very well on these occasions, expect that the deer will come out. If a proper deer come out, and it is suspected that the brace or leash of greyhounds, slipped after him, will not be able to kill him, it is proper to way-lay him with a couple of fresh greyhounds.

The Coursing upon the lawn is the most agreeable of all other ways. When the keeper has notice of this, he will lodge a deer for the course, and then, by coming under the wind, the greyhounds may be brought near enough to be slipped for a fair course.

The best method of Coursing a hair, is to go out and find a hair sitting, which is easily done in the summer, by walking a-cross the lands, either stubble, fallow, or corn grounds, and casting the eye up and down; for in summer they frequent these places for fear of the ticks, which are common in the woods at that season; and, in the autumn, the rain falling from the trees offends them. The rest of the year there requires more trouble, as the bushes and thickets must be beat to rouse them, and often they will lie so close, that they will not stir till the pole almost touches them: the sportsmen are always pleased with this, as it promises a good Course.

If a hare lies near any close or covert, and with her head that way, it is always to be expected that she will make to that immediately on being put up: all the company are therefore to ride up, and place themselves between her and the covert before she is put up, that she may take the other way, and run on an open ground. When a hare is put up, it is always proper to give her ground or law, as it is called, that is, to let her run twelve-score yards or thereabouts, before the greyhounds are slipped at her; otherwise she is killed too soon, and the greater part of the sport thrown away, and the pleasure of the several windings and turnings that the creature will make to get away, is all lost. A good sportsman had rather see a hare save herself, after a fair Course, than see her murdered by the greyhounds, as soon as she is up.

In Coursing the fox, no other art is required than standing close, and on a clear wind, on the outside of some grove, where it is expected he will come out; and, when he is come out, he must have head enough allowed him, or else he will turn back to the covert. The slowest greyhound will be able to overtake him after all the odds of distance necessary; and the only danger is, the spoiling the dog by the fox, which too often happens; for this reason, no greyhound of any value should be run at this Course, but the strong, hard-bitten dogs, that will seize any thing.

COW, *bos*, in zoology, a quadruped too well known to need a description.

The use of the Cow is either for the dairy, or for the breed. The red Cow is generally supposed to give the best milk, and the black Cow to bring the best calves. The Cow that gives the milk longest is the best both for the breed and dairy; and, for the latter use, it is most convenient that the Cow should calve in the spring. Either in the month of March or April, when a Cow is near calving, she should be put into good grass three or four weeks before the time; or, if it happens in winter, she is to be fed well with hay. The day and night after she has calved, she should be kept in the house, and the water that she drinks should be a little warmed. The next day, at noon, she may be turned out; but she should be taken in at night, for three or four days afterwards, and then she may be left to herself. Every night that she is taken in, she should be kept till the cold of the morning is over, and a drink of warm water given her before she goes out.

CRAB, in zoology, a species of squilla. See SQUILLA.

The cancer major, or common large Crab-fish, has its abode from twenty to forty fathom water. These animals herd together in distinct tribes, and have their separate haunts for feeding and breeding, and will not associate with their neighbours. This has been carefully tried, by marking the shell of a Crab, and carrying it two or three miles distance, and there leaving it among the same species: this Crab has, after this, found its way home, and been caught in its old abode by the same fishermen.

The fishermen find the Crabs of this species from the size of a chesnut to twelve pound weight. Nothing, in the history of this creature, is so singular, as its breaking off its own limbs, which it occasionally does, in the following manner; the creature is able to do this in any position, but the most advantageous way of making the experiment is the laying it on its back; then, with a pair of iron pincers, break the shell, and bruise the flesh of one of the outer joints of a small leg; the wound will bleed, and the creature shew signs of pain, by moving it about; afterwards, it holds it quite still, in a direct and natural position, without touching any part of its body, or other legs with it; then, on a sudden, with a gentle crack, the wounded part of the leg drops off, at the internodium of the second joint, from the body. If a hole be pierced in the great claws, or legs, and an iron put in to lacerate the muscle, the effect is the same, and this large limb is thrown off in the same manner, only with more violence.

When the leg is off, a mucus overspreads the wound, and stops the bleeding; and a small leg is, by degrees, produced, which afterwards attains to the size of the former. Nature seems to have given this singular power to this creature for the preservation of its life, in the mutual quarrels it very frequently has with others of its own species: in these, one Crab lays hold of the claws of another, and crushes it in such a manner, that it would bleed to death, had it not this power of giving up the limb,

limb, and healing the wound. *Philosophical Transactions*, N°. 478.

CRAB, or *gin*, in mechanics, an engine used for mounting guns on their carriages. It is made of three pieces of oak, ash, or other strong wood, of about fourteen feet long, two of which are joined by transoms; so that they are wide asunder at bottom, and join at top, on a strong piece of wood, crooking forwards, called the head, in which are three brass pullies. Over these comes a rope called the gin rope, which likewise goes through other pullies in a block, and returns through the head, down the back of the gin, and then goes round a windlace. The third piece of the Crab is round; one end of it goes into the head, and the other stands on the ground; so that all three make a triangle called a pye. When a gun is to be mounted, a strong rope is rived through the block and the trunnions; and then, the windlace being turned round, the gun is lifted up, and placed in her carriage with ease. *Guillet*. The Crab is used also to launch ships, or heave them into the dock, or off the key. *Manœuvring*.

CRA'CKER, in zoology, the name of a fresh water fowl, of the duck kind, known by authors under the title of anas cauda acuta, and cauda lancea, and called in some parts of England the sea pheasant. It is of the size of the common widgeon; its head is all over of a ferrugineous brown, but behind the ears there is a slight tinge of purple; its neck is somewhat longer than in the widgeon, and its beak of a bluish colour; its head is small, and there is a white streak on each side of it, which reaches down to the throat; the throat is grey, variegated with transverse lines, as is also the back, but the shoulder feathers are, in a great measure, black. The tail is grey, with a mixture of white about the edges of the feathers, and is of a very different shape from that of all the other species of the duck kind, having two feathers much longer than the rest, and running out into narrow points, whence the fowl has the name of the pheasant. The female differs much in colour from the male, and much resembles the common tame duck; she has the same long feathers, however, in the tail. *Ray's Ornithol.*

CRA'DLE, in ship-building, a frame of timber raised along the outside of a ship, by the bildge, for the more commodious and secure launching of the vessel. The cradle is much used in Italy, Spain, and Turkey, where they also trim great ships in the cradle.

CRA'MBE, wild sea cabbage, in botany, the name of a genus of plants, the characters of which are these: the flowers consist of four leaves, and are of the cruciform kind: the pistil arises from the cup, and finally becomes an unicapsular fruit, containing one oblong seed.

This plant may be propagated in a garden, by sowing the seeds, soon after it is ripe, in a sandy or gravelly soil, where it will thrive exceedingly, and increase greatly by its creeping roots, which will soon overspread a large spot of ground, if encouraged; but the heads will not be fit to cut until the plants have had one year's growth; and, in order to have it good, the bed in which the plants grow, should, at Michaelmas, be covered over with sand or gravel about four or five inches thick, which will allow a proper depth for the shoots to be cut before they appear above ground; and, if this is repeated every autumn, in the same manner as is practised in earthing of asparagus beds, the plants will require no other culture. This may be cut for use in April and May, while it is young; but, if the shoots are suffered to remain, they will produce fine regular heads of white flowers, which appear very handsome, and will perfect thin seeds, by which they may be propagated. *Miller's Gard. Dict.*

CRANE, in mechanics (*Dict.*) — Mr. Padmore has made a very good improvement in Cranes, in a machine of that kind erected on the bank of the river at Bath, whereby Mr. Allen lets down his stone in the vessels that come for it.

The Crane itself is not of the uncommon sort, but a rat-tailed Crane, with a double axis in peritrochio and two handles, whereby four men may raise very great weights; and then, turning the whole Crane about upon its upright shaft, can fix it in any position, and let down the weights speedily into the boats or barges, which come near the wharf to receive them. See a view of this Crane (*plate* XI. *fig.* 5.) But this construction is not new. Neither is it a new invention to let down goods after they have been raised by a Crane, by pressing the arch of a circle strongly upon a wheel fixed to the principal axis, in order to retard and regulate the descent by a friction increased or diminished at pleasure, as is done in stopping windmills. The catch also, that hinders a Crane or capstane from going back, is of common use; but I do not know that any one has applied them both together in the same Crane, so as to depend upon one another, before Mr. Padmore did it, though many have done it since. Therefore I shall give a particular description of this contrivance, whose chief intent is to prevent the great mischiefs which often happen by the carelesness of the men employed to raise and let down heavy burthens by the use of the Crane. The *sixth figure* represents an upright section of so much of the Crane as the contrivance abovementioned is applied to.

A B is the great wheel, whose large axis A, moving on two iron center pins such as *a*, receives the rope, or lets it run down, according as it is turned, by the means of the handles fastened at C to the lesser wheel or pinion C, or as it is suffered to turn the other way by the gravity of the descending weight, when all obstacles are removed. Upon the axis of the pinion is the ratchet wheel D, whose teeth successively receive the iron catch *f* F (moveable on a pin at F on the iron standard G, and to be raised up occasionally by the upright iron H *h*) to hinder the weight from going back, when the handles are loosed. Upon the same axis behind the wheel D is a wooden wheel E *p*, over which hangs the half-ring of iron O P *o* with a groove or hollow made in it to fit the circumference of the said wheel, so as to retard, or stop, or any way regulate the motion of the wheel (and consequently of the axis and pinion C, and the great wheel and axis A B which has the rope V A) according as it is more or less strongly pressed down to make a friction on the wood, as it moves after the catch is raised out of the teeth of the ratchet. The horizontal lever K L governs all these motions in the following manner, viz. When the string Q *q* K, fastened to the said lever at K, is pulled, the lever, moving on its center M, does, by an horizontal pin fixed at right angles to its side at I, raise the piece H, and consequently release the ratchet by raising the catch at *f* out of the teeth: then the weight descends swiftly, moving the wheel and pinion round by its force; but, to prevent the two swift descent, the lever is pulled up a little more strongly by the guider who holds the string Q *q* K, which brings down the contrary end of the lever L, and consequently the iron N, so low as to make the semicircular ring O P *o* press hard upon the wheel E *p*, which it did not do when the catch was raised but just out of the ratchet. N. B. A strong pull stops the whole motion, and a more gentle one regulates the descent. And, if the guider should be careless and let go the string, then immediately the spring S *s*, whose end *s* had been depressed by the end L of the lever, will raise it up again (by its lateral pin X) and, restoring the whole lever to its first horizontal position, the other lateral pin I, in the long arm M K of the lever, will, through the notch H, press upon I the lower end of the upright piece H, and so bring down the catch F *f* into the ratchet wheel at *f*, the curved piece O P *p* at the same time flying up and no longer pressing the wooden wheel E *p*. Thus will mischief never be the consequence of carelesness, because of the catch; nor will the weight go down by jerks, which would have been the consequence of the catch used without the half-ring, because the catch is lifted quite out of the way, when the half-ring is brought down and applied by pulling the string at Q. N. B. T, *t* 1, *t* 2, is part of the upright section of the timber of the frame.

To make this the plainer, let us examine the *seventh figure* of *plate* XI. where we have an horizontal section of the parts above-mentioned. T *t* T is part of the timber of the frame. B B is the great wheel, whose axle that holds the rope is marked A A A, and its iron axis goes through bell-metal boxes at *a a*. C C is the small wheel or pinion, whose axis is *c c*. D *d* is the section of the ratchet wheel made of iron. Between the pricked lines A *p* and E *i* is supposed the wooden wheel upon the axis of the pinion (not drawn here to avoid confusion, no more than the semicircular pressing piece marked O P *o* in the last figure) the basis of whose upright fixed supporter is represented by R, and the end of the piece which brings it down upon occasion is shewn at N. K L is the horizontal lever, whose center is at M, moving vertically by a pull of the string fastened to it at K. I *i* is the first lateral pin of the lever, which at I goes through the bottom of the piece H, raiser of the catch F *f*, already described with its supporter G, on whose top the catch moves by a center pin. A *p* A is the second lateral pin of the lever, whose office is to press upon the end *s* of the crooked spring S *s* fastened to the bottom of the frame at the farther end S. So that, when the end K of the lever is pulled up, the end L which is depressed, must be lifted up again into its place by the force of the spring restoring itself.

N. B. The crooked figure of the spring, and the manner of its lifting the pin, is best shewn in *fig.* 6.

CRANE, *grus*, in zoology, the name of a genus of birds very tall, and remarkable for the length of their legs and neck. It is supposed by many, that this bird eats fish, but erroneously; the structure of its stomach plainly shews it to be a carnivorous bird, and its flesh is very delicate, and much valued in the Italian markets.

The ingenious Mr. Edwards, in his curious History of Birds, has figured different sorts of Cranes; one of which we shall give our readers. See *plate* XVI. *fig.* 3. It is called the brown and ash-coloured Crane. The bill of this bird has a channel on each side, with the nostrils placed therein; of a black or dusky colour, except the point of the lower mandible, which is light flesh-coloured. The top of the head from the bill to the ear-holes is covered with a bare skin of a reddish colour, thinly beset with black hairs; the sides of the head beneath the eyes, and the under side or throat, are white; the hinder-part of the head and the neck all round are ash-coloured; the bottom of the neck, or beginning of the breast, from ash-colour gradually becomes brown; the beginning of the back and covert-feathers of the wings are also of a light-reddish brown, their tips

Printed for J. Hinton in Newgate Street.

Engraved for the Supplement

tips being something darker, which forms an agreeable variety; the greater quills are of a blackish brown with white shafts; those that fall next the back are brown, and of a loose, soft texture, whose points extend beyond the prime quills, when the wings are closed. In the lower part of the wing, there passes obliquely above the black quills a whitish ash-coloured plat of feathers; the inner coverts of the wings are ash-colour. The tail-feathers are of a brownish ash-colour. The breast from brown becomes of an ash-colour, which reaches to the covert-feathers of the tail inclusive, growing lighter in its advance backwards, so that the under coverts of the tail are whitish; the lower part of the back, the rump, and upper coverts of the tail are of a light ash-colour; the legs are bare of feathers above the knees, the outer toe is joined a little way to the middle one; the legs, feet, and nails, or claws, are all of a black colour. *Edwards's History of Birds.*

CRANE-*fly*, a name given by some to the creature we commonly call father long-legs, and the authors of histories of insects, tipula terrestris. This creature affords the microscopic observer many curious particulars; but the most remarkable is, the surprizing contraction of the muscular fibres in the legs. These being dissected in a drop of water, and placed before the microscope, the fleshy fibres contract and distend themselves in a manner not to be imagined, and continue this motion for several minutes; and this is constantly to be observed in this insect, and never in any other, so far as has been yet observed. *Lewenhoek, Arcan. Nat.*

The intestines of this creature are also very wonderful, consisting of numberless vessels and organs, which may be seen as plainly by the microscope, as the bowels of larger animals can by the naked eye. The tails both of the male and female are also of an amazing structure; the female's end in a sharp point, with which she perforates the ground, and deposits her eggs under the grass in meadows. *Baker's Microscope.*

CRA'NNY, in the glass trade, a round iron, whereon the workmen in the glass-houses roll the glass, to make the neck of it small. *Neri's Art of Glass, Append.*

CRASSIRO'STRÆ, in zoology, the names of a genus of small birds, distinguished by the thickness of their beaks, as the sparrow, green-fish, and the like. *Ray's Ornithol.*

CRAY-*fishes.* — The delicate flavour of these fish seems to be in a great measure owing to their food. When they have well tasted food, their flesh preserves the relish of it; but, when they feed on other things, they are often rendered of no value, by the flavour communicated to their flesh by them. There are great quantities of these fish in the river Obra, on the borders of Silesia; but the people find them scarce eatable, because of a bitter aromatic flavour, very disagreeable in food. It has been since observed, that the calamus aromaticus grows in vast abundance on the banks of that river, and that these creatures feed very greedily upon its roots. These have a very remarkable bitterness mixed with their aromatic flavour, while fresh, which goes off very much in the drying; and, on comparing the taste of these roots with that of the Cray-fish, there remains no doubt of the one being owing to the other. *Act. Lipsf.* 1690.

CREE'NGLES, in a ship, are small ropes spliced into the bolt-ropes of the sails of the main-mast and fore-mast, into which the bowling bridles are made fast; and are also to hold by when a bonnet is shaken off. *Manwaring.*

Indian CRESS.—The several kinds of this plant are easily propagated, by sowing their seeds in March or April, in a good soil, and warm situation, and should be planted near a hedge or wall, being great climbers, and their lying on the ground being subject to rot them. They flower in June, and continue flowering till October, when the frosts soon destroy the whole plant.

The double-flowered kind produces no seeds, and must therefore be propagated by cuttings of it. This may be done in any of the summer months; but the plants must be carefully preserved in winter, being very subject to rot. If this be confined in pots, and those filled with a poor soil, it will ramble less in the branches, and will produce more flowers. The flowers of this kind, though very beautiful, are not nearly so well tasted in sallads as those of the single kind, which are very warm and agreeable. *Miller's Gard. Dict.*

CRIB, in the English salt works, the name given to a sort of case used in some places instead of the drab, to put the salt into, as it is taken out of the boiling-pan.

These Cribs are like hay racks, wide at the top, and tapering to a narrow bottom, with wooden ribs on each side, placed so close, that the salt cannot easily fall through them. Through these apertures, however, the superfluous saline liquor drains out, and leaves the salt, after a few days, dry enough to be added to the heaps that stand ready for sale. At Limington, and some other places, they use, instead of these Cribs, a sort of wooden troughs with holes in the bottom, through which the saline liquor drains from the salt, and falls into vessels placed underneath to receive it; and in other places they use barrows or wicker baskets, out of which the liquor runs, with great ease, on all sides at once. See DRAB.

CRI'THE, in medicine, a small tubercle, hard, red, and immoveable, seated upon the eye-lid above the cilia, or range of hairs. It is always included in a kind of cyst, and by inflammation degenerates into a thickish matter, from whence frequently proceed intense pains, and various disorders of the sight. It is sometimes seated immediately under the skin of the eye-lid; sometimes it is within, under the muscle. When this tubercle is moveable, it is generally called chalazium, or in English stye, or stithe. *Heister's Surgery.*

CRI'THMUM, *samphire*, in botany, a genus of plants whose characters are: the leaves are thick, succulent, narrow, branchy, and trifid: the flowers grow in an umbel, each consisting of five leaves, which expand in form of a rose: the empalement of the flower becomes a fruit, consisting of two plain and gently striated seeds.

We have but one species of this plant common in England. This plant grows in great plenty upon the rocks near the sea-shore, where it is washed by the salt water; but will not grow to any strength in a garden, though it may be preserved several years, and propagated by parting its creeping roots in the spring. This should be planted in pots filled with gravelly coarse soil, and, in summer, plentifully watered: in this management it will grow tolerably well, and produce flowers; but rarely perfects its seeds in a garden, nor is the herb near so good for use as that gathered from the rocks. This plant is greatly esteemed for pickling, and is sometimes used in medicine.

CRI'ZZELLING, in the glass trade, a kind of roughness arising on the surface of some kinds of glass. This was the fault of a peculiar kind of glass made in Oxfordshire, and some other places, of black flints, a crystallized sand, and a large quantity of nitre, tartar, and borax. The glass thus made is very beautiful, but, from the too great quantities of the salts in the mixture, is subject to crizzel; that is, the salts in the mixture, from their too great proportion, are subject, either from the adventitious nitre of the air from without, or from warm liquors put in them, to be either increased in quantity, or dissolved, and thereby induce a scabrities, or roughness, irrecoverably clouding the transparency of the glass. This was what was called Crizzelling; but by using an Italian white pebble, and abating the proportions of the salts, the manufacture is now carried on with advantage, and the glass made with these salts is whiter than the finest Venetian, and is subject to no faults. *Plot's Oxfordshire.*

CRO'CODILE, *crocodilus*, a very large and terrible animal; its head is broad; its nose like that of a hog; the opening of its mouth monstrously large, reaching even to the ears, and the upper jaw moving in the opening it, which gives it a very terrible aspect. The teeth are large, white, and very numerous, and set by one another, like the teeth of a comb; the legs stand sideways; and the feet are armed with extremely sharp claws. The length of the tail is equal to that of the whole body; the skin of the belly is soft and easily wounded, but that of the rest of the body so hard as to be impenetrable to spears or darts, and is covered with strong prickly scales. The colour is in some a dusky reddish yellow, but in most a disagreeable brown, with a mixture of grey; and even those which, when alive, had much yellowness, always acquire this dusky colour in drying.

It is a very slow and unweildy animal, turning sideways with difficulty; it has an agreeable smell, but is a very terrible creature, tearing to pieces and devouring every living thing that is so unhappy to come in its way.

Its eggs are about the size of a goose egg, and it lays sixty of these for one brood, burying them in the sands, and leaving them for the sun to hatch them. The Crocodile is found in the great rivers of the Nile, the Niger, and the Ganges, and in some other places. *Ray's Syn. Quad. Werm. Musc.*

CRO'CUS, *saffron (Dict.)*— See *Plate* XVI. *fig.* 2, which represents the whole plant with its root, *d*, the flower, *c*, the stamina, or saffron of the shops.—In the Philosophical Transactions, N°. 405, we have the following method of cultivating saffron.

As saffron grows at present most plentifully in Cambridgeshire, and has grown formerly in several other counties of England, the method of culture does not, I believe, vary much in any of them; and therefore I judge it sufficient to set down here the observations which I employed proper persons, in different seasons, to make, in the years 1723, 1724, 1725, and 1728, up and down all that large tract of ground that lies between Saffron Walden and Cambridge, in a circle about ten miles diameter.

In that county saffron has been cultivated; and therefore it may reasonably be expected, that the inhabitants thereof are more thoroughly acquainted with it than they are any where else.

I shall begin with the choice and preparation of the ground; the greatest part of the tract already mentioned is an open level country, with few inclosures; and the custom there is, as in most other places, to crop two years, and let the land be fallow the third. Saffron is always planted upon fallow ground, and, all other things being alike, they prefer that which has borne barely the year before.

The Saffron grounds are seldom above three acres, or less than one; and, in chusing, the principal thing they have regard to, is, that they be well exposed, the soil not poor, nor a very stiff clay, but a temperate dry mould, such as commonly lies upon chalk,

chalk, and is of an hazel-colour; though, if every thing elſe anſwers, the colour of the mould is pretty much neglected.

The ground being made choice of, about Lady-day, or the beginning of April, it muſt be carefully plowed, the furrows being drawn much cloſer together, and deeper, if the ſoil will allow it, than is done for any kind of corn; and, accordingly, the charge is better.

About five weeks after, during any time in the month of May, they lay between twenty and thirty loads of dung upon each acre; and, having ſpread it with great care, they plow it in as before; the ſhorteſt rotten dung is the beſt; and the farmers, who have the conveniency of making it, ſpare no pains to make it good, being ſure of a proportionable price for it. About Midſummer they plow a third time, and, between every ſixteen feet and a half or pole in breadth, they leave a broad furrow or trench, which ſerves both as a boundary to the ſeveral parcels, when there are ſeveral proprietors to one incloſure, and to throw the weeds in at the proper ſeaſon.

To this head likewiſe belongs the fencing of the grounds, becauſe moſt commonly, though not always, that is done before they plant. The fences conſiſt of what they call dead hedges, or hurdles, to keep out not only cattle of all ſorts, but eſpecially hares, which would otherwiſe feed on the ſaffron leaves during the winter.

About the weather we need only obſerve, that the hotteſt ſummers are certainly the beſt: and therewith, if there be gentle ſhowers from time to time, they can hardly miſs of a plentiful crop, if the extreme cold, ſnow, or rain of the foregoing winter have not prejudiced the heads.

The next general part of the culture of ſaffron, is planting or ſetting the roots: the only inſtrument uſed for which is a narrow ſpade, commonly termed a ſpit-ſhovel.

The time of planting is commonly in July, a little ſooner or later, according as the weather anſwers. The method is this: one man with his ſpit-ſhovel raiſes between three and four inches of earth, and throws it before him about ſix or more inches; two perſons, generally women, following with heads, place them in the fartheſt edge of the trench he makes, at three inches diſtance from each other, or thereabouts: as ſoon as the digger or ſpitter has gone once the breadth of the ridge, he begins again at the other ſide, and digging, as before, covers the roots laſt ſet, and makes the ſame room for the ſetters to place a new row, at the ſame diſtance from the firſt as they are from one another: thus they go one, till a whole ridge, containing commonly one rod, is planted; and the only nicety in digging is, to leave ſome part of the firſt ſtratum of earth untouched, to lie under the roots; and, in ſetting, to place the roots directly upon their bottom.

What ſort of roots are to be preferred, ſhall be ſhewn under the fourth head; but it muſt be obſerved in this place, that formerly, when roots were very dear, they did not plant them ſo thick as they do now; and that they have always ſome regard to the ſize of the roots, placing the largeſt at a greater diſtance than the ſmaller ones.

The quantity of roots, planted in an acre, is generally about ſixteen quarters, or 128 buſhels, which, according to the diſtances left between them, as before aſſigned, and ſuppoſing all to be an inch in diameter one with another, ought to amount to 392,040 in number.

From the time that the roots are planted, till about the beginning of September, or ſometimes later, there is no more labour about them; but as they then begin to ſpire, and are ready to ſhew themſelves above ground (which is known by digging a few out of the earth) the ground muſt be carefully pared with a ſharp hoe, and the weeds, &c. raked into the furrows, otherwiſe they would hinder the growth of the plants.

In ſome time after appear the ſaffron flowers; and this leads us to the third branch of our preſent method. The flowers are gathered as well before as after they are full blown; and the moſt proper time for this is early in the morning. The owners of the ſaffron get together a ſufficient number of hands, who place themſelves in different parts of the field, pull off the whole flowers, and throw handful by handful into a baſket, and ſo continue till all the flowers are gathered, which happens commonly about ten or eleven o'clock.

Having then carried home all they have got, they immediately ſpread them upon a large table, and fall to picking out the filamenta ſtyli, or chives, and together with them a pretty long proportion of the ſtylus itſelf, or ſtring to which they are joined; the reſt of the flower they throw away as uſeleſs. The next morning they return into the field again, whether it be wet or dry, weather; and ſo on daily, even on Sundays, till the whole crop be gathered.

The chives being all picked out of the flowers, the next labour about them is to dry them on the kiln. The kiln is built upon a thick plank (that it may be removed from place to place) ſupported by four ſhort legs: the outſide of eight pieces of wood about three inches thick, in form of a quadrangular frame, about twelve inches ſquare at the bottom on the inſide, and twenty-two inches at top; which is likewiſe equal to the perpendicular height of it. On the foreſide is left a hole about eight inches ſquare, and four inches above the plank, through which the fire is put in. Over all the reſt laths are laid pretty thick, cloſe to one another, and nailed to the frame already mentioned; and then are plaiſtered over on both ſides, as are alſo the planks at bottom very thick, to ſerve for an hearth. Over the mouth or wideſt part goes an hair-cloth, fixed to the ſides of the kiln; and likewiſe to two rollers, or moveable pieces of wood, which are turned by wedges or ſcrews, in order to ſtretch the cloth. Inſtead of the hair-cloth, many people now uſe a net work, or iron wire, with which it is obſerved that the ſaffron dries ſooner, and with a leſs quantity of fuel; but the difficulty in preſerving the ſaffron from burning makes the hair-cloth be preferred by the niceſt judges in drying.

The kiln is placed in a light part of the houſe; and they begin by laying five or ſix ſheets of white paper on the hair-cloth, upon which they ſpread the wet ſaffron, between two and three inches thick; this they cover with other ſheets of paper, and over theſe lay a coarſe blanket five or ſix times doubled; or, inſtead thereof, a canvas pillow filled with ſtraw; and, after the fire has been lighted for ſome time, the whole is covered with a board, having a large weight upon it.

At firſt they give it a pretty ſtrong heat, to make the chives ſweat (as their expreſſion is;) and in this, if they do not uſe a great deal of care, they are in danger of ſcorching, and ſo of ſpoiling all that is on the kiln.

When it has been thus dried about an hour, they take off the board, blanket, and upper papers, and take the ſaffron off from that which lies next it; raiſing, at the ſame time, the edges of the cake with a knife; then, laying on the paper again, they ſlide in another board between the hair-cloth and under papers, and turn both papers and ſaffron upſide down; afterwards, covering them (as above.)

This ſame heat is continued for an hour longer; then they look on the cake again, free it from the papers, and turn it: then they cover it, and lay on the weight, as before. If nothing happens amiſs during theſe firſt two hours, they reckon the danger to be over: for they have nothing more to do, but to keep a gentle fire, and to turn their cakes every half-hour, till thoroughly dry: for the doing of which as it ought, there are required full twenty-four hours.

In drying the layer plump chives they uſe nothing more, but towards the latter end of the crop, when theſe come to be ſmaller, they ſprinkle the cake with a little ſmall beer, to make it ſweat as it ought; and they begin now to think, that uſing two linen cloths next the cake, inſtead of two innermoſt papers, may be of ſome advantage in drying: but this practice is followed as yet but by few.

Their fire may be made of any kind of fuel; but that which ſmokes the leaſt is beſt; and charcoal, for that reaſon, is preferred to any other.

What quantity of ſaffron a firſt crop will produce, is very uncertain; ſometimes five or ſix pounds of wet chives are got from one root; ſometimes not above one or two; and ſometimes not enough to make it worth while to gather and dry it. But this is always to be obſerved, that about five pounds of wet ſaffron go to make one pound of dry, for the firſt three weeks of the crop; and ſix pounds during the laſt week; and, now the heads are planted very thick, two pounds of dried ſaffron may, at a medium, be allowed to an acre for the firſt crop, and twenty-four pounds for the two remaining; the third being conſiderably larger than the ſecond.

In order to obtain theſe, there is only a repetition to be made every year of the labour of hoeing, gathering, picking, and drying, in the ſame manner as before ſet down, without the addition of any thing new; except that they let cattle into the field, after the leaves are decayed, to feed upon the weeds; or, perhaps, mow them for the ſame uſe.

About the Midſummer after the third crop is gathered, the roots muſt be all taken up and tranſplanted: the management requiſite for which is the fourth thing to be treated of. To take up the ſaffron heads, or break up the ground (as the term is) they ſometimes plow it, ſometimes uſe a forked kind of hoe, called a pattock, and then the ground is harrowed once or twice over; during all which time of plowing or digging, and harrowing, fifteen or more people will find work enough to follow and gather the heads, as they are turned up.

They are next to be carried to the houſe in ſacks, and there cleaned and raiſed: this labour conſiſts in cleaning the roots thoroughly from earth, and from the remains of old roots, old involucra, and excreſcences; and thus they become fit to be planted in new ground immediately, or to be kept for ſome time, without danger of ſpoiling.

The quantity of roots taken up, in proportion to thoſe which were planted, is uncertain; but, at a medium, it may be ſaid, that, allowing for all the accidents which happen to them in the ground, and in breaking up from each acre, may be had twenty-four quarters of clean roots, all fit to be planted.

The owners are ſure to chuſe for their own uſe the largeſt, plumpeſt, and fatteſt roots; but do leaſt of all approve the longeſt-pointed ones, which they call ſpickets, or ſpickards; for very ſmall round or flat roots are ſometimes obſerved to flower.

This is the whole culture of ſaffron in the country abovementioned; and we have only now to conſider the charges and profits which may be ſuppoſed, one year with another, to attend that branch of agriculture; and of theſe I have drawn up the following computation for one acre of ground, according to the price of labour in this country.

Rent

	l.	s.	d.
Rent for three years	3	00	0
Plowing for three years	0	18	0
Dunging	3	12	0
Hedging	1	16	0
Spitting and ſetting the heads	1	12	0
Weeding or pairing the ground	1	04	0
Gathering and picking the flowers	6	10	0
Drying the flowers	1	06	0
Inſtruments of labour for three years, with the kiln, about	0	10	0
Plowing the ground once, and harrowing twice	0	12	0
Gathering the ſaffron heads	1	00	0
Raiſing the heads	1	12	0
Total charge	23	12	0

This calculation is made upon ſuppoſition, that an acre of ground yields twenty-ſix pounds of net ſaffron in three years; which I ſtated only as a mean quantity between the greateſt and the leaſt; and therefore the price of ſaffron muſt be judged accordingly; which I think cannot be done better than by fixing it at thirty ſhillings per pound; ſince, in plentiful years, it is ſold at twenty, and is ſometimes worth three or four pounds: at this rate, twenty-ſix pounds of ſaffron are worth thirty-nine pounds; and the net profits of an acre of ground, producing ſaffron, will, in three years, amount to fifteen pounds thirteen ſhillings, or about five pounds four ſhillings yearly.

This, I ſay, may be reckoned the net profit of an acre of ſaffron, ſuppoſing that all the labour were to be hired for ready money: but, as the planter and family do a conſiderable part of the work themſelves, ſome of this expence is ſaved: that is, by planting ſaffron, he may not only reaſonably expect clear about five pounds yearly per acre, but alſo to maintain himſelf and family for ſome part of each year: and it is upon this ſuppoſition only, that the reſult of other computations can be ſaid to have any tolerable degree of exactneſs; but the calculations themſelves are undoubtedly very inaccurate.

I have ſaid nothing here concerning the charge in buying, or profits in ſelling the ſaffron heads; becauſe, in many large tracts of ground, theſe muſt at length balance one another, while the quantity of ground planted yearly continues the ſame; which has been pretty much the caſe for ſeveral years paſt.

Crocus *antimonii*, the name given, in the late London Diſpenſatory, to the preparation of antimony and nitre, commonly known by the name of Crocus metallorum. It is made of equal parts of antimony and nitre, powdered fine, and thrown, at times, into a red-hot crucible, and, when thoroughly melted, poured out, and ſeparated from its ſcoriæ. This looks more yellow, the longer it has been melted: it is but little uſed, except among horſes; but, when intended for internal uſe among men, ſhould be procured, faithfully prepared in this manner: for our chemiſts generally abate of the nitre to ſave charges, and render the medicine of a very different effect. *Pemberton's Lond. Diſ.*

Crocus *martis*, ſignifies alſo a chemical preparation, uſed by the glaſs-makers, to give a red-colour to glaſs. The glaſs-makers prepare this themſelves, and have four ways of doing it. The firſt is this: take filings of iron, mix them with three parts of powdered brimſtone, and keep them in a melting-pot, in a furnace, to calcine, and burn off the ſulphur; let them ſtand four hours in this ſtate, then take them out, and, when cold, powder and ſift them, and put the powder into a crucible, which lute over, and ſet in the leer of the furnace for fifteen days, or more; it will then be of a reddiſh purple, and muſt be kept for uſe. *Neri's Art of Glaſs.*

The ſecond way of making this, is by ſprinkling filings of iron with ſtrong vinegar, and ſetting them in the ſun to dry; when dry, powder and ſift them, and wet them again with vinegar, and, when dry, powder them again. Repeat this eight times, and then powder the whole, and ſift it fine for uſe.

The third way is to uſe aqua-fortis, inſtead of vinegar, in the ſame manner.

The fourth way, which is the beſt of all, is this: diſſolve filings of iron in aqua-regia, and let the ſolution ſtand three days in a veſſel cloſe ſtopped, ſhaking it about at times; then evaporate the liquor gently, and there will remain a moſt valuable Crocus martis. *Neri's Art of Glaſs.*

CRO'PPER, or *Dutch* Cropper, the name of a particular ſpecies of pigeon, called the columba gutturoſa Bataviæ, by Moore. It is naturally thick, and has its name from its large crop, or bag of wind, which it carries under its beak, and can, at pleaſure, either raiſe, or depreſs. Theſe are thick bodied and ſhort; their legs are alſo thick and ſhort, and are feathered down to the feet; the crop is large, and hangs low; the feathers on the thighs hang looſe; and their legs ſtand wide; they are gravel-eyed, and are generally very bad breeders.

There are of theſe pigeons of all colours, and thoſe who are careful of them, generally take them away from their proper parents, while young, and breed them under the females of other ſpecies. *Moore's Columbarium.*

CROPS *of corn.* The great buſineſs of the farmer is to produce the largeſt Crops he can, and, at the ſame time, to injure his land the leaſt. The common way of ſowing exhauſts the whole land, without giving half the nouriſhment it might give to the corn. Inſtead of the ſcattering way of ſowing corn by the hand, if it be let in with the drill, in ſingle, double, treble, or quadruple rows, and an interval of five feet of naked ground be left between theſe ſeries of rows, the uſe of horſe-hoeing in theſe intervals will be found to give all that the farmer requires: the Crop will be larger, though ſo great a quantity of ground is left vacant, than if all were ſoon over, as the plants will ſtand vaſtly thicker in the rows, and will have twenty or thirty ſtalks a-piece; and the more the ſucceſſive Crops are planted, and the oftener the ground is hoed in this manner, the better will the plants be maintained, and every Crop will be larger and larger from the ſame ground, without dunging, or without changing the ſort of plant, as is uſually neceſſary in other caſes. See AGRICULTURE.

This is very evident in ſeveral parts of the ſame field, where this ſort of huſbandry has been entered upon at different times; and ſome have a firſt crop, others a ſecond, and others a third, all growing up at the ſame time, the older worked land always invariably ſhewing the beſt crop. Dunging and fallowing are both neceſſary to recover land to its virtue, in the common way, after a few Crops. Theſe are both of them expences to the farmer; but the horſe-hoeing, when the corn is ſown in rows, anſwers all the intent of them, and is much leſs expenſive. It has, in ſhort, every year, the good effect of a ſummer fallow, though it every year produces a good crop, and no time, or uſe of it, is loſt to the farmer. *Tull's Horſe-hoeing Huſbandry.*

CROSS *Hairs*, in a teleſcope, are hairs drawn a-croſs the focus, for making more accurate obſervations.—In order to determine the right aſcenſions, &c. of the ſtars, it is requiſite to have four Croſs hairs in the focus of the teleſcope; of which *a b* (*Plate* XV. *fig.* 13.) and *c d* croſs at right angles, as alſo *e f* and *g h*; which are inclined to the two former in half right angles; and all croſs one another at the point *i*. Then having directed the teleſcope to make the preceding ſtar appear upon the hair *a b*, and having turned the teleſcope about its axis till the ſtar moves along *a b*, let it remain fixed; and obſerve by a pendulum clock the time of this ſtar's appulſe to the center *i*; and alſo the time of the ſubſequent ſtar's appulſe to the perpendicular hair *c d*. The interval of time between theſe appulſes to the hair *c d*, which coincides with part of an hour circle, being turned into degrees and minutes, gives the number of them contained in the correſponding arch of the equator that paſſed over the ſaid hour circle; which arch is the difference of the right aſcenſions of the ſtars. To find the difference of their declinations, the times of the ſubſequent ſtar's appulſes at *k* and *l* to the oblique hairs *e f*, *g h*, muſt alſo be obſerved; half of which is the time it ſpends in deſcribing half the line *k l*, that is, *m k* or *m l*. This half, being converted into minutes of an arch, gives the number of them contained in the correſponding arch of the equator that paſſed by the fixed hour circle *c d* in that time; and this number, being diminiſhed in the ratio of the radius to the ſine complement of the given ſtar's declination, gives the difference of their declinations, or the number of minutes in the arch *m i*. This rule may be eaſily demonſtrated, and is ſufficiently accurate, though the ſine complement of the given ſtar's declination is uſed inſtead of the ſine complement of the unknown ſtar's declination, becauſe their difference is but ſmall, in compariſon to the whole.

Signor Caſſini who firſt introduced this uſeful and accurate method of obſerving by 4 hairs, has ſhewn us how he applies it to determine all the particulars obſervable in eclipſes. See Phil. Tranſ. Numb. 236. It has one great advantage, that the obſervations are not liable to the uncertainty of the air's refraction. For, the teleſcope being fixed, all objects that appear in it, having nearly the ſame altitudes, are equally refracted very nearly; it is therefore the beſt method of obſerving the places of Mercury and Venus, or any other of the planets and comets, when near the ſun, and by conſequence but little elevated in the night time, as Dr. Halley has obſerved, Phil. Tranſ. Numb. 366. Where ſpeaking of the accuracy of this way of obſerving, he tells us, 'that he himſelf was preſent when Dr. Pound and his nephew Mr. Bradley did this way demonſtrate the extreme minuteneſs of the ſun's parallax ſo exactly, that, upon many repeated trials, it was not more than 12″ nor leſs than 9″. Theſe obſervations may be ſeen in the Phil. Tranſ. Numb. 363; from which Dr. Halley calculated the parallax by Caſſini's method (deſcribed in his book upon the Comet in 1680) which is very well explained in the 7th of Mr. Whiſton's aſtronomical Lectures.

The only trouble, in this way of obſerving, lies in turning the teleſcope about its axis in ſuch a poſition, that the ſtars ſhall move parallel to one of the hairs. But this difficulty is entirely removed, though the teleſcope be never ſo long, by a very pretty contrivance, invented by that ingenious and accurate aſtronomer the reverend Mr. James Bradley, Savilian profeſſor at Oxford. As near as I can remember, it is this: Let ABC (*Plate* XVII. *fig.* 4.) repreſent a flat ring of braſs fixed in the focus of the teleſcope; and *a b c* a ſmaller concentric ring lodged in a circular groove turned within the larger, and kept in the groove by three ſmall plates of braſs fixed to the

the outward ring and extended over the edge of the inner one. Upon the inner ring is fixed a concentric arch of a wheel *d e*, having teeth cut in its convexity, which are driven round by the threads of an endless skrew, whose axis D E F turns in a collar at E and upon a point at F, both fixed to the outward ring. The hairs *g h*, *i k*, cross at right angles in *f* the center of the rings, and, when the telescope is so fixed that the image of a star falls upon *f*, let it move along any line *f q*, and by turning the skrew D E F and by consequence the hair *f k* about the fixed point *f*, till it touches the star at *q*, it will then coincide with the tract of the star's motion; and then all other stars will move parallel to it, as was required.

To find the difference of declination of two stars, he observes the times of their appulses to the edges of two slender brass bars *g i o*, *g k p*, fixed to the inner ring, and equally inclined to its diameter *g h* in such angles that the perpendiculars *f i*, *f k*, on each side of *f g*, shall be severally equal to half *f g*; and consequently that the whole base *i k*, of the equicrural triangle *i g k*, shall be equal to its perpendicular height *f g*; and by consequence that the difference of any two bases *i f k*, *l m n*, shall be equal to *f m*, the difference of their height; so that the difference of the times of the transits of two stars over these bases may give the difference of their declinations. *Smith's Optics.*

CROSS-*trees*, in a ship, cross pieces of timber set on the head of the mast, and bolted, and let into another very strongly. They are four in number, and are generally called Cross-trees, but, strictly speaking, only those which go thwart ships, are Cross-trees; the other, in the largest ships, are called treisle-trees. Their use is to keep and bear the top-mast up; for the foot of the top-mast is always fastened into them, so that they bear all the stress. They also bear the tops, and are necessary to all masts which carry any other top or flag-staff. *Manwayring.*

CRU'CIBLE (*Dict.*)—These vessels, so much used by assayers, &c. are best made of a pure and well washed clay, with an admixture of the purest sand, powder of flint, or the powder of other broken Crucibles, which have already sustained a great fire, and are very clear. They are formed in wooden, or brass moulds, divided longitudinally into two parts, and to be disjointed or put together again at pleasure: for this purpose also a broad iron ring is adapted to the outside of the mould, in such manner, that the two sides are kept firmly together, while this ring is on, and fall asunder, as soon as it is taken off. This mould, however, gives only the outer shape of the Crucible; its cavity must be made by a pestle, or other similar instrument. See *plate* XVII. *fig.* 7.

When the vessels are to be made, the ring is put upon the mould, and the whole set upon a strong support: then the cavity of the mould is to be filled with the matter very stiff; this is to be pressed down first with the fingers, or with a stick, making a hollow in the middle, and leaving the edges of the matter above the sides of the mould; then apply to this hollow the pestle, rubbed over with the fat of bacon, and drive it in with several strong strokes of a mallet: then take away the pestle, and, taking the ring off from the mould, the Crucible is taken out perfect, and finished, and is to be dried, and baked in a potter's kiln. See Sections of these moulds, *plate* XVII. *fig.* 5, 6.

If, from the too great moisture of the matter, when put into the mould, or from any inequalities or roughnesses in the mould, the Crucible will not readily separate from its sides, as soon as made, place the mould, in a dry warm place, for a few minutes, and the vessel will, after that, come out easily.

In the making these vessels, a sufficient quantity of the matter must always be put at once into the mould; for, if you add to the matter once compressed a new lump of the same, it will not cohere with the first. If the matter be put into the mould in small masses, not moulded thoroughly together first by handling, these never cohere neither; but the vessel, when finished, will be full of chinks and pores, which, though not to be discovered either by the eye, or by the sound of the vessel when struck, yet let the salts in fusion pass through them.

If these vessels are not made with a large bottom, the concave mould must not be greased; for, if it be, the vessel comes out of it with the pestle, and sticks so firmly to it, as not to be got off without breaking. *Cramer's Art of Ass.*

CRU'CIFORM *Flowers*, in botany, a term for such flowers as are composed of four leaves, disposed in form of a cross. Some of these flowers have a cup, others have not; those which have cups, usually have them composed of four leaves, and placed in the same order and direction with those of the flower. Of this class of plants are the cabbage, rocket, wall-flower, &c. *Tourn. Inst.*

CRU'ISERS, in the navy, are small men of war, made use of to and fro in the channel, and elsewhere, to secure our merchant-ships, and vessels, from the enemy's small frigates and privateers. They are generally such as sail well, and are commonly well manned: and, indeed, the safety of the trade in the channel, and up and down the soundings, and other places, absolutely requires the constant keeping out of such ships at sea.

CRU'STA, *crusta lactea*, in surgery, signifies a crust of scabby ulcers, apt to affect the faces of children. The cure of it depends principally on regulating the diet of the nurse, and giving her gentle purges, and sweating powders; the infant ought also to take at times a few gentle doses of physic, and, in the intervals, between the purges, to take powder of crude, or diaphoretic antimony, with flour of brimstone, and crab's claws, and other of the testaceous powders. When this method has been pursued for some time, the parts may be anointed with cream, with a small quantity of chalk, or cerus, mixed in it, or with a mixture of oil of eggs, with a small quantity of oil of bricks. Ointments of mercury, or sulphur, are very dangerous in the beginning of this disorder, or to weakly infants; and, when such have been used by ignorant persons, the best method to be taken is the endeavouring to throw out the humour again by sudorifics. *Heister's Surgery.*

CRY'STALS, (*Dict.*)—The original coalescence and formation of those bodies of which spar is the basis, we well know may have been but of yesterday, since we have evident proofs, that spar is concreting to this day, and that sparry bodies are forming every moment. This is evident, from the sparry stalactitæ in the arches of modern buildings, particularly in one so lately built as the new bridge at Westminster, the roofs of the arches of which were filled with these spars, within a year after the arches were built; and there are evident proofs, that spars are not made of matter educed from stone, since brick arches equally abound with them; and the brick vault which supports part of the ground terrace at Windsor, has been of late so full of them, that there was not room to walk for them.

From these observations, as also those of the sparry incrustations round vegetable and other bodies in spring, and at the bottoms of our tea-kettles being all incrusted with it; we have evident proof, that sparry bodies are formed to this day, but we have no such clear evidence of the present growth of Crystal. Whether or not it is so, however, we may be led by a few propositions to prove, by the only sure test, experiments,

1. If crystallized spar can be at this day dissolved in water, or suspended in it, in their minima or ultimate particles, and again separated from it, these stony or other fossils, composed of Crystal and spar, may be formed at this day; if these bodies are not thus dissolved, they cannot.

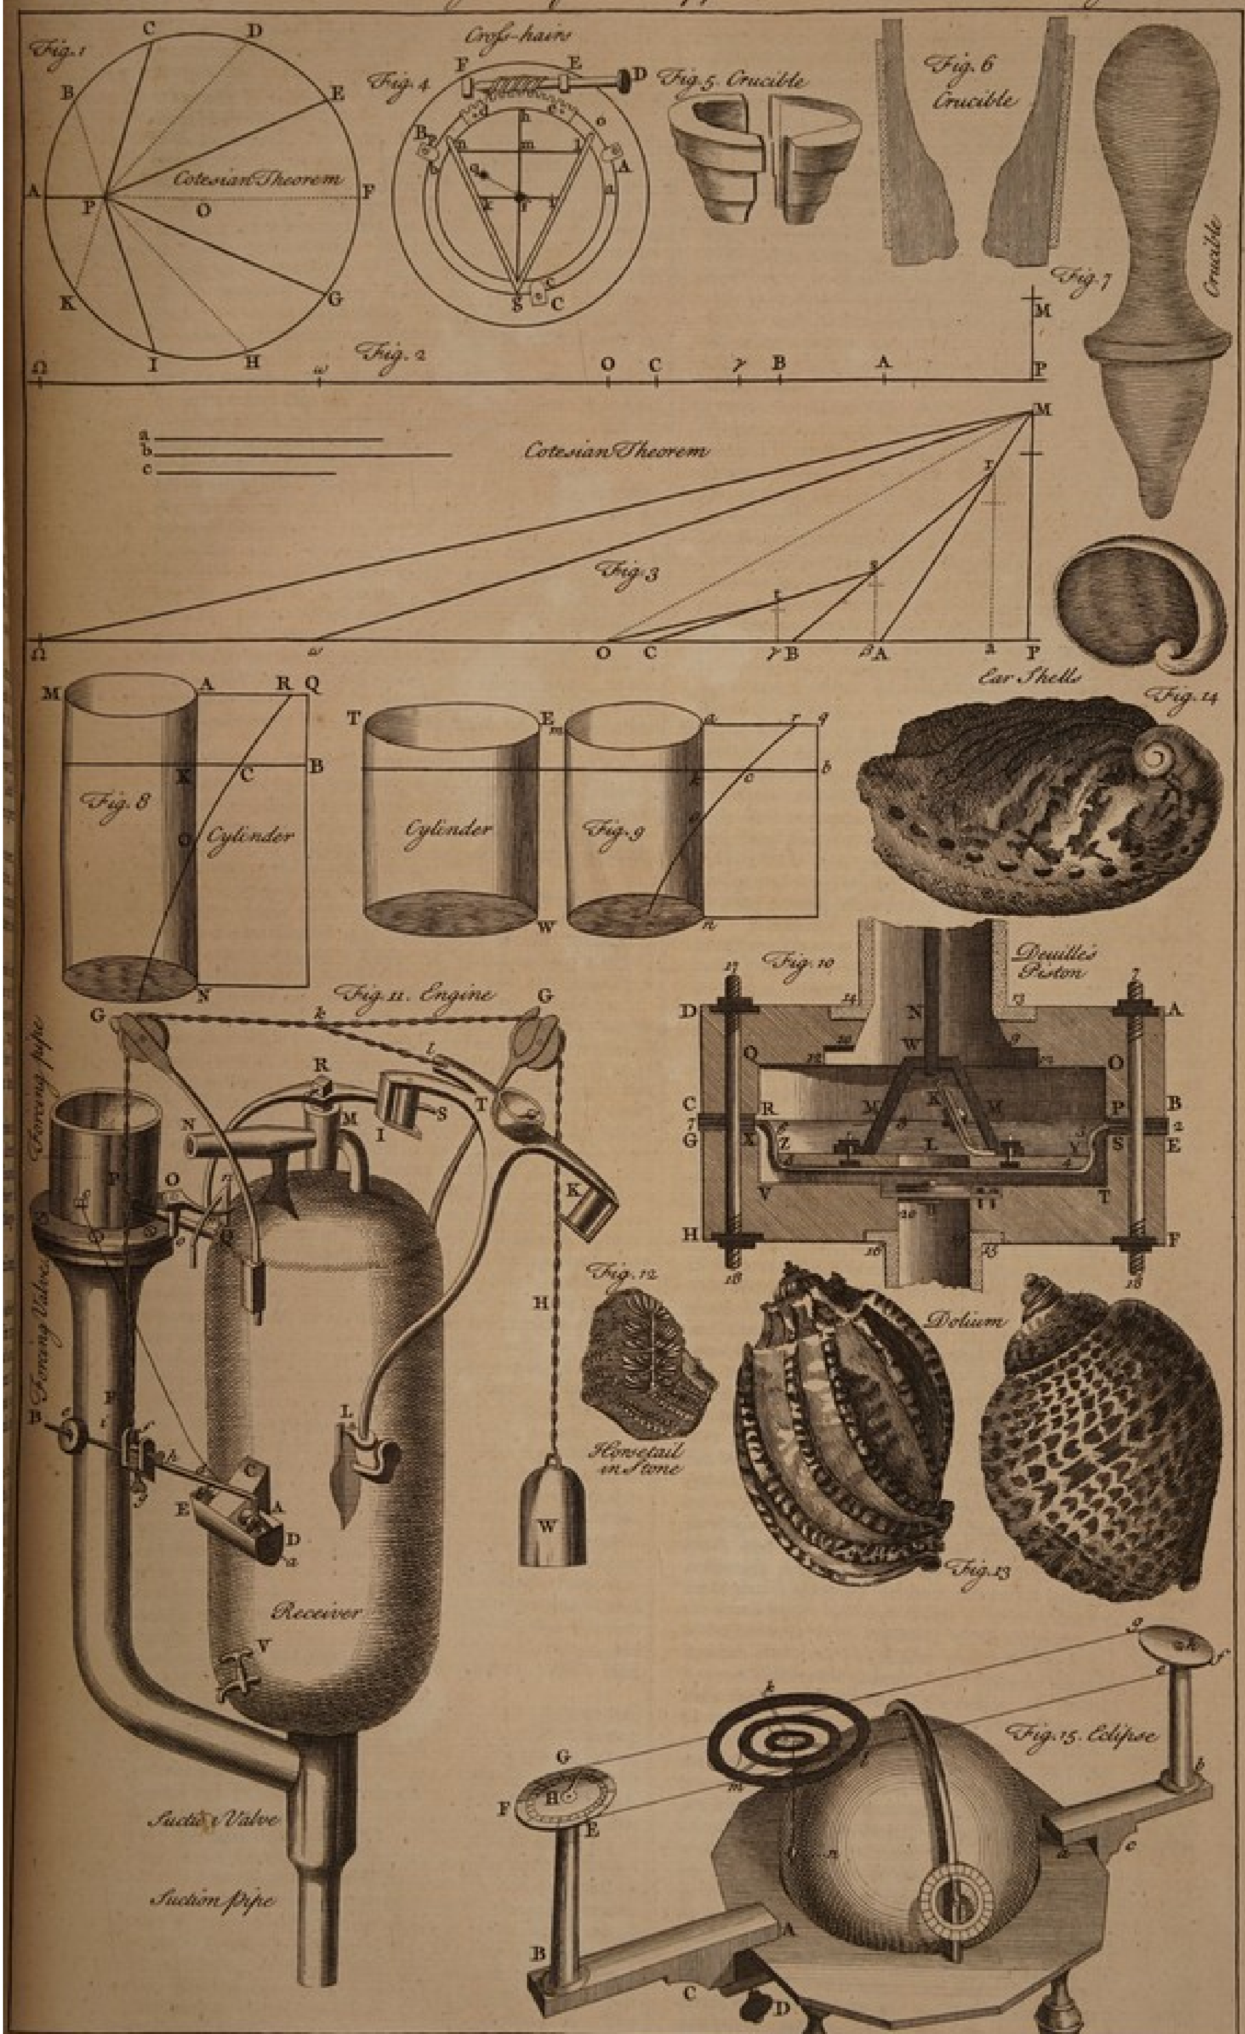
2. If Crystal and spar can be raised in vapour, or suspended in effluvia, then crystalline and sparry concretions may at this day be formed in places where water cannot be supposed to have come: if they cannot be thus suspended, then the Crystals and spars found in such places cannot have been formed at this day, but must have been there from some distant time.

The subject of enquiry is by these propositions reduced to a narrow compass; and all that experiments have to determine is: 1. Whether Crystal or spar are at this time found suspended in water, in imperceptible particles, or whether they are not; and 2. If they are thus suspended, whether they are or are not capable of being raised in vapour?

These things Dr. Hill has been at the pains to determine, by a great number of experiments.

The bottom of every tea-kettle, as has been before observed, informs us, that some solid fossil body is suspended in imperceptible particles in all, even the clearest water, and is easily separated from it by no other agent than heat; as heat therefore is found capable of separating this substance, and no other agent that we know of is so, that is the natural means to be used in the investigation of the subject.

The substance incrusting tea-kettles, &c. is found to be a genuine spar, with a greater or lesser admixture of earth, and is wholly the same with the incrustation on vegetables in springs, &c. Here, therefore, is a proof of spar and earth being suspended in common water, but none of Crystal. This was alone to be determined by repeated and cautious distillations. In distilling the water of the same spring, with different degrees of fire, a different quantity of matter was found at the bottom of the vessel. It appeared hence, that, in a greater degree of heat, a great part of the matter had been raised in vapour, and the remainder, on trial, always proved to be only spar and earth. Here, were therefore, both the questions answered in the affirmative, in regard to spar, viz. that it is continually suspended in water, and may be raised in vapour. The water of these distillations being returned into the cucurbit, and re-distilled, leaves a second sediment in small quantity, and of a white colour. This, being examined according to the known laws of fossils, proves to be part spar, and part Crystal, and undissolved powder remaining from it, after pouring on aqua-fortis to take up the spar; and this in all tests appearing to be true and perfectly pure Crystal. A third distillation of the same water produced not the least residuum. Hence, therefore, it is evident, that Crystal, as well as spar, is continually suspended in water, and may be raised in vapour, and separated by no other agent than heat. And hence the conclusion is plain, that crystalline as well as sparry bodies may be, and doubtless are, continually formed in the earth to



Printed for J. Hinton in Newgate Street.

this day, and need not be supposed all of as old a date as the creation or deluge. *Hill's Hist. of Foss.*

Having thus from experiments gone through the history of what may be the origin of many of the crystalline bodies we daily meet with, it remains to say something of their form.

The perfect regularity of the figures of Crystals cannot but be the effect of some fixed, permanent, and invariable cause; these being ever, unless altered by accidents, which rarely happens, the very same in the same genus. The antients esteemed Crystal a congelation of water, and thought it only ice harder than ordinary. Signior Lana, who had an opportunity, in the Valsabbia, of seeing many of the perfect double kinds, imagined, that they owed their origin to dews congealed by nitrous exhalations. Rohault imagines the figure of common Crystal the effect of six drops of water thrown together.

Others are for its being formed of radiations, others from all its parts being like the whole; and others from the mutual tendency of the parts of it towards the same center. But all these the laws of action in matter, and the structure of Crystal in the several species, easily shew to be erroneous.

Many think they have solved all difficulties, when they say, that Crystals are salts; but we know no more of the true figures of salts, than we do of those of Crystals. And it is to be added, that, if Crystals are salts, then salts are something else from what we have been taught to think they are, Crystals by no means answering to the definitions given us of them by authors. As we yet know so little of the causes of the regular crystallizations of salts, why are we to suppose no other bodies but salts capable of such crystallizations; and why may not the same almighty agent, who has implanted, in the minima of saline bodies, a tendency to these their several appropriated forms, have allowed the same tendency to other bodies?

How it is, that Crystal, in its smallest concretions, obtains its determinate figure, according to the genus it is of, is assuredly yet to us unknown; but how it is enlarged afterwards, yet still kept in its same form, seems not so difficult to be accounted for, and may indeed be traced from observations of the several bodies in their present state.

We are not to doubt, but that the smallest concretions are regularly formed in all Crystals, according to their kinds, and we see the smallest that even the microscope can discover to us, regularly are so. These are formed, among water or vapour, solid with the same particles, and only wanting a slow evaporation to part them from the water or vapour.

These particles, though, when collected in a body, they be more than twice the specific gravity of water, yet, while suspended in a vast proportion of water, attract the particles of the water more strongly than they do one another, and hence give way to that repulsive power so well known in nature, which is properly the effect of another attraction, by which all things are made to ascend in water, which are less than water attracted by the gravitating power of the earth: the particles of Crystal therefore, attracting the particles of water more strongly than one another, recede from one another, as far as the quantity of water they are suspended in will permit. When this quantity of water is so far evaporated, that the particles of Crystal are nearer to one another, and brought within the verge of one another's attraction, they become more attracted by one another, than by the particles of water, and thence form concretions. This they usually do in many parts of the same fluid at once; and hence it is, that we usually find many shoots in the same place. The whole crystalline matter might now be expected to form itself into these small concretions: but there is now a new law or power established in the evaporating fluid; for these small aggregates of bodies, now formed in separate concretions, attract the particles yet suspended in the fluid, more than they do one another: hence they naturally become applied to these, and, being every way equally extended over them by the ambient fluid, they no way alter their first figure, while they ever so much increase their bulk. And it is evident, from examining the columns of Crystals, which are ridged and striated across, while their pyramids are all smooth, that this new matter has ever been added to the pyramidal planes, and thence extended down the sides of the columns. *Hill's Hist. of Foss.*

When any piece of workmanship in Crystal is become foul and dark, the method of recovering its lustre, without hurting its polish, is this: mix together six parts of common water, and one part brandy; boil these over a brisk fire, and let the Crystal be kept in it, in a boiling state, a quarter of an hour, then take it out, and rub it carefully over, with a brush dipped in the same liquor; after this, it is not to be left to dry of itself, but to be wiped with a clean napkin, and its surface will by this means be perfectly cleansed, and rendered as bright as at first, without that injury to the points of the cutting, or to the surfaces of the planes or facets, which would naturally have been the consequence of doing it by mere rubbing or wiping. Natural Crystal may be reduced, by calcination, into the state of the bodies proper for making glass with alkaline salts, and makes a most fine and valuable fritt. The method of doing it is this: calcine natural Crystal in a crucible; when it is red-hot, throw it into cold water to quench it; repeat this eight times, covering the crucible, that no dust or ashes may get in and mix with the Crystal; dry this calcined mass, and reduce it to an impalpable powder; mix this powder with the pure salts of polverine, and with these make fritt, in the usual proportions, and with the common quantity of manganese; wash this often in cold water, and, after a proper time, work it; it will yield a most beautiful glass. *Neri's Art of Glass.* See FRITT.

Natural Crystal may be coloured of several colours, without melting or running it into glass, in the following manner: take a number of pieces of fine, clear, and pure Crystal of various sizes, of crude antimony and crude orpiment in powder, of each two ounces; sal armoniac one ounce; powder this also, and mix them well together; put this powder into a strong crucible, and lay upon it the pieces of Crystal in their natural state; then cover this crucible with another, mouth to mouth: lute them well, and, when the lute is dry, set them in coals, which kindle by little and little; and, when they begin to fire, let them kindle of themselves, and, they will then smoke very much. Let this be done in a large chimney, taking care to avoid the fumes. When it fumes no more, let the fire go out of itself, and all stand till cool; then unlute the crucible, and take out the Crystals; those at top will be coloured to a fine yellow, with a deep and pale red, the colours of the common fine and balass ruby, with beautiful spots; and those which be at the bottom upon the powder, will be of a watery colour, mottled like that of the viper. This Crystal comes out so fair from this process, that it may be cut as a gem, and, though many are spoiled, yet in making a large quantity, there are always some fair and perfect. *Neri's Art of Glass.*

Prepared Crystal, a term among the makers of counterfeit gems, for a powder of natural Crystal, made for their purpose. The manner of preparing it is as follows: take the purest and clearest natural Crystal, put it into a crucible covered at the top; set it among burning coals; let the Crystal be made red-hot, then plunge it into a large vessel of cold water. When the Crystal is cold, put it into the fire again, heat it red-hot, and quench it again; and repeat this operation twelve times, carefully keeping ashes or any other foulness out of the crucible. When the calcination is finished, the Crystal will be brittle and crumbly; powder it, and levigate it on a porphyry to an impalpable powder. This powder must be made perfectly fine, otherwise the gems made with it will be all foul and coarse; and no brass or copper vessels must be used about the operation. If the Crystal should be powdered in a brass or bell-metal mortar, there could be nothing but an emerald be made of it, from the quantity of copper it would take up in the powdering. When carefully prepared, it receives all the colours of the gems, by proper additions, and affords a mass softer indeed, but not less bright and pellucid, or not less beautifully tinged than the finest of the oriental gems. *Neri's Art of Glass.*

CRYPTOGA'MIA, in botany, a class of plants whose flowers are either wholly invisible, or scarce discernable by the eye.

CU'BITUS, (*Dict.*) — *Fractured* Cubitus. The lower part of the arm, which is called the Cubitus, contains two bones, the radius and ulna: fractures of this part, therefore, sometimes happen only to one, sometimes to both those bones, and that sometimes near their extremities, but oftener toward their middle: but, when they are both broke together, the bones are not only very easily distorted from each other, but they are not to be replaced without a great difficulty also: if one should, on the contrary, be broken while the other remains whole, the fractured parts do not much recede out of their places, nor are they very difficult to reduce and retain; for the bone, remaining sound, is found, in this case, to be a better direction and support than either splinters or bandages. When the fracture happens towards the lower head, near the pronator quadratus muscle, the fractured part is strongly drawn by that muscle, and the intervening ligament that is extended between the radius and ulna, toward the sound bone; and this makes it more difficult to replace. If the radius is to be replaced, whose fragment is contracted towards the ulna, an assistant must hold the arm, while the surgeon inclines the patient's hand towards the ulna, to draw back the contracted parts of the radius. When this is done, he must carefully reduce them by compression on both sides with his hands, so as to restore the compressed muscle between the radius and ulna, and the fragments of the radius, to their proper places. The arm is then to be bound up with the proper bandage, and the limb must afterwards be placed in a sort of case made of paste-board, or light wood, to be suspended in a sling put about the neck.

In setting a fracture of the ulna, the whole method must be the same with this of the radius, except that, in the extension, the hand must be bent toward the thumb, and radius, before the distorted part of the ulna can be compressed into its proper place. When both bones of the Cubitus are broken, the method of cure is much the same with that used to each of them, when broken singly; but there is required more strength and circumspection, both in the replacing them, and a great deal of caution in applying the bandage to retain them. Care must

muſt alſo be taken, that, while the arm continues in this caſe a great while, without motion, the mucilage of the joint does not harden, or the ligament become ſtiff, and the arm, or Cubitus, be thereby rendered immoveable. To guard againſt this, it will be proper to unbend the arm once in two or three days, and to move it a little carefully and gently, backwards and forwards, and ſometimes to foment it with warm water or oil; by which means its motion will be preſerved. *Heiſter.*

Luxated CUBITUS. The Cubitus conſiſting of two bones, the ulna and radius, is articulated by a gynglymus; and the connection of theſe bones is ſuch, that the ulna, or Cubitus, as being the largeſt bone, and ſeated in the lower part of the arm, does of itſelf perform the whole flexion, and extenſion of the arm, yet it cannot perform thoſe motions without carrying the radius along with it; but, on the other hand, the radius may be turned along with the hand both inward and outward, without at all moving or bending the ulna, as when the pronation and ſupination of the hand are made thereby. Both theſe bones of the Cubitus are ſo articulated with the lower head of the os humeri, that large protuberances are received into deep cavities, or grooves, and the whole inveſted and faſtened with exceeding ſtrong ligaments; ſo that, notwithſtanding the Cubitus may be luxated in all four directions, outward or inward, backward or forward, yet it is but ſeldom that it ſuffers a perfect or intire diſlocation, unleſs the upper part of the ulna be broken, or the ligaments of the Cubitus much weakened by ſome great external violence. The ſlighter and more recent luxations of this kind are, the more eaſy is the reduction of them. Be the caſe better or worſe, however, the patient muſt be placed in a chair, and both parts of the limb, the humerus and the Cubitus, muſt be extended in oppoſite or contrary directions, by two ſtrong aſſiſtants, till the muſcles are found pretty tight, with a free ſpace between the bones: then the luxated bone muſt be replaced, either with the ſurgeon's hands alone, or with the aſſiſtance of bandages, that the proceſſes may fall into their ſinuſes; and, when this is done, the Cubitus muſt be ſuddenly bent. But, if the tendons and ligaments are ſo violently ſtrained that they can ſcarce perform their office, it will be proper to anoint them with emollient oils, ointments, and the fat of animals; or to apply emollient cataplaſms and fomentations. As ſoon as the reduction has been effected, the articulation muſt be bound up with a proper bandage, and the arm afterwards ſuſpended in a ſling hung about the neck. But care muſt be taken that the bandage is not kept on too long, nor the arm kept intirely without motion all the time, but the mucilage of the joint ſhould become inſpiſſated, and the articulation rendered, by that means, ſtiff, or the motion of the part be intirely loſt. To prevent this, it will be proper to undo the bandage every other day, and gently to bend and extend the limb: afterwards, compreſſes dipped in warm wine may be applied, and held on with the bandage. *Heiſter's Surg.*

CUCU'RBITA, *the gourd*, in botany, a genus of plants whoſe characters are:

It hath a flower conſiſting of one leaf, which is of the expanded bell-ſhape, for the moſt part ſo deeply cut, that it ſeems to conſiſt of five diſtinct leaves: this, like the cucumber, has male and female flowers upon the ſame plant: the fruit of ſome ſpecies is long, of others round or bottle-ſhaped, and is commonly divided into ſix cells, in which are contained many flat oblong ſeeds, which have ſometimes a border round them.

There are ſeveral varieties of this plant, which are annually brought from America, where are numberleſs varieties of theſe, and of pumpkins and calabaſhes: but theſe ſorts are ſo apt to ſport, that there is no certainty of their producing the ſame ſhaped fruit for two years together, unleſs it is that with the long fruit, which I do not remember to have ſeen change or alter; but all the others will run from one ſhape to another, ſo as rarely to produce the ſame as thoſe which the ſeeds were ſaved from.

They may be all propagated by ſowing their ſeeds in March, on an hot bed; and, when the plants come up, they ſhould be tranſplanted on another moderate bed, where they ſhould have a great deal of air to ſtrengthen them; and, when they have got four or five leaves, they ſhould be tranſplanted into holes made upon an old dunghil, or ſome ſuch place, allowing them a great deal of room to run; for ſome of the ſorts will ſpread to a great diſtance. I have meaſured a ſingle plant, which had run upwards of forty feet from the hole, and had produced a great number of ſide branches; ſo that if the plant had been encouraged, and all the ſide branches permitted to remain, I dare ſay it would have fairly overſpread twenty rods of ground: which, to ſome people, may ſeem like a romance; yet I can affirm it to be fact. But what is this to the account printed in the Tranſactions of the Royal Society, which was communicated to them by Paul Dudley, Eſq; from New England, wherein mention is made of a ſingle plant of this kind, which, without any culture, ſpread over a large ſpot of ground, and from which plant were gathered two hundred and ſixty fruits, each, one with another, as big as an half peck. *Miller's Gard. Dict.*

CU'CULUS, *the cuckow*, in ornithology, a bird well known in England, by the ſingularity of its note; its beak is long and ſtrait, only it is a little hooked at the end, of a blackiſh brown above, and of a yellowiſh white below; its mouth is yellow within, and the iris of its eyes of a hazel colour; its noſtrils round, open, and ſtanding out beyond the ſurface of the bill, by which mark alone, it is to be diſtinguiſhed from all other birds; its throat, breaſt, and belly, are white, variegated with tranſverſe ſtreaks of brown; the feathers of its head are brown, with white edges, and its rump is grey; its back, neck, and wings, are of a browniſh hue; its long wing feathers have white tips, and are variegated with black, brown, and white; and the tail feathers are beautifully variegated with white. Its feet and legs are yellow. Its food is caterpillars, and other inſects. *Ray's Ornith.*

It never builds itſelf a neſt, but ſeizes upon that of any other ſmall bird, and, deſtroying its eggs, leaves its own in their place.

Whether it hides in hollow trees, &c. during the winter, with us, or whether it leaves us for a warmer climate, is not certainly known. It is pretended that many have been found in hollow trees, but the truth of it has never been well atteſted.

CU'CUMBER, *cucumis*, in botany, a genus of plants whoſe characters are:

It hath a flower conſiſting of one ſingle leaf, which is bell-ſhaped and expanded towards the top, and cut into many ſegments; of which ſome are male or barren, having no embryo, but only a large ſtyle in the middle, which is charged with the farina: others are female or fruitful, being faſtened to an embryo, which is afterwards changed into a fleſhy fruit, for the moſt part oblong and turbinated, which is divided into three or four cells incloſing many oblong ſeeds.

To raiſe Cucumbers you muſt provide in January a quantity of new horſe-dung, with the litter mixed together, in proportion to the number of plants you intend to raiſe, which, if for a private family, two loads will be full enough: this ſhould be thrown into an heap, mixing a few ſea coal aſhes therewith; in about four or five days after, the dung will begin to heat, at which time you may draw a little part of the heap on the outſide flat, laying thereon a little good earth, about two inches thick; this you ſhould cover with a bell-glaſs, laying a little dry litter thereon: and in a day or two after, when you perceive the earth to be warm, you muſt put your ſeeds therein, covering them, about a quarter of an inch, with the ſame earth; then put the glaſs on again: and alſo at night, or in bad weather, obſerve to cover the glaſs with dry litter or mats, &c. and in three or four days time, if the dung be in a good temper of heat, the plants will appear above ground; which when you firſt obſerve, you muſt immediately with the adjoining heap of dung make a bed for one ſingle light, being careful not to take the dung away too cloſe to the bell-glaſs, but obſerving to lay a little dung round about it, as alſo to keep it covered, that the young plants may not receive a check thereby. This hot bed will require to be three feet thick in dung at leaſt, which, in the making, ſhould be carefully mixed, and beat pretty cloſe with the fork, to prevent the heat from being too ſudden and violent: then lay ſome freſh earth upon the dung, about three inches thick, levelling it very even, and put on the frame, covering it over in the night, or in bad weather, with a mat, &c. as before, in order to excite an heat in the bed; and, as ſoon as you perceive the bed to be in a good kindly temper of heat, you ſhould prick your young plants thereon, at about two inches diſtance each way, obſerving to put them into the earth almoſt up to their ſeed leaves.

If the bed is of a good temper of heat, your plants will take root in leſs than twenty-four hours; after which time you muſt be careful to let in a little air, at ſuch times when the weather will permit, as alſo to turn the glaſs upſide downwards every day to dry; for the ſtem of the bed, condenſing on the glaſſes, will fall down upon the plants, and be very injurious to them; and, therefore, whenever the weather is ſo bad as not to permit the glaſſes to lie turned long, you ſhould at leaſt turn them once or twice a day, and wipe off the moiſture with a woollen cloth; but you muſt alſo be very careful how you let in too much cold air, which is equally deſtructive to the tender plants; therefore, to avoid this, it is a very good method to faſten before the upper ſide of the frame, where the air is ſuffered to enter the bed, a piece of a coarſe cloth, or a mat, ſo that the air which enters, may paſs through that, which will render it leſs injurious to your plants.

You muſt alſo be very cautious in giving water to the plants, while young; and, whenever this is done, it ſhould be ſparingly, and the water ſhould be placed either in the heap of dung, or in ſome other warm place, for ſome time before it is uſed, ſo as to be nearly of a temperature for warmth with the incloſed air of the hot bed; and, as the plants advance in height, you ſhould have a little dry ſifted earth always ready, to earth up their ſhanks, which will greatly ſtrengthen them.

These

These directions, if carefully attended to, will be sufficient for raising the plants in the first bed: you must therefore, when you perceive the third or rough leaf begin to appear, prepare another heap of fresh dung, which should be mixed with ashes, as was before directed: this should be in quantity according to the number of holes you intend to make. The common allowance for ridging out the earliest plants is, one load to each light or hole, so that the bed will be near three feet thick in dung; but, for such as are not ridged out till March, two loads of dung will be sufficient for three holes; for I could never observe any advantage in making these beds so thick with dung as some people do: their crops are seldom better, if so good, as those which are of a moderate substance; nor are they forwarder, and the fruit is rarely so fair; nor do the vines continue so long in health.

In four or five days time your bed will be in fit order to receive your plants; of which you may easily judge, by pulling out one of the sticks which was put in the middle of the holes, and feeling the lower part of it, which will satisfy you what condition your bed is in: then you must stir up the earth in the middle of the hole with your hand, breaking all clods, and removing all large stones, making the earth hollow, in form of a bason. Into each of these holes you must plant four plants; in doing of which, observe to make the holes a little slanting towards the middle of the bason, especially if your plants are long-shanked: this is intended to place the roots of the plants as far as possible from the dung, to which, if they approach too near, the lower part of their roots is subject to be burned off: then settle the earth gently to each plant; and, if the earth is dry, it will be proper to give them a little water, which should be warmed to the temper of the bed, as was before directed; and, if the sun should appear in the middle of the day, they should be shaded therefrom with mats until the plants have taken root, which will be in two or three days; after which, you must let them enjoy as much of the sun as possible, observing to turn the lights in the day-time to dry, as also to give a little air, whenever the weather will permit.

You must also observe to keep the glasses covered every night, and in bad weather; but be very careful not to keep them covered too close, especially while the bed has a great steam in it, which will cause a damp to settle upon the plants, which, for want of air to keep the fluid in motion, will stagnate and rot them.

When your plants are grown to be four or five inches high, you must, with some slender forked sticks, incline them toward the earth, each one a separate way; but this must be done gently at first, lest, by forcing them too much, you should strain or break the tender vessels of the plants, which would be very hurtful to them. In this manner you should, from time to time, observe to peg down the runners, as they are produced, laying each in exact order, so as not to interfere or cross each other; nor should you ever after remove them from their places, or handle them too roughly; whereby the leaves may be broken or displaced, which is also equally injurious to them; but, whenever you have occasion to weed the bed between the plants, do it with great care, holding the leaves aside with one hand, while with the other you pull out the weeds.

In about a month after they are ridged out, you may expect to see the beginnings of fruit, which very often are preceded by male flowers, which many people are so ignorant as to pull off, calling them false blossoms: but this I am fully convinced, by many experiments, is wrong; for these flowers are of absolute service to promote the welfare of the fruit; which, when these male flowers are intirely taken off, does very often fall away, and come to nothing: nor should the vines be pruned, as is too often the practice of unskilful people, especially when they are too luxuriant; which often happens when the seeds were fresh, or of the last year's saving, and the plants in good heart.

At this time, when your vines are spread, so as to cover the hot bed, it will be of great service, when you water them, to sprinkle them all over gently, so as not to hurt the leaves; but observe to do this not at a time when the sun is very hot; for hereby I have known a whole bed of Cucumbers spoiled. The watering of the beds all over will be of great service, by giving nourishment to those roots, which by this time will have extended themselves all over the bed: and if the warmth of the bed should now decline, it will be of great service to add a lining of fresh dung round the sides of the beds, to give a new heat to them: for, as the nights are often cold at this season, where the beds have not a kindly warmth left in them, the fruit will frequently drop off the vines, when grown to the size of the little finger: and, if upon this lining of dung there is a thickness of strong earth laid for the roots of the plants to run into, it will greatly strengthen them, and continue the plants in vigour a much longer time than they otherwise will do; for the roots of these plants extend to a great distance when they have room, which they cannot have in a bed not more than five feet wide; so that, when they have no greater extent for their roots, the plants will not continue in vigour above five or six weeks, which, if they have a depth and extent of earth, will continue three months in bearing; so that, where there are several beds made near each other, it will be the best way to fill up the bottom of the alleys between them with warm dung, and cover that with a proper thickness of earth, so as to raise them to the level of the beds.

The season for sowing the Cucumbers for the last crop, and for pickling, is towards the latter end of May, when the weather is settled: these are sown in holes dug to a little depth, and filled up with fine earth, in form of a bason, eight or nine seeds in each hole. These will come up in five or six days, and, till they are about a week old, are in great danger from the sparrows; after they require only watering now and then, and keeping clear from weeds. There should be only five plants, at first, left in each hole, and, when they are grown a little farther up, the worst of these is to be pulled up, that there may finally remain only four. The plants of this crop will begin to produce fruit in July. *Miller*.

CUNI'CULUS, in mining, a term used by authors, in distinction from puteus, to express the several sorts of passages and cuts in these subterranean works. The Cuniculi are those direct passages in mines, where they walk on horizontally; but the putei are the perpendicular cuts or descents. The miners in Germany call these by the names stollen and schachts; the first word expressing the horizontal, and the other the perpendicular cuts. It is an observation with our miners, that the damps, so much dreaded in all mines, happen generally in the horizontal cuts; but Dr. Brown, in his examination of the gold and silver mines in Hungary, observes, that they as often happen there in the putei or schachts, as in the Cuniculi or stollen. Another observation, as to the damps with us, is, that they are more frequent in clayey and soft places under ground; but in those mines they are as frequent where the matter is hard stone; and one of the most mischievous that had then lately happened, was in a place every-where surrounded with stone, so hard, that the tools of the miners could scarce work through it; and the descent had, in the very spot where the damp was, been made by means of gunpowder. In some of the Cuniculi in these mines, there are damps that regularly return on certain occasions; as, if the lower end of the Cuniculus be filled up with water, certain parts in going to it are always affected with damps, which will put out a lamp or candle, the moment it enters them, and often do great mischief to the miners in passing them. *Phil. Transf.* N°. 48.

CUP-*galls*, in natural history, a name given by authors to a very singular kind of galls found on the leaves of the oak, and some other trees. They are of the figure of a cup, or drinking-glass, without its foot, being regular cones, adhering by their point or apex to the leaf; and the top or broad part is hollowed a little way, so that it appears like a drinking-glass with a cover, which was made so small, as not to close it at the mouth, but to fall a little way into it. This cover is flat, and has in the center a very small protuberance, resembling the nipple of a woman's breast. This is of a pale green, as is also the whole gall, excepting only its rim which runs round the top; this is of a scarlet colour, and that very beautiful. Besides this species of gall, the oak leaves furnish us with several others, some of which are oblong, some round, and others flatted; these are of various sizes, and appear on the leaves at various seasons of the year.

CUPRE'SSUS, *the Cypress-tree*.— This tree is very proper to intermix with ever-greens of a second size next to pines and firs, to form clumps; in which class it will keep pace with the trees of the same line, and be very handsome. Besides, the wood of this tree is very valuable, when grown to a size fit for planks; which I am convinced it will do, in as short a space as oaks; therefore, why should not this be cultivated for that purpose, since there are many places in England where the soil is of a sandy or gravelly nature, and seldom produces any worth cultivating? Now, in such places these trees would thrive wonderfully, and greatly add to the pleasure of the owner, while growing, and afterwards render as much profit to his successors, as perhaps the best plantation of oaks; especially should the timber prove as good here, as in the islands of the Archipelago, which I see no reason to doubt of: for we find it was so gainful a commodity to the island of Candia, that the plantations were called Dos Filiæ; the felling of one of them being reckoned a daughter's portion.

The timber of this tree is said to resist the worm, moth, and all putrefaction; and is said to last many hundred years. The doors of St. Peter's church at Rome were framed of this material, which lasted from the great Constantine to pope Eugenius IV's time, which was eleven hundred years, and were then found and intire, when the pope would needs change them for gates of brass. The coffins were made of this material, in which, Thucydides tells us, the Athenians used to bury their heroes; and the mummy-chests, brought with those condited bodies out of Egypt, are many of them of this material.

This tree is by many learned authors recommended for the improvement of the air, and a specific for the lungs, as sending forth great quantities of aromatic and balsamic scents; wherefore many of the ancient physicians of the eastern coun-

tries

tries used to send their patients, who were troubled with weak lungs, to the island of Candia, which at that time abounded with these trees, where, from the effects of the air alone, very few failed of a perfect cure.

CU'RRAN-*tree*, *ribes*, in botany, a genus of plants, whose characters are:

It hath no prickles; the leaves are large; the flower consists only of five leaves, which are placed in a circular order, and expand in form of a rose: the ovary, which arises from the center of the flower cup, becomes a globular fruit, which is produced in bunches.

All sorts of Curran-trees may be easily propagated by planting their cuttings, any time from September to March, but the autumn is the best, upon a spot of fresh earth, which, in the spring, must be kept very clear from weeds; and in very dry weather, if they are watered, it will greatly promote their growth. These may remain two years in the nursery; during which time, they must be pruned up for the purposes designed, i. e. either to clear stems, if for standards; or, if for walls, pales, or espaliers, they may be trained up flat.

Then they should be planted out where they are to remain; the best season for which is soon after the leaves begin to decay, that they may take root before winter, so that they may be in no danger of suffering from drought in the spring.

These plants are generally planted in rows about ten feet asunder, and four distance in the rows; but the best method is to train them against low espaliers, in which manner, they will take up much less room in a garden, and their fruit will be much fairer.

The distance they should be placed for an espalier, ought not to be less than ten or twelve feet, that their branches may be trained horizontally; which is of great importance to their bearing.

Those that are planted against pales or walls, should also be allowed the same distance; if they are planted against a south-east wall or pale, it will cause their fruit to ripen, at least a fortnight or three weeks sooner than those in the open air; and those which are planted against a north wall or pale, will be proportionably later, so that by this method the fruit may be continued a long time in perfection; especially if those against the north pales are matted in the heat of the day.

These plants produce their fruit upon the former year's wood, and also upon small snags which come out of the old wood; so that, in pruning them, these snags should be preserved, and the young shoots shortened in proportion to their strength. The only method, very necessary to be observed in pruning them, is, not to lay their shoots too close, and never to prune their snags to make them smooth: this, with a small care in observing the manner of their growth, will be sufficient to instruct any person how to manage this plant, so as to produce great quantities of fruit.

These plants will thrive, and produce fruit, in almost any soil or situation, and are often planted under the shade of trees; but the fruit is always best when they are planted to the open air, and upon a dry soil. *Miller's Gard. Dict.*

CU'RRIERS, mechanics, or artificers, who prepare, after the tanners, the leather chiefly used for the upper parts of shoes and boots, saddles, &c. a pretty hard, dirty business, though not numerous, but profitable.

They take with an apprentice ten or fifteen pounds, and pay a journeyman fifteen shillings a week, who work from six to eight. To set up a master, it will take from 200 to 500 pounds; and some of them are also leather-cutters.

They were a brotherhood in the year 1367, in the reign of king Edward III, and were not incorporated into a company, till 1605, by James I. Livery fine 9 l. 13 s. 4 d.

Their hall is over-against London wall, near Cripplegate; and their court-day on the Saturday next after quarter-day.

Arms. Sable, a cross ingrailed or, between four pair of sheaves in saltier argent.

Motto. Spes nostra Deus: God is our hope.

CUT-*water*, the sharp part of the head of a ship below the beak. It is so called, because it cuts or divides the water before it comes to the bow, that it may not come too suddenly to the breadth of the ship, which would retard her.

CU'TLERS, artificers, whose business is making, forging, tempering, in which part some have been remarkably famous, and mounting all sorts of knives, razors, sheers, scissars, surgeons instruments, and sword-blades; but making the hilts is a different trade; and, formerly, cutlery was divided into blade-smiths, haft-makers, and sheath-makers.

It is an ingenious branch of the smithery, and not hard work; many Cutlers also keep handsome shops, and deal in divers other things, as buckles, buttons, canes, &c. though not very numerous.

They take with an apprentice ten or fifteen pounds, who must work from six to nine: of journeymen there are but few, and about fifty pounds will make a master of him; but many shopkeepers employ a great deal more.

They were incorporated into one joint company in the year 1417, in the reign of king Henry V. Livery fine 10 l.

Their hall is in Cloak-lane, or Dowgate-hill, Thames-street; but their court-day uncertain.

Arms. Gules, six daggers in three saltier crosses argent, handled and hilted or, pointing toward the chief.

Motto. Pour parvenir à bonne foy: to arrive at good faith.

CY'ANUS, *the blue-bottle*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the flosculous kind, being composed of a number of floscules; but these of two different kinds: those which stand in the middle of the flower are small, and divided into a number of equal segments; but those placed nearer the edges are much larger and more conspicuous, and are, as it were, bilabiated: both kinds, however, are placed on the embryo's, and all are contained together in a general cup, which is scaly, and not prickly. The embryo's afterwards become seeds winged with down.

CY'BELE, generally called the mother and grandmother of the gods, was by the ancients thought to be Saturn's wife; they called her Ops, Rhea, Dyndimene, Berecynthia, Good-goddess, &c. They represented her crowned with towers, with a key in her hand, and clad in flowered stuff, placed upon a chair drawn by four lions. The pine-tree was consecrated to her; after Atis, whom she loved so well, was metamorphosed into it. Her priests were eunuchs, and they, as well as their sacrifices, are laughed at by Tertullian in his Apologetic. The pagan divinity, which always conceals some natural truth in its fabulous mysteries, teacheth us, that this goddess called Cybele, either from the mountain of this name, whereon she was sacrificed to, or from the word cube, was the earth which produces all things; and it was for this reason she was called the great mother. Her crown of towers and cities represents what the earth is covered with. The key she holds in her hand, implies that she locks up all her fruitfulness during winter, which in the spring begins to appear, and then it is said the earth opens. This painted or flowered garment can become nothing so well as the earth, which is variegated with all kinds of flowers. The four beasts that draw the chariot, mark the four seasons of the year, wherein the earth appears so differently. Some take them for the four qualities of the earth, the four elements, four cardinal winds. And, if the ancients had known the four parts of the world, they might have been compared to them. In fine, Saturn, which signifies time, is believed to be the earth's husband, to shew that it must have time to bring forth its productions. Eusebius believes with Diodorus Siculus, that Cybele was a woman who had very good remedies for young children, and that the ancients had all their philosophy from this source. *Eusebius, Diodorus.*

CYCLA'MEN, *sow-bread*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, and is globose, and of a rotated form, and usually divided into five segments, which all bend upwards; from the cup there arises a pistil, which is fixed, in the manner of a nail, to the hinder part of the flower, and afterwards becomes a roundish membranaceous fruit, which contains numerous seeds, usually of a longish figure, and angular, and fixed to a placenta.

There are several species of this plant cultivated in gardens, for the pretty appearance of its flower: they are propagated by the curious from seed, in the manner of the xyphium. See XYPHIUM. But they are four or five years before they come to flower, and, for the first year or two of their flowering, their roots are so small, that the flowers they produce are but few: the roots, however, annually increase in bulk, and the number of flowers increase in proportion, so that they will grow to fourteen inches in diameter, and, when of this size, will produce upwards of an hundred flowers in one season. The best season for transplanting these roots is in June and July, soon after the seed is perfected; but they should not be kept long out of the ground, for the roots are disposed to shoot out fresh fibres, with the first moist weather after the seeds have fallen, and in about six weeks produce their flowers, which appear upon long single footstalks before the leaves appear: these sprout up after the flower is fallen, and remain green all the winter, and being of a fair green, and spotted in the middle with white, they make a very pretty appearance during that dead season. The pedicle of the flower afterwards twists like a skrew, inclosing the embryo of the fruit, which is buried among the leaves, and, by that means, screened from the severity of the winter, and ripens its seed in June. *Miller's Gard. Dict.*

CY'CLE, *Chinese*, a period of 60 years, whose use had some relation, or at least resemblance, with that of the olympiads, indictions of the solar and lunar cycles, or the golden number. This cycle is composed of ten repeated letters, and twelve Chinese characters that mark the hours. Each year is distinguished by a letter and chifre, continuing until they come to a year that has the first letter and chifre, which is the 60th. These Cycles have their perpetual revolution from sixty to sixty years, and are very certain rules for chronology; for, marking the number of the Cycle with the letter and chifre of the year, they give an infallible knowledge of the time a thing is done in. As, for example, in saying 1 Cycle K. 2,

K. 2, I mark the 50th year of the firft Cycle, which begins the year 2697 before Chrift's birth; fo that the 50th year of this Cycle is the 2648th before the Meffias, which is known by fubtracting 49 from 2697. *Couplet. Confucius.*

CY'DER.—Under the article CIDER, in the Dictionary, we have given its chemical analyfis, and ufes; we fhall here give the method of making this liquor.

As it has been thought neceffary, in every part of England, to lay the harder Cyder-fruits in heaps for fome time before breaking their pulps, the Devonfhire people have much improved the practice; in other counties the method is to make thefe heaps of apples in a houfe, or under fome covering inclofed on every fide; this method we found defective, becaufe, by excluding the free air, the heat foon became too violent, and a too great perfpiration enfued, by which, in a fhort time, the lofs of juices was fo great, as to reduce the fruit to half their former weight, attended with a general rottennefs, rancid fmell, and difagreeable tafte. In the South-Hams, a middle way has been purfued to avoid the inconveniences and lofs attending the aforementioned practice; they make their heaps of apples in an open part of an orchard, where, by the means of a free air and lefs perfpiration, the defired maturity is brought about, with an inconfiderable wafte of the juices and decay of the fruit, intirely free of ranknefs; and, though fome apples rot, even in this manner, they are very few, and are ftill fit for ufe; all continue plump and full of juices, and very much heighten the colour of Cyders, without ill tafte or fmell.

In purfuing the Devonfhire method, it is to be obferved,

1. That all the promifcuous kinds of apples that have dropped from the trees, from time to time, are to be gathered up and laid in a heap by themfelves, and to be made into Cyder after having fo lain about ten days.

2. Such apples as are gathered from the trees, having already acquired fome degree of maturity, are likewife to be laid in a heap by themfelves for about a fortnight.

3. The latter hard fruits, which are to be left on the trees till the approach of froft is apprehended, are to be laid in a feparate heap, where they are to remain a month or fix weeks, by which, notwithftanding froft, rain, &c. their juices will receive fuch a maturation, as will prepare them for a kindly fermentation, and which they could not have attained on the trees by means of the coldnefs of the feafon.

It is obfervable, that, the riper and mellower the fruits are at the time of collecting them into heaps, the fhorter fhould be their continuance there; and, on the contrary, the harfher, immaturer, and harder they are, the longer they fhould reft.

Thefe heaps fhould be made in an even and open part of an orchard, without any regard to covering from rain, dews, or what elfe may happen during the apples ftaying there, and, whether they be carried in and broke in wet or dry weather, the thing is all the fame; if it may be objected, that, during their having lain together in the heap, they may have imbibed great humidity, as well from the air, as from the ground, rain, dews, &c. which are mixed with their juices; the anfwer is, this will have no other effect than a kindly diluting, natural to the fruit, by which means a fpeedier fermentation enfues, and all heterogeneous humid particles are thrown off.

It is a conftant practice, in the Ifles of Jerfey and Guernfey, to put a pail of water into every fermenting hogfhead of Cyder, to dilute and fet its parts more quickly at liberty.

By purfuing the above methods, befides making the beft Cyder, hurry and expence will be prevented, as they require no room within doors.

Among other improvements in Cyder-making, the people in Devonfhire have been fuccefsful in their invention of an engine, which leaft bruifes the fkin, pulp, and kernels of the apples; for fuch as leaft do fo are to be preferred, becaufe from an immoderate breaking of them, in fome kinds of apples, there proceeds fuch an aufterity and bitternefs, as the Cyder never can be cured of.

To evince, that there is fuch aufterity attending the fkins or rinds of fome particular fruits, the pear called the winter rouffelit is an inftance; this fruit, when the fkin is taken off, is in efteem at the table, but without this treatment it has fuch a roughnefs as renders it uneatable.

The engine I here recommend is worked by coggs and rounds, which turn two or more tumblers ftuck full of teeth. In fome places it is worked with horfes, but, where moderate quantities of Cyders only are made, it it worked by hand. I forbear a further defcription of it, fuppofing it to be at prefent in ufe where-ever Cyder is made in the different counties in England. Its further excellencies are, it quicker difpatches the work; the pummice of the apples, broke therewith, produces lefs foul Cyder when it comes from the wring, alfo much fooner, and it certainly becomes fine after; and is lefs liable to harfhnefs and ill taftes in the vat and cafks, than what is broken by any other engines.

The pummice of the apples is to be received into a large open-mouthed veffel, capable of containing as much thereof as is fufficient for one making, or one cheefe. Though it has been a cuftom to let the pummice remain fome hours in the veffel appropriated to contain it, yet I would by no means advife the practice; for if the fruits did not come ripe from the trees, or otherwife matured, the pummice, continuing in the vat too long, will acquire fuch harfhnefs and coarfenefs from the fkins as never to be got rid of; and, if the pummice is of well-ripened fruit, the continuing too long there will occafion it to contract a fharpnefs that very often is followed with want of fpirit, and pricking, nay, fometimes it becomes arrant vinegar, or always continues of a wheyifh colour; all which proceeds from the heat of fermentation that it almoft inftantly falls into on lying together; wherefore I recommend, that the pummice remain no longer in the vat, than until there may be enough broke for one preffing, or that all be made into a cheefe, and preffed the fame day it is broken.

Of all the preffes now in ufe throughout the kingdom, there is none to be compared to the great wring or prefs with two fcrews, worked or brought home with a capftan, either for a quicker difpatch of the work, as frequently a cheefe or cake is made that produces a tun and half of Cyder, or for preffing dry, and keeping the cheefe upright and together, or with more eafe, as it requires but two men to work it.

A defcription of fuch a Cyder-prefs, and its feveral parts. See the *Plate* XV. *fig.* 12.

The great or upper beam, in which are female fcrews, fhould be feventeen feet four inches in length; and two feet fix inches or three feet fquare, either of one folid piece of timber or more; when formed of feveral pieces, they fhould be firmly united with wooden keys, and bound about with iron braces, near and on each fide each hole where the fcrew paffes.

The whole length of the pieces, out of which each fcrew is is to be formed, ought to be fourteen feet fix inches, viz. ten feet the fhaft of the fpiral line, or fcrew. Two feet the fquare part, containing the holes for letting in the hand-fpikes for turning the fcrews, and two feet fix inches for the fpindle.

The fpindle of the fcrews, which fhould have the fame diameter as the ftem of the fpiral line, muft be let into fockets made in a large beam of equal dimenfions with the upper beam. This great beam is to reft on the floor. The diftance between the fcrews fhould be eleven feet ten inches.

The reafon for leaving the upper and under beam fo long on the outfide of each fcrew, and the fpindles, is, to give the ends of the beams more ftrength, as the fcrews and fpindles otherwife would be apt to make the ends open.

The holes for admitting hand-fpikes fhould be quite through, one hole above another, that the fcrews may be turned with two hand-fpikes at the fame time.

The holes fhould be guarded by two iron plates to prevent their wearing, which fhould be faftened with two iron bands, bracing round that part of the fcrew, and neceffary to ftrengthen it.

The buckler, which is to cover the top of the cheefe or cake, is an affemblage of thick planks, united and ftrengthened by fubftantial traverfe pieces of eight inches fquare, to which the planks are faftened by oak pins. On the traverfe pieces are laid two floors of blocks of wood, each croffing one the other, on which depends the upper beam.

The buckler is fometimes made round, and fometimes fquare; in the dimenfions of either, great allowance muft be made for the fpreading of the cheefe or cake, when very much preffed. The round buckler may be fomething more in diameter than five feet, and the other five feet fix inches fquare.

The floor of the prefs may be compofed of elm planks, three inches thick and feven feet fquare, joined together by fubftantial traverfe pieces of eight inches thick or fquare, placed about the diftance of one foot from each other, to which the planks of the bafon are faftened by oak pins. Every part fhould be very firm and well connected, as the floor muft refift a very great force and preffure, when the upper beam is fcrewed down upon the cheefe.

The floor is to be borne up to the heighth of two feet fix inches from the ground, and fupported partly by the under beam, where are fpaces to be cut for letting down the traverfe pieces of the bafon, and partly by blocks of wood, or ftillings laid under it for that purpofe; there muft be care in fixing the bafon, that every part bears equally on each other.

Between the fcrews and the bafon, on each fide, will be a fpace of two feet clear, for a paffage round the bafon, except where the under beam croffes.

The ftage or bafon is to be floped with a gentle declivity from the feat of the cheefe to a groove or gutter, which is made near the edges of the bafon, to convey the expreffed juice of the apples into a veffel fixed under the middle of the fore part of the bafon.

Befides this groove or gutter, there muft be a ledge nailed round

round the sides of the bason, to prevent the Cyder from overflowing the bason, which it will be apt to do on the first pressing.

In fixing the bason on stillings or blocks, it should be observed, that it stoops a very little on the fore part, that the Cyder might tend that way in draining from the cheese.

The capstan is placed at about twelve feet distance, more or less, from one of the screws, and is made use of after two men, or more, have used their utmost efforts to screw down the great beam; then they have recourse to the capstan, by which they screw down the great beam something lower, and the Cyder runs a-fresh, and the cheese is squeesed quite dry.

The length of the capstan depends, as does its distance from the screw, on the conveniency of fixing a beam for taking in the upper spindle; it ought to be eight or ten feet; the under spindle is let into a socket made in a square block of wood sunk into the ground. It ought to be so large as not to be apt to start.

The end of the rope which is round the capstan is fastened to the end of a hand-spike which is in a hole of the screw, and the capstan turned till the hand-spike is brought so near the capstan as to have no more purchase; then the hand-spike is put into another hole, and the same repeated. The capstan is turned by poles of about twelve feet in length, run through the square, or holes of the capstan, and form a cross. These poles are fixed about two feet ten inches above the floor, which should be considered when the capstan is making, that the square and round parts of it may have proper situations.

This press requires a spacious house for its reception, which is the only inconvenience that attends it. Other presses may be commodious enough for making small quantities of Cyder; but this is necessarily required where it is made in abundance.

As the Cyder runs from the wring or press, it is to be received into a vessel fixed within the ground for the more commodious dipping of a ladle or bucket, and, as it fills, from time to time, to be taken from thence and put into another vessel or cask that stands on its bottom, the head being struck out, over the top of which, is to be laid a-cross a frame, or two simple sticks, a coarse hair sieve for straining the Cyder, that the pummice, or grosser part of the pulp of the apples, mixed with the juice, may be kept back.

I would caution every one against mixing the last expressed juices or droppings with the Cyder intended for keeping, because it is of too weak a nature; but yet it makes a pleasant beverage, by which name it is known in Devonshire, and, if assisted with a small quantity of spices, will continue good two months. If it could be had in summer, or would keep so long, it would serve as an agreeable, cool, refreshing liquor.

I come now to treat of that, on which the whole success depends, in making sweet Cyder, viz. fermentation, which is attended with no manner of difficulty; but care and watchfulness is absolutely required, and to be well furnished with clean casks in proper readiness.

In order to avoid a great deal of trouble, and to perform the work more effectually, by divesting the new made Cyder of what pummice and other impurities remain; after straining it through a hair sieve, on its coming from the wring, or press, it is necessary to be provided with a large open vat, keeve, or clive, which will contain a whole pounding, or making of Cyder; or as much as can be pressed in one day: after the Cyder has remained in this vat a day, or sometimes less, according to the ripeness of the fruit, of which it has been made, and the state of the weather, you will find rise to the top the pummice, or grosser parts of the pulp, &c. of the apples; and in a day or two more, at most, grow very thick; and when little white bubbles or fermentations, of the bigness of the top of your finger, break through it, then presently draw it off through a cock or faucet-hole, within three inches of the bottom, if large; but, if small, not nearer than four inches of the bottom, that the lees may not be drawn off, but quietly remain behind.

If the Cyder is not immediately drawn off, on the first appearance of these white fermentations, all the head which is then become a thick crust, will sink to the bottom; so that, if this crisis, which happens but once, of the first separation of the Cyder from its lees is neglected, the opportunity of making sweet Cyder will be lost and irrecoverable.

On drawing off the Cyder from the vat, it must be tunned into close casks well scented, wherein, on letting it remain a shorter or longer time, with what lees and impurities it carried with it, depend the hardening or softening it at pleasure.

To have Cyder perfectly sweet, after it is tunned into close casks, you are again carefully to watch and observe its state, and when you find white bubbles or fermentations, as aforesaid, at the bung-hole, as before in the vat, immediately rack it off again into another clean and well scented cask; after which, by making frequent trials of its fineness (and it commonly happens to be fine in two, three, four, or five days, or sooner, according to the weather) by drawing some of it into a glass from a spile-hole, you will discover if proper to repeat the racking, which should again be immediately done, if found to be fine; which repetition of racking should be continued till the Cyder is as sweet as you desire, and ceases hissing.

It is to be noted, that the weaker Cyders cannot support themselves under many rackings, one or two being all they can bear, for they have not body enough to undergo the operation. But, as to the bolder and stronger Cyders, when you intend to render them very soft and mellow, and perfectly sweet, which these frequent rackings will effect, you may repeat them till they are brought to your palate, and quieted to such a degree as to be entirely mute, which is an infallible indication of their being absolutely free of impurities, and not liable to be troubled by any future commotions.

The manner of making rough Cyder differs from that of the sweet, as it is necessary to refrain drawing it off, on the first appearance of the white bubbles, as before mentioned; but, letting that crisis pass unregarded, do it on the next tolerable separation from the fouler and thicker lees, by which a luscious sweetness will be avoided. But, even in rough Cyder, the omission of one or two rackings is attended with a disagreeable coarseness, harshness, bitterness, fetidness, and sometimes with all these faults, which it can never be divested of. Wherefore I would propose, after racking out of the vat, to give it another clarification, at the end of November or December, if made very late.

There must be care taken, after the fermentation is over, to fill every hogshead in the cellar up to the bung, which is to be continued once a month, and without which the Cyder will be apt to grow flat and heavy, and likewise to contract an ill taste and smell, from an ingendered rancid air lodged in the cavity between the upper part of the cask and the Cyder. Vent should be sometimes given at a spile-hole during the first three months after the Cyder is made. Until it has done hissing, &c. the bung-hole would be best covered with a tile, slate, or flat stone, but, when found to be perfectly quiet, it should be closely bunged down. *Treatise on Cyder-making.*

Pepin CYDER. This is a sort of Cyder which, in many places, might be made in great quantities, where the red-streak Cyder-apple will not thrive: the harshness that is apt to be in this sort of Cyder, is the only objection to its value, it being of a good body, and otherwise, in all respects, commendable. The great reason of this harshness is the light foulness; or, as the Cyder people express it, the flying lee that always is in this sort. But it is easy, by watching a proper time, to draw of the liquor from this into other vessels, or to strain it through a cloth: in either case, much of the lee will be left out, and the Cyder lose its harshness. *Phil. Trans.* N°. 70.

CYDER-*spirit*, a spirituous liquor drawn from Cyder by distillation, in the same manner as brandy from wine. The particular flavour of this spirit is not the most agreeable, but it may, with care, be divested wholly of it, and be rendered a perfectly pure and insipid spirit, upon rectification. The traders in spirituous liquors are well enough acquainted with the value of such a spirit as this: they can give it the flavours of some other kinds, and sell it under their names, or mix it in a large proportion with the foreign brandy, rum, and arrack, in the sale, without danger of a discovery of the cheat.

CYDO'NIA, *the quince-tree*, a genus of trees whose character are:

The tree is of a low stature: the branches are diffused and crooked: the flower and fruit are like that of the pear-tree; but, however cultivated, the fruit is sour and astringent, and is covered with down. See *plate* XVIII. *fig.* 1. where *a* is the blossom, *b* the fruit, *c* the fruit open, *d* the seed.

All sorts of quince-trees are cultivated in most nurseries near London; but the Portugal kind is most valued for the goodness of its fruit.

They are all easily propagated, either by layers, suckers, or cutings, which must be planted in a moist soil. Those raised from suckers are seldom so well rooted as those which are obtained from cuttings or layers; and are subject to produce suckers again in greater plenty, which is not so proper for fruit-bearing trees. The cuttings should be planted early in the autumn, and in dry weather must be often watered to encourage their rooting. The second year after, they should be removed into a nursery at three feet distance row from row, and one foot asunder in the rows; where they must be managed as directed for apples. In two or three years time, these trees will be fit to transplant, where they are to remain for good; which should be either by the side of a ditch, river, or in some other moist place; where they will produce a greater plenty, and much larger fruit than in a dry soil; though those in the dry soil will be better-tasted, and earlier ripe. *Miller's Gard. Dict.*

CYLINDER *(Dict.)* — The ingenious Mr. Francis Blake, in the forty-seventh vol. of the Philosophical Transactions, has considered what are the best proportions for steam engine Cylinders, which, we presume, will not be unacceptable to the reader.

 The

Printed for J. Hinton in Newgate Street.

The fire-engine, or (to term it more properly) the ſteam-engine, for draining of mines, is a maſter-piece of machinery, a very capital contrivance in the work of art, and meriting our attention for further improvements. This is univerſally allowed, as well upon account of the theory it is founded on, as its uſefulneſs in practice. And is it arrived then at the laſt degree of perfection, that we appear at a ſtand? I think not. The prodigious veſſel of water to be kept always boiling, when only an inconſiderable part of it is employed in the work, favours too little of the frugality of nature, which we ought ever to imitate. But, waving that now, what I would inquire into here, and endeavour to regulate, is, the Cylinder's proportion of the altitude and baſe; which hath not, as I know of, been hitherto noticed.

It is evident, in the firſt place, from a fundamental law of mechanics, that, the content of the Cylinder remaining the ſame, the quantities of water diſcharged at each lift will in all caſes be equal, by only changing the diſtance of the center of the piſton from the fulcrum of the balance. You will agree likewiſe (for I ſuppoſe the principles and working-part to want no deſcription) that the exceſs of the pillar of the atmoſphere above that of the water is a weight on the piſton, driving it to a depth of five feet, or thereabouts, by the preſent conſtruction, with the cavity of the Cylinder; acceleratedly till friction and an impediment from the ſteam, which remains in the Cylinder even after the jet d'eau, and is increaſed in elaſticity, whilſt its bounds are diminiſhed, ſhall equal the accelerative force; and that then again the piſton is retarded the reſt of the way. It may be convenient to remark too, that, if the rarefaction be ſo complete, that the deſcent would be greater than the conſtruction admits of, the retardation is augmented by a brachium of the balance preſſing upon ſprings. But, to ſay nothing of friction here, we can, notwithſtanding this diminution of force by the remainder of ſteam within the cavity of the Cylinder, demonſtrate the ratio of the velocities, and the times of deſcent of the piſtons, in Cylinders of unequal altitudes, to be exactly the ſame, as if the reſiſtance was nothing; whence we ſhall without difficulty arrive at ſome concluſion in this matter.

M N (*plate* XVII. *fig.* 8.) is the working-part of a ſteam-engine Cylinder, of the uſual height, equal in diameter to a ſhorter one *m n*, *fig.* 9; and, the rarefaction in both being ſuppoſed the ſame, $AQ = aq$, $RQ = rq$, and $AR = ar$, may repreſent the exceſs of the atmoſphere's weight above the pillar of water, the reſiſtance to the piſtons from the remainder of ſteam, and the effective force, reſpectively, *e. g.* at the beginning of the deſcent. Take, then, every-where $ak : AK :: an : AN$, and at all ſimilar poſitions the reſiſtance *b c* of *m n* and the force *k c* on its piſton will equal the reſiſtance B C of M N and force K C on its piſton; and, by what Sir Iſaac Newton has demonſtrated (Book I. Prop. 39.) of the deſcent of bodies, we have $\sqrt{akcr} : \sqrt{AKCR} ::$ celerity in *k* : celerity in K. But, theſe areas being evidently as the correſponding parallelograms *k q* and K Q, and they again as their heights, the celerities generated are in the ſubduplicate ratio of $ak : AK$, as though the reſiſtance had been nothing; and, by an obvious enough reaſoning from the ſaid propoſition, the times alſo appear to be in the above-mentioned ratio; which ratio is not any way varied, though the reſiſtance prevails from the interſecting points O.

Now, to apply what has been ſaid to the buſineſs in hand; if T W be a Cylinder of equal content with the Cylinder M N, the quantity of water delivered by both will, as a conſequence of the fundamental law of mechanics obſerved above, be the ſame at each lift: but the Cylinder T W is no higher than *n m*, and, ex hypotheſi, their rarefactions are equal; and therefore, by what has been proved with regard to the times, the time of the piſton's deſcent in T W will be to that of the piſtons deſcent in $MN :: \sqrt{EW} : \sqrt{AN}$; whence, in any given time, the broad Cylinder T W will perform more than the longer one M N of equal content, and that in the ratio of their diameters; for $\overline{ET}|^2 \times EW = \overline{MA}|^2 \times AN$, ex hypotheſi, $EW : AN :: \overline{MA}|^2 : \overline{ET}|^2$, and, conſequently, $\sqrt{EW} : \sqrt{AN} :: MA : ET$. The friction too is diminiſhed with the ſlowneſs of the motion, and becauſe the periphery increaſes, in a leſs ratio than does the area of a circle.

The reſult of the whole then is in favour of the broad Cylinder; and ſtill the broader the better; for, unleſs ſome mechanical conſiderations ſhould limit the problem, it is evident in a geometrical ſenſe, that there is no limitation. A diſadvantage might ariſe perhaps to the effect of the jet d'eau from thus increaſing the breadth; which however would be remedied, I think, by a number of theſe jets: but, be that as it will, it is certain, that to augment the diameters, and diminiſh the lengths of the ſmaller kind of Cylinders, now uſed, could have no ſuch inconvenience, nor fail of being attended with an augmentation of force.

CY'LINDRUS, in conchyliology, the name of a genus of ſhell-fiſh, of which there are many very elegant and precious ſpecies. This genus is more generally, at preſent, called rhombus, though this is very improper, the word Cylindrus very aptly expreſſing the ſhape of the ſhell, which is cylindric and oblong; and the rhombus, which ſignifies that figure we call a lozenge, not being at all expreſſive of it.

CY'PRESS-*tree.* See CYPRESSUS.

CYST, in ſurgery, the bag, or membrane, in which an encyſted tumor of the ſteatomatous, atheromatous, or ſarcomatous kind, is included. In the extirpating theſe tumors, if, by neglect, or accident, the Cyſt, or any conſiderable part of it, be left behind, the tumor will not fail to return. Indeed, if the tumor be a ſchirrus, the contents are hard enough to make a clear extirpation of it, notwithſtanding its including coats be wounded: but, when the matter of the tumor is ſoft, or fluid, by its eſcaping the tumor will be come flaccid; ſo that it will be hardly poſſible to make a clear extirpation of the Cyſt, without leaving ſome fragments of it behind, which muſt, in that caſe, be brought away afterwards by ſuppuratives, digeſtives, and a proper treatment; and, when the ſinus is by this means cleared, the wound may be ſafely healed, without any danger of the return of the complaint. *Heiſter's Surgery.*

CY'TISUS, *ſhrub trefoil*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the papilionaceous kind; from its cup there ariſes a piſtil, which finally becomes a flat pod, which ſeparates, when ripe, into two parts, and is full of oblong ſeeds. The leaves ſtand three on every ſtalk.

We have ſeveral ſpecies of this plant cultivated in the gardens of the curious, where ſome ſpecies make a very agreeable figure, as they grow to be eight or ten feet high, and in May are beautifully loaded with long ſtrings of yellow flowers.

They are all propagated by ſowing their ſeeds, which they afford in great plenty, in March, on a bed of good, freſh, light earth, ſifting over the ſeeds about half an inch of fine mould: in a month's time the plants will come up; they muſt be kept clear from weeds, and watered at times, if the ſeaſon prove dry. They ſhould remain in the ſeed-bed, till the March following, when they ſhould be removed into nurſery beds of a foot diſtance, in rows three feet aſunder: here they muſt be watered, and the roots mulched till they are thoroughly rooted, and then the ground kept clear from all weeds. They ſhould remain here three years, and be then removed to the places where they are to remain, in October, or elſe in February.

The ancient botaniſts evidently were acquainted with two very different ſhrubs, under the name Cytiſus; and there have been no ſmall errors about the true meaning of ſeveral paſſages in Dioſcorides and Theophraſtus, on occaſion of the miſtaking one of theſe things for another.

Dioſcorides deſcribes the Cytiſus, as being a ſhrub with leaves white and hoary, both on the upper and under ſide, and of no uſe, or value, to mankind: as to its wood, Pliny tranſlates this account, and adds to it from Hyginus, that it was a very hardy and ſtrong ſhrub, not being affected by heat, or cold, ſnow, or hail, or any other injuries of the weather, nor of its enemies, as Pliny expreſſes it (hoſtium.) It is not very eaſy to conceive what enemies theſe ſhould be; but the moſt probable conjecture, as to this odd paſſage, is, that Pliny had tranſcribed it in his uſual careleſs way, and that what is called hoſtium ſhould be the word noſtrum.

The ſenſe then is clear enough; the author had juſt before ſaid that the wood was good for no uſe to mankind; and therefore, when he was ſpeaking of the trees ſtanding a long time, and fearing the injuries of no weather, he might very well add, nor of us; for, the wood being good for nothing, men would not be at the trouble of cutting it up. It is plain, however, that Theophraſtus means quite a different ſhrub by this name Cytiſus; for as Dioſcorides ſays that the wood of his was white throughout, and very light, Theophraſtus obſerves, that it was black at the heart, and as heavy and ſolid as ebony; and, in many places, where he ſpeaks of the hard and elegant woods uſed for inlaying, he mentions the Cytiſus wood, coupling it with the ebony, heart of oak, and other the hardeſt and moſt elegant woods known in his time. Pliny mentions no other Cytiſus than that of Dioſcorides, which was the common kind cultivated by the Greeks and Romans, as a food for cattle: he ſays, it was raiſed by ſeed, and came to its perfection in three years, and that it was gathered in the ſpring juſt after the time of its flowering; he adds, that this was uſually the office of children, or old women, unfit for other work, and was the cheapeſt of all the offices of huſbandry. It is eaſy to conceive that ſuch a ſhrub as the Cytiſus of Theophraſtus, with a wood as firm as the heart of oak, and hard as ebony, did not come to perfection in three years from the ſowing; nor could any more be cut up by boys and old women, than eaten by cattle, when taken up. There were, therefore, two kinds of Cytiſus among the ancients, the one ſown and cultivated as food for cattle; the other a wild tree, or ſhrub, growing in woods, and being larger than the ſown kind. Dioſcorides and Pliny deſcribe the firſt, and Theophraſtus alone the latter, except that Pliny has now and then taken a ſentence from Theophraſtus, when he mentions the Cytiſus occaſionally among other hard woods, and placed it to the account of his manured Cytiſus.

D.

DAA'LDER, a name given by the Dutch to pieces of thirty sols, coined by them, and which are worth one florin, or guilder and half, being equivalent to the small French crown of three livres Tournois, or sixty sols. Formerly, according to the old rate of money in that kingdom, the Daalder went for thirty-seven sols, six deniers.

Daalders are coined also at Hamburgh, called Daalders, lups, or lubs, of two marks lubs each. It is worth from thirty-two to thirty-three sols of Holland, and from sixty-six to seventy sols in France. It is used as current money in many other cities of Germany, and in keeping their books of accounts. Formerly, they went for forty French sols. The Hollanders call also every sort of crown a Daalder, which is worth no more than thirty sols; they denominate them differently, viz. ryks Daalder, that is to say, an imperial crown.

DA'BAS, cloths and woollen stuffs of the manufacture of Bas in Languedoc, are so called at Lyons.

DA'BUIS, a white cotton stuff made in the East-Indies. It is in the number of baffetas, and takes its name from the place where it is made.

DACE, in ichthyology, the English name for the fish called by authors the leuciscus. According to the new system of Artedi, this is a species of the cyprinus; and it is called by some albicula and albicilla.

This fish is extremely common in our rivers, and gives the expert angler great diversion. The Dace will bite at any fly; but he is more than ordinarily fond of the caddis, or May fly, which is plentiful in the latter end of April, and the whole month of May. Great quantities of these may be gathered among the reeds or sedges by the water side, and on the hawthorn bushes near the waters. These are a large and handsome bait, but, as they last only a small part of the year in season, recourse is to be had to the ant-fly. Of these the black ones, found in large mole-hills or ant-hills, are the best. These may be kept alive a long time in a bottle, with a little of the earth of the hill and some roots of grass; and they are in season throughout the months of June, July, August, and September. The best season of all is when they swarm, which is in the end of July, or beginning of August; and they may be kept many months in a wooden vessel, washed out with a solution of honey and water, even longer than with the earth and grass roots in the phial; though that is the most convenient method to be taken with a small parcel, procured for one day's fishing. In warm weather this fish seldom refuses a fly at the top of the water: but, at other times, he must have the bait sunk to within about three inches of the bottom. The winter fishing for Dace requires a very different bait: this is a white maggot with a reddish head, which is the produce of the eggs of the beetle, and is turned up with the plough in great abundance. A parcel of these put in any vessel, with the earth they were taken in, will keep many months, and are excellent bait.

Small Dace may be put into a glass-jar with fresh water, and there preserved alive a long time, if the water be properly changed. They have been observed to eat nothing but the animalcula in the water. They will grow very tame by degrees. See *Philos. Trans.* N°. 478.

DA'CZAJIE, a silver money current in Persia, worth five mamoudis; two Daczajies make the hasaer denarie.

DA'ILS. See DOTTLE *Fish*.

DA'LLE, a nominal money, used in keeping books of accounts in many cities of Germany: it is worth thirty-two sols lubs, which make forty French sols; the sol lubs being somewhat more than the sol Tournois.

DAMASQUE'TTE, a kind of stuff made at Venice, that sells well in the Levant, particularly at Constantinople.

There are two sorts of it; one with gold flowers, the other with silk: the pieces are eighteen ells long. Those with gold flowers are somewhat like the gold and silver stuffs formerly made at Lyons.

DAMASSE', or *Petite Venise*, a kind of wrought linen made in Flanders, so called from the fashion of its large flowers, something like those of damasks: it is used chiefly for tables. A table-cloth and a dozen napkins of this, is called a damask service.

There is also a silk stuff so called, which looks like a damask on one side, and on the other is plain.

DAMPS (*Dict.*) — Naturalists furnish us with very surprizing instances of the effects of Damps. In the History de l'Academie des Sciences Anno 1701, we read of a well in the city of Rennes, into which a mason, at work near its brink, letting fall his hammer, a labourer who was sent down to recover it, before he reached the water, was strangled. A second, sent to fetch up the corpse, met with the same fate, and so a third: at last a fourth, half drunk, was let down, and charged to call out, as soon as he felt any thing incommode him. He called accordingly, as soon as he came near the water; and was instantly drawn out: yet he died three days afterwards. The information he brought them was, that he felt a heat, which scorched up his entrails. A dog, being let down, cried about the same place; and died as soon as he came to the air; but, throwing water on him, he recovered; as happens to those thrown into the Grotto del Cani near Naples. The three carcasses being drawn up with hooks, and opened, there appeared not any cause of their death.—Now, what renders the relation the more considerable, is, that the water of this well had been drawn, and drunk several years, without the least ill consequence.

In the same history, anno 1710, a baker of Chartres, having carried seven or eight bushels of brands out of his oven into a cellar thirty-six stairs deep; his son, a robust young fellow, going with more, his candle went out on the middle of the stairs; having lighted it a-fresh, he was no sooner got into the cellar, than he cried out for help; and they heard no more of him: his brother, an able youth, run immediately after him; cried out he was dead; and was heard no more. He was followed by his wife; and she by a maid, and still it was the same. Such an accident struck the whole neighbourhood with a panic; and nobody was forward to venture any farther: till a fellow, more hardy and zealous than the rest, persuaded the four people were not dead, would go down to give them help: he cried too and was seen no more. Upon this a sixth man, requiring a hook to draw some of them forth without going to the bottom, drew up the maid: who, having taken the air, fetched a sigh and died. Next day, the baker's friend, undertaking to get up all the carcasses with a hook, was let down with ropes on a wooden horse, to be drawn up, whenever he should call. He soon called, but, the rope breaking, he fell back again; and, though the rope was soon pieced again, he was drawn forth dead. Upon opening him, his meninges were found extravagantly stretched; his lungs spotted with black, his intestines swelled as big as one's arm, inflamed and red as blood; and, what was most extraordinary, all the muscles of his arms, thighs, and legs, torn and separated from their parts. The magistrate, at length, taking cognizance of the case, and the physicians being consulted; they gave their opinion, that the brands had been but ill extinguished: the consequence of which must be, that, as all the cellars in Chartres abound with saltpetre, the unusual heat in this had raised a malignant vapour which had done the mischief: and that a good quantity of water must be thrown in to put out the fire, and lay the vapour. This performed, a dog and a lighted candle were let down without injury to either: an infallible sign the danger was over.

A third history we shall add from Dr. Connor, in his Differt. Med. Phys. Some people digging in a cellar at Paris, for supposed hidden treasure; after a few hours working, the maid, going down to call her master, found them all in their digging postures, but stark dead. The person who managed the spade, and his attendant who shovelled off the earth, were both on their feet, and seemingly intent on their several offices: the wife of one of them, as if a-weary, was sat down on the side of a hopper, very thoughtful, and leaning her head on her arm; and a boy, with his breeches down, was evacuating on the edge of the pit; his eyes fixed on the ground: all of them, in fine, in their natural postures and actions, with open eyes, and mouths that seemed yet to breathe; but stiff as statues, and cold as clay.

The German miners think themselves not qualified for their business, if they are not able to make their weather, as they express it; that is, to cure their Damps. These are of various kinds in their mines; some so strong that they suffocate the workmen; others less violent, and only making them faint without doing them any farther hurt, unless they are so imprudent as to continue a long time in the place. The common way of curing the Damps is by letting the air in and out, and, causing a circulation in it, they sometimes have cured very considerable Damps by blowing, for many days together, with large bellows: but the ordinary method of working is by means of long tubes communicating with the air above, by means of which they have continual fresh air, and are able to work on, as far as they please: some of the cuniculi of these mines are five

five-hundred fathoms long; and, in the silver Trinity mine by Sebemnitz, there is a passage quite through a very large hill, coming out on the opposite side to that where it enters. The tubes always answer very well in the horizontal cuts; but not in the perpendicular ones, when they go to great depths: in these they place a tube all the way down by one side, and they then fit a piece of wood work to the size of the hole or cut; and several times in a day they are forced to thrust this down, in order to force up all the foul air that is in the pit by the tube, to give room for fresh air in its place. *Phil. Transf.* N°. 48.

In some of the coal-pits in the neighbourhood of Mendip-hills, fire Damps almost continually happen, so that great numbers have been killed, maimed, and burnt by them. The colliers however continue their work notwithstanding, only using the cautions of renewing their air very quick, and using no candles in their work but those of a single wick, and of sixty or seventy to the pound; which notwithstanding will give as good a light there, as others of ten or twelve to the pound in other places. They always have the caution to place even these behind them, and never present them to the breast of the work. When any person is burnt by these Damps, they presently betake themselves to a good fire, and, sending for a large quantity of cows-milk, they bathe the burnt places with this, while warm; and, afterwards, the places will heal by the common cooling ointments, and healing plaisters.

In regard to the periodical return of these Damps, mentioned by some, we find that, by the caution of small candles, used by the colliers of these places, there is a continual propensity in them to take fire at all times of the year; and, though these works seldom do take fire, yet, as the colliers say, they are most subject to it in the violence of winter, and chiefly in a black frost. The danger of firing is alike both in wet and dry grounds. There are no flames coming out at the mouth of any shaft in these places, which will take fire at lighted torches or candles being held over them. They sometimes take fire of themselves, and set fire to the coal of the mine: they seem to be as frequently on or near the floor of the pits, as about their roofs; and no current of vapours, or wind, is to be met with at the mouths of the shafts by which they go down to these pits. In wet works there are many times bubbles standing on the surface of the water, which will take fire, if a candle be held to them; but these, on a close examination, do not appear to be occasioned by subterraneous vapours; but are owing to the dropping of water from the roof of the mine, or the falling in of pieces of coal. These Damps are commonly observed in our coal pits; but the lead-mines on Mendip-hills are also sometimes affected by them. *Phil. Collect.*

DANK, or DANCK, a little piece of silver current in Persia, and some parts of Arabia. It weighs the sixteenth part of a drachm.

DANK, is also a little weight, used by the Arabians to weigh jewels and drugs, when these last are used in the composition of medicines. It is the sixth part of an Arabian drachm, which is eight grains French weight.

DARIA'BANIS, a white cotton stuff that comes from Surat.

DARI'DAS, a sort of India taffeta, made of silk drawn from plants.

DARNA'MAS, the best sort of cotton that comes from Smyrna, is so called, from a plain near that city, where it is cultivated in such great quantities, that, one year with another, 10,000 bales are bought, though at least as much more is consumed in the manufactures of the country.

DAU'CUS, *the carrot*, in botany, a genus of plants, whose characters are:

It hath, for the most part, a fleshy root: the leaves are divided into narrow segments: the petals of the flower are very unequal, and shaped like an heart: the umbel, when ripe, is hollowed and contracted, appearing somewhat like a bird's nest: the seeds are hairy, and in shape of lice.

Carrots are propagated at two or three different seasons, or sometimes oftener, where people are fond of young carrots through all the summer months. The first season for sowing the seeds is soon after Christmas, if the weather is open, which should be in warm borders, under walls, pales, or hedges: but they should not be sown immediately close thereto; but a border of lettuce, or other young sallad-herbs, of about a foot wide, should be next the wall, &c. for, if the carrots were sown close to the wall, they would run up to seed without making any tolerable roots.

They delight in a warm sandy soil, which is light, and should be dug pretty deep, that the roots may the better run down; for, if they meet with any obstruction, they are very apt to grow forked, and shoot out lateral roots, especially where the ground is too much dunged the same year that the seeds are sown, which will also occasion their being worm-eaten; it is, therefore, the better method to dung the ground intended for carrots the year before they are sown, that it may be consumed, and mixed with the earth.

These seeds have a great quantity of small forked hairs upon thin borders, by which they closely adhere, so that they are difficult to sow even, so as not to come up in patches; you should therefore rub it well through both hands, whereby the seed will be separated before its sown; then you should chuse a calm day to sow it; for, if the wind blows, it will be impossible to sow it equal; for the seeds, being very light, will be blown into heaps. When the seed is sown, you should tread the ground pretty close with your feet, that it may be buried, and then rake the ground level.

When the plants are come up, you should hoe the ground with a small hoe about three inches wide, cutting down all young weeds, and separating the plants to four inches distance each way, that they may get strength; and in about three weeks after, when the weeds begin to grow again, you should hoe the ground over a second time, in which you should be careful not to leave two carrots close to each other, as also to separate them to a greater distance, cutting down all weeds, and slightly stirring the surface of the ground in every place, the better to prevent young weeds from springing, as also to facilitate the growth of the young carrots.

In about three weeks or a month after, you must hoe them a third time, when you must clear the weeds as before; and now you should cut out the carrots to the distance they are to remain, which must be proportioned to the size you intend to have them grow: if they are to be drawn, while young, five or six inches asunder will be sufficient; but, if they are to grow large before they are pulled up, they should be left eight or ten inches distant every way: you must also keep them clear from weeds, which, if suffered to grow amongst the carrots, will greatly prejudice them.

The second season for sowing the seeds is in February, on warm banks situated near the shelter of a wall, pale, or hedge; but those which are intended for the open large quarters, should not not be sown before the beginning of March, nor should you sow any later than the end of the same month; for those which are sown in April or May, will run up to seed before their roots have any bulk, especially if the weather should prove hot and dry.

In July you may sow again, for an autumnal crop; and in the end of August you may sow some to stand the winter; by which method you will have early carrots in March, before the spring sowing will be fit to draw; but these are seldom so well tasted, and are often very tough and sticky. Many people mix several other sorts of seeds, as leek, onion, parsnip, radish, &c. amongst their carrots; and other plant beans, &c. but, in my opinion, neither of these methods are good; for, if there is a full crop of any one of these plants, there can be no room for any thing else amongst them; so that what is got by one is lost by the other; and, besides, it is not only more sightly, but better, for the plants of each kind to be sown separate; and also, by this means, your ground will be clear, when the crop is gone, to sow or plant any thing else; but, when three or four kinds are mixed together, the ground is seldom at liberty before the succeeding spring: besides, where beans, or any other tall growing plants, are planted amongst the carrots, it is apt to make them grow more in top than root; so that they will not be half so large as if sown singly without any other plants amongst them.

But, in order to preserve your carrots for use all the winter and spring, you should, about the beginning of November, when the green leaves are decayed, dig them up, and lay them in sand in a dry place, where the frost cannot come to them, taking them out from time to time as you have occasion for them, reserving some of the longest and straightest roots for seed, if you intend to save any; which roots should be planted in the middle of February, in a light soil about a foot asunder each way, observing to keep the ground clear from weeds; and, about the middle of August, when you find the seeds are ripe, you must cut it off, and carry it to a dry place, where it should be exposed to the sun and air for several days to dry; then you may beat out the seeds, and put it up in bags, keeping it in a dry place till you use it. This seed is seldom esteemed very good after the first or second year at most; but new seed is always preferred, nor will it grow when it is more than two years old. *Miller's Gard. Dict.*

DAZE, in natural history, a name given by our miners to a sort of glittering stone, which often occurs in their works; and, as it is an unprofitable substance, is one of those things which they call weeds. The word Daze takes in, with them, every stone that is hard and glittering; and therefore it comprehends the whole genus of the telangia, or stony nodules, which have flakes of talc in their substance: these, according to the colour of the stony matter they are bedded in, and their own colour, give the name of black Daze, white, red, and yellow Daze, to these stones. The Daze stones, in general, much resemble some of those nodules with which the streets of London are paved. But in some, instead of the matter forming regular nodules of a compact substance, it forms itself into a vast number of thin plates, which are applied closely over one another, and form shelves or even series of planes, encompassing, sometimes a roundish, sometimes an oblong mass of ore.

DEA'CONS (*Dict.*) — The name of Diaconi is as old as the Apostles time; but whether it was always used as it is now, for the third order of the clergy, is a matter of some doubt. It is certain, Ignatius stiles them ministers of the mysteries of Christ, and of the church of God: though the council of Trullo says, the seven Deacons, spoken of in the Acts, are to be understood only of such as served at tables, and attended the poor. But the whole current of antiquity runs against this notion, as well as Ignatius. Cyprian calls them ministers of episcopacy, and

and of the church; and ſays they were called ad altirias miniſterium, to the miniſtry and ſervice of the altar. Tertullian join them with biſhops, ſtiles them guides and leaders of the laity, and makes them, in their degree, paſtors and overſeers of the flock of Chriſt: and St. Jerom does the ſame in ſome places, though he ſpeaks more contemptuouſly of them in others.

But, though they were eſteemed a ſacred order, the name of prieſts was not generally given them. They were commonly diſtinguiſhed from prieſts by the names of miniſters and levites. The fourth council of Carthage ſays, they were not ordained to the prieſthood, but only to the miniſtering office, or inferior ſervice.

Certain it is, the ordination of a Deacon differed from that of a preſbyter, both in the form and manner of it, and in the gifts and power conferred thereby. The ordination of a Deacon might be performed by the biſhop alone, becauſe, as the council of Carthage words it, he was ordained not to the prieſthood, but to the inferior ſervices of the church.

The moſt common office of a Deacon was to aſſiſt the biſhop and preſbyters at the altar; alſo to take care of the holy table. It was the Deacon's office alſo to receive the people's offerings, and preſent them to the prieſt, who preſented them to God at the altar: and, after that, to repeat publickly the names of thoſe that offered. In ſome churches, but not in all, the Deacons read the goſpel both in the communion ſervice, and before it alſo.

In the adminiſtration of the euchariſt, it was the Deacon's buſineſs to diſtribute the elements to the people that were preſent, and carry them to thoſe that were abſent alſo.

In ſome caſes Deacons had the power to adminiſter baptiſm ſolely.

Another office of the Deacons was to direct the people in the exerciſe of their public devotions in the church, by giving them notice when each part of their ſervice began, and exciting them to join them; which they did by certain known forms of words appointed for that purpoſe. The Deacons alſo were to give the catechumens, penitents, and energumens, notice when to come up and make their prayers, and when to depart; and in ſeveral prayers they repeated the words before them, to to teach them what they were to pray for. And this was called κηρύττειν, among the Greeks, and prædicare, among the Latins; not to ſignify preaching, but performing the office of a κήρυξ, or præco, in the aſſembly. And hence Deacons were called ἱεροκήρυκες, i. e. the holy cryers of the church.

Deacons were allowed to preach, only when they had the biſhop's licence, and not without it.

Deacons had alſo the power of reconciling penitents, with the ſame limitation. In caſes of extreme neceſſity, when neither biſhop nor preſbyter were at hand to do it, Deacons were ſometimes authorized, as the biſhop's delegates, to give men the ſolemn impoſition of hands, which was the ſign of reconciliation.

They might be deputed by their biſhops to be their repreſentatives and proxies in general councils: and then they ſat and voted, not as Deacons, but as proxies, in the room and place of thoſe that ſent them.

DEADS, in mining, is uſed to expreſs that part of the ſhelf or faſt ground which contains no ore, but which incloſes the view or bed of ore, like a wall, on every ſide. The drifts which they ſink for the tin ore in Cornwall are generally about three feet over, and about ſeven feet high; ſo that a man may conveniently ſtand upright at work, and manage his tools. In caſe the vein itſelf is not broad enough to allow this, as in many places it is not half a foot over, then they pick down the ſtrata that incloſe it, ſo as to make an opening of the ſame breadth. This work they call breaking up the Deads. *Phil. Tranſ.* N°. 69.

DECA'NDRIA *, in botany, a claſs of plants with hermaphrodite flowers, and ten ſtamina, or male parts, in each. See *plate* XXII. *fig.* 1.

* The word is formed of the Greek δέκα, ten, and ἀνδρός, male.

Of this claſs of plants are the judas tree, baſtard dittany, &c.

DECLAMA'TION (*Dict.*)—It is amazing that in all ages and nations of polite learning, no ſchools for Declamation have ever yet been eſtabliſhed: the maſters of public ſchools and colleges give boys ſome ſlight notions which they never reduce to practice in any of the ſtages of civil life; but indeed, as their principal employment is to teach the dead languages, they have no time to beſtow on other ſtudies: Beſides, the boys whom they have commonly under their care are too young, and incapable either to make ſolid reflections by themſelves, or to comprehend the precepts of their maſter. Should an old orator fill a public chair, and teach the art of Declamation, he would be as uſeful to ſociety as moſt of the fine eſtabliſhments that are in great cities: young people would then ſtudy oratory, when moſt of their own ſtudies were over, when they were advanced in age, and conſequently more capable to comprehend the reaſons that would be offered; but, above all, they would retain the natural and ſtriking impreſſions conveyed by animated ſpeech in the practice of declaiming, and all the different branches of that art.

Declamation, or manner of ſpeaking upon the ſtage, was by the ancients compoſed with notes; which, however, was not ſinging to muſic: In this ſenſe we ſhould often underſtand in the Latin poets the words canere, cantus, and even carmen, which do not always ſignify ſinging, properly ſo called, but a certain manner of ſpeaking or reading. According to Bryennius, this declaiming or ſpeaking was compoſed with accents, and in conſequence it was neceſſary, in writing it, to make uſe of the characters which expreſſed thoſe accents. At firſt they were only three, the acute, the grave, and the circumflex; they afterwards amounted to ten, each marked with different characters. We find their names and figures in the ancient grammarians. The acute is the certain rule by which the voice ſhould be raiſed or depreſſed in the pronunciation of every ſyllable: as the manner of ſounding their accents was learned at the ſame time, with reading, there was ſcarce any body who did not underſtand this kind of notes: beſides the help of accents, the ſyllables in the Greek and Latin languages had a determinate quantity, that is to ſay, they were either long or ſhort. The ſhort ſyllables had only one, and the long, two ſeconds of time: this proportion of ſyllables was as abſolute as that in theſe days between notes of different length, viz. that two black notes in our muſic ought to have as much time, as one white one in the muſic of the ancients; two ſhort ſyllables had neither more nor leſs than one long one. Hence, when the Greek or Roman muſicians were to compoſe any thing whatſoever, they had no more to do, in ſetting the time to it, than to conform to the quantity of the ſyllables upon which they placed each note. It is a pity the muſicians amongſt us, who compoſe muſic to hymns, &c. do not underſtand Latin, and are ignorant of the quantity of words; from whence it often happens, that upon ſhort ſyllables, over which they ought to run lightly, they inſiſt and dwell a great while, as if they were long ones: this is a conſiderable fault, and contrary to the moſt common rules of muſic.

We have obſerved, that the Declamation, or manner of ſpeaking of the actors upon the ſtage, was compoſed and wrote in notes, which determined the note it was proper to take. Amongſt many paſſages, which demonſtrate this, we ſhall only obſerve one from Cicero, where he ſpeaks of Roſcius, his contemporary, and intimate friend. Every body knows that Roſcius became a perſon of very great conſideration, by his excellency in this art, and his reputation for probity; the people were ſo much prejudiced in his favour, that, when he did not act ſo well as uſual, they ſaid it was either out of negligence or indiſpoſition. In fine, the higheſt degree of praiſe, that they gave to a man who excelled in his profeſſion, was to ſay he was a Roſcius, in his way. Cicero, after having ſaid, that an orator, when he grows old, might ſoften his manner of ſpeaking, quotes, to a proof, an example of it, what Roſcius declared, that, when he perceived himſelf grow old, he obliged the inſtruments to play in a lower key. Cicero, accordingly, in a later work than that now cited, makes Atticus ſay, that actor had abated his Declamation or manner of ſpeaking, by obliging the player on the flute, that accompanied him, to keep a ſlower time with the ſound of his inſtruments. It is evident that the ſinging, for it was often called ſo, of the dramatic pieces on the ſtages of the antients, had neither diviſions, recitatives, continued quaverings, nor any of the characters of our muſical ſinging: in a word, that this ſinging was only declaiming, or ſpeaking, as with us. This manner of utterance was, however, compoſed, as it was ſuſtained by a continued baſs, of which the ſound was proportioned, in all appearance, to that made by a man, who declaims or pronounces a ſpeech. This may ſeem to us an abſurd and almoſt incredible practice, but is not therefore the leſs certain; and, in matter of fact, it is uſeleſs to object any arguments. We can only ſpeak by conjecture upon the compoſition which the continued baſs might play, that accompanied the actor's pronunciations; perhaps it only played from time to time ſome long notes, which were heard at the paſſages, in which it was neceſſary for the actor to aſſume ſuch tones as it was not eaſy to hit with juſtneſs; and thereby did the ſpeaker the ſame ſervice as Gracchus received from the player upon the flute, he always had near him, when he harangued, to give him, at proper times, the tones concerted between them.

DEER, *cervus*, in natural hiſtory, the name of a genus of animals, comprehending the common Deer, and the elke. The characters of this genus are, that the horns fall off every year, that they are ſolid and branched, and that the animal chews the cud.

The word cervus, uſed alone, is underſtood by authors to mean the ſtag, or red Deer, the others being all diſtinguiſhed by their ſeveral adjectives; the common fallow Deer being called cervus, platyceros, or the broad-horned Deer. *Ray's Synopſ. Quad.*

The red Deer differs from the common kind in its ſize, and in the figure of its horns. The common Deer is more preſerved in England than in any other part of the world, and carries its diſtinction from the red Deer in the falcated figure of its horns.

We keep ſeveral ſpecies of thoſe however, and may perhaps increaſe them in ſome ſort to many more, as they are a very ſalacious falacious animal, and will be apt to mingle one species with another. The principal kinds we know at present, are 1. The Spanish Deer, which is almost as large as the red Deer, but has a very slender neck, and is of a deep dusky colour; the tail in this species is also longer than in ours, and is black all over, not white next the body. 2. The mottled Deer, which are beautifully variegated with black, white, and tawny. 3. The Virginia Deer, which are larger and stronger than ours, and have thicker necks, and are of a grey or ash colour rather than tawny, and remarkable for the largeness of their penis and scrotum. 4. A species which have their hinder hoofs marked with white on the outside; the ears and tails of these are long, their horns branched, and their forehead a little depressed or hollowed between the eyes. These will eat bread, fruits, and any thing that is offered them, and are often beautifully variegated; many of them have black variegations, and a black list down their back, with a series of white spots on each side; others are so beautifully marked with white spots and other variegations, as to equal the zelora in beauty: these they call monated Deer. *Ray's Synops. Quad.*

DELPHI'NIUM, *lark-spur*, in botany, the name of a large genus of plants; the characters of which are these: the flower is of the polypetalous anomalous kind, consisting of several irregularly sized petals, the upper one ending in a spur or tail, and receiving into its hollow another of the petals, which has also its tail or spur: the pistil which occupies the center of this flower, finally becomes a fruit composed of several vaginæ, which open lengthwise, and contain a number of seeds, usually of an angular form. The species of lark-spur, enumerated by M. Tournefort, are thirty-eight.

DELPHI'NUS, *the dolphin*, in the Linnæan system of zoology, makes a distinct genus of fishes of the plagiuri, or transverse-tailed order; the characters of which are, that the back has two fins, and there are teeth in both jaws. *Linnæi Systema Naturæ.*

In the Artedian system of ichthyology, Delphinus is also the name of a genus of the plagiuri, or cetaceous fishes; the characters of which are these: the teeth are placed in both the jaws, the pipe or opening is in the middle of the head, and the back is always pinnated.

The dolphin is a cetaceous fish, covered with a smooth but very tough and firm skin; its body is long and rounded, and its back prominent; its nose long, and rounded at the end; its mouth very large, but shutting very nicely and exactly; its teeth small and sharp, and placed like the teeth of a comb; its tongue broad and serrated; its eyes large, but so covered with the skin that the pupil only appears. Its eyes are placed near the angle of the mouth; and behind these are its ears, or auditory passages, which are very small. Above the snout it has a double pipe, by which it throws out the water necessarily taken in with food. It has two fins joined like the shoulders of a human body to the muscles, which move them. In the middle of the back it has also one fin, which is partly cartilaginous, and partly bony, but has no spines or prickles. Its back is black, and its belly white; the flesh is blackish, and it has a regular lungs in its breast of a more tough consistence than those of quadrupeds. These fish are supposed to live a great number of years. The figures of them on some antique marbles and coins, which represent them crooked, are unnatural; and have been conceived originally by persons who had seen them playing about on the surface of the water, in which case they sometimes deceive the eye, and appear crooked: from these probably our sign-painters took their idea of the dolphin. They are an extremely swift fish in swimming, and are able to live a long time out of the water, though they can continue but a little while under it without air; hence they are sometimes taken up dead by fishermen in their nets, having been suffocated by being forcibly kept under water: they have been known to live three days on dry ground. *Willughby, Hist. Pisc.*

DE'LVIN, in natural history, a name sometimes given by the miners of Cornwal to that sort of talky stone or slate, which they more generally call killas; but in some places, as at Lowancowiggan, they use it as the name of a coarse but very hard stone in which the ore lies. The ore is tin, and is considerably rich there, but the hardness of this stone makes it difficult to be got out.

DENDRANA'TOMY, a term used by Malpighi and others to express the dissection of the ligneous parts of trees and shrubs, in order to the examining their structure and uses.

DENS *Canis*, dog's-tooth, in botany, the name of a genus of plants: the characters of which are these: the flower is of the liliaceous kind, and is composed of six petals, which are pendulous, and bend backward. The middle of the flower is occupied by a pistil, which finally becomes a round fruit, or seed vessel, divided into three cells, and containing a number of oblong seeds: to this it is to be added, that the root is fleshy, and of the shape of a dog's fruit.

The species of Dens canis, enumerated by M. Tournefort, are eight.

The powder of the dried root of this plant is said to kill worms in children. Drank in wine, it is an approved remedy for the cholic. It is said to be restrictive and restorative, and, taken in water, cures children of the epilepsy: it is also esteemed a great provocative to venery.

DENS *Leonis*, dandelion, in botany, the name of a genus of plants, the characters of which are these: the flower is of the semi-flosculous kind, and the petals it is composed of are placed on the embryo-seeds, and surrounded by the cups. The embryo's finally become seeds winged with down, which are affixed to the thalamus, but expand their downy ends into a globular head, and the stalks are usually hollow and not branched. The species of Dandelion, enumerated by M. Tournefort, are twenty-two.

The common species of this plant has much the same virtues as the common endive, but in a greater degree: the roots eaten in spring are esteemed of great service in obstructions in the liver and spleen.

DENTA'LE, in natural history, the name of a genus of the tubuli marini: the characters of which are, that they are shelly tubes, resembling the tusks of elephants, or the horn of some animal which is a little bent. Some authors have called these elephants teeth.

DE'NTES *Canini*, dogs teeth, are so termed, because they are naturally a little pointed, and appear longer than the rest, almost in the same manner as in dogs: they might also be properly enough be called angular, because they make an angle, by which the incisores are separated from the grinders; the two superior have also been named eye-teeth from their situation. The bodies of the Dentes canini are thicker and more prominent than those of the incisores; they are convex, and a little rounded on the outside, and end in a short triangular point, one of the sides of which is a continuation of the convexity of the outside, and the other two are flatter and turned inwards. These points are often worn out by mastication: their roots are commonly larger, thicker, longer, and more pointed than those of the incisores, and sometimes perforate to the bottom of the maxillary sinus. *Winslow's Anatomy.*

Dentes incisores, the cutting teeth, have their name from their use; and are by some authors called risorii, because they appear in laughing; the four upper incisores are larger and broader than the four lower; and, of the upper, the two in the middle are larger than the other two: the bodies of these teeth resemble large cutting wedges, and their roots are pointed. Their bodies are so disposed that their sharp ends lie all in a line, making one uniform edge; each body has properly four sides; one anterior a little convex, one posterior a little concave, and two lateral much narrower than the former, and almost flat: the anterior and posterior sides decrease in breadth towards the neck, the lateral sides towards the edge; so that they represent in some degree four triangles, with their apices and bases reciprocally opposite.

These teeth have long roots, the lateral sides of which are broad and flat, the anterior and posterior narrower: they terminate by degrees in a point, in which a small hole is observable, in children pretty considerable, but almost obliterated in old age. *Winslow's Anatomy.*

DESIDERA'TUM, is used to signify the desireable perfections in any art or science: thus, it is a Desideratum, with the black-smith, to render iron fusible, by a gentle heat, and yet preserve it hard enough for ordinary uses; with the glass-man and looking-glass maker, to render glass malleable; with the clock-maker, to bring pendulums to be useful where there are irregular motions; with the brazier and coppersmith, to make malleable solder; with the shipwright, to build vessels that will sail under water: with the diver, to procure manageable instruments for conveying fresh air to the bottom of the sea, sufficient for respiration, and the burning of lights; with the assay-master, to melt or copel ores, immediately, without the use of bellows or furnace; and, with the carvers and joiners, to fashion wood in moulds like plaister of Paris or burnt alabaster, &c. And though, as Mr. Boyle observes, the obtaining of these Desiderata may be thought chimerical, yet it is proper they should be proposed; for, although perfection may not be attainable, yet approaches to it may be made, and arts thereby improved.

To this we may add, that the making iron malleable with pit coal was once perhaps looked upon as chimerical, yet it is now put in practice, to the great advantage of the owners of several mines in this kingdom.

It is a Desideratum, in the tin works, to find a method of obtaining the silver out of the tin, as it is now got out of the lead, in places where the ores are so rich as to make it worth the while.

In the glass-works, it is a Desideratum to solder up the cracks and flaws in the pots, while they are detained in the fire, and another to make glass without veins.

A tasteless and inodorous wine is a Desideratum among vintners, and a tasteless, acid, inodorous spirit among distillers.

The painters want a permanent green, and the callico-painters a lasting blue.

In short, all arts have their defects, and it is not at first to be guessed, for how many of these remedies may be found, by means of chemical researches properly directed.

Chemistry itself is greatly defective in many particulars, as in in an experimental history of general fermentation, separatory and combinatory, in subjects of the animal, vegetable, and mineral kingdoms. A history of putrefaction, rancidness, mustiness, mouldiness; and of the making of glues, mulages, and the like preparations, in the most perfect manner is also wanted.

The sublimer metallurgy is in particular yet greatly defective. It wants a more easy method of extracting the mercuries of metals, than those commonly described; a cheaper method of meliorations is wanted, and, in general, all the parts of this branch of the art seem equally defective.

The schemes for new trades will rise occasionally in the prosecuting many of the subjects; thus, it is natural for the common operations of brewing and sugar-baking to suggest that sugar may be procured from malt and other vegetables. That nurseries of peculiar ferments, both native and foreign, may be raised on the common principles; and it is evident, that the introduction of such new trades would greatly improve the business of brewing, sugar-baking, and the like.

If a proper number of persons duly qualified for making experiments, and improving from them, would set about each his particular share of the necessary experiments, and communicate the result of all their processes to one another, the business of chemical experiment would be much better directed in regard to future students, and many of the Desiderata in the art probably supplied. *Shaw's Chem.*

DESI'GN, or *Designing*, in the manufactories, expresses the figures wherewith the workman enriches his stuff or silk, and which he copies after some painter, or eminent draughtsman; as in diaper, damask, and other flowered silk and tapestry, and the like, &c.

In undertaking of such kinds of figured stuffs, it is necessary, says Monf. Savary, that, before the first stroke of the shuttle, the whole Design be represented on the thread of the warp; we do not mean in colours, but with an infinite number of little packthreads, which, being disposed so as to raise the threads of the warp, let the workmen see, from time to time, what kind of silk is to be put in the eye of the shuttle for woof.

This method of preparing the work is called reading the Design, and reading the figure, which is performed after the following manner:

A paper is provided, considerably broader than the stuff, and of a length proportionate to what is intended to be represented thereon. This they divide lengthwise, by as many black lines as there are intended to be threads in the warp; and cross these lines by others drawn breadthwise, which, with the former, make little equal squares.

On the paper thus squared the draughtsman designs his figures, and heightens them with colours, as he sees fit. When the Design is finished, a workman reads it, while another lays it on the simblot.

To read the Design, is to tell the person who manages the loom the number of squares, or threads, comprised in the space he is reading, intimating, at the same time, whether it is ground or figure.

To put what is ready on the simblot, is to fasten little strings to the several packthreads, which are to raise the threads named: this they continue to do, till the whole is read.

Every piece being composed of several repetitions of the same Design, when the whole Design is drawn, the drawer, to re-begin the Design a-fresh, has nothing to do but raise the little strings with slip-knots to the top of the simblot, which he had let down to the bottom. This he is to repeat as is necessary, till the whole be manufactured.

The ribbon-weavers have likewise a Design, but far more simple than that we have described. It is drawn on paper, with lines and squares, representing the threads of the warp and woof. But, instead of lines, of which the figures of the former consists, these are constituted of points only, or dots, placed in certain of the little squares, formed by the intersection of the lines. These points mark the threads of the warp that are to be raised, and the spaces left blank denote the threads that are to keep their situation. The rest is managed as in the former.

DE'TENTS, in a clock, are those stops which, by being lifted up or let fall down, lock and unlock in striking.

Detent-wheel, or hoop-wheel, in a clock, that wheel which has a hoop almost round it, wherein there is a vacancy, at which the clock locks.

DE'VENSHRING, or *Denshiring*, a term used by the farmers to express the burning land by way of manure: the method is to cut off the turf about four inches thick, and burn it in heaps, and then spread the ashes upon the land; they probably call it Devenshring, from its having been earliest practised in Devonshire. See the article BURNING *of land*.

DEUILLE's *Piston*, in hydraulics, a piston without friction invented by Messieurs Gosset and de la Deuille, and successfully made use of in the king of France's garden at Paris.

This piston may be made as big as you please, even to have 36 inches diameter; but I shall only give 15 to that I am going to describe, this bigness seeming most convenient for the reasons that will appear, as we describe this piston. As it is to act in a pump different from those commonly described, I will shew in what it consists. It is made of two boards of oak or elm, 20 inches diameter, and five inches thick: in the middle of each of these boards, you must cut a hollow cylindrical cavity 15 inches diameter, and 2½ inches deep, which forms two boxes, which must be applied to one another with their hollows together; their profile taken diametrically is represented by each of the rectangles A B C D, and E F H G (*Plate* XVII. *fig.* 10.)

The piston is made of a circular board Y Z, an inch thick, whose diameter must be a little less than that of the hollow T O Q V, to facilitate its play: this board is fixed to a great circle of leather (or to several, when one is not strong enough) in such manner that the leather may extend all round beyond it six or seven inches; then you must put the board Y Z in the bottom of the box S T V X, and what exceeds of the leather must be folded up all round the edge E X G of the same box. Then you put down the other box upon the first, so as to squeese the leather between; and, that it may be pressed the more strongly, so that the two boxes may make but one, they are drawn together by means of several iron pins 17, 18, whose ends are cut into screws, to fit into nuts; then the piston makes a sort of a purse 3, 4, 5, 6, which turns inside out every time the bottom Y Z is drawn upwards.

At the bottom of this purse there is an hole L, covered with a valve K, which, when it is raised, comes to lean against the handle M W M, which handle is fastened to the rod N, that works the piston up and down; for doing of which there is another hole 9, 10, in the bottom of the upper box, which answers to the rising pipe 13, 14, in which the rod N goes up. This hole is made spreading downwards, that the moveable board may apply itself close to the top O Q, when the piston rises. In the lower bottom of the box there is another hole 19, 20, which answers to the sucking pipe 15, 16, that stands in the water to be raised; this hole is covered with a valve I, as usual.

When the piston rises, the water from the sucking pipe opens the valve I, and passes into the hollow that is made in an height of four inches, which is all the play that the piston ought to have, not to weaken the leather too much, which would not hold out long, if it had too long a stroke; whereas, having at most but 2 inches and ½ to rise from 5 to X, it wears but little: when the piston comes down, the valve I shuts again, the other K opens, and the water which is between the bottom T V, and the leather 3, 4, 5, 6, goes through the hole L, and comes into the space O P Y Z Q, whence it is lifted into the rising, or forcing, pipe; thus you see that the piston, always moving between the water above, and that below, has no friction. I shall add, that, when it is made of good leather, it may be continually worked for three or four months, without repairing, as experience has shewn it in those pumps, that Messieurs Gosset and de la Deuille had made for draining the mines in Brittany.

The only fault to be found with this piston, is, that, of whatsoever diameter the rising pipe 13 and 14 is, the power is always loaded with the weight of a column of water, whose base is the circle O Q, and height the elevation of the reservoir above the spring; it is true, that one may increase the diameter of that pipe, and decrease that of the piston, that, when they are equal, the power may only raise its natural weight.

It may may yet perhaps be objected, that this piston, having so short a stroke, will give but a little water every time; but that is not a fault, since one may make the strokes more frequent; so that what may be lost on one hand may be gained on the other, and as much water be raised as if the stroke were longer.

As the rod of the piston goes through the rising (or forcing) pipe, water may not be raised to a considerable height by this pump, yet the rod of the pump, erected in the king's garden, is at least 25 feet long; and, if the same length be given to the sucking pipe, one may however raise water 50 feet above its spring, in a very plain and cheap way. For, if you make use of wood, such a pump will cost under ten pistoles: and that serves, upon many occasions, where a pump of great expence would raise no more water with the same power.

DEW (*Dict.*)—Those who have made no other reflections on Dew than such as present themselves naturally, think that all the moisture one finds in the morning on plants and upon the ground, comes in reality from above; but, when the affair is examined with more attention, one sees that at least a great part of the Dew arises from the earth itself and the plants, and keeps hanging to their surface. Mr. Gersten who hath made a dissertation on this subject in particular, hath even thought that there fell no Dew from above on the ground, and that all which we see under the form of Dew arose from the earth or plants, on which it keeps hanging in pearls till the heat of the day hath dispersed it.

This opinion of Mr. Gersten was not new, and we find, in the History of the Academy for 1687, that some persons of the company had advanced, that the Dew rose from the earth and did not descend from above, because they found under glass-bells as much Dew as in other places exposed to the air; it is probable, that since that time several persons have been of the same sentiment; one finds even traces of it in ancient authors:

thors: but Mr. Gerſten did not derive his notion from thence; he had given, in the work which we have cited, a new explication of the riſings and fallings of the barometer that did not agree with the deſcent of Dew; this made him think of examining the thing with more attention, than had hitherto been done. He had already obſerved in gardens that the graſs was full of a moiſture in the evening, and covered with very perceptible little drops, whilſt the leaves of trees, and plants that were more raiſed from the ground, had not the leaſt appearance of it; he remarked moreover that all the plants had it not equally, that on ſome it was very abundant, whilſt he could ſcarce perceive it on others.

We ſhall not relate a great number of experiments, that were made by Mr. Gerſten, although ſome of them are extremely curious; but the reader will ſee by thoſe which we ſhall give an account of afterwards, that it was neceſſary, in order to draw certain and exact conſequences, to have a knowledge of ſeveral facts, the diſcovery of which was reſerved for Mr. Muſſchenbroek; who after having verified the greateſt part of Mr. Gerſten's experiments, at firſt ſubmitted himſelf to his opinion, but he hath ſince changed, and is fixed in acknowledging ſeveral ſorts of Dews, of which one more denſe than all the others riſes from lakes, rivers, and marſhes.

And a third falls from above: Mr. Muſſchenbroek founds the exiſtence of this laſt on a great number of experiments which he hath made upon the leaden terras of the Obſervatory at Utrecht; it was not poſſible that any vapour ſhould riſe from this terras of lead, yet ſeveral bodies which he expoſed there received Dew on their upper ſurface; from whence Mr. Muſſchenbroek concludes that there is really a Dew that falls.

Several obſervations and experiments repeated very often, and which always proved uniform, leave no longer any doubt with me concerning the nature of Dew, at leaſt with regard to its riſing or falling; and I think one may be ſatisfied that it riſes only from the earth and plants; that this moiſture or this vapour conſiſts of an infinite number of little aqueous globules extremely light with which the air is loaded, and which it carries with it whitherſoever it is driven by its fluctuating motion: thus the bodies which are met by this aqueous vapour, receive it in all the parts of their ſurface, and are immerſed all at once.

In the experiments of Mr. Muſſchenbroek where bodies expoſed on the leaden terras received Dew on their upper ſurface, it is true, the moiſture did not come from the terras, but it roſe from the earth, and from the plants round about; it came ſucceſſively, and by the vehicle of air to the terras of lead; it was afterwards diffuſed through all the air that was above this terras, and faſtened to the bodies which were expoſed to receive it: if Mr. Muſſchenbroek had attended to the time when the Dew began to be perceived on the terras, he would have remarked, that it was ſenſible a long time before at the foot of the tower, on whoſe ſummit he made the obſervation; I even doubt not but, if he had raiſed a mirrour or piece of glaſs to ſix feet above the leaden terras, he would have found drops of Dew attached to the inferior ſurface of the glaſs, as ſoon and in as great quantities as on the ſuperior ſurface: this I cannot doubt of from experiments I have made along the different heights of the ſteps of a ladder. I placed two ladders oppoſite each other, joined at their tops, ſpreading wide aſunder at their bottoms, and ſo high as to reach thirty-two feet. To the ſeveral ſteps of theſe I faſtened large ſquares of glaſs, and ſet them in ſuch a manner that they ſhould not ſhade or over-hang one another. It was plain that, if the Dew deſcended without firſt riſing, the top ſquares muſt be firſt wetted, and that on their upper ſurface; but on the contrary, if the Dew firſt aſcended from the earth, the bottom ſurfaces of the lower panes muſt firſt receive it: and thus in fact it happened; the lower ſurface of the loweſt piece of glaſs was firſt wetted, then its upper ſurface; then the lower ſurface of the pane next above it, and ſo on gradually till the whole was wetted to the top of the ladders.

But, in order to aſſure myſelf more certainly, and leave no room for doubt on this ſubject, I have lately repeated the ſame experiments at Paris upon a leaden terras. I ſuſpended a glaſs upon a wooden frame, raiſed only two feet, and I conſtantly found drops of Dew pretty nearly in equal quantity on the under ſide as on the upper ſide of the glaſs; which is different from the former experiments that were made in the country, where the inferior ſurface was always ſooner and more abundantly moiſtened than the ſuperior; but the reaſon of this difference is very evident, for in the country the aqueous vapours roſe directly from the earth, and faſtened themſelves to the under ſurface of the glaſs; but it is not ſo on a terras of lead, and ſurrounded by lofty buildings; in this caſe, the air that is loaded with moiſt vapours cannot arrive thither but by long windings, and a very irregular fluctuation; ſo that there is no more reaſon why it ſhould faſten itſelf to the under than to the upper ſide of the glaſs; or, in other words, the vapour doth not riſe there perpendicularly as in the country, but is driven in a lateral direction.

Notwithſtanding all I have been ſaying, I do not pretend that there is but one kind of Dew, and deny not but there may be a Dew whoſe parts are groſs enough, and have ſufficient weight to fall to the ground; yet I think in that caſe it would be viſible, and form what we know by the name of fog: but our inquiry is at preſent of that kind of Dew, ſo ſtiled by all, which is imperceptible to the eyes, and becomes ſenſible only by wetting thoſe bodies that are expoſed to the air in the night. *Mem. Acad. Roy. Sciences.*

The reverend Dr. Hales, in his treatiſe of Vegetable Statics, tells us, that in order to find out the quantity of Dew that fell in the night, on the 15th of Auguſt, at 7. p. m. he took two glazed earthen pans, which were three inches deep, and twelve inches diameter in ſurface; that he filled them with pretty moiſt earth, taken from off the ſurface of the ground, and they increaſed in weight by the night's Dew 180 grains; and decreaſed in weight by the evaporation of the day one ounce + 282 grains.

He ſays likewiſe, he ſet theſe in other broader pans to prevent any moiſture from the earth ſticking to the bottom of them. He adds, the moiſter the earth is, the more Dew falls on it in a night, and more than a double quantity of Dew falls on a ſurface of water than there does on an equal ſurface of moiſt earth: the evaporation of a ſurface of water in nine hours winter's dry day, is $\frac{1}{31}$ of an inch: the evaporation of a ſurface of ice, ſet in the ſhade during a nine hours day, was $\frac{1}{21}$. So here are 540 grains more evaporated from the earth every 24 hours in ſummer, than fall in Dew in the night; that is, in 21 days near 26 ounces from a circular area of a foot diameter; and circles being as the ſquares of their diameters, 10 pounds + 2 ounces will in 21 days be evaporated from the hemiſphere of 30 inches diameter, which the ſunflower's root occupies; which, with the 29 pounds drawn off by the plant in the ſame time, makes 39 pounds, that is, 9 pounds and $\frac{3}{4}$ out of every cubic foot of earth, the plant's roots occupying more than 4 cubic feet: but this is a much greater degree of dryneſs than the ſurface of the earth ever ſuffers for 15 inches deep, even in the drieſt ſeaſons in this country.

In a long dry ſeaſon therefore, eſpecially between the tropics, we muſt have recourſe, for ſufficient moiſture to keep plants and trees alive, to the moiſt ſtrata of earth, which lie next below that in which the roots are.

Now, moiſt bodies always communicate of their moiſture to more dry adjoining bodies; but this ſlow motion of the aſcent of moiſture is much accelerated by the ſun's heat to conſiderable depths in the earth, as is probable, he ſays, from the twentieth experiment in the ſaid book.

Now, 180 grains of Dew falling in one night, on a circle of a foot diameter = 113 ſquare inches; theſe 180 grains being equally ſpread on this ſurface, its depth will be $\frac{1}{159}$ part of an inch $= \frac{180}{113 \times 254}$. He adds, that he found the Dew in a winter's night to be the $\frac{1}{90}$ part of an inch; ſo that if we allow 151 nights for the extent of the ſummer's Dew, it will in that time ariſe to one inch deep: and, reckoning the remaining 214 nights for the extent of the winter's Dew, it will produce 2, 39 inches deep; which makes the Dew of the whole year amount to 3, 39 inches deep.

And the quantity which evaporated in a fair ſummer's day from the ſame ſurface, being as 1 ounce 282 grains, gives $\frac{1}{40}$ part of an inch deep for evaporation, which is four times as much as fell at night.

He ſays likewiſe, that he found, by the ſame means, the evaporation of a winter's day to be nearly the ſame as in a ſummer's day; for, the earth being in winter more ſaturated with moiſture, that exceſs of moiſture anſwers to the exceſſive heat in ſummer.

It is very certain, that ſubſtances of a very different kind from the uſual and natural matter of the Dew, have ſometimes fallen in that form. Our Philoſophical Tranſactions give an account, that, in the year 1695, there fell in Ireland, in ſeveral parts of the provinces of Leinſter and Munſter, for a conſiderable part of the winter and ſpring, a fatty ſubſtance, reſembling butter, inſtead of the common Dew; it was of a clammy texture and dark-yellow colour; and was, from its great reſemblance, generally called Dew-butter by the country people. It always fell in the night, and chiefly in the mooriſh low grounds, and was found hanging on the tops of the graſs, and on the thatch of the houſes of the poor people. It was ſeldom obſerved to fall twice in the ſame place, and uſually, wherever it fell, it lay a fortnight upon the ground before it changed colour, but, after that, it gradually dried up, and became black. The cattle fed in the fields where it lay, as well as in others, and received no hurt from it: it fell in pieces of the bigneſs of one's finger end, but they were diſperſed ſcatteringly about, and it had an offenſive ſmell, like that of a church-yard. There were, in the ſame places, very ſtinking fogs during the winter, and ſome people ſuppoſe this no other than a ſediment or connection of the heavier matter of thoſe fogs. It would not keep very long, but it never bred worms. The country people, willing to have ſome good of it, tried it on their children's foreheads, and it always cured them of a ſcald-head. *Phil. Tranſ.* N°. 220.

Cryſtalline Dews, a term uſed by ſome modern writers, to expreſs certain Dews, or ſteams, which, in their fall upon the earth, become, as they ſay, cryſtal. This greatly favours the opinion of the ancients, that all cryſtal was only water frozen into a kind of ice harder than ordinary, but it is erroneous. Mr. Beaumont gives an account, in the Philoſophical Tranſac-

Tranfactions, of thefe cryftal Dews on Mendip-hills; in which he tells us, that the miners of that place find fometimes, in the roads where the earth is bare, triangular cryftals, about two inches in length, and an inch over, not with fharp angles, but roundifh and blunted ones, and carried up round at the ends like a cocoa-nut; and that none of thefe are ever found under ground in digging, but only lying on the furface. He tells us alfo, that he had feen fome taken up in Gloucefterfhire, and confirms the opinion of thefe cryftalline Dews producing real cryftals, by the account given of fome places in Italy, where cryftals are, as it is faid, frequently produced in clear evenings by a coagulation of the Dews falling on nitrous fteams. Whatever the cryftals are, which authors feem to fuppofe to have been generated in this manner, it is very certain, that they have in reality another origin; and thefe are only the accounts of ignorant and inconfiderate people, to give credit to the ftrange and unnatural method here given for their formation. *Phil. Tranf.* N°. 129.

DIA'BOLUS *Marinus*, the fea devil, in zoology, the name of an ugly and ftrangely ill-fhaped fifh, of the ray kind. Its nofe or fnout is bifid, and runs out into two horns, and its fides are both terminated by thin fins: its skin toward the head is variegated with dusky fpots. It grows to a very confiderable fize, being fometimes caught of fix or feven feet long. *Ray's Ichthyogr. Append.* p. 5. See *Plate* XXII. *fig.* 2.

DIADE'LPHIA, in botany, a clafs of plants with hermaphrodite flowers, whofe ftamina, by the conjunction of thin filaments, are formed into two bodies.

The characters of the Diadelphia are thefe: the perianthium confifts of one leaf, and is of a bell-like fhape, and gibbous at the bafe; this always falls with the flower. It ftands on a pedicle, is obtufe at the top, and carries a drop of honey-like juice at the bafe. Its mouth or rim is divided into five fegments, which are fometimes erect, fometimes oblique, and always irregular, and acute. The bottom fegment, which has no fellow, is longer than all the reft; and the top pair are fhorteft of all, and ftand fartheft afunder. The receptacle of the fructification is inclofed in the bottom, where it is wetted with the drop of honey. The flower is of an irregular fhape, and is of that kind called by authors papilionaceous, from its fomewhat refembling the wings of a butterfly.

DI'AMOND (*Dict.*)— *Valuation of* DIAMONDS. Mr Jeffries lays down the following rule for the valuation of Diamonds of all weights. He firft fuppofes the value of a rough Diamond to be fettled at two pounds per carrat, at a medium; then, to find the value of Diamonds of greater weights, multiply the fquare of their weight by two, and the product is the value required. E. g. to find the value of a rough Diamond of two carrats, $2 \times 2 = 4$, the fquare of the weight, which, multiplied by two, gives eight pounds, the true value of a rough Diamond of two carrats. For finding the value of manufactured Diamonds, he fuppofes half their weight to be loft in the manufacturing them; and, therefore, to find their value, we muft multiply the fquare of double their weight by two, which will give their true value in pounds: thus, to find the value of a wrought Diamond, weighing two carrats; we firft find the fquare of double the weight, viz. $4 \times 4 = 16$, then $16 \times 2 = 32$. So that the true value of a manufactured Diamond of two carrats is 32 pounds.

By this rule, Mr. Jeffries has conftructed tables of the price of Diamonds, from 1 to 100 carrats. *Jeffries on Diamonds, p.* 8, 9, *and p.* 11 *& feq. of his Tables.*

Rough Diamonds are more commonly found of a fix-pointed figure than of any other; and thefe are called fix-pointed rough Diamonds, the figure of which is compofed of two fquare pyramids, joined at their bafes. Hence the whole figure is compofed of eight triangular faces, or planes, four of which meet in a point above the bafe, and four below it, in another point. The diftance of thefe two points is the axis of the figure.

Shining of DIAMONDS *in the dark.*— The ancients having mentioned many precious ftones which fhone in the dark, the moderns have made a great number of experiments, in order to difcover whether Diamonds had really any luftre in the dark. The great Mr. Boyle made a multitude of experiments of this kind; and Mr. Du Fay has lately repeated thefe experiments, and added feveral others, an extract of which will not, perhaps, be difagreeable to the reader.

After having verified upon feveral Diamonds the experiments related by Mr. Boyle, I plainly difcovered that it was not neceffary that the Diamond fhould be heated, in order to contract a tranfient light, fuch as that which it produces, when rubbed upon glafs or metals; but I thought that it muft be fenfibly heated to acquire that permanent and durable light, which fubfifted for feveral minutes, when the Diamond had been near to a lighted candle, or expofed to any other heat. With this view I expofed to a very burning fun-fhine, for 22 minutes, feveral Diamonds, namely, one white, of a very beautiful water; two yellow, of which one was lefs coloured than the other, weighing about 60 grains; one of a rofe-colour, one green, and one of an amethyft-colour.

I examined afterwards all thefe Diamonds in the dark, and I found only the two yellow luminous, but they were extremely fo, and principally the fmalleft, which was of the deepeft colour; they were fo, to fuch a degree, that they enlightened the others which were placed near them, infomuch that it was neceffary for me to take thefe two away, in order to be affured that the others were not luminous: thefe two yellow Diamonds kept their light very perceptibly for more than 12 minutes.

Although every one knows how neceffary it is that thefe experiments be made in the moft perfect obfcurity that is poffible, yet I believe, that it will not be ufelefs to mention the precautions which it is neceffary to take, in order to fee thefe experiments in all their beauty, without which, I might be fufpected of exaggeration fometimes in the defcription I give, becaufe, without thefe precautions, the fame experiments fucceed much lefs perfectly.

It is neceffary to continue a quarter of an hour, at the leaft, in the moft perfect darknefs that is poffible, before you let the Diamonds be brought you which have been expofed to the fun; it requires fuch a time, in order to let the vibration ceafe, which the light of the day caufes in the eyes, and that the pupil, which had been extremely contracted, fo as to permit only a certain quantity of rays to pafs, whilft you was expofed to the light, might have time enough to dilate itfelf fufficiently to receive the moft that is poffible, from objects the leaft luminous, or the leaft enlightened. There is no one but muft have obferved, feveral times in his life, that, when he goes out of broad day-light, and enters into an obfcure place, he fees none of the objects which he eafily difcerns after having ftaid there a quarter of an hour, where the eyes no longer feel the impreffion of the day-light. I do not know whether others have remarked the little relation, and the independency there is in this refpect between the two eyes; for if you clofe one for a quarter of an hour, and the other continues open, the luftre of the Diamonds, and of other phofphori of the like nature, will be feen very diftinctly by the eye that hath been clofed, whilft the other will not perceive it in leaft degree; which proves, that the dazzling caufed by broad day-light, and which renders the eye infenfible of a weak light, acts upon each eye diftinctly, and that its action ceafes before the union of the two optic nerves. There refults from this obfervation a very great conveniency, with regard to the performance of thefe experiments; for you may clofe one eye, and yet make all the little preparations that are neceffary, and which it is often difficult to leave the care of to another perfon: this, at leaft, is certain, that the obfervation hath been of great fervice to myfelf, ever fince I made the difcovery.

As I had obferved, in the firft experiment I have related, that the Diamonds, although they had been 22 minutes in the fun, had not acquired any fenfible heat, I tried the effect of expofing them to the fun for a lefs time; I left them there only 10 minutes; there were two large white Diamonds, weighing between 70 and 80 grains; two blue, one of which weighed 18 grains, but the other was fmaller and deeper in colour; one green, one of a rofe-colour, and two yellow; the two white Diamonds did not take any luftre at all, nor did the deepeft-coloured of the two blue; the green and the rofe-coloured affumed a little fplendor; but two fmall carrat Diamonds that were fet round one of thefe rings, the two yellow, and above all, the large and bright-blue Diamond, appeared extremely luminous, and their luftre continued twelve or thirteen minutes, growing weaker by imperceptible degrees.

I tried afterwards feveral other Diamonds of various fizes, and of all the colours I could meet with; I found feveral of them extremely luminous, and others that were not fo at all. But hitherto I have not difcovered any difference in this refpect, which could be attributed to the colour alone of the ftone, except that the yellow Diamonds which I have tried have all been luminous; there were, indeed, fome more luminous than others, but they were not always thofe whofe colour was the deepeft. Befides a great number of yellow Diamonds, weighing from 8 or 10 to 80 grains, which I have tried, I have had the opportunity of having in my hands about four hundred yellow carrat Diamonds, and there was not one of them but was luminous; fo that we may eftablifh it as a general law, that all yellow Diamonds, having been expofed to the light, are impregnated with it in fuch a manner, that they preferve it in the dark for a confiderable time.

Artificial DIAMONDS.— Art, which imitates nature in fo many things, hath attempted alfo in this admirable production, but very imperfectly, the beft of them being far fhort of the natural; for which reafon they bear no price, in comparifon to the other. There is, however, a pretty great trade in them for mafquerades and play-houfe habits.

There is a particular fort of falfe Diamonds, called Alencon Diamonds, made of ftones or cryftals, found near Alencon, a city of Normandy. The village where they are produced, and which is about two leagues from the city, is called Hertré; the foil is full of glittering fand, and of a hard and grey rock. There are of thefe Diamonds fo clean and brilliant, that fome are deceived herein.

On the coast of Medoc, also are found certain hard and transparent flints, which, being properly cut, are not to be distinguished, among false Diamonds.

Method of making the DIAMONDS *of Alencon.*—Take an earthen glazed pot, set it on a little furnace, put in it filings of steel, with some vine ashes at discretion; place therein by one another crystals cut and polished; then pour common water gently upon them, which keep boiling during the space of twelve hours, taking care to add boiling water fresh into the vessel, as the water in it consumes by boiling, and take care it boil continually. Then see if your crystals have acquired the colour and hardness you expected: if not, continue the fire some hours longer, and they will be like the true Diamonds of Alencon; taking care to polish them again at the wheel, to give them colour and brightness.

A method of giving the true colour and hardness of a DIAMOND *to crystals and Diamonds of Alencon.*— There are crystals and precious stones, which have neither the colour nor natural hardness of Diamonds, and which, some have asserted, may be imitated by art, according to the following process:

Take good Dutch tripoli, and make a paste of it with water out of the smith's forge; in this paste wrap up the quantity you design of crystal, or Diamonds of Alencon cut and polished; then set it in a crucible covered and luted on a gradual fire, where let it stand till the crucible becomes red-hot. A little time after take it out, and take out the stones; then polish them again at the wheel, to give them their colour.

To set them in work, take Indian paper, with leaves of tin, like those you put behind looking-glasses; then let them be set by a skilful jeweller, and they will not be distinguishable from some natural Diamonds, but by nice discerners.

Another method of hardening crystals and DIAMONDS *of Alencon.*— Crystals also acquire hardness in the paste we are now going to describe, because their humidity exhales, and they become more fixed.

Take barley-meal well diluted, with petroleum, or rock oil; then cut that paste in the middle, and put all your stones in order, so that they may not touch one another. Then cover your stones with more of the same paste, and put them in a crucible covered with another, and luted well together, and let it dry. After which, set this crucible in a gradual wheel fire, from five to six hours; a small fire the two first hours, which increase every two hours, till the end of the six: let the whole cool of itself. Then break your crucibles, and you will find your stones mended beyond expectation, which repolish at the wheel, and let them be set by an experienced jeweller.

Another process said to answer the same end as the preceding, and to give a superior lustre.— Although this is said to be an important secret, and may be abused, yet we shall communicate it; because, if true, it will put people upon their guard, and convince them of the necessity of dealing only with people of honour and credit in the Diamond way.

Take one pound of loadstone, a pound of quicklime, and half a pound of common sulphur, the whole reduced to powder, and well mixed. With this powder cement your crystals and Diamonds of Alencon well cut, in a crucible covered and well luted: being dry, set it in a glass-house furnace, if you have not one ready for the purpose, three days, in a place where the matter may be continually red-hot, without fusion; and take care not to take out the crucible all at once, but let it cool gently, otherwise the stones might break. Having broken the crucible, you will find your stones to have acquired an additional brilliancy as well as hardness, and will resemble the Diamonds of the old rock, which repolish at the wheel to give the colour, and let them be well set.

The method of making artificial DIAMONDS.— Take, of the finest natural crystal, calcined, and reduced to subtile powder, what quantity you please; fill a pot with it, and set it in a glass-house furnace twelve hours, to be melted and purified: then drop the melted matter into cold water, dry it, and reduce it again to powder; add to that powder its weight of fine salt of tartar. Mix these two powders well, and make little pills of them, with common water. Then wipe these pills, and put them into an earthen pot on a strong fire, there to grow red-hot for twelve hours space, without melting. Afterwards put them into a pot in a glass-house furnace, where leave them two days, to be well melted and purified. Then put the matter twelve hours in the annealing furnace, to cool very gradually. Break the crucible, and you will have a fine material for the imitation of Diamonds, which cut and polish at the wheel.

DIA'NDRIA *, in botany, a class of plants, which have hermaphrodite flowers, with two stamina or male parts in each.

* The word is formed of the Greek δὶς twice, and ἀνὴρ male.

Of this class of plants are, the jessamine, phyllerea, olive, rosemary, &c. See *Plate* XXII. *fig.* 3.

DICTA'MNUS *albus*, bastard dittany.— The roots of this dittany are pretty large, white, and spreading, sending forth long pinnated leaves, pretty much resembling the leaves of the ash-tree: the stalks arise to be about two feet high, having smaller leaves growing alternately on them: the flowers grow at the top of the stalks, in spikes, of an irregular shape, consisting of five pretty long and narrow leaves, set on like the flowers of violets, of a pale red colour, and several crooked stamina coming out of the middle, and turning upward: the seed is black, roundish, and shining, growing in long horned seed vessels. The whole plant has a strong and somewhat resinous scent. It grows wild in several places of Germany and France; but is only planted with us in gardens, and flowers in June and July. See *Plate* XVIII. *fig.* 2. where *e* is the flower, *f* the stamina, *g* the seed.

The root is esteemed a cardiac and alexipharmic, and serviceable against pestilential contagions, if it be taken any way. Matthiolus affirms it to be good against poisons, and the bites of venomous animals. Drank to the weight of a drachm, it kills worms in the intestines. It is prescribed in cold diseases of the uterus; for it provokes urine and the menses, promotes delivery, and brings away the secundines, and the dead child, if it be used either in a pessary, or in a suffumigation with penny-royal, or taken to the quantity of two drachms in pure wine; it is, also, good for the gripes of the belly, and to cleanse the kidneys of the gravel, and is a useful ingredient in potions for internal wounds. The women in Rome use the distilled water as a cosmetic, and for inflammations of the eyes; which is a plain argument, says C. Hoffman, that it cannot be used as a succedaneum to the true dittany; but, since it is bitter and acrimonious, says Ray, I see no reason why it should not be effectual for the same purposes as this plant. The pods and flowers excite an itching by their contact, and, in hot countries, exulcerate the skin: the plant varies with respect to its flower, which is sometimes white. *Raii Hist. Plant.*

The whole plant has a most fragrant smell, abounding with oil: the flowers and stalks are aromatic, balsamic, and sweet; whence it is reckoned among balsamic and vulnerary herbs. This species may be had in all the shops: it has a balsamic smell, and is very sweet and fragrant in all its parts: the bark is much commended for facilitating delivery, and purging the lochia; and, on account of its intense bitterness, is prescribed against worms: the seeds, leaves, and roots, are used in the shops; and the plant, for want of the true dittany, supplies its place in the Theriaca Andromachi: the conserve of the flowers, by its astringent virtue, corroborates the stomach and intestines. *Hist. Plant. ascribed to Boerhaave.*

DIDYNA'MIA *, in botany, a class of plants, whose flowers have two of their male parts or stamina of greater efficacy in the action of impregnation of the seeds than the others: they are known by the two efficacious stamina being always much longer than the others.

* The word is formed of the Greek δὶς twice, and δύναμις power or efficacy.

Of this class of plants are thyme, lavender, basil, &c.

DI'GGING, in minerology, a term appropriated by the miners, to express that penetrating into the earth, where they have the ore before them, and every stroke of the tools turns to account. They appropriated the word to this sense, expressing the random openings, which they make in search of mines, by the word hatching, or essay-hatching. See the article *Tracing of* MINES.

When the essay-hatches have been opened so long, that the orifice of the mine or load is found, the opening which has led to it, loses its name of essay-hatch, and is called a shaft or metal-hatch; this is to be sunk down about a fathom, and then they leave a square space, called a shamble, and so continue sinking from cast to cast; that is, as high as a man can conveniently throw up the ore with a shovel, till the load is found to grow small, or else to degenerate into some unprofitable substance, or weed, as they metaphorically express it. The degeneracy of the ore is soon perceived, by the finding mundic or marchasite growing more plentiful among it. This is a sulphureous mineral, of a yellow, whitish, or greenish colour, and is very troublesome to the Cornish miners. The other unprofitable substance found in the place of the ore, or mixed in large quantities with it, where it degenerates, are daze, which is white, black, or yellowish; iron mould, which is black or rusty; caul, which is red; glister, which is blood-red, or black, is also another degeneracy of the ore. In this case, they begin to drive either east or west, as the goodness of the land, or the convenience of the hill, unite. The drift or opening, on this occasion, is three feet over, and seven feet high, so that a man may conveniently stand and work: but in case the land is not broad enough of itself, as some are scarce half a foot; then they break down the deads, first on the north side of the lands, for the greater conveniency of the right arm working, and then they begin to rip the load itself; by the term deads, they mean that part of the shelf, which contains no metal, but incloses the load or vein as a wall between two rocks.

The instruments commonly used in mines with us, and that serve for ripping the lands, are the beele, or, as it is called in Cornwall, the tubber. This is a weapon of eight or ten pounds weight; well steeled and sharpened at each end, ending in a point each way, and having a hole in the middle: this

this will laſt half a year, but muſt be new ſharpened every fortnight. The ſecond inſtrument is a ſledge; this is uſually made from ten to twenty pounds weight, and will laſt ſeven years, if new ordered once in three or four months. Beſides theſe, they have gadds, or wedges; theſe are of about two pounds weight; they are made four-ſquare, and well ſteeled at the point, and they muſt have ladders and wheel-barrows to carry the deads and the ore out of the adits to the ſhambles. The general proportion of the workmen in Cornwall is this: two ſhovel-men, and three beele-men in a drift; theſe are as many as the drift will contain without ſtanding in one another's way. The beele-men rip the deads and the ore, and the ſhovel-men carry it off and land it, by caſting it up from one of the ſhambles to another all the way up; in ſome places they ſave the trouble of this caſting it to the ſhambles by a winder and two buckets; theſe are ſo contrived, that one goes up as the other comes down, and they are filled and emptied with great eaſe. *Phil. Tranſ.* N°. 69.

DIGE'STION, in chemiſtry *(Dict.)*—The chemiſts of late years have too much given into the more elaborate and forced proceſſes, and neglected the more natural and eaſy ones. Among theſe latter is Digeſtion; a proceſs ſo eaſy, that it requires ſcarce any quality in the operator but patience, and yet will do ſuch things, as all the elaborate proceſſes of that art can never arrive at without it. There is ſcarce a proceſs that has more puzzled the chemiſts of an age or two ago, than the volatalizing ſalt of tartar; yet Langelot aſſures us, that, after uſing all the caution in the common proceſſes that an earneſt deſire of ſucceſs could inſpire him with, he failed in them all, till, trying the effect of a long Digeſtion, he ſucceeded ſo well in the firſt attempt, that he converted almoſt the whole ſalt into a pure white volatile ſubſtance, leaving only a few earthy fæces behind.

Another great uſe of Digeſtion is, the duly preparing the eſſences of mineral ſulphurs; the ſtony ſea plants, which greatly reſemble the nature of foſſils, are alſo better treated by this proceſs than by any other; tartariſed ſpirit of wine receiving a very high tincture from red-coral, after a long Digeſtion, in any diſtilled vegetable oil, though it will not in the common way be at all coloured by it. *Philoſ. Tranſ.* N°. 87.

DI'GITAL *Arithmetic*, is a very ancient, as well as natural art; for this way of reckoning by the fingers ſeems to have been inſtituted by nature, which has given us this expedient as more eaſy than any of the reſt. The fingers are limited to ten, which is a myſterious number, and repreſents any thing that is moſt perfect and compleat: thus we plight our truth to one another, by joining our two right-hands together.

That Digital arithmetic is very ancient, is certain from Nicarthus, who, in a Greek epigram, tells us of an old man, who began again to reckon his years upon his left-hand. St. Jerom informs us, as to this matter, that the number of 100 was carried on from the left-hand to the right, and was reckoned upon the ſame fingers, but not upon the ſame hand; upon which account, Juvenal, ſpeaking of the happy old age of Neſtor, tells us, that he reckoned hitherto the number of his years upon his right-hand.

Numa erected a ſtatue of Janus, according to the relation of Pliny, whoſe fingers of its right-hand were ſo diſpoſed, as to ſignify the number 300, the thumb and fore-finger ſtanding out at full length, while the other three were bended towards the palm of the hand, and the fingers of the left-hand; ſignified fifty-five, the thumb and middle-finger being bended inwards, while the three others ſtood ſtraight. Beda treats of the ſame thing in the firſt book of the Nature of Things, but after a different manner.

It will not be impertinent to our preſent ſubject to relate a diſcourſe, which Francis the Firſt had one day at dinner, as it is ſet down by Viginere.

A diſcourſe was begun in praiſe of Auguſtus, whoſe cuſtom it was to keep always in his chamber two great regiſters; one, in which were entered the receipts; and the other, in which were the expences of ſo vaſt an empire. 'As to myſelf, ſaid the king, I have likewiſe two regiſters which I never part with night nor day, viz. my two hands, whereof the left repreſents to me my receipts; for the thumb, which is the ſtrongeſt of all the fingers, ſignifies my demains, which is alſo the moſt ſolid and lawful revenue a good prince can have; the fore-finger ſignifies my aids and ſubſidies; the the middle-finger, which is longeſt, denotes the taxes; the finger next to it, the caſual forfeitures; and, laſtly, the little-finger, the ſalt and exciſe. The right-hand repreſents to me my expences in general; the thumb ſignifies the maintenance of my houſe, the ſalaries of my menial ſervants, the great and little equerries, and the treaſury; the fore-finger ſignifies the fund reſerved for the neceſſities of the ſtate; the middle-finger, a fund for the armies by land; the ring-finger or the fourth, the payment of all officers of the kingdom, and particularly of the judges in the courts of juſtice, which I ought to adminiſter gratis to my ſubjects; and the little-finger, a fund for the armies by ſea'.

Now, if we reflect upon this way of counting, we may eaſily underſtand that it had its original only from hence, that men, having begun at firſt to reckon upon the fingers, they counted till it came to five upon one hand, and then, having added the other to that number, they made of them both ten, which is the double of the former; and this is the true reaſon why the progreſſion in theſe numbers is always from one to five, and then from five to ten.

All the Roman figures themſelves are alſo owing to the ſame original. For what can be more natural than to ſay, that the I is the ſame thing, as if a man ſhew one, by holding forth one finger only; and that the figure V is the ſame thing, as if a man, catching the three middle fingers, ſhould hold forth only the little-finger and the thumb, as containing the whole hand; and that, if you add to theſe the ſame two fingers of the other hand, joined to either at the top, they will make as it were two V's, whereof one will run acroſs under the other, and ſo make an X, which ſignifies ten.

There is a Digital arithmetic ſtill practiſed by ſome, and often found uſeful: it is the rule of multiplication performed by the fingers, which we ſhall always find ready at hand on all occaſions, when through ſtudy, long calculations, &c. our mind may ſometimes be ſo diſturbed as to be liable to make the greateſt miſtake. The rule is this:

Double down of one hand ſo many fingers as the multiplicant wants digits of ten; do the like with the other hand by the multiplier, and all the fingers that are left ſtanding will be tens, and the fingers doubled down digits to be multiplied, the one hand by the other; which will be eaſily done as the product will be but ſmall.

Example. Suppoſe the numbers 7 times 8
Double of
the right-hand 3, of the left 2, twice 3 — 6.
ſtanding 2 —— 3 —— 50.
——
56.

Again, 9 times 9.
Double down
right hand 1 left 1 —— 1
ſtanding 4 — 4 —— 80
——
81.

The like rule may alſo by a little alteration be made to ſerve for multiplying by 12, &c.

DIGITA'LIS, *fox-glove*, in botany, a genus of plants, whoſe characters are:

The leaves are produced alternately on the branches: the cup of the flower conſiſts of one leaf, which is divided into ſix ample long ſegments: the flower conſiſts of one leaf, is tubuloſe and compreſſed, and a little reflexed at the brim: theſe flowers are diſpoſed in a long ſpike, and always grow upon one ſide of the ſtalk: the ovary of the flower becomes a roundiſh fruit, which ends in a point, and opens in the middle: has two cells, in which are contained many ſmall ſeeds.

M. Tournefort has enumerated twenty ſpecies of Digitalis, and Mr. Miller ten.

Theſe plants may all be propagated by ſowing their ſeeds in March, in a freſh ſoil, that is not too ſtiff; and, when the plants come up, they ſhould be tranſplanted into beds ſix inches aſunder, where they may remain until the Michaelmas following, obſerving to keep them clear from weeds; then you may tranſplant them into the middle of large borders, intermixing the variety of colours at regular diſtances amongſt flowers of the ſame growth. In May following theſe will produce their flowers, which will continue near a month in beauty, if the ſeaſon is not too hot and dry, and in Auguſt the ſeeds will ripen; which, if permitted to fall to the ground, will come up in great plenty, and abundantly ſtock the garden with plants.

DILI'CTUM, a term uſed by Agricola, to expreſs a brine, made by pouring water upon ſand, ſtones, earth, &c. that had been before ſtrongly impregnated with ſea-ſalt; from this brine, a ſalt, for the uſe of the table, was made by evaporation in his time, and is ſo ſtill in many parts of the world. At Junthall in Germany they have a ſalt work of this kind, where they make at the rate of eight hundred loaves of ſalt in a week, each loaf weighing four hundred weight.

The ſand of the ſea is alſo in ſome places uſed as a ſubſtance to make ſalt from. There are works of this kind on the coaſt of Normandy, where a brine is made from the ſand, and evaporated at ſo ſmall an expence, that it is worth their while to export it to England and other countries. We had formerly ſome works of this kind in England, as at Wirewater, and ſome other places in Lancaſhire and Weſtmoreland, where, pit coal being ſcarce, they boiled it with turf fires; but ſince the works of the brine-ſalt, and purified rock-ſalt, have ſucceeded ſo happily with us: theſe are all laid aſide, except ſome inconſiderable ones in Lancaſhire. Theſe are near Ulverſtone, and the ſand from which they make their brine there, is extracted from the flat ſandy ſhores, which are only covered with water in the higheſt tides, which flow two or three days before, and three or four days after the new and full moon; for thoſe parts of the ſand which are overflowed by the neap-tides are ſeldom ſufficiently dried, and are at too great a diſtance from the ſalterns.

 This

This ſand they collect in flats and waſhes, or in parts of the ſands, which are perfectly plain, and in little hollows, where the ſea-water is left, and either ſinks into the ſand, or is dried up by the heat of the ſun, and leaves the ſalt behind. This is only collected in dry weather, and at ſuch times when the ſea-water has been exhaled from it by the ſun, and there have been no rains afterwards to waſh the ſalt out of it. They dig a pit adjoining to the ſaltern eighteen feet long, three broad, and one deep; the bottom of this they cover with ſtraw, or ruſhes, and then fill it up with ſand collected in this manner; they pour upon this ſea-water, and this, imbibing the ſalt from the ſand, is filtred through the ſtraw or ruſhes, and runs clear through a pipe at the bottom. *Brownrig of Salt*, N°. 136.

DIMI'NISHED *Interval*, is applied to ſuch as are leſſened by a ſemitone minor. Thus from C ♮ to E, being a third minor, if E be lowered by a ſemitone minor, we ſhall have E♭, and then from C ♮ to E♭ is called a Diminiſhed third, in the language of practical muſicians, and occurs frequently in their works. But, ſtrictly ſpeaking, in this caſe, the note E muſt be lowered more than a ſemitone minor.

DIMINU'TION *of a column*, in architecture.— *Plate* IV. *fig.* 6, in the Dictionary, repreſents an upright ſection of a column, in order to ſhew its Diminution, which decreaſes in proportion as the diameters *g g*, *f f*, *e e*, *d d*, *c c*, *b b*, *a a*.

DIOCTAHÆ'DRIA, in natural hiſtory, the name of a genus of ſpars. The word is derived from the Greek δὶς twice, ὀκτὼ eight, and ἕδρα a ſide. The bodies of this genus are ſpars compoſed of twice eight planes, or two octangular pyramids joined baſe to baſe, without any intermediate column. Of this genus there are three known ſpecies. 1. One with long pyramids, which is found in the mines of Rammelſberg in the Hartz foreſt in Germany, and no where elſe, ſo far as is yet known. 2. One with ſhort and ſharp-pointed pyramids found in many of the mines of the Hartz foreſt, and ſometimes tinged with the colours of the gems; and 3. One with ſhort and obtuſe pyramids, which is found in the mines of Cornwal, and lodged in the cotton-ſtone of Rutland. *Hill's Hiſt. of Foſſils.*

DIOE'CIA *, in botany, a claſs of plants which have the male and female parts, not in the ſame, but in different flowers, and thoſe not on the ſame individual, but on different plants of the ſame ſpecies; either of which, though they are called the male and female plants, from their thus carrying the ſeparate male and female flowers, might have ariſen from the ſame ſeed.

* The word is formed of the Greek δὶς twice, and οἶκος habitation. Among the plants of this claſs, are the willow, miſletoe, hemp, ſpinach, &c.

DI'PPING, in minerology, a term uſed to expreſs the deviation of the veins of ore from that regular and ſtraight line, in which they uſually run. A great deal of the ſkill of the miners conſiſts in the underſtanding this Dipping of the veins, and knowing how to manage it. In Cornwal they have this general rule to guide them in this reſpect: moſt of their tin-loads, which run from eaſt to weſt, conſtantly dip towards the north. Sometimes they underlie; that is, they ſlope down toward the north three feet in eight perpendicular. This muſt carefully be obſerved by the miners, that they may exactly know where to make their air ſhafts, when occaſion requires; yet, in the higher mountains of Dartmoor there are ſome conſiderable loads, which run north and ſouth; theſe always underlie toward the eaſt.

Four or five loads may run nearly parallel to each other in the ſame hill; and yet, which is rare, they may meet all together in one hatch, as it were a knot, which well tins the place, and ſo ſeparate again, and keep their former diſtances. *Philoſ. Tranſ.* N°. 69.

DI'PSACUS, *the teaſel*, in botany, a genus of plants, whoſe characters are:

The whole flower hath no proper calyx, but leaves repreſenting the perianthium encompaſſing the bottom of the head; the little flowers, which are produced ſingly from between the ſcales, are collected into an head ſomewhat like a bee-hive: theſe are ſucceeded by longiſh four-cornered ſeeds.

There are four ſpecies of this plant. But the fourth ſort only is cultivated for uſe, which is called carduus fullorum, or fullonum, being of ſingular uſe in raiſing the knap upon woollen cloth; for which purpoſe there are great quantities of this plant cultivated in the weſt country.

This plant is propagated by ſowing the ſeed in March, upon a ſoil that has been well dried: about one peck of this ſeed will ſow an acre; for the plants ſhould have room to grow, otherwiſe the heads will not be ſo large, nor in ſo great quantity. When the plants are come up, you muſt hoe them in the ſame manner as is practiſed for turnips, cutting down all the weeds, and ſingling out the plants to about ſix or eight inches diſtance; and, as the plants advance, and the weeds begin to grow again, you muſt hoe them a ſecond time, cutting out the plants to a wider diſtance; for they ſhould be, at laſt, left at leaſt a foot aſunder: and you ſhould be particularly careful to clear them from weeds, eſpecially the firſt ſummer; for, when the plants have ſpread ſo as to cover the ſurface of the ground, the weeds will not ſo readily grow between them. The ſecond year after ſowing, the plants will ſhoot up to heads, which will be fit to cut about the beginning of Auguſt; at which time they ſhould be cut, and tied up in bunches, ſetting them in the ſun, if the weather be fair; but if not, they muſt be ſet in rooms to dry them. The common produce is about a hundred and ſixty bundles or ſtaves upon an acre, which they ſell for about one ſhilling a ſtave. Some people ſow caraway and other ſeeds amongſt their teaſels: but this is not a good method, for one ſpoils the other; nor can you ſo eaſily clear them from weeds, as when alone.

The leaves of the common wild teaſel dried, and given in powder, or infuſion, are a very powerful remedy againſt flatus's and crudities of the ſtomach. There is alſo another, though ſomewhat whimſical uſe, for which this plant is become famous among the country people. If the heads are opened longitudinally about September or October, there is generally found a ſmall worm in them: one of theſe only is found in each head, whence naturaliſts have named it the vermis ſolitarius Dipſaci. They collect three, five, or ſeven of thoſe, always obſerving to make it an odd number, and, ſealing them up in a quill, give them to be worn as an amulet for the cure of agues. Faith has wrought ſo many cures for them, that they are in many parts of the kingdom of much higher reputation than the bark.

DIRE'CTOR, in ſurgery, a grooved probe, to direct the edge of the knife or ſciſſars in opening ſinus's or fiſtula's, that, by this means, the ſubjacent veſſels, nerves, and tendons, may remain unhurt. Sometimes one end is made in form of a ſpoon, to contain powders to ſprinkle upon wounds or ulcers. Sometimes alſo it is forked at the end to divide the frænum of the tongue. *Heiſter's Surg. Introd.*

DISDIACLA'STIC *Cryſtal*, in natural hiſtory, a name given by Bartholine, and ſome others, to the pellucid foſſil ſubſtance, more uſually called, from the place whence it was firſt brought, Iſland cryſtal; though properly it was no cryſtal at all, but a fine pellucid ſpar, called by Dr. Hill, from its ſhape, parallelopipedum.

This cryſtal is met with in other places beſides Iſland, but not ſo plentifully. It is there found in great abundance all over the country, but is particularly plentiful in a mountain, not far from a bay of Roeziford, where the fineſt and moſt pellucid pieces are found on digging. The mountain lies in 65 degrees of latitude, and has its whole outſide made up of it; but, though this makes a very bright and glittering appearance, it is not ſo fine as that which lies at a little depth, and is met with on opening the ſurface. This is generally taken up out of the earth in maſſes of a foot long, and its corners are very frequently terminated in theſe large maſſes, by a ſort of cryſtals, very different in figure and quality from the reſt of the maſs. The ſtone itſelf is of a parallelopiped figure; but theſe excreſcences are either ſingle pyramids affixed to columns, like common cryſtal or double pyramids, with or without columns between. The ſtone itſelf is ſoft; theſe are hard, and cut glaſs; the ſtone calcines to lime in the fire, theſe run into glaſs; in ſhort, the ſtone itſelf is true ſpar, and theſe are true cryſtal: beſide theſe, there ſometimes grows out of the end of the larger maſſes a pure and fine aſbeſtus. This likewiſe is the caſe ſometimes in the ſpar, found about Barege in France, and ſhews how nearly together the formation of bodies wholly different from one another may happen. The general figure of the ſtone is parallelopiped, or, as ſome expreſs it, rhomboide; and it retains this, not only while whole, but alſo when broken to pieces; every fragment it naturally falls into, though ever ſo ſmall, being truly of that ſhape. But it is remarkable, that, in ſome places of this mountain, the ſame ſort of matter is found in form of triangular pyramids, all which have the ſame property of the double refraction with the parallelopipeds of the ſame ſubſtance; ſo that the original error of ſuppoſing its qualities owing to its ſhape is refuted by this, as well as by the trials made with other pellucid bodies of the ſame figure, which do not ſhew this remarkable property. *Bartholine de Cryſtal. Iſland. Phil. Tranſ.* N°. 67.

DISH, in mining, is a trough made of wood, about twenty-eight inches long, four inches deep, and ſix inches wide; by which all miners meaſure their ore. If any be taken ſelling their ore, not firſt meaſuring it by the bar-maſter's diſh, and paying the king's duties, the ſeller forfeits his ore, and the buyer forfeits for every ſuch offence forty ſhillings to the lord of the field, or farmer. *Houghton's compl. Miner.*

DISPA'RT, in gunnery, is uſed for the ſetting a mark on the muzzle-ring of a piece of ordnance, or thereabouts; ſo that a right-line taken upon the top of the baſe-ring againſt the touch-hole, by the mark ſet on or near the muzzle, may be parallel to the axis of the concave cylinder. The common way of doing which, is, to take the two diameters of the baſe-ring, and of the place where the Diſpart is to ſtand, and divide the difference between them into two equal parts, one of which will be the length of the Diſpart, which is ſet on the gun with wax or pitch, or faſtened there with a piece of

twine

twine or marlin: but an inftrument may be made to do it to all poffible nicety.

DISSIPA'TION. Circle of Diffipation, in optics, is ufed for that circular fpace upon the retina, which is taken up by one of the extreme pencils of rays iffuing from an object.

To underftand which, it is to be obferved, that when the diftance of an object from the eye is too fmall, or too great, for perfect or diftinct vifion, the rays of each pencil iffuing from the object cannot be united at a point on the retina, but beyond it, or before they arrive at the retina; confequently the rays of each pencil will occupy a circular fpace upon the retina; and this circle is called the circle of Diffipation, becaufe the rays of a pencil, inftead of being collected into a central point, are diffipated all over this circle.

The confideration of the circles of Diffipation, formed by the rays coming from the extremities of objects, is of ufe to account for feveral curious phænomena of vifion.

DISTE'MPERATURE *of trees.*—Some of thefe are in the tree itfelf, and others in the foil and other things about it. Of the laft kind are weeds, which are of the utmoft ill confequence to all forts of trees, while young, and fhould be pulled up by hand after rain: if they are too ftrong rooted for this, they muft be dug up; and this will have a double advantage, as the ftirring the earth about their roots will do the tree a great deal of good. When the trees are grown to a tolerable height, they require no care about weeds, for they kill them with their own droppings. Suckers are another Diftemperature of trees arifing from the tree itfelf: they muft be pulled off, or cut up clofe to the place where they come out, opening the earth to come at them there. Over much wet often is a very great prejudice to trees, and efpecially to thofe kinds which naturally love a dry foil. This is to be remedied by cutting drains: and if a drip fret the body of the tree by the head, which will certainly decay it, the place muft be firft cut fmooth, and then fome loam or clay, mixed well with horfedung, is to be applied to the place, which will defend it from mifchief till a new bark is formed over it. All wounds, made in trees in winter, are much harder to cure than thofe made in fummer; and for thefe it is proper to add fome tallow to the mixture of loam and dung.

When trees are bark-bound, which is eafily feen by the unnatural tightnefs and ftraining of the bark over them, it is to be remedied by cutting through the bark with a knife, from the top to the bottom of the tree. This may feem a dangerous remedy to thofe who have not experienced it, but it never was found to do any injury to trees. It is to be done in February or March; and, if the wound gape very much, it may be filled up with cow-dung, which will defend the tree from injury till it heals. The digging about the root of the tree is a very good practice alfo on this occafion, and the cutting off the dead or withered branches.

The grubs of beetles, called teredines and coffi, which get between the bark and the tree, do great mifchief: if the places can be found out where they lie, it is proper to pierce into the bark with a pointed inftrument upon them, and then to open a fmall hole below, to let out whatever moifture may be there. When trees of the fruit kind are burnt up and bliftered on the bark with hot and dry feafons, and this is followed by a vaft number of pucerons or tree-lice, which feed on the juices, fome recommend the boring a large hole in the main root, and pouring in fome brandy, then ftopping up the hole with a pin of the fame wood. The tree fuffers nothing by this, but the juices are fo much altered for the prefent by it, that thefe animals do not like them, and confequently quit their habitation.

If a tree is, by any accident, barked or ftripped all round, fo that it cannot grow any longer, the proper method is to cut it off juft above fome principal branch; the ftump muft be cut off flanting, and covered with clay; and the branch will foon become the body of a tree in the place of the other: the place where the ftump is cut off being covered with a bark, in the manner of a tree that is grafted.

Deer and hares, as alfo rabbits, are apt to bark trees, and do them great mifchief. The defence againft deer is by paling them round, or painting the lower part of the tree; but the firft is much the better method. The hares and rabbits may be kept off by tying bands of ftraw round the foot of every tree, as far as they can reach. Evelyn recommends the rubbing them over with human dung made into a foft pafte with urine, fo that it may be laid on with a brufh; but this is attended with great trouble, as it muft be renewed after every hard rain. Some ufe tar and lime mixed together, but this always damages the tree more than thefe creatures would have done; and, in general, ftraw-bands, where any thing is neceffary, do beft. *Mortimer's Hufbandry.*

DISTILLA'TION (*Dict.*)—*Simple* DISTILLATION.—Simple Diftillation is the method of feparating and collecting the inflammable fpirit, clear of all the other parts of fermented liquors, by means of fire and the alembic.

This operation includes not only what in the language of diftillers is called working from wafh, and the producing of low-wines, or fpirits of the firft extraction; but alfo fimple rectification, or the production of fimple proof-fpirit, and fimple alcohol.

The common ways of charging, working, and managing a ftill, regulating the fire, &c. are here fuppofed to be underftood: but, in order to improve this operation, and bring it to a truth, feveral obfervations and methods are required, befides thofe vulgarly known and confidered.

1. It is remarkable that the action of fermentation works fuch a change in the body of the tincture or folution, as to render it feparable, by the action of the fire, into parcels of matter that are fpecifically different; and of a nature entirely foreign to what, by the fame means, the liquor would have afforded before fermentation.

2. The ftill being charged, luted, and brought to work, with a foft boiling heat, there firft comes over a quantity of intenfly pungent, aromatic, nidorous liquor; which, if received into a large proportion of cold water, throws off a copious, effential, acrid, or aromatic oil; though the original fubject were ever fo cooling, mild, or contrary to a fpicy nature.

3. This effential oil is, by experiment, found to be the principal thing that gives the predominant or peculiar flavour to fpirits; which are hence, by their tafte and odour, denominated malt-fpirit, melafs-fpirit, cyder-fpirit, wine-fpirit, arrack, &c.

4. The fineft, moft fubtile, and moft efficacious part of this effential oil is what comes firft; the fucceeding portions growing gradually more fluggifh, vifcous, refinous, naufeous, and terreftrial.

5. The fpirit running in a continued ftream from the nofe of the worm, being examined at different intervals, will be found greatly to differ from itfelf, both in fmell and tafte; as changing the nature of its oil, much oftener than, without trial, could have been expected.

6. Befides this effential oil, the fpirit of the firft running contains alfo an acid, more or lefs in quantity, and more or lefs pungent, volatile, and fenfible to the nofe, as the fermentation has been more or lefs continued, or according to the degree of acidity acquired in the operation. And this acid alfo may, along with the aqueous part that rifes with it, be in plenty kept back upon a gentle rectification; though, where the acid is very volatile, fome part thereof is ever apt to rife along with the totally inflammable fpirit, fo as to give it a vinofity, not unlike a dilute fpiritus nitri dulcis.

7. It is manifeft, both a priori, and a pofteriori, that brandies are a compound, confifting of at leaft four different parts; viz. totally inflammable fpirit, effential oil, acid, and water.

8. And as thefe feveral parts do not differ greatly in their fpecific gravity, or degree of volatility; a ftrong, tumultuary, boiling heat will drive them all over promifcuoufly together.

9. As, at the beginning of the operation, there ufually rifes more totally inflammable fpirit than water; fo, after fome time, the ftream contains more water than inflammable fpirit: and this gives the foundation for what they call low-wines, proof-fpirit, and faints: low-wines being the whole quantity of fpirit, weak and fmall mixed together; proof-fpirit, a mixture of about equal parts of totally inflammable fpirit and water; but faints all that runs after the proof is fallen off, where the proportion of water is much greater than of the totally inflammable fpirit.

10. Thefe low-wines are commonly rediftilled, to make what they call proof-fpirit, by leaving out their fuperfluous phlegm: and in the fame manner may the faints alfo be ferved; by which means they are fuppofed reducible to a certain ftandard, or ftated merchantable degree of ftrength, called proof.

11. When once the ftream falls off from proof, the liquor contains a groffer effential oil, which, though not fo communicative as the firft, never fails to impregnate the whole with its flavour.

12. Hence all common fpirits or brandies are really dilute quinteffences, as the chemifts call them; that is, a mixture of the ardent fpirit and effential oil of the concrete; only here let down to proof with water, and impregnated with a fmall proportion of a volatile acid.

13. When the proof falls off, the liquor grows milky; that is, the oil, which before remained diffolved by the ftrong fpirit, is fet loofe from it by an over-proportion of water; and may now be commodioufly feparated by the chemical glafs fitted for that purpofe.

14. It is cuftomary to continue the Diftillation fo long as the liquor that runs will take fire at the flame of a candle, applied to the vapour of a fmall quantity thrown upon the hot ftill-head: and indeed there is a certain point of time, when the fpirit obtained will not pay the fire and labour; viz. when not above a twelfth or fourteenth part of totally inflammable fpirit comes over in the water.

15. With other views however, as particularly the obtaining a more fixed vegetable acid, and a groffer effential oil, the operation might be continued, till the danger of an empyreuma comes on.

16. The matter remaining in the ftill, after the operation is ended, has feveral ufes; and might in particular be made to afford Mr. Boyle's acid fpirit of wine.

17. When by repeated Diſtillation, without addition, any ſpirit is entirely freed of its aqueous parts; it is then called totally inflammable ſpirit, alcohol, or perfect ſpirit of wine.

Upon theſe general obſervations may be formed ſome new practical methods for the improvement or perfection of Diſtillation.

1. And, firſt, as the fermented liquor affords different parcels of matter, of different ſpecific gravities or degrees of volatility; when a pure ſeparation of the lighteſt part is intended, the fire ſhould never riſe to a boiling heat, which jumbles and confounds all the parts together, rather than ſeparates them.

In the chemical way this rule may be practiſed to advantage; but great difficulties will attend the obſervance of it in the common buſineſs of Diſtillation.

To render it more commodiouſly practicable, theſe two methods are propoſed; viz. 1. Either to increaſe the height of the ſtill above the liquor; or, 2. To work in balneo mariæ.

1. By running the ſtill-head to the height of two or three yards above the liquor, it has been expected that a boiling heat would carry up the pure inflammable ſpirit, without any great mixture of phlegm, and yet continue to run a full ſtream. But this does not perfectly anſwer upon experience; though the thing is ſtill improveable, and has been attempted by the addition of a tall ſerpentine pipe, for the ſpirit to creep through and depoſit the phlegm, as it aſcends. And thus indeed the ſpirit may in a good meaſure be dephlegmed: but the great objection againſt this method, is, that it requires a boiling heat, which in the caſe of ſimple ſeparatory Diſtillation ſhould never be uſed: becauſe it throws up ſo much oil, as to foul at leaſt the breaſt and head of the ſtill and bottom of the pipe; whence it infects the ſubſequent ſpirit that waſhes them.

2. The other way by the balneum mariæ is preferable on many accounts; ſo that, by a proper regulation, we might hope for a pure ſimple ſpirit almoſt at the firſt extraction. Such an expectation will not appear unreaſonable to one who has ſeen what ſpirit is obtainable even in the common method of the balneum mariæ, where the water of the bath is made to boil with the utmoſt violence, and compared it with another parcel of ſpirit, prepared from the ſame fermented liquor in the common way of the hot ſtill. Indeed the difficulties of working from waſh in this way of the balneum mariæ are very conſiderable; eſpecially if cheapneſs and diſpatch be the principal thing in view. For at once to work both quick and perfect ſeems hitherto impracticable in the buſineſs of Diſtillation. The whole affair has a great dependence upon a ſuitable engine and apparatus. And perhaps a large or long rectangular boiler might commodiouſly be turned into the balneum we ſpeak of; and fitted with a number of low alembics, that ſhould all work, day and night, with a little fire and leſs attendance. The contrivance in general is obvious; but to avoid encumberance and loſs is the principal difficulty. A large number of veſſels or alembics is abſolutely neceſſary; but no worms and refrigeratories are required. And by an eaſy apparatus the whole number of the ſmall veſſels may be charged with nearly as much eaſe as a large one. When the operation proceeds ſo ſlow as not to quit the coſt, all the bottoms may be emptied into a common ſtill, and worked in the uſual way, for a coarſer commodity, that may afterwards be rectified at pleaſure. The heat of the balneum ſhould only be tepid, or at moſt but ſcalding.

By this means a ſurprizingly cool and almoſt inſipid ſpirit has been obtained, at the very firſt extraction, though mixed with a conſiderable proportion of phlegm; ſo that it needed no manner of rectification to fit it even for the finer uſes. The method, therefore, at leaſt is curious, and in ſome caſes uſeful, though it ſhould never be brought into a general practice. And indeed a thing of this nature deſerves to be kept in curious hands, as by a due application it may furniſh productions fit for the cloſets of princes.

In the common method of ſimple Diſtillation all proper means ſhould be uſed to prevent the groſſer eſſential oil from getting into the ſpirit. Theſe means have regard, 1. To the preparation of the fermented liquor: 2. The regulation of the fire: 3. The uſe of percolation: and, 4. To the keeping out the faints.

1. For the manner of preparing the fermented liquor, and clearing it of its groſs oleaginous fæces, before it is committed to the ſtill, ſee Brewing and Fermentation.

We ſhall only add that the liquor, thus fined, ſhould not poſſeſs above two thirds of the ſtill, that the groſſer oleaginous matter may the better be kept down, and the whole have free ſcope to work, riſe, and purge itſelf in the operation: which it never can do, if it wants room. 2. As in this Diſtillation a boiling heat is neceſſary, care ſhould be had that the liquor only boil gently and uniformly, without raiſing the fire by ſtarts; which never fails to throw over the coarſe oil in plenty, and foul the ſpirit: ſo that, if poſſible, the operation ſhould be begun and ended with the ſame uniform and invariable degree of heat.

3. The groſſer oil may in ſome degree be kept from mixing amongſt the ſpirit, by ſtretching a piece of very thick woolly flannel over the mouth of the ſtill, or by ſuffering the ſtream to paſs through ſuch a flannel, ſeveral times doubled and placed at the noſe of the worm: and it is ſurprizing what a quantity of groſs, offenſive, fœtid, unctuous matter may thus be collected, eſpecially in the Diſtillation of malt ſpirits.

4. The faints ſhould never be ſuffered to run among the finer ſpirit, on account of the large quantity of this groſs oil, or greaſy matter they contain; eſpecially if the fire be increaſed, as it uſually is to bring them over: though ſome, who value proof more than purity, will uſually have a doſe thereof to give their goods a face. Which prevailing fondneſs for a ſtrong hanging proof, however abſurd in itſelf, is one principal reaſon why the common malt-ſpirits are no cleaner.

This caution of keeping out the faints ſhould likewiſe extend to the keeping out a little of the firſt running, which too, in this operation, is a kind of faints; as containing largely of the oil of the concrete, though much more ſubtile than that in the proper faints. A farther regard muſt alſo be had to the ſtill-head and worm, through which the faints have once paſſed; as theſe all along depoſit ſuch a copious infecting oil, as gives a predominant flavour to an almoſt incredible quantity of pure ſpirit. Nor is this oil eaſily diſlodged from the pores of the ſpongy metal, by running hot water through the worm; but either requires a quantity of boiling lixivium, or elſe ſome highly rectified ſpirit to ſtand in the worm all night, to imbibe, diſſolve, and carry it away. And, if theſe cautions are carefully obſerved, a much better and purer ſpirit may be obtained after the common method, than thoſe who have not tried it would expect.

When, now the faints have run off, and it becomes unprofitable to continue the operation longer, the original maſs of fermented liquor is ſeparated into ſtill-bottoms and low wines, or ſpirit of the firſt extraction. The ſeveral parcels of ſpirituous liquor, come over, are then uſually mixed together, and thrown into another ſtill, to be rectified into what they call a ſaleable commodity, or proof goods.

This operation is a ſecond ſpecies of ſimple Diſtillation, which, without any addition, tends to cleanſe the whole body of the ſpirit from the groſſer oil of the faints, provided the work be carried on in a mild and gentle manner: otherwiſe it ſerves but to keep back the ſuperfluous phlegm that ſunk the ſpirit much below proof, rather than to improve its quality.

Combinatory Distillation, a term introduced into uſe by Dr. Shaw, in his Eſſay on Diſtillation, to expreſs that ſort of rectification of diſtilled ſpirits which is done with additions, and which he otherwiſe calls improper rectification, by way of diſtinction from that proper rectification, which is only the method of reducing a ſpirit to its utmoſt degree of purity and perfection.

In the combinatory Diſtillation many ingredients are added, in order to rectify the ſpirit, as the diſtillers expreſs it; and ſome parts of theſe actually come over and mix themſelves along with the ſpirit ſo intimately, as not to be ſeparable again without great difficulty. This is done with a deſign to alter, improve, or aboliſh the natural flavour of the ſpirit, but, inſtead of rectifying it, they only obſcure and pervert its true qualities. In the buſineſs of rectification, properly ſo called, of the malt ſpirit, all that is neceſſary is the rediſtilling the low wines procured from the waſh; the again diſtilling over the ſpirit thus obtained, and called proof-ſpirit, into a totally inflammable liquor called alcohol. This is done by the common proceſſes, only taking care not to increaſe the fire by ſudden ſpurts, ſo as to raiſe the oil with the ſpirit, which, if once mixed, will not be eaſily ſeparated again, and ſcarce ever perfectly, whatever care is uſed. *Shaw's Eſſay on Diſtillery.*

The methods of combinatory rectification, on the other hand, are very numerous, every diſtiller having his peculiar noſtrum about it. Malt ſpirit is the general ſubject of this proceſs, and the means uſed to rectify it on this plan may be reduced to three heads: 1. That by fixed alkaline ſalts alone. 2. That by fixed alkaline ſalts and acid ſpirits. And, 3. That by ſaline bodies and flavouring additions. The general method is that by fixed alkaline ſalts alone; but it is ſurpriſing to ſee in how careleſs and ſlovenly a manner this is done by the generality of our diſtillers, though we are allowed to excel all other nations in it. The effect of this operation, when carefully performed, is to attenuate and thin the ſpirit, and to keep back a part of its groſs and fœtid oil, and ſo far to alter the part of the oil which comes over, as ſcarce to leave the ſpirit diſtinguiſhable for a malt ſpirit.

This end is greatly promoted by a prudent and ſteady management of the fire, and by leaving out the faints; but this is a thing our diſtillers never attend to: they hurry over the operation, working the ſtill in its full force, and by this means raiſe and carry over the oil, though the whole buſineſs of the proceſs is to keep it back; and they even ſuffer the fulſome bitter oil, made into a kind of liquid ſoap with the ſalt in this proceſs, to run among the ſpirit with the faints; by this the whole intent of the proceſs is fruſtrated, and the ſpirit rendered much harder to clean than it was before.

This operation is uſually performed on proof-ſpirit, and the quantity allowed is from eight to fourteen pounds of ſalt of tartar,

tartar, fixed nitre, pot-aſh, or more commonly calcined tartar, to the piece. The tartar, being only roaſted to a blackneſs in this laſt proceſs, is ſold under the abſurd notion of a vinous ſalt, and the dealers will often praiſe the vinoſity of their ſpirit, becauſe diſtilled from this ſalt; but the truth is, that this ſalt never fails to give, inſtead of a vinoſity, a ſaponaceous, urinous, or lixivial taſte and ſmell. This is the great misfortune that attends the method of rectifying by means of fixed ſalt, for they all of them become volatile in part during the operation; and this volatile portion paſſes over the helm with the ſpirit, and impregnates it, uniting itſelf alſo with that portion of oil yet retained in the ſpirit, and much more firmly combining it and the ſpirit together than they were before; ſo that in reality the ſpirit thus rectified is no other than an alkaline or tartariſed ſpirit, as the chemiſts call it; a thing extremely different from a true vinous ſpirit.

This method therefore, though it were practiſed to the utmoſt perfection, would never do what was intended by it, but would alter inſtead of rectifying the ſpirit. Hence there appears the neceſſity of ſome acid to deaden the force of the alkali thus uſed in the rectification. The neceſſity of this gave occaſion to the method of mixing acids and alkalies together for theſe purpoſes. The acids uſed by our diſtillers on this occaſion are thoſe of the mineral kingdom, by reaſon of their cheapneſs; and the moſt common in uſe among them are oil of vitriol, ſpirit of nitre, oil of ſulphur, and the like. There is ſome choice however to be made of the ſpirits according to the greater or leſſer foulneſs and need of rectification, and they muſt not only be well proportioned, but carefully introduced, and regularly mixed; and indeed, without ſome ſkill and judgment in the management of the corroſives, no diſtiller ought to attempt to meddle with them.

Theſe ſtrong and violent acids, at beſt, are not ſo well adapted to the work as the milder ones, particularly the ſulphureous ſpirit of vitriol, which comes over in the rectification of the oil; to this may be added the common ſpiritus nitri dulcis, and Mr. Boyle's acid ſpirit of wine well prepared.

Some of our rectifiers inſtead of the fixed ſalts uſe quick-lime, which cleanſes and dephlegmates conſiderably: but this method requires the aſſiſtance of acids alſo afterwards, to take off not only the alkaline diſpoſition, but alſo the ſtinking flavour it leaves behind it. Some alſo uſe chalk, virgin earth calcined, and burnt animals bones. Theſe are of conſiderable uſe in the rectifying brandy without rendering the ſpirit any more unfit for the purpoſe of the compounders than before, or requiring much acid afterwards.

The great art of uſing the flavouring ingredients in rectification is, the proper admixture of ſalts in the operation, for, without theſe, the flavours added by this means do very little. The ſalts uſed on this occaſion are either the fixed alkalies, as pot-aſh and calcined tartar, or decrepitated common ſalt, or calcined vitriol, alum, or ſandiver. The flavouring ingredient is to be applied afterwards, and the whole quantity of the ſpirit either drawn over again, or not, as the occaſion and nature of the addition require. But theſe ſaline bodies perform ſo very little, that the ſpirit is uſually left impregnated with a flavour from its own oil, which is but badly hidden, or overpowered by the other ingredients. The moſt common flavourers, as they call them, are theſe, mace, orrice root, parſnip, artichoak, rhodium, raiſin-ſtalks, damaſk-roſes, wine-lees, rape or grape-huſks, and the oil of wine. The laſt of theſe is infinitely preferable to all the others, but is not ſo well known. Theſe and the like ingredients, judiciouſly mixed, will, when the ſpirit is very well purified firſt, give the flavour of foreign brandies with ſome tolerable exactneſs; but if this is not attained, their flavour will be loſt in the original one, and the general taſte reſulting from the whole will be like nothing at all. The ultimate perfection, aimed at in all the proceſſes of combinatory Diſtillation, is the depurating the Engliſh malt ſpirit at one operation, ſo as to render it taſtleſs and inodorous, and yet vinous; or elſe to make it reſemble the French brandy, arrac, or ſome other low-flavoured vinous ſpirits.

This is certainly practicable, though not uſually practiſed to the perfection that it might be: the principal thing, to be endeavoured after, is the obtaining a taſteleſs ſpirit, capable of receiving any impreſſion, and then the buſineſs of flavouring is eaſy. The method of rectifying, by fixed alkaline ſalts, is capable of great improvement, as by ſteeping the ſpirit firſt brought near to the ſtate of alcohol, upon a well dried ſalt of tartar, or any other cheaper, but pure fixed alkali; by this means, it will be almoſt totally freed of its oil without volatilizing much of the ſalt, as it does in the way of Diſtillation; by this means a weak tincture of ſalt of tartar may be procured, and an acid added to this, to take off the effects of the alkali in the ſpirit; the whole is then to be diſtilled; and, the fire being well managed, a very clean ſpirit will be thus procured at one operation, ſuch as can no way elſe be obtained at once.

The uſe of the compound neutral ſalts in rectification ſeems not yet to be ſufficiently known; what is meant by theſe ſalts is a fixed alkaline ſalt ſaturated with an acid one. Such a ſalt has indeed been expected from the caput mortuum, or white ſaline cake, remaining upon Diſtillation of the ſpirit of nitre with oil of vitriol; but it proves too hard, ſtony, and inſoluble, to be of any great uſe on this occaſion: a much better effect may be expected from ſoluble tartar, carefully prepared, and properly uſed; though even this is apt to render the ſpirit a little ſaponaceous. Some compound neutral ſalts have been made however upon this foundation, that would rectify common malt ſpirit from proof at a ſingle operation, much better than all the other more perplexed and tedious methods in uſe. A prudent uſe of fine dry ſugar may alſo be of ſome ſervice, as it readily unites with the eſſential oil, and detains and fixes it, without imparting any urinous or other nauſeous flavour to the ſpirit rectified upon it; another hint to this purpoſe, which may be made to turn to very good account, is, that given by the ingenious method invented by Dr. Cox, of taking all the oil out of the volatile ſalts, by firſt bringing them to a neutral ſtate with ſpirit of ſalt, and then ſubliming them with ſalt of tartar, which does the buſineſs to perfection. In the caſe of ſpirits the acid may be varied, and virgin earth, chalk, calcined flints, or the like abſorbents uſed in the ſtead of ſalt of tartar, and yet the general effect will be the ſame. *Shaw's Eſſay on Diſtillery.*

Compound DISTILLATION.—By compound Diſtillation, is meant that wherein the addition of certain ingredients gives the ſpirit ſome new properties, virtues, and uſes, different from thoſe of a ſimple ſpirit. Thus the cordial waters of the diſtillers, and the compound waters of the apothecary, are productions of this operation.

The apothecaries have long been ſubject to the ridicule of diſtillers, on account of their inelegant way of making compound waters; and at preſent ſeem to yield the diſtillers maſters of the art, without venturing farther to diſpute the point. But, as apothecaries are all expected to be chemical operators, I do not ſee how they can ſubmit to be out-done in a chemical branch of their buſineſs; eſpecially, how they can acknowledge the diſtillers to make better compound waters than themſelves; yet conſtantly ſupply their patients with thoſe of their own making.

The diſtillers uſually think themſelves ſo perfect in this art, as to need no farther inſtruction; but they will not, it is hoped, be unwilling that a little aſſiſtance ſhould be given the apothecary, in a point that concerns the health of his patients.

In all compound Diſtillation, it is a principal rule, that the ſpirit employed be well rectified, cleanſed, and rendered nearly inſipid; eſpecially if a malt-ſpirit be choſe: otherwiſe the oil of the ſpirit will prevent its being well impregnated with the virtues of the ingredients, and alſo be apt to taſte through them all. And for this reaſon, as well as others, the ſpirit ſhould be brought into the form of alcohol. At leaſt, if a clean proof-leſs malt-ſpirit cannot be procured, let a fine melaſſes ſpirit, which, though proof, ſhews thin and attenuated, be uſed without any farther addition of water in the ſtill. An additional quantity of water only takes up room to bad purpoſe, and not only prolongs, but prejudices the operation. And, when alcohol is employed, let it only be mixed with an equal quantity of fair water.

In the next place, due regard muſt be had to the buſineſs of digeſtion; without which the virtues of ſome ingredients will not riſe in Diſtillation. Thus, without good maceration, the ponderous oil of the cinnamon is not very ready to riſe with the ſpirit: whence the virtue of it ſometimes remains in the ſtill, and requires to be fetched out by cohobation. The apothecaries, to avoid this trouble, or for other reaſons, are uſually content to have their ſtrong cinnamon-water poor, that their ſmall cinnamon-water may be rich. But this is perverting the deſign of the phyſician, who expects both to be made in perfection, and ſecundum artem.

When the ingredients, according to their reſpective natures, have ſtood a due time in digeſtion, the ſpirit is to be drawn from them in the manner that beſt tends to bring over the virtues, whereon the character and expectation of the water are founded. So, if the ingredients naturally abound in a heavy viſcous oil, the operation ſhould be performed with a briſker fire, than when the oil is thin, light, and ethereal. Thus ſtrong cinnamon-water, after ſufficient digeſtion to looſen the oil, might be drawn over ſmarter than citron-water, the ſpirit of mint, or the like; where the eſſential oil aſcends much eaſier along with the ſpirit.

The capital thing of the whole reſts here, that a due proportion of the finer eſſential oil of the ingredients be received into, and embodied with the ſpirit; whilſt the groſſer, leſs ſubtile, and leſs agreeable oil is kept out. To effect this fully requires, 1. That the operation be well regulated from the firſt; 2. That the receiver be changed in due time; and, 3. That the ſpirit be prudently made up. When no regard is had to theſe ſeveral particulars, as it rarely ſeems to be among the apothecaries, the conſequence is the production of a milky, thick, turbid liquor, that taſtes more like what the diſtillers call faints than a cordial water; and, indeed, ſeems more fitted to give ſickneſs, than to cure it. At leaſt, before it can be uſed, it muſt either ſtand a long time to fine of itſelf, if ever it will fine; or have its groſs, unctuous,

unctuous, and terrestrial parts precipitated by art. On the contrary, when these rules are prudently observed, the water proves, without farther trouble, clean-tasted, clear, brisk, pleasant, and refreshing; supposing it intended for a common cordial, and not for physic.

What seems to have led the distillers into this clean way of compounding, is their particular esteem and fondness for the bubble-proof; a thing little understood by apothecaries, and less regarded in their productions. The distillers, in the making of compound waters, find, if they suffer their faints to run among the high spirit, this procedure kills their proof before its time. Hence they are instructed to leave them out, and make up with fair water; reserving their faints for other uses, to which, as containing a copious oil, they are better adapted: so that, by a little management, they may be turned into waters themselves, or made to give out their essential oil. In which manner, and by continuing to run the still longer than the advantage from the spirit requires, a large quantity of oil may frequently be procured. And this piece of knowledge among the distillers, or their servants, has sent many parcels of oil of aniseed, oil of juniper, oil of caraway, oil of cloves, &c. to the druggist, the chemist, and the apothecary, at such an under-price, as ought to shew them the trick; if they could not otherwise distinguish between a perfect essential oil, and one that has by spirit been robbed of its more subtile and ethereal part. And this may serve to shew the nature of that extemporaneous method of making some compound and cordial waters with the essential oils of aromatics, and certain plants. The common practice is to rub these oils into a kind of elæosaccharum with sugar, and thus dissolve it in a proof-spirit. And if the essential oil be fresh and genuine, the spirit clean and thin, and the operation dextrously performed; better waters may be made in this manner than are vulgarly found, either at the distillers or apothecaries: the chief fault being, that they contain too little of the fine ethereal oil, and too much of the grosser unctuous matter of the ingredient.

The fine light oil, of which this grosser is robbed by a careful Distillation, is the very thing that gives the flavour, virtue, and specific difference of the compound spirit: and this is generally found to come over with the spirit, while the fire is kept moderate, or so as to cause only a simmering, and not a boiling, in the liquor of the still. When once the fire is raised, as it usually is, when the still works slow; part of the grosser oil also comes over, and thus impregnates the spirit. In general, it may be a rule to change the receiver, as soon as ever the stream appears proof: though there are some cases, as particularly in cinnamon, where a little of the faints ought to be mixed in among the water. But this is universal, that so much of the faints should in no case be used, as to bring a cloudiness or milkiness upon the water, usually kept in the state of full proof: this state being supposed to mellow and ripen it sooner; as indeed it does much sooner than a lower state would, because the oil could not then remain dissolved. But most cordial waters, for the apothecaries use, had perhaps better be preserved in the condition of a three fifth of brandy, that is, as they come from the still unmade up.

The water employed for making up should either be soft river-water, or spring-water, softened by art or Distillation; otherwise it is apt to turn the spirit thick, and precipitate a sediment; especially if made below proof: or if the spirit partake of an alkaline nature, from the manner of its rectification. But when this happens, or there is a necessity for making goods below proof, they may be fined in a day or two, either with a small proportion of alum, the white of eggs, or with jelly of ising-glass, beat up to a froth, and applied in the same manner as in the fining of wines.

All compound waters should likewise be a little edulcorated with the finest sugar; as this serves to unite the essential oil of the ingredients more intimately with the spirit, and at the same time makes the water taste softer and pleasanter in the mouth.

DITCH. — In marshes, and other wet land, where there are no hedges, the common fence or inclosure for land is a Ditch. They allow these Ditches six feet wide against highways that are broad, and against commons five feet. But the common Ditches about inclosures, dug at the bottom of the bank, on which the quick is raised, are three feet wide at the top, one at the bottom, and two feet deep; by this means each side has a slope, which is of great advantage; for where they neglect this, and dig them perpendicular, they are always washing down; beside, in a narrow-bottomed Ditch, if cattle get down into it, they cannot stand to turn themselves to crop the quick; but where the Ditch is four feet wide, it should be two and a half deep; and, where it is five wide, it should be three deep, and so in proportion.

DITRIHÆ'DRIA, in natural history, the name of a genus of spars. The word is derived from the Greek δὶς twice, τρεῖς three, and ἕδρα, a side, or plane. The bodies of this genus are spars composed of twice three planes, being formed of two trigonal pyramids joined base to base, without the intervention of any intermediate column.

DI'VER, in zoology, the English name of the colymbus, a genus of water birds; the characters of which are: they have narrow, straight, and sharp bills; their heads are small, their wings short, their feet placed far backward on the body, and near the tail; their legs broad and flatted, and their claws broad like the nails of one's fingers. They are called colymbi, and in English Divers, from their great expertness in diving, and long continuance under water.

DI'VING (*Dict.*)— Diving-bladder, a term used by Borelli for a machine, which he contrived for Diving under the water to great depths, with great facility, and prefers to the common Diving-bell. The vesica, or bladder, as it is usually called, is to be of brass or copper, and about two feet in diameter. This is to contain the Diver's head, and is to be fixed to a goat's skin habit, exactly fitted to the shape of the body of the person. Within this vesica there are pipes, by means of which a circulation of air is contrived; and the person carries an air-pump by his side, by means of which he may make himself heavier or lighter, as the fishes do by contracting or dilating their air bladder: by this means, the objections all other Diving machines are liable to, are obviated, and particularly that of the air; the moisture by which it is clogged in respiration, and by which it is rendered unfit for the same use again, being here taken from it by its circulation through the pipes, to the sides of which it adheres, and leaves the air as free as before. *Borelli Opera Posthuma.*

DIURE'TICS (*Dict.*) — The medicines of this kind are, by Celsus, in the thirty-first chapter of his second book, characterized and enumerated in the following words: 'Every fragrant vegetable, which is cultivated in gardens, provokes a discharge of urine; such as smallage, rue, dill, basil, mint, hyssop, anise, coriander, cresses, rockets, fennel, asparagus, capers, cat-mint, thyme, savory, nipplewort (lampsana) parsnip, skirret, and onions.' But, of the vegetable kind, I recommend, says Hoffman, as Diuretics, the roots of parsley, celeri, asparagus, grass, liquorice, madder, parsnip, crowfoot, pareira brava, acmella; the herbs, parsley, ground-ivy, horse tail, chervil, common nettle, all leeks, and all the species of garlic; the flowers of butchers broom, and blue bottles; the seeds of carrots, parsley, celeri, fennel, grumwell, common nettle, violets, the four greater cold seeds, the seeds of club-moss, winter cherries, dog-hips, juniper-berries, straw-berries, the wood of the juniper-tree, sassafras, and its bark. Among resins and balsams, mastic, amber, the balsamum de Mecha, and the balsum Capivi. In the animal kingdom, cantharides, millepedes, May-worm, scorpions, toads, earth-worms, cochineal, and whey. To the class of Diuretics, also, belong all alcaline salts prepared by incineration, as also the salt of amber, the arcanum duplicatum, a solution of crab's eyes and nitre. The compound medicines belonging to this class are, the lixivium benedictum of Mynsicht, the tincture of tartar, the acrid tincture of antimony, the terra foliata tartari, the liquor silicum, the lithontriptic liquor of Michaeli, soluble tartar, the spirits of turpentine, mastic, and amber, balsam of sulphur with oil of turpentine, balsam of juniper, oil of juniper, malvaticum juniperinum, the syrupus dialthææ of Fernelius, and the trochischi Alkekengi. As the discharge of the urine may be impaired and rendered difficult from several causes, such as, first, a defect of due moisture in the blood, or, secondly, thick and tenacious juices obstructing the small urinary ducts of the kidnies, thirdly, a violent spasmodic constriction of the renal ducts, or, fourthly, their preternatural relaxation and weakness; so also the medicines, calculated for restoring a due discharge of the urine, must be adapted to the removal of these several causes. Thus, for instance, some substances, by conveying a due degree of fluidity to the inspissated blood, augment the discharge of urine; of which kind are all aqueous diluting medicines, liberal draughts of spring water, whether cold or warm, especially, if herbs of a diuretic quality are infused in them: this intention is likewise answered by tea and coffee, as also by mineral waters, either hot or cold, as they not only dilute the blood, but, by their alcaline quality, dissolve the viscid and tenacious humours, and remove the obstructions of the kidnies. The same effect is produced by whey, which is possessed of an aqueous, abstergent, and gently stimulating principle, as also of a sweet nitrous salt. Other substances dissolve the tough and viscid humours which obstruct and block up the secretory ducts of the kidnies, and, by that means, render them fit for performing their functions. Of this kind are all fixed salts, and the lixiviums prepared from them; as also tincture of tartar, the acrid tincture of antimony, the liquor silicum, the terra foliata tartari, the tartarus tartarisatus, the arcanum duplicatum, a solution of crab's eyes, and the magnesia alba, which, with the acid of the primæ viæ, is converted into an aperient salt; as also the tincture of quick-lime, mother of pearl, and coral, prepared with citron juice; as also the salts obtained by exhalation from mineral waters. Other substances sooth and alleviate the spasmodic constrictions of the emunctories of the kidnies, which obstruct and prevent the due discharge of the urine. The most considerable and efficacious of this kind are, nitre, the four greater cold seeds, and emulsions prepared of them; the seeds of the white poppy, of carrot, and of club-moss, as also winter cherries, and troches prepared of them: the same

intention

intention is anſwered by the anodyne mineral liquor, which is both a ſafe and efficacious medicine; as alſo by ſaffron, and its eſſence; the juice of graſs, in conſequence of its nitrous ſalt; a decoction of the roots of graſs and aſparagus, and oil of ſweet almonds, which is a liquor of a highly demulcent quality. Other ſubſtances, by their oleous, ſubtile, and balſamic principle, corroborate and ſtrengthen the kidnies; ſuch as maſtic, amber, the balſamum de Mecha, the balſam of Capivi, turpentine, the wood and berries of the juniper-tree, ſaſſafras, parſley, parſnip, fennel, aniſe, crow-foot, celeri; and the oils, eſſences, ſpirits, decoctions, and infuſions of them. Other medicines corroborate the kidnies, by their ſtrengthening, fixed, terreſtrial, and ſulphureous principle. Of this kind are dog-hips, rob of juniper, and the malvaticum juniperinum prepared of it, dried ſtrawberries, pareira brava, ground-ivy, the bark of the root of Egyptian thorn, horſe-tail, Paul's betony, and chervil. Laſtly, other medicines powerfully ſtimulate the renal ducts, when they are ſo far weakened as to have their functions either impaired, or totally deſtroyed: of this kind are almoſt all inſects, eſpecially cantharides, millepedes, ſpiders, ſcorpions, and dried toads: and, in the vegetable kingdom, all the ſpecies of leeks and garlic.

Since there is ſo great a difference among Diuretic medicines with reſpect to their principles, and manner of operation, their uſe muſt, of courſe, be different, and they muſt be judiciouſly adapted to the particular natures of different caſes; for, if to plethoric patients, labouring under the ſtone, we ſhould, before veneſection, and the diminution of the quantity of the blood, exhibit hot ſubſtances impregnated with a ſubtile balſamic oil; ſuch as preparations of turpentine, and juniper, or the balſams of Mecha, Capivi, or Peru; or acrid ſubſtances; or ſuch inſects as abound with a cauſtic ſalt, garlic, onions, or leeks; we ſhould certainly injure the patient, bring on an inflammation of the kidnies, and promote the generation of ſtones. On the contrary, in moiſt, leſs delicate, and more robuſt patients, who live upon coarſe food; as alſo, in diſeaſes ariſing from a redundance of impure ſerum, a fluor albus, a gonorrhœa, a diſpoſition to an anaſarca, and leucophlegmatia; theſe draſtic medicines are of ſingular uſe and ſervice.

Still greater misfortunes are produced by acrid and ſtimulating ſubſtances, in caſes where, in conſequence of ſpaſmodic or nephritic pains, a diſcharge of the urine is ſuppreſſed. Diſorders of this nature are far more ſafely and efficaciouſly removed by ſuch medicines as alleviate pain, and relax ſtrictures; ſuch as winter cherries, the ſeeds of carrot, club moſs, white poppy, and grumwell; as alſo emulſions of the four greater cold ſeeds, the trochiſci Alkekengi with opium, antimoniated nitre depurated, the water of the leaves meadow ſweet, of the lime-tree, and of the Egyptian thorn; oil of ſweet almonds, ſweet ſpirit of nitre, the anodyne mineral liquor, whey; and externally, emollient baths, and fomentations; the virtues of all which are ſo great, that, by alleviating the racking ſpaſms, they not only reſtore the free diſcharge of the urine, but alſo facilitate the progreſs of the ſtone through the ureters, and promote its expulſion.

In diſorders ariſing from a redundance of ſalt and tartareous ſerum, which is generally the cauſe of arthritic and rheumatic pains, this peccant humour is carried off by gentle Diuretics, though not of the hot kind, leſt, by their means, the ſpiculæ of the ſalts ſhould be put into a briſker motion, and the parts in which they are lodged, be more violently racked. The gentle Diuretics, by which this intention is moſt effectually anſwered, are, the roots of ſarſaparilla, pareira brava, ſaſſafras, and China root; as alſo thoſe of liquorice, aſparagus, madder, ſuccory, fennel, parſley, and graſs, together with the wood of the juniper-tree, and the preparations of theſe boiled in broth made with fleſh, or in water. To this claſs, alſo, belong whey, and, more eſpecially, the temperate mineral waters and warm ſprings.

But in caſes where peccant, viſcid, and tenacious humours are lodged in the urinary bladder, and eſpecially when the intention is to expel the firſt beginning of a ſtone, more acrid and powerful medicines become neceſſary. This intention is anſwered by garlick, exhibited with ſpirit of juniper; as alſo by the powder of millepedes, May-worms, eſſence of cantharides, and tincture of antimony, liquor ſilicum, and tincture of quicklime; which may alſo be cautiouſly exhibited in a virulent gonorrhœa, when a viſcid and tenacious matter lodged in the proſtatæ, the neck of the bladder, or the urethra, is to be carried off by urine.

But the moſt ſafe and efficacious medicines for procuring a free diſcharge of the urine, are all kinds, not only of alcaline fixed ſalts, but alſo thoſe called neutral; for they not only diſſolve the tough and viſcid juices, which obſtruct the urinary ducts, but alſo, by a gentle ſtimulus, promote their diſcharge. This intention is excellently altered by ſolutions of the ſalt of tartar, pot-aſh, and fixed nitre, as alſo the tartarus vitriolatus, ſalt of wormwood, the arcanum duplicatum, a ſolution of crab's eyes, tartarus ſolubilis, the terra foliata tartari, antimoniated nitre, and ſal polychreſtum.

Theſe medicines not only contribute to reſtore a due and natural diſcharge of the urine, but alſo produce ſome other excellent effects in the cure of diſeaſes: for, as many of them are poſſeſſed of an aperient and inciding quality, as others of them are corroborative, balſamic, and reſtore the tone of the parts; and others of them of an anodyne nature; ſo they prove highly efficacious in thoſe chronical diſorders, which ariſe from an obſtruction of the glands of the viſcera, and emunctories, or from an impurity of the juices, or a redundance of ſaline, acrid, and tartareous ſerum. And certainly, if relief is to be expected from any medicines in dropſies, œdematous ſwellings, ſtony concretions, the gout and arthritic pains, we are to look for it from the prudent uſe of Diuretics: but we are to beware of all hot, acrid, and cauſtic Diuretics, and uſe thoſe which are of a milder nature, and fit for common uſe, ſuch as ſmall Moſelle wine, the Selteran mineral waters, and ſuch ales and decoctions as are gently Diuretic. *Frederic. Hoffman. Medicin. Rational Syſtemat.*

DO'BCHICK, in zoology, the common Engliſh name of a ſmall water fowl, the leaſt of all the diver kind, and known among authors by the name of colymbus minor. It ſeldom exceeds ſix ounces in weight, and has a ſhort beak not more than a finger's breadth long, large at the baſe, but tapering to a point at the end; its eyes are large, and it is covered with a very thick, downy plumage; it is of a very deep blackiſh brown on the back, and very white on the belly; its wings are very ſmall, and it has no tail.

DOCK-*yards*, in ſhip-building, are magazines of all ſorts of naval ſtores; the principal ones, in England, are thoſe at Chatham, Portſmouth, Plymouth, Woolwich, Deptford, and Sheerneſs. In time of peace, ſhips of war are laid up in theſe Docks, thoſe of the firſt rates moſtly at Chatham, where, and at the yards, they receive, from time to time, ſuch repairs as are neceſſary.

Theſe yards are generally ſupplied, from the northern crowns, with hemp, pitch, tar, roſin, and ſeveral other ſpecies. But, as for maſts, particularly thoſe of the largeſt ſize, they are brought from New England.

How much it imports the good of the public, to keep thoſe magazines conſtantly repleniſhed, every one is able to judge: and it were much to be wiſhed, the improving the forementioned commodities, in our Engliſh plantations, might meet with all poſſible encouragement, leſt, one time or other, it may prove difficult to get them elſewhere. It is reaſonable to think ſuch an undertaking will put the nation to ſome conſiderable charge, before it be brought to perfection; but, when ſo, many are the advantages that will ariſe from it.

DODECA'NDRIA *, in botany, a claſs of plants which have hermaphrodite flowers, with twelve ſtamina or male parts in each. See *plate* XXII. *fig.* 4.

* The word is formed of the Greek δώδεκα twelve, and ἀνὴρ male. Of this claſs of plants are the aſarabacca, agrimony, &c.

DO'DO, in zoology, the name of a bird, called alſo by ſome *cygnus cucullatus*, by others *gallus gallinaceus perigrinus*, and by Bontius *dronte*. It is a very ſingular bird, ſomewhat larger than a ſwan, but wholly different from the ſwan in ſhape, tho' by ſome eſteemed a kind of that bird. Its head is large, and is covered with a membrane reſembling a hood; its beak is of an oblong figure, and is yellow at its origin, and black at the point, and is ſomewhat crooked: it is very naked, having only a few feathers ſcattered over its body, and the rudiments of wings made up of a few naked quills; the hinder part of its body is very bulky and fat, and has a tail made of four or five curled greyiſh feathers, reſembling thoſe of the oſtrich. Its legs are very thick and ſtrong.

DOGS-BANE, *apocynum*, in botany, the name of a plant which conſtitutes a large genus, the characters of which are theſe: the flower conſiſts of one leaf, and is made in the faſhion of a bell, but not regularly figured in all the ſpecies.

In ſome the flower is bell-faſhioned, and divided into ſeveral ſegments; and from its cup there ariſes a piſtil, which perforates the bottom of the flower, and is fixed to its hinder part like a nail; this changes into a fruit, compoſed of two vaginæ, and opening from the baſe to the apex, and filled with large quantities of ſeeds, winged with down, and fixed to a rough placenta. *Tournefort, Inſt.*

In others the flower is bell-faſhioned, and is multifid and inverted; and its middle is filled by a very elegant head, compoſed of five little horns expanded into a circle; to the lower part of this head there is affixed a piſtil, which is joined to it in the manner of a nail; this ariſes from the cup, and finally ripens into a fruit, compoſed of two vaginæ, which open from the baſe to the apex, and contain numerous ſeeds, winged with down, and placed in the manner of ſcales, and affixed to a foliaceous placenta. To this it is to be added, that the apocynums all abound with a milky juice.

DOG-FLY, *cynomyia*, in natural hiſtory, the name of a ſpecies of fly common in woods and among buſhes, and particularly troubleſome to dogs. It uſually ſeizes upon the ears, and it is in vain to beat it off, for it returns in a moment, and cannot be prevented but by being killed. It ſtings very ſeverely, and always raiſes a bliſter in the part. It ſomewhat reſembles the flat black fly ſo troubleſome to cattle. It has no trunk, but has two teeth much reſembling thoſe of the waſp. Its wings are always placed ſo cloſe upon its body that they are not ſeen. There are two kinds of it, one larger and found in woods, and the other common in hedges.

DOG-*roſe*, a name of the common briar or hip-tree. It is obſervable

servable of some kinds of this shrub, that the flowers smell extremely sweet in the night, or very early in the morning, but not at all so in the day-time. The reason of which seems to be the same as in all the noctuolent plants, of which there are several kinds, as some of the geraniums, and of the jasmines, &c. that is, that the sun exhales and dissipates their odorous effluvia in the day-time, as soon as they are expanded from the flower; but that in these cold times the vapours are condensated, and reach our nose in an agreeable manner. *Phil. Transf.* N°. 114.

DO'GGERS, in the English alum works, a name given by the workmen to a sort of stone found in the same mines with the true alum rock, and containing some alum, though not nearly so much as the right kind. The county of York, which abounds greatly with the true alum rock, affords also a very considerable quantity of these Doggers; and in some places they approach so nearly to the nature of the true rock, that they are wrought to advantage.

DO'LIUM, in natural history, the name of a genus of shells, called by some conchæ globosæ, and by the French tonnes. The characters are these: it is an univalve shell, with a globose or round belly, with a lax aperture, sometimes smooth and sometimes dentated. The clavicle is either moderately umbonated or depressed; and the columella is, in some species, smooth, in others wrinkled. Some authors have called these conchæ ampullaceæ; and they have had, at times, many other names, but all tending to the same sense, and expressing the globular figure of the body, which is the great character by which these are distinguished from all other shells. See *plate* XVII. *fig.* 13.

DO'LPHIN, in ichthyology, the English name of a fish of the cetaceous kind, called also sometimes the porpesse, but improperly. The word porpesse is properly the name of the conicbodied Dolphin, with a broad back and subacute snout; but the Dolphin, properly so called, and to which the name porpesse is erroneously given, is the delphinus of Artedi, with an oblong and subcylindric body, and a long and acute snout. This is the delphis of Aristotle, and the other Greek writers; and the other properly called the porpesse is their phocæna. Ælian, Appian, and Athenæus, all join in calling this Dolphin, properly so named, the delphis, and the same name is preserved by all the more accurate of the Latin writers.

DOLPHIN, is also a name given by the English to the fish called hippuris, by the generality of authors; but by some hipposele, and equisele, and by others dorado.

DOMI'NICAN-CARDINAL, in ornithology, the name of a curious bird, found only in the Brasils, at a great distance from any habitation. See *plate* XVIII. *fig.* 3, where this bird is drawn in its natural size.

It hath legs and feet rather strong than weak in proportion to its size. The bill is of a moderate bigness, the upper mandible dusky, or horn-coloured, the lower whitish. The eyes are black with dark hasel-coloured irides. The whole head is of a very beautiful red, or scarlet-colour, which colour reaches down the fore-part of the neck or throat, as far as the breast, and ends in a point. The upper side of the neck, the back, wings, and tail, are all of a black colour. The quills that fall next to the back are bordered round with white, as are the covert-feathers next above them; the lesser covert-feathers of the wings and the back have a small mixture of grey, the feathers being as it were finely fringed with grey. The tail-feathers are edged with white. The sides of the neck, breast, and whole under side as far as the tail, are purely white. It hath four toes, three standing forward and one backward, after the usual manner, all of a brown colour. In brief it may be described thus: the head is red, the upper side black, and the nether white. *Edwards's Hist. of Birds.*

DOOR (*Dict.*)—*Plate* IV. *fig.* 16, in the Dict. represents folding Doors, adapted to the Ionic order.

DORA'DO, in zoology, the name of a large sea fish, called by the Brasilians guaracapema; and so much resembling the hippuris, as by many to be supposed to be the same fish; it grows to six or seven feet in length, and is of a somewhat broad and flatted form, being a foot and a half broad near the head; the head ends in a square, and is thinned away to an edge, for the advantage of the creature's swimming the more swiftly. Its mouth is but small for its size, and is furnished with very sharp teeth; its eyes are large and round, and placed but a little above its mouth; its gills are large. It has one long fin running the whole length of the back, and another answering it on the belly, reaching from the anus to the tail; the tail is long, large, and forked; its scales are very smooth, and scarce sensible to the touch; its head, back, and sides are of a silver green, its belly white; its back and sides are spotted with blue; it is a very swift fish in swimming, and is a very delicate and well tasted one. *Willughby, Hist. Pisc.*

DOREE', or *John Doree*, in ichthyology, a name given by us to a fish, called, by authors, the faber and gallus marinus. We have borrowed the name Doree from the French; and, as to the word John, by some writers prefixed to it, it seems only a corruption of the French word jaune, yellow. They expressing the colour of the sides of this fish, which is a gold yellow, by the phrase jaune Doree: this has given us the words John Doree, or, by those who spell yet worse, John Dory, as we see it in some authors.

DORO'NICUM, *leopard's bane*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the radiated kind; its disk is composed of floscules, and its outer edge of semiflosculcs, all standing upon embryo's, and inclosed in a funnel-like or bason-like cup. The embryo's finally become seeds winged with down, and affixed to the thalamus of the flower.

DO'SSIL, in surgery, is lint made into a cylindric form, or resembling the shape of dates or olive-stones. Dossils are sometimes secured by a thread tied round their middle. *Heist. Surgery.*

DO'TTLE *Fish*, or DAILS, in natural history, a name given by the French to a particular species of shell-fish, which shines in the dark. They are of the genus called pholas by the ancients, and resemble in figure a truncated cone.

M. Reamur observes that it is not the shell, which is luminous, but the animal that it covers; and that it is more luminous in proportion as it is fresher, and but newly taken from the sea.

DOUBLE *Cast*, in husbandry, a term used by the farmers for that method of sowing that does not dispense the necessary quantity of seed for a piece of land at one bout, but requires the going over it every-where twice in a place. *Plot. Oxf.*

DRABS, in the English salt works, a name given to a sort of wooden cases into which the salt is put, as soon as it is taken out of the boiling-pan. These are partitions like stalls made for horses; they are lined on three sides, and at the bottom with boards, and at the front have a sliding board to put or take out occasionally. Their bottoms are made shelving, being highest at the backside, and gradually inclining forwards; by which means the saline liquor that remains mixed with the salt easily drains out from it, and the salt in three or four days becomes sufficiently dry, and is then taken out and laid in large heaps for sale. In some places they use cribs instead of the Drabs. See CRIBS.

DRA'CO *volans*, in natural history, a name given by some people to one of the flying Lizards. Others have applied the same term to a very different subject, expressing by it a sort of ignis fatuus very common in this island, and others of the more northern countries, which are much redder, larger, and more terrible than our common lambent fires, or will in the wisps, as our country people express them. This sort of exhalation is principally seen on the borders of rivers, and in marshy places, and seldom rises very high from the ground, but plays and dances about the surface in an agreeable manner; and, if people go up to it, will stick to their hands or cloaths without burning, or doing them any injury. They are more common in the summer months than in the winter, and are more frequently seen in thick weather than in clear.

DRACU'NCULUS, *dragon*, in botany, a genus of plants, whose characters are:

The leaves are like those of arum, but are divided into many parts: the stalk is spotted, but in other respects it agrees with the arum.

They are propagated by their knobby roots, which, if suffered to remain two or three years undisturbed, will afford many offsets. The best season for transplanting these roots is in autumn, soon after green leaves decay; for, if they are removed, after they have taken fresh root, and begun to shoot, they seldom produce flowers the succeeding summer; or, if they do, they are very weak: these will thrive almost in any soil and situation, but best in an open exposure, and a light soil.

DRAINS, a name given in the fen countries to certain large cuts or ditches, of twenty, thirty, nay sometimes forty feet wide, carried through the marshy ground to some river, or other place capable of discharging the water they carry out of the fen lands. Most of these Drains are made in our fen countries by a body of men called the undertakers, whose reward is one third of the ground they drain. They erect sluices also at a great expence, often not less than two thousand pounds each; yet these, with all the care they employ in erecting them, are subject to be blown up by the vast weight of water that lies upon them, when the lands are overflown. Some of these sluices have two or more pair of doors, of six, eight, or ten feet high, which shut, when the water in the river is higher than in the Drains, by the weight and force of it; and so, è contra, throw out a body of eight feet square of water for about six or seven hours during the ebb. The real use of these Drains is very evident from the present state of the land where they are cut, and that of it before. In Camden's time, all this was bog, and now it is all firm land. The country about Crowland was in that author's time so soft, that it was not passable by carriages; and thus grew a witticism upon it, that all the carts that entered this town were cased on the wheels with silver: but this is now so firm ground, that carriages of any kind pass over it. The duck-ponds used to be called the fen corn fields, and they now are such in reality, their bottoms being dry, and producing oats, and rape-seed, or cole-seed, with great increase. *Philos. Transf.* N°. 223.

DRANK, a name given by our farmers to the great wild oats. These are often very troublesome to the plowed lands, especially after wet seasons and much frost. Many to destroy this weed sow the land with black oats, which, being ripe much sooner than the seeds of this plant, are cut down, before it can

 sow

sow itself for another year; especially, if they are cut a little the earlier, which will do them no harm, if they be suffered to lie a little upon the ground a while afterwards for the grain to swell before they are carried in. But, in general, when plowed land begins to run to these weeds and thistles, it is a token to the farmer that it is time to fallow them, or else to sow them with hay seed, and make pastures of them. The sowing beans upon a land subject to these weeds is also a good method, because the farmer may send in his sheep, when they are about three inches high, which will eat up the Drank, and all the other weeds, and will not hurt the beans. The general method is to put twenty sheep to an acre; but they must be put in only in dry weather, and not left too long. *Mortimer's Husb.*

DRE'SSING *of ores*, the preparing them, as they come rough from the mine, for the working by fire. This is done several ways in different countries, and in respect to the different ores of the metals; in Devonshire we have a very easy method, which is so expeditious, and so good for all the purposes, that it is worthy copying in other places. After the ore is dug, it is tossed up by hand from shamble to shamble by the shovelmen in the mine, and drawn up in buckets by a winch at the top of the shaft. As soon as the whole quantity for one dressing is brought up, the large stones are broken, and the whole is then carried to the mills, where one horse turns a wheel that moves the machines for powdering a great quantity of it; these are called the stamping or knocking mills. The ore is unloaded at the head of the pass or entrance into these mills; this pass is made of two or three bottom boards and two side boards, in form of a hollow trough, and stands in a slanting direction. The ore by its own weight is carried down this trough, and lodges itself in the coffer. The coffer is a long square box made of the firmest timber, and of three feet long, and a foot and a half broad; the ore is not suffered to fall into this all at once, but is stopped over the mouth of the trough by a cross board, where a cock turns in a quantity of water at the same time, which washes down just as much of the ore with it into the trough, as there ought to be. In this coffer there are three lifters placed between two strong board leaves, having two braces or thwart pieces on each side to keep them steady, as a frame with stamp heads. These heads are of iron, and weigh about thirty or forty pounds a-piece, and serve to the breaking the lumps of ore in the coffer.

The lifters are about eight feet long, and half a foot square. They are always made of heart of oak, and have as many in timbers or guiders between them; they are lifted up in order, by a double number of toppits, which are fastened to as many arms passing diametrically through the greatest beam, which is either turned by the wheel and horse, or where there is conveniency of water, by an over-shot water wheel on two boulsters. The toppits exactly but easily meet with the tongues, which are so placed in the lifters, as that they easily slide from each other, and suffer the lifters to fall with great force on the ore in the trough. The frequent pounding of these soon reduces the large masses into a sort of sand, which is washed out of the trough by the continual current of the water from the cock through a brass grate, which is placed at one end of the coffer between two iron bars.

The powdered ore is conveyed out of the trough into the launder, which is a trench cut in the flower of eight feet long, and ten feet over; this is stopped at the lower end with turf, so that the water is all suffered to pass away, and the powder of the ore is stopped. Thus the launder by degrees fills up with the dressed ore, and this is removed out with shovels, as occasion requires. The launder is divided into three parts, the forehead, the middle, and the tail; that ore which lies in the forehead, that is, within a foot and half of the grate, is always the richest and best, and is laid up in a heap by itself; the middle and tail afford a poorer ore; and these are sometimes laid up in separate heaps; sometimes thrown into one heap together.

DRILL, or DRILL-*box*, a name given to an instrument used in the new method of horse-hoeing husbandry for sowing the land. The Drill is the engine that plants the corn and other seeds in rows; it makes the channels and sows the seeds in them, and covers them with earth when sown, and all this at the same time, and with great expedition. The principal parts of the Drill are the seed box, the hopper, the plow and its harrow. The seed box is the chief of these, it measures or rather numbers out the seeds which it receives from the hopper, and is for this purpose as an artificial hand, but it delivers out the seed much more equally, than that can be done by a natural hand. The plow and hopper are drawn by a horse, and by these the ground is opened, and the seed is deposited in it; the harrow follows, and lightly rakes in the earth over them. When the ground is fine, and the seeds small, a hurdle, with some prickly bushes fastened to its under part, will serve better than the harrow.

DRILL, in mechanics, a small instrument for making such holes as punches will not conveniently serve for. Drills are of various sizes, and are chiefly used by smiths and turners. *Moxon, Mechan. Exerc.*

It is a very well known fact, that a Drill, made of iron, has frequently not only a polarity, but so strong an attractive virtue of the magnetic kind, that it will suspend a common needle from its point. It is usually supposed that a Drill acquires this polarity by boring iron. But it is not only by boring of iron, that this power is obtained, but in the very making. As soon as one of them is finished and hardened, its point becomes a north pole before it has ever been worked either in iron or any other materials, so that, of the great numbers of these instruments found in a shop, endued with this power, it is to be supposed that more of them owe it to their original make, than any after use. All pieces of wrought iron which in shape resemble Drills, that is, which are of a long and slender form, will not only have this polarity, but they will change it on being placed for some time in an inverted posture, and that which was the opposite to the north pole, by standing downwards, will be the north pole. This has been an old observation, but, on a fair experiment, it does not prove to be true in all things without exception, though it be so in most particulars. The larger pieces of iron seem to be most easily influenced in their polarity, by changing their position; but the small ones will sometimes be found to have fixed poles, which no change of posture will alter. *Philos. Transf.* N°. 246.

DROCK, in husbandry, a name given by our farmers to a part of the common plow. It is an upright piece of timber, running nearly parallel with the hinder-part of the plow, but belonging to the right side of the tail, as that does to the left. The ground wrist of the plow is fastened to this, as is also the earth-board. *Tull's Husbandry.*

DRO'MEDARY, in natural history, a species of the camel, about which authors are divided in their opinion, some calling that which has one bunch on its back the camel, and that with two the Dromedary; while others call that with one bunch the Dromedary, and that with two the camel; we have followed the former, being the most general opinion, and shall give a description of the camel under the article HEGEN, the name given to that creature by the Arabians.

The neck of the Dromedary is long, the body very thick and broad, having two bunches on its back; his buttocks small, considering the bulk of his body, and his legs very long. See *plate* XXII. *fig.* 7.

The bunches on the Dromedary's back are generally supposed to be a callous sort of flesh; but the academists of Paris found it mere hair, and that, when this was pressed close down, the creature appeared no more bunch-backed than a swine.

Taverrnier assures us, on his own knowledge, that it will travel nine days without water; and, even in the coupling season, forty days without either drink or meat.

DRONE, in natural history, a bee of a much larger size than the common working bee, and of a lazy disposition. They are the males of the swarm, the common working bees being of no sex, and the female, generally called the queen bee, is only one in a hive. See QUEEN *Bee.*

The Drones are commonly a third bigger and longer than the bees; their head is rounder and more full of hairs. It is certain they have no sting, and their internal parts are very different from those of the common bees.

One rarely sees them go out of their hive, and, whenever they do go out, it is not till two or three o'clock in the afternoon, and never but in fine weather. They do not return loaded with wax; but we have found their bladder or reservoir full of honey as in the common bees, whether it be that they have collected it in the fields, or that they took it in the hive before they went out; which latter we are the most inclinable to believe, because we have never seen them settle upon flowers, and, after they have returned into the hive, we have never seen them lay the honey in the cells; we are even apt to think that they have not the organs for disgorging it, as the other bees do; for in the other bees you cannot compress, ever so little, that part of the body which is opposite the bladders, when it is full of honey, but you see the honey issue immediately at that part of the head by which they are accustomed to discharge it into the cell; whereas it is not so with regard to the Drones, although, after having opened them, their bladder hath been found quite full of honey.

In some hives the Drones are few in number, in others they are extremely numerous. During a part of the summer they are disposed in the hive. Afterwards, in proportion as their number increases, they assemble together in companies, in different parts of the hive, where they continue cantoned and almost intirely motionless.

At the time that the swarm sallies forth, and that the bees are all in motion, the Drones keep their place, and do not go out with the swarm, or, if any attend the colony, they are only a few in number. But, from the end of July to the middle of August, these Drones are attacked by the common bees; several bees fall upon a single Drone and seize him by his wings and body; and although the Drones resist as much as they are able, they are obliged to withdraw and leave the hive; they disappear so intirely, that we could never discover what was become of them.

When this sort of combat happens, you see all these animals in great commotion, as well without as within the hive. All the Drones are so generally expelled, that of several hundreds, which we have often remarked in one hive, by the end of October, we have not found a single Drone in several hives that we have examined.

Their origin is the same as that of the bees; they are the offspring of the queen, and produced in the same circumstances, with

with this difference alone, that the Drones are lodged in separate combs made expressly for them.

We have said that in an hive there are combs whose cells are a third or an half bigger and longer than the common cells. The pregnant bee chuses these great cells for depositing there, with all the state and attendance, that authors have observed with regard to the common bees, those eggs from which the Drones are to be hatched, and which cannot be distinguished by the sight from the common eggs; but it is probable that the mother hath some exquisite feeling to distinguish them, since she allots them abodes, proportioned to the size they are to have, when they are inclosed in the cell in their utmost perfection. The Drones undergo the same metamorphoses as the other bees; they are many days before they sally forth from their cells, and become recluses after the eighth day from their birth.

Lastly, they are nursed with the same care and tenderness as the common bees: but it is surprizing that this attention and love which the bees have for those little ones, should be turned, as I may say, into so great an hatred at the end of the summer. This hatred is so universal, that it spares not even the young Drones, who are yet only worms or nymphs included in the cells; for we have often remarked, that, at the time when a part of the bees have been expelling the great Drones from the hive, there were other bees employed in unstopping the cells, where the imperfect Drones were inclosed; in dragging them out of the cell, in killing them, and throwing their bodies out of the hive; where we have sometimes seen two or three hundred killed of different ages. *Mem. de la Acad. des Sciences.*

DRONE-*fly*, or *Bee-fly*, a two winged fly, so extremely like the common bee, as to be at first sight not easily distinguishable from it; the distinction between the two insects, however, besides the different number of the wings, is that the bee has a somewhat longer and less thick body, and the head is proportionably much smaller, than that of the fly which so much resembles them. The bee-fly, also, ever carries its wings parallel in their position, but without its body; whereas the bee itself usually carries its wings crossed on the back, and covers its body with them; this is not however an invariable posture with the wings of the bee, though it is the most frequent one. The bee-fly is found among the flowers, as is the bee, and, though it gathers no wax, it has a trunk by means of which it sucks the honey.

The trunk, by means of which the fly is enabled to do this, has no teeth, and consequently the fly belongs to Mr. Reaumur's first general class of the two-winged flies; and the form of its body, which is short and flat, determines it to be of his first subordinate genus of that class. This is properly a separate genus of flies, of which there are many species. Mr. Ray has described six, and a close observation will enable us to add much to that number. The different species vary extremely from one another in size. The smaller of them are not so large as the common blue flesh-fly; the others equal or exceed this fly in size. They differ also in colour, in different shades of brown; and some of them have spots of a fine deep black, and others of a fine glossy yellow, which make them very distinguishable from bees.

DROUGHTS. Great Droughts are very prejudicial to the farmer and his pasture, and such years afford but very little reward for the labour and expence of keeping it in order. The only remedies are high inclosures, and plenty of water at hand. The first of these is always in the farmer's power, and should be carefully provided by planting hedges in a proper manner, in countries most subject to suffer by this disadvantage. The other is not always so easy, but may be managed several ways, as by sinking wells; but these, when deep, are very expensive; or by bringing the water in pipes, gutters, or other conveyances: and this is easily done where there is a spring or brook in the neighbourhood higher than the lands. Pumps, wheels, and such other engines are also used in some places to bring on the water, and, in others, ponds, cisterns, and receptacles are made to take in the rains and winter floods, and retain the water till summer, when it is wanted.

The farmers of England are very deficient in this last method, which they might use to their great benefit in many places. In Spain they have no water in many parts but what they preserve in this manner. And at Amsterdam and Venice they have whole cellars made into cisterns, which receive the water that falls in rains, and preserve it all the year. Want of water for the earth in summer in many places might be easily remedied by some care of this kind, and many thousand acres of land made useful, which are now left as waste, by this means alone. It is very evident that this is feasible, because it is done in places where there falls much less rain annually than with us; and yet by this the inhabitants have always fresh water enough for the use of their houses, cattle, and gardens, none of which ever fail. *Mortimer's Husbandry.*

DRY-CUPPING, in surgery, the application of cupping-glasses to various parts of the body, and raising the common tumors under them without opening them with the scarificator.

The use of Dry-cupping is two-fold, either to make a revulsion of the blood from some particular parts affected, or else to cause a derivation of it into the affected part upon which the glass is applied. It is in the first sense that Hippocrates orders a large cupping-glass to be applied under the breasts of women who have a too profuse discharge of the menses, intending thereby to cause a revulsion of the blood upwards from the uterus. And upon the same principles hæmorrhages at the nose have been stopped by applying cupping-glasses to the legs and feet, particularly about the ancles and knees. Spitting of blood from the lungs has also been cured by the same method; and Scultetus gives a remarkable instance of a woman, who, by the repeated application of six cupping-glasses, without scarification, to her thighs, was not only relieved of the troublesome symptoms arising from an obstruction of the menses, but was also freed from the obstruction itself.

Dry-cupping is also used with success to make a revulsion by applying the glasses to the temples, behind the ears, or to the neck and shoulders, for the removal of pains, vertigo's, and other disorders of the head; they are also applied to the upper and lower limbs, to drive blood and spirits into them, when they are paralytic, and lastly to remove the sciatica, or other pains in the joints: the operation in these cases is to be repeated till the part looks red and becomes painful. *Heister's Surgery.*

DUCK, *anas*, in zoology, the name of a very large genus of birds, the characters of which are these: the beak is shorter, in proportion, than that of the goose, and the feet proportionably larger. The legs are shorter and are placed farther backward, and the beak is flatter, and the body more compressed. Some of these love the fresh water, others are found only at sea, and of both these there are very numerous species.

This fowl is furnished with a peculiar structure of vessels about the heart, which enable it to live without respiration a considerable time under water, as is necessary for it in diving. This made Mr. Boyle think it a proper object for experiments by the air-pump, than any of the other birds. A full grown Duck being put into the receiver of the air-pump, of which she filled one third part, and the air exhausted, the creature seemed to bear it better for the first moments, than a hen or other such fowl; but, after about a minute, she gave great signs of discomposure, and in less than two minutes her head fell down, and she appeared dying, till revived by letting in the air. Thus, whatever facility of diving this and other water fowl may have, it does not appear, that they can subsist without air for respiration, any longer than other animals. A young callow Duck was afterwards tried in the same manner, and with the same success, being reduced very near death in less than two minutes. But it is observable, that both birds swelled extremely on the pumping out of the air, so as to appear much larger to the spectators, especially about the crop. It not being intended that any water fowl should live in an exceedingly rarified air, but only be able to continue on occasion some time under water; nature, though she has provided them with the means of this, has done nothing for them in regard to the other.

Northern DUCK, *anas arctica*, a name given by Clusius to a water fowl well known on our coasts, and called by several other names both by authors and our own common people. Aldrovand calls it pica marina, and fratercula from Gesner, and Wormius and Hoier, the lunda. We call it in some places the puffin, and in others the golden head, bottlenose, helegug, coulta-neb, or counter-neb, and the mullet and pope. It is smaller than the common Duck; its beak is flatted sideways, and is broad and short, somewhat of a triangular figure, and ending in a point; it has a callous substance at its base, like that over the beak of the parrot. It is partly grey, partly red, and has three remarkable furrows on it. Its legs are placed very backward, and are yellow, when the bird is young; they afterwards are red, and have no hinder toe. Its head, neck, and back are black; its breast, throat, and belly white; but there is a remarkable black ring which surrounds the throat. The sides of the head are also whitish, or of a very pale grey. Its wings are extremely short, and furnished with very small feathers; yet by the help of these it flies very nimbly along the surface of the water, but it cannot fly at all, except its wings continually touch the water. It builds no nest, but lays its eggs on the naked earth, or in the deserted rabbit-holes; and, what is very remarkable, each lays only one egg. This is very large, and of a reddish colour. They breed with us, but are birds of passage, leaving us in autumn, and returning about March in small numbers, as if to examine the place, after which they again depart, and in May return with the whole numbers; and, if it happens to be a stormy season, multitudes of them are thrown dead upon the shores, for they are neither able to travel, nor to get food, except in calm weather.

The sharp-tailed DUCK, *anas cauda acuta*, in zoology, the name of a peculiar species of Duck, having a long tail like a pheasant. It is called in some places the sea pheasant, but more generally is known, with us, by the name of the cracker.

Horn DUCK, *anas Cornicensis*, the name of an American Duck, described by Nieremberg, and having its name from its imitating, with its note, the sound of the huntsman's horn. It is a very bold though weak bird, and is very difficultly tamed. This is one of the many birds mentioned by this author, which, from his imperfect account, it is impossible to know whether it be a new ſpecies, or ſome of thoſe deſcribed by Margrave or others.

Indian DUCK, *anas Indica*, the name of a bird of the Duck kind, deſcribed by Geſner and others, as a diſtinct ſpecies, but ſeeming by the deſcription to be the ſame with what we call the Muſcovy Duck.

Lybian DUCK, *anas Lybica*, a name given by Aldrovand, Bellonius, and ſome other authors to a ſpecies of Duck, brought from that part of the world, but which appears to be the ſame with what we commonly know by the name of the Muſcovy Duck. *Ray's Ornithology.*

Muſcovy DUCK, *anas Moſcata*, the name of a ſpecies of Duck, the largeſt of all the Duck kind. The general colour, both in the male and female, is a purpliſh black, though the female is ſometimes quite white. It has red fleſhy protuberances about its beak and eyes, and its voice is hoarſe, very ſoft, and ſcarce to be heard, unleſs when it is angry. The eggs of this bird are of a remarkably round figure. *Ray's Ornitholog.*

The fly-catching DUCK, *anas muſcaria*, a name given by ſeveral authors to a ſpecies of Duck, from its catching flies that play on the ſurface of the water. It is deſcribed as a diſtinct ſpecies, but Mr. Ray ſuppoſes it the ſame with our wild Duck.

DUCTILITY (*Dict.*)—DUCTILITY *of glaſs*.

We all know, that, when well penetrated with the heat of the fire, the workmen can figure and manage glaſs like ſoft wax: but, what is moſt remarkable, it may be drawn, or ſpun out into threads exceedingly fine, and long.

Our ordinary ſpinners do not form their threads of ſilk, flax, or the like, with half the eaſe and expedition, as the glaſs-ſpinners do the threads of this brittle matter. We have of them uſed in plumes for children's heads, and divers other works, much finer than any hair; and which bend and wave, like it, with every wind.

Nothing is more ſimple and eaſy than the method of making them: there are two workmen employed: the firſt holds one end of a piece of glaſs over the flame of a lamp; and, when the heat has ſoftened it, a ſecond operator applies a glaſs-hook to the metal thus in fuſion; and, withdrawing the hook again, it brings with it a thread of glaſs, which ſtill adheres to the maſs. Then, fitting his hook on the circumference of a wheel about two feet and a half in diameter, he turns the wheel as faſt as he pleaſes; which, drawing out the threads, winds it on its rim; till, after a certain number of revolutions, it is covered with a ſkain of glaſs thread.

The maſs, in fuſion over the lamp, diminiſhes inſenſibly, being wound out, as it were, like a pelotoon, or clue upon the wheel; and the parts, as they recede from the flame, cooling, become more coherent with thoſe next to them, and this by degrees: the parts neareſt the fire are always the leaſt coherent, and of conſequence muſt give way to the effort the reſt make to draw them towards the wheel.

The circumference of theſe threads is uſually a flat oval, being three or four times as broad as thick. Some of them ſcarce ſeem bigger than the thread of a ſilk-worm, and are flexible to a miracle. If the two ends of ſuch threads be knotted together, they may be drawn and bent, till the aperture, or ſpace in the middle of the knot, do not exceed one 4th of a line, or one 48th of an inch in diameter.

DUCTILITY *of ſpiders webs.* — The ingenious M. Reaumur obſerves, that the matter whereof ſpiders and ſilk-worms form their threads, is brittle when in the maſs, like dry gums. As it is drawn out of their bodies, it aſſumes a conſiſtence, much as glaſs-threads become hard, as they recede from the lamp, though from a different cauſe. The Ductility of this matter, and the apparatus thereto, being much more extraordinary in ſpiders, than in ſilk-worms; we ſhall here only conſider the former. Something has already been ſaid of each under the article SILK in the Dictionary, which ſee.

Near the anus of the ſpider are ſix papillæ, or teats. The extremities of the ſeveral papillæ are furniſhed with holes, that do the buſineſs of wire-drawers, in forming the threads. Of theſe holes, M. Reaumur obſerves, there are enough in the compaſs of the ſmalleſt pin's-head, to yield a prodigious quantity of diſtinct threads. The holes are perceived by their effects: take a large garden-ſpider ready to lay its eggs, and applying the finger on a part of its papillæ, as you withdraw that finger, it will take with it an amazing quantity of different threads.

Hence M. Reaumur advances, that, as the flexibility of glaſs increaſes in proportion to the fineneſs of the threads, had we but the art of drawing threads as fine as thoſe of a ſpider's web, we might weave ſtuffs, and clothes hereof, for wear.— Accordingly he made ſome experiments this way: he could make threads fine enough, as fine, in his judgment, as any ſpider's web, but could never make them long enough, to do any thing with them.

M. Reaumur has often told 70, or 80, with a microſcope, but has perceived, that there were infinitely more than he could tell. In effect, if he ſhould ſay, that each tip of a papilla furniſhed a thouſand, he is perſuaded, he ſhould ſay vaſtly too little. The part is divided into an infinity of little prominences, like the eyes of a butter-fly, &c. each prominence, no doubt, makes its ſeveral thread; or rather, between the ſeveral protuberances, are holes that give vent to threads; the uſe of the protuberances, in all probability, being to keep the threads, at their firſt exit, before yet hardened by the air, aſunder. In ſome ſpiders thoſe protuberances are not ſo ſenſible; but in lieu thereof there are tufts of hair, which may ſerve the ſame office, viz. to keep the threads apart. Be this as it will, there may threads come out at above a thouſand different places in every papilla; conſequently, the ſpider, having ſix papillæ, has holes for above ſix thouſand threads. It is not enough that theſe apertures are immenſely ſmall: but the threads are already formed before they arrive at the papilla, each of them having its little ſheath, or duct, in which it is brought to the papilla from a good diſtance.

M. Reaumur traces them up to their ſource, and ſhews the mechaniſm by which they are made. Near the origin of the belly, he finds two little ſoft bodies, which are the firſt ſource of the ſilk. Their form and tranſparency reſemble thoſe of glaſs-beads, by which name we ſhall hereafter denote them. The tip of each bead goes winding, and makes an infinity of turns, and returns towards the papilla. From the baſe, or root of the bead, proceeds another branch much thicker; which, winding variouſly, forms ſeveral knots, and takes its courſe, like the other, towards the hind-part of the ſpider. In theſe beads, and their branches, is contained a matter proper to form the ſilk, only that it is too ſoft. The body of the bead is a kind of reſervoir, and the two branches two canals proceeding from it. A little further backward, there are two leſſer beads, which only ſend forth one branch a-piece, and that from the tip. Beſide theſe, there are three other larger veſſels on each ſide the ſpider, which M. Reaumur takes for the laſt reſervoirs, where the liquor is collected. The biggeſt is near the head of the inſect, and the leaſt near the anus. They all terminate in a point; and from the three points of theſe three reſervoirs it is, that the threads, at leaſt the greateſt part of the threads drawn out at the three papillæ, proceed. Each reſervoir ſupplies one papilla. Laſtly, at the roots of the papilla, are diſcerned ſeveral fleſhy tubes: probably, as many as there are papillæ. Upon lifting up the membrane, or pellicle, that ſeems to cover theſe tubes, they appear full of threads, all diſtinct from each other, and which of conſequence, under a common cover, have each their particular one; being kept like knives in ſheaths. The immenſe quantity of threads contained here, M. Reaumur concludes, upon tracing their courſe, does not all come from the points of the reſervoirs; but ſome from all the turns and angles; nay, probably, from every part thereof. But by what conveyances the liquor comes into the beads, and out of the beads into the reſervoirs, remains yet to be diſcovered.

We have already obſerved, that the tip of each papilla may give paſſage to above a thouſand threads; yet the diameter of that papilla does not exceed a ſmall pin's-head: but we were there only conſidering the largeſt ſpiders.

If we examine the young, riſing ſpiders, produced by thoſe; we ſhall find, that they no ſooner quit their egg, than they begin to ſpin. Indeed their threads can ſcarce be perceived; but their webs, formed thereof, may: they are frequently as thick, and cloſe, as thoſe of houſe-ſpiders; and no wonder: there being often four or five hundred little ſpiders concurring to the ſame work. How minute muſt their holes be? The imagination can ſcarce conceive that of their papilla! the whole ſpider is, perhaps, leſs than a papilla of the parent which produced it.

This is eaſily ſeen: each big ſpider lays four or five hundred eggs; theſe eggs are all wrapped up in a bag; and, as ſoon as the young ones have broke through the bag, they begin to ſpin. How fine muſt their threads be?

Yet is not this the utmoſt nature does: there are ſome kinds of ſpiders ſo ſmall at their birth, that they are not viſible without a microſcope. There are uſually found an infinity of them in a cluſter, and they only appear like a number of red points. And yet there are webs found under them, though well nigh imperceptible. What muſt be the tenuity of one of theſe threads? The ſmalleſt hair muſt be to one of theſe what the moſt maſſive bar is to the fineſt gold-wire drawn by art.

The matter whereof the threads are formed, we have obſerved, is a viſcid juice. The beads are the firſt receptacles where it is gathered, and the place where it has the leaſt conſiſtence. It is much harder when got into the ſix great reſervoirs, whither it is carried by canals from the former: this conſiſtence it acquires in good meaſure in its paſſage; part of the humidity being diſſipated in the way, or ſecreted by parts deſtined for that purpoſe.

Laſtly, the liquor is dried ſtill further, and becomes thread, in its progreſs through the reſpective canals to the papillæ. When theſe firſt appear out at the holes, they are ſtill glutinous; ſo that ſuch as ſpring out of the neighbouring holes, ſtick together. The air compleats the drying.

By boiling the ſpider, more, or leſs, the liquor is brought to a greater or leſs conſiſtence, fit to draw out into threads; for it is too fluid for that purpoſe, while yet incloſed in its reſervoirs.

The matter contained in theſe reſervoirs, when well dried, appears a tranſparent gum or glue, which breaks, when much bent: like glaſs, it only becomes flexible by being divided into

into the fineſt threads. And probably it was on this account nature made the number of holes ſo immenſe. The matter of ſilk formed in the bodies of ſpiders, being much brittler than that formed in ſilk-worms, needed to be wound ſmaller. Otherwiſe we do not conceive, why ſhe ſhould form a great number of threads, which were afterwards to be reunited: a ſingle canal might have done.

DUCTUS *Alimentarius*, in anatomy, a name given by Dr. Tyſon to the gula, ſtomach, and inteſtines; all which make but one continued canal or duct. This duct he makes the proper characteriſtic of an animal.

DUNG, in agriculture, &c. All kinds of Dung contain ſome matter, which, when mixed with the ſoil, ferments therein, and, by that fermentation, diſſolves the texture of the earth, and divides and crumbles its particles very much. This is the real uſe of Dung in agriculture, for, as to the pure earthy part of it, the quantity is ſo very ſmall, that it bears an extremely inconſiderable proportion to that of the earth it is intended to manure.

The fermenting quality of Dung is chiefly owing to the ſalts it contains, and yet thoſe or any other ſalts, applied immediately to the roots of plants, always deſtroy them. This proves that the buſineſs of the Dung is not to nouriſh but to divide and ſeparate that terreſtrial matter, which is to afford the nouriſhment to vegetables, through the mouths of their roots. And the acrimony of the ſalts of Dung is ſo great, that the niceſt managers of vegetables we have, (the floriſts) have wholly baniſhed the uſe of it from their gardens. The uſe of Dung ſhould be alſo forbid in kitchen gardens, for it is poſſible to ſucceed full as well without it; and it gives an ill taſte to all the excellent roots and plants, that are to ſtand in the earth in which it is an ingredient. The water of a cabbage raiſed in a garden, manured with Dung, if boiled, is of an intolerable ſtink; but this is not ſo much owing to the nature of the plant, as of the manure uſed to it; for, a field cabbage being boiled, the water has ſcarce any ſmell, and what it has, is not diſagreeable.

It is alſo a well known fact in the country, that a carrot, raiſed in a garden, has nothing of that ſweet flavour, which ſuch as grow in the fields have, but, in the place of this natural reliſh, the garden one has a compound taſte, in which the matter of the manure has no ſmall ſhare. And there is the ſame ſort of difference in the taſte of all roots, nouriſhed with ſuch different diet. Dung not only ſpoils the flavour of the eſculent vegetable, but it ſpoils the drinkables into the original compoſition of which it enters: they are obliged to uſe Dung to the poor vineyards of Languedoc, and the conſequence is, that the wine is nauſeous. The poor who only raiſe a few vines for the wine they drink themſelves, and cannot be at the expence of this manure, have the leſs of it, but then it is better by many degrees than the other; and it is a general obſervation which the French expreſs in theſe words, that the poor people's wine in Languedoc is the beſt, becauſe they carry no Dung into their vineyards. *Tull's horſehoeing Huſbandry.*

Another diſadvantage attending the uſe of Dung is, that it gives riſe to worms. It is for this reaſon, that garden carrots are generally worm-eaten, and field carrots ſound; and the ſame obſervation will hold good in other vegetables, in the field and in the garden. Vegetable and animal Dung are in fact only the putrefaction of earth, after it has been altered by paſſing through vegetable or animal veſſels. Vegetable Dung, unleſs the vegetable be buried alive in the ſoil, makes a much leſs ferment in it, than animal Dung does: but the Dung or putrid matter of vegetables is much more eligible and wholeſome for the eſculent roots and plants, than that of animals is. Venomous animals are found to be very fond of Dung, and are brought into gardens by the ſmell of the Dung uſed in them as manure. The ſnakes uſually frequent Dung-hills, and lay their eggs in them; and gardens, where Dung is much uſed, are always frequented by toads; whereas the fields where roots are planted, are much leſs infeſted by them.

However unneceſſary and prejudicial Dung is in gardens, it is however very neceſſary in the corn-fields, and little can be done without it in the old method of huſbandry. Dung is not ſo injurious in fields as in gardens; becauſe it is uſed in much ſmaller quantities in proportion to the quantity of ſoil, and cabbages, turnips, potatoes, and other things growing in fields, and intended only for the food of cattle, will not be injured by Dung, tillage, and hoeing all together; for the crops will by this means be the greater, and the cattle will like the food never the worſe. Dung is very beneficial in giving large crops of wheat; and it is found by experience, that the country farmers, at a diſtance from a large town, can never have ſo good crops by all their tillage, as thoſe who live in the neighbourhood of cities, where Dung is produced in great plenty, and eaſily had. The Dung uſed in fields, beſides its diſſolving and dividing virtue, is of great uſe in the warmth its fermenting gives to the young plants of the corn in their weakeſt ſtate, and in the moſt ſevere ſeaſons; the laſting of this ferment is not eaſily determined, becauſe the degrees of heat are very difficult to be judged of, when they become ſmall.

The farmers uſually underſtand, by the term Dung, not only the excrements of animals, with the litter, but every thing that will ferment with the earth, ſuch as the green ſtalks and leaves of plants buried under ground and the like, and every thing they add to it except fire.

The uſes of the Dungs of ſeveral animals are ſufficiently proved every day. They are uſed to repair the decays of exhauſted and worn out land, and to cure the ſeveral defects in different naturally bad ſoils; the faults of which are as different, as the nature of the different Dungs uſed to improve them. Some land is too cold, moiſt, and, heavy, and the other too light and dry: and, to improve and meliorate theſe, we have ſome Dung hot and light, as ſheep's, horſes, pigeons, &c. and other fat and cooling, as that of oxen, dogs, &c.

There are two remarkable qualities in Dung; the one is to produce a certain ſenſible heat capable of bringing about great effects. The other is to fatten the ſoil, and render it the more fertile. The firſt of theſe is ſeldom found in any other Dung, but that of horſes and mules, while newly made and a little moiſt. The great effects of this are ſeen in the kitchen garden, where it invigorates and gives a new life to every thing, ſupplying the place of the ſun; and to this we owe, in a manner, all the vegetable delicacies of the ſpring.

Beſide this, horſe-Dung is the richeſt of all improvements that can be had in any quantity for poor hungry lands; yet, when either too new, or when uſed alone, it is very prejudicial to ſome lands; and, if ſpread too thin on dry lands in ſummer, it becomes of very little ſervice, the ſun ſoon exhaling all its richneſs, and leaving it little more than a heap of ſtubble or dry thatch. And, though too much of it can hardly be uſed in the kitchen garden among colliflowers, cabbages, and the like, yet it is eaſy to over-dung land intended for corn, and gives riſe by that means to a very fatal quantity of weeds.

Horſe-Dung is always beſt for cold lands, and cow-Dung for hot ones; but, being mixed together, they make a very good manure for moſt ſorts of ſoils, and for ſome they are very properly mixed with mud.

Sheep's-Dung and Deer's-Dung differ very little in their quality, and are eſteemed by ſome the beſt of all Dung for cold clays; for this purpoſe ſome recommend the beating them to powder and ſpreading them thin over the autumn or ſpring crops, at about four or five loads to an acre, after the ſame manner as aſhes, malt duſt, &c. are ſtrewed. And, in Flanders and ſome other places, they houſe their ſheep at nights in places ſpread with clean ſand, laid about five or ſix inches thick, which, being laid on freſh every night, is cleaned out once a week, and, with the Dung and urine of the ſheep, is a very rich manure, and ſells at a very conſiderable price. It is principally uſed for ſtubborn lands; but Mr. Quintiney is of opinion, that it is the beſt of all manure for lands in general.

Hog's-Dung is by many recommended as the fatteſt and richeſt of all Dung, and is found, on experience, to be better than any other kind, for fruit-trees, apples, pears, and the like; it is alſo a very rich Dung for graſs, and is ſaid to do as much good in one load, as any other Dung whatever in two.

The Dungs of pigeons, hens, and geeſe are great improvers of meadow and corn land. That of pigeons is unqueſtionably the richeſt that can be laid on corn land; but, before it is uſed, it ought to be expoſed for ſome time out of the dove-houſe to the open air, to take off its fiery heat. It is in general very proper for cold clay lands, but then it always ſhould be well dried before it is laid on, becauſe it is apt to clod in the wet. It is beſt alſo to mix it with ſome dry earth to break its parts, that it may be ſpread the more regularly; and it is in itſelf ſo very rich and hot, as to bear ſuch an admixture, without greatly impoveriſhing it. This Dung is alſo by ſome recommended as better than any other for aſparagus and ſtrawberries, and for the propagation and culture of the tender garden flowers. The Dung of pigeons is alſo particularly recommended by Mr. Gentil for thoſe trees, whoſe leaves are apt to turn yellow, if they grow in cold ſoils; but for this uſe it ſhould firſt lie three years in a dunghil, and then be applied ſparingly in autumn, laying about an inch thickneſs of it at the root of the tree, and ſuffering it to remain there till the March following.

The Dung of poultry, being hot and full of ſalts, tends much to facilitate vegetation, and is abundantly quicker in its operation than the Dung of animals, which feed on the leaves of plants. It is an obſervation of Sir Hugh Plat, that one load of grains will enrich ground, more than ten loads of common Dung; and it is eaſy to infer from hence, that the ſame grain muſt needs be of greatly more virtue, when it has paſſed through an animal body. Human Dung is alſo a great improver of all cold and ſour lands, but ſucceeds beſt, when mixt with other Dungs or earths to give it a fermentation.

But, for all ſtubborn clayey ſoils, there is no manure ſo good as the cleanſing of London ſtreets; the parts of tough land will be more expeditiouſly ſeparated by this, than by any other compoſt, and, where it is to be had, it is of the greateſt value both for field and garden land. *Miller's Gard. Dict.*

Gooſe DUNG. This is a very valuable manure, and as uſeful to the farmer as pigeon's Dung, or that of any other fowl. The antients thought otherwiſe, and condemned it as prejudicial both to corn and graſs, and many are of the ſame opinion ſtill, but without any foundation in fact. Indeed

3 U where

where corn is high, and when grafs is ready to mow, thefe birds, if they got among it, will do great damage by treading it down with their feet; but their Dung, inftead of being hurtful to the land, does it a great fervice. Near Sutton in Nottinghamfhire, there is a barren piece of land given by the town, for a goofe pafture; the geefe have been kept in it many years, and their Dung has fo enriched it, that it is one of the fruitfulleft pieces of ground, in the whole country. There has been an opinion alfo, that cattle feeding on grafs, where thefe creatures had much dunged the ground, would fuffer by it; but it appears from trial, that cattle are moft fond of all of thofe parts of paftures, where the geefe have dunged moft; and that they fuffer no alteration by it, except the growing fat upon it. The Dung of fowls in general is very enriching to land. Fig-trees, afparagus beds, and ftrawberries, and many curious flowers fucceed better in earth manured with pigeon's Dung, than in any other; and Fowley ifland in Lancafhire, a place fo called from the abundance of wild fowl continually found on it, is fo enriched with their Dung, that it fattens fheep in a furprizing manner. *Mortimer's Hufbandry.*

DU'RION, in natural hiftory, the name of a fruit common in China and the Eaft-Indies, and efteemed by the Indians the fineft of all fruits; but the Europeans do not allow this, becaufe of its difagreeable fmell. The tree which bears it is large and much branched, and its wood is like that of the hazel. The leaves are of a very fingular figure, being about fix inches long, and fixteen or eighteen inches broad: they terminate in a long and flender point. The upper fide of the leaves is of a dufky green, the under fide is whitifh with fome yellow fpecks. The leaves grow on fhort pedicles, which are joined to the ftalks by a protuberance or oblong knot. The fruit grows to the large branches, adhering to their middles by a ftrong woody ftalk. It is of the fize of an ordinary melon, and of a conic fhape, pointed at the extremity, and is all over befet with prickles refembling thofe of a hedge-hog: they are green, and very large and thick. When thoroughly ripe, the fruit opens at the extremity into five parts, and, the cracks or openings running by degrees to the top, the inner fubftance or pulp is difcovered. This is of a whitifh colour, and of a very agreeable flavour, which may not unaptly be compared to that of cream and fugar; but it is of a more firm confiftence. This fruit contains in every compartment five large feeds perfectly refembling the common chefnut, but that they have no other covering than their own fkins.

The courfe of vegetation is elegantly feen in diffecting the pedicle which fupports this fruit; for in this are feen the three different juices which ferve to the nourifhment of three different parts of the fruit. In cutting this pedicle tranfverfly, we firft find, between the bark and the woody fibres, a yellowifh, thick, and glutinous juice: this ferves for the nutriment of the thorns. A fecond juice difcovers itfelf between the firft woody fibres, which is white and more folid, and lefs glutinous. This gives nourifhment to a thick fkin of a filver white, which lines the pulpy part of the fruit. And, finally, in the center of the pedicle there runs a third, much whiter and fofter than the former, which ferves to the nourifhment of the pulp, or foft and fweet-tafted part of the fruit.

The fruit itfelf, were its fmell as agreeable as its tafte, would vie with any fruit in the world; but its very difagreeable fcent requires time and cuftom to enable any one to bear it; but ufe makes the natives wholly difregard it. The fmell is very like that of onions, that have lain in heaps till they are very rotten. The fruit is not only agreeable to the tafte, but of a very cordial virtue; but it will intoxicate and get into the head, if eaten in a large quantity, efpecially fuch of the fruits as are of a yellowifh colour. The natives make debauches with it, as our poorer people do with fpirituous liquors. But it is not fo eafily come at as thofe, and therefore is very fatal to many families among them, who will fell their liberties for a time to purchafe enough of it for a debauch.

The Durion tree flowers in January. The flowers are of a dufky colour, and of the fize of a nut. As foon as thefe fall, the fruit begins to appear. It afterwards increafes flowly in fize till the month of June, in which it begins to ripen. Others continually fucceed thefe early ones during the whole fummer, fo that there is a fucceffion of them during that feafon, and they do not begin to grow fcarce till about the middle of October. *Mem. Acad. Scienc. Par.* 1699.

DU'TY (*Dict.*)—Duties, in regard to trade, are thofe impofts or taxes, which are laid on merchandizes at importation or exportation, which are commonly called the Duties of cuftoms; the taxes of excife, alfo, are frequently diftinguifhed by the Duties of excife.

The principles on which all Duties and cuftoms fhould be laid on foreign merchandizes, which are imported into thefe kingdoms, are fuch as tend to cement a mutual friendfhip and traffick between one nation and another; and, therefore, due care fhould be taken in the laying of them, that they may anfwer fo good an end, and be reciprocal in both countries: they fhould be fo laid as to make the exports of this nation, at leaft, equal to our imports from thofe nations wherewith we trade; fo that a balance in money fhould not be iffued out of Great Britain to pay for the goods and merchandizes of other countries; in order that no greater numbers of our land-holders and manufacturers fhould be deprived of their revenues arifing from the product of the lands, and the labour of the people, by foreign importations, than by exportations to fuch countries.

Thefe are the national principles, upon which all our treaties of commerce with other countries are to be grounded: and, as all ftates and empires are daily making their utmoft efforts for the advancement of commerce, and to prevent the importation of our manufactures into their kingdoms: as fuch-like meafures are the moft effectual reftraints and prohibitions upon our commerce, there feems no other way to redrefs the grievance, than by retaliating upon them, and fupplying ourfelves, at leaft, with their commodities in a degree of proportion diminifhed equal to what they have leffened in ours. For, if this policy is neglected, and traders are left to act at random, according to their own will, nothing is more certain than that they are taking fteps gradually to ruin the nation, notwithftanding the Duties of cuftoms fhould be daily increafed by thefe augmented impofts. So that the additional increafe of the cuftom-houfe revenue is not the criterion of an increafe of national commerce and treafure, but the infallible touch-ftone of the reverfe.

But one fundamental branch of the fupport of the royal revenue depending on the good plight and augmentation of the Duties arifing on cuftoms, it is no wonder that, ever fince thofe Duties have exifted, every meafure has been taken to improve and increafe them. But let every judicious man confider upon what principle of policy can this part of the public revenue poffibly be increafed. Does not this increafe of revenue arife from the increafe of foreign imports? And, as the importation and confumption of thefe imports diminifh, will not the cuftom-houfe revenue decline?

Now, fince the increafe of the confumption of foreign productions and manufactures, among us, has an inevitable tendency to impoverifh our own nation, and enrich others, the greater care that is taken to increafe and improve the cuftom-houfe branch of the revenue, can it have any other effect than to haften the ruin, rather than promote the opulence of the kingdom? Unlefs our exports in value keep pace with our imports. As our exports, however, do not, according to the conftitution of the public revenue, afford an increafe of the Duties of cuftoms any way proportionate to our imports, men in power have not thofe inducements to roufe and ftimulate them fo much in regard to the one, as they have in regard to the other.

Wherefore, fince an increafe of the public revenue, nay, the increafe of the king's own royal revenue of the civil lift, depends, in a great meafure, upon the increafe of our foreign imports, rather than our native exports; does it not appear, that the very fundamental conftitution of the revenue, both generally public, and perfonally royal, depends on our purchafing more of foreign commodities than in felling of our own; or, to fpeak in the modern phrafe, now familiarly ufed in France, Spain, and Italy, more on a paffive than on an active kind of commerce; that is, in buying more foreign commodities than we fell of our own native ones?

In regard, likewife, to our Duties of excife, let it be candidly confidered, how far they may affect the general commerce, and wealth, and power of the nation. Are they not laid even upon thofe neceffaries of life which affect the labour of the hufbandman and the farmer; and, confequently, the country gentleman, as well as the artfman, mechanics, and manufacturers of every clafs, throughout the whole kingdom? The public, as well as the perfonal royal revenue of our fovereign himfelf, doth alfo greatly depend on the keeping up, if not increafing, the product of the excife funds; and the very being and exiftence of thefe funds depend upon clogging and incumbering our native productions and manufactures: as this is the cafe, no one will prefume to fay that the conftitution of this, any more than the cuftom-houfe branch of the revenue, is fo laid, as neceffarily to advance that commerce and navigation, which alone can uphold and fupport the ftate. It is true there are drawbacks allowed of the excife Duties upon the exportation of fome commodities to foreign countries; fuch as on beer, ale, &c. yet the Duties on foap and candles, and other neceffaries of life, that are confumed in our mechanic and manufactural arts, are not drawn back, but render the workmanfhip of thofe artifts dearer, in proportion to the weight of thefe taxes; which muft unavoidably prove detrimental to our traffic, as it occafions other nations to under fell us.

As our intent is only to fet things in that fingle point of view which relates to trade, I fhall confider excifes in no other light than as taxes on commodities, but attempt to fhew the augmentative faculty of all fuch taxes, and the great prejudices they do to trade; for whatever raifes the neceffaries of life, raifes labour, and, of courfe, the price of every thing that is produced by labour. How our excifes do really encumber our traffic will eafily appear, they trebbling themfelves almoft to the people for what they raife to the government; and it is to be greatly feared it would appear much more, if we could go to the bottom of the incumbrance; for it is to be confidered that tradefmen in a country, by their

PLATE XIX. *Engraved for the Supplement.* *Facing* Dye-house

Printed for J. Hinton in Newgate Street.

their mutual dependence on each other, are like wheels in a machine, in which, if one is touched, the others are affected.

Amidst so many trading movers, to what degree the oppression is increased, is not easy to say; nor can we be startled at the largeness of such computations; for, circulated chiefly among ourselves, and going out by dribblets, we hardly perceive them, but yet are surprized to find wages and necessaries grow dearer and dearer, because few use themselves to consider the immensity of such collected advances in such sums; if, however, we compare the difference of the prices of necessaries between England and France, we shall find that difference obviously accounting for the prodigious amount of the consequences of our taxes; nor can it be a trifle that makes such a fruitful country, as England is, so dear, and its trade declining: for our working people, being forced to purchase the necessaries of life dear, must work dear to live, until their willing working hands are tied up by foreigners, who live less taxed, and, of course, work cheaper; so that they must, and do, undersell us at all markets for manufactured goods, where they come in competition with us, and, in time, must and will stop all such exports.

And we may appeal to the judgment of every honest man conversant in trade, whether he does not experience our trade to decline year after year, more especially our woollen trade, which has been estimated to be as necessary to us as bread is to the life of man; for our dearer goods must lie unsold, or be sold with loss, which must stop, or break our merchants; they, our clothiers, and weavers, &c. they, their journeymen who must either starve, turn beggars, thieves, or fly to our enemies, and help them to ruin us the faster; which has certainly happened too much of late years.

DWARF-*Trees* (*Dict.*)—These were formerly in much greater request than they are at present; for, though they may have many advantages to recommend them, yet, the disadvantages attending them greatly over-balance; and, since the introducing of espaliers into the English gardens, Dwarf-trees have been destroyed in most good gardens, for the following reasons.

1. The figure of a Dwarf-tree is very often so much studied, that in order to render the shape beautiful, little care is taken to procure fruit, which is the principal design in planting these trees.

2. The branches, being spread horizontally near the surface of the ground, render it very difficult to dig, or clean the ground, between them.

3. Their taking up too much room in a garden, especially when they are grown to a considerable size; for nothing can be sown or planted between them.

4. These trees, spreading their branches near the ground, continually shade the surface of the earth, so that neither the sun nor air can pass freely round their roots and stems, to dissipate noxious vapours; whereby the circumambient air will be continually replete with crude rancid vapours, which, being drawn in by the fruit and leaves, will render its juices crude and unwholesome, as well as ill-tasted.

These evils being intirely remedied by training the trees to an espalier, hath justly gained them the preference; however, if any one has a mind to have Dwarf-trees, notwithstanding what has been said, I shall lay down a few rules for their management.

If you design to have Dwarf pear-trees, you should bud or graft them on quince-stocks; but as many sorts of pears will not take, if they are immediately budded, or grafted on quince-stocks, some of those sorts which will take freely, should be first budded on the quince-stocks; and, when these have shot, the sorts you intend to cultivate, should be budded into these: for free stocks are apt to make them shoot so vigorously, as not to be kept within bounds. These grafts or buds should be put in about four or six inches above the surface of the ground, that the heads of the trees may not be advanced too high; and, when the bud or graft has shot out four eyes, you should stop the shoot, to force out lateral branches.

Two years after budding, these trees will be fit to transplant where they are to remain; for, though many people chuse to plant trees of a greater age, yet they seldom succeed so well as young ones. The distance these trees should be planted is twenty-five feet square; for less will not do, if the trees thrive well. The ground between them may be cultivated for kitchen-garden herbs, while the trees are young; but you should not sow or plant too near their roots.

In order to train your trees regularly, you should drive stakes into the ground round the tree, to which the branches should be nailed down with list in an horizontal position; for, if they are suffered to take a perpendicular figure, while young, they cannot be afterwards reduced, without great violence, to any tolerable figure. The necessary directions to be afterwards followed are, not to suffer any branches to cross each other; and always in shortening any shoots be sure to leave the uppermost eye outwards, whereby the hollowness in the middle of the tree will be better preserved; and be careful to rub off all perpendicular shoots in the middle of the trees, as soon as they are produced. The other necessary rules you will find under the article of PRUNING.

The sorts of pears which do best in Dwarfs, are all summer and autumn fruits: for winter pears are not worth planting in Dwarfs, they seldom bearing well, nor are ever well tasted, and commonly are very stony; because they are commonly grafted on quince-stocks.

Apples are also planted in Dwarfs, most of which are new budded or grafted on paradise-stocks; but, as these are for the most part of a short duration, they are not profitable, and are fit only for small gardens, as a matter of curiosity; producing fruit sooner, and in greater plenty, than when they are upon crab or apple-stocks.

The distance these trees should be planted, if on paradise-stocks, should be six or eight feet: but, if on crab-stocks, sixteen or twenty feet asunder each way. The management of this being the same with pears, I need not repeat it.

Some persons also plant apricots and plums for Dwarfs; but these seldom succeed well, as being of a tender constitution; and those which will produce fruit on Dwarfs, are much more likely to do so, when trained on an espalier, where they can be much better managed; and, therefore, I judge it much the better method, as being more certain, and the trees will make a better figure.

DYE-HOUSE, a place where cloth, linen, &c. are dyed.

Explanation of *Plate XIX*, representing part of the inside of a Dye-house.

1. A copper containing the dye, which is kept boiling during the operation.

2. A winch by which the cloth, or linen, is turned in the copper; for the linen, one part of which is placed on the winch, is, by turning it round, made to come out and fall again into the dye in the copper without any fold in it, which would have been the consequence, had the whole piece been put at once into the copper: but by this contrivance every part of the stuff is equally exposed to the action of the dye.

3. The linen on the winch.

4. A man turning the winch, which causes every part of the linen to be equally affected with the action of the dye. The man keeps turning the winch all the time the linen is continued in the dye, but not constantly the same way; for, when he comes to the end of the piece, he turns the winch the other way, by which means the linen is again moved in the dye.

5. A pipe to supply the coppers with water.

6, 6. Cocks to the pipe.

7. Another copper covered with its lid, 8.

9. Lid of another copper, which could not be expressed in the view, it being behind that marked 7.

10. A winch for washing the linen, after it is dyed, in cold water.

11. The linen on the winch.

12. A tub containing cold water, in which the linen is washed.

13. A man turning the winch, in order to wash the linen in the water.

14. A pipe for supplying the tub with water.

15. A man wringing the linen after it has been washed; after which it is hung up to dry, and then calendared.

16. The linen on a pin, or hook.

17. A tub that receives the water, which is wrung out of the linen.

18, 18. Two pails.

19. A common chimney to all the coppers.

20, 20. Tubs which contain the dye.

21. A back for washing the linen. Its use is the same with that of the tub before described; but, being generally much larger, several men can work at it, at one time; whereas only one can work at a tub.

DYING (*Dict.*)— The art of Dying is of great antiquity, as appears from the traces of it in the oldest sacred as well as prophane writers. The honour of the invention is attributed to the Tyrians, though, what lessens the merit of it is, that it is said to have owed its rise to chance. The juices of certain fruits, leaves, &c. accidentally crushed, are supposed to have furnished the first hint; and that coloured earths, and minerals washed and soaked with rain, gave the next Dying materials. But purple, an animal juice, found in a shell-fish, called murex, seems to have been prior to them all. The discovery of its tinging quality is said to have been taken from a dog, which, having caught one of the purple fishes among the rocks, and eaten it up, stained his mouth and beard with the beautiful liquor, which struck so strongly the fancy of a Tyrian nymph, that she refused her lover Hercules any favours, till he had procured her a mantle of the same colour.

Till the time of Alexander we find no other sort of dye in use but purple and scarlet.— It was under the successors of that monarch, that the Greeks applied themselves to the other colours; and invented, or at least perfected, blue, yellow, green, &c.—For the ancient purple, it has been long lost, but the perfection to which the moderns have carried the

 other

other colours abundantly indemnifies them of the loss. In this the French, under the auspices of that excellent minister M. Colbert, seem to have outstripped most of their neighbours.

Among the Romans, dye-houses, baphia, were all under the direction of the comes sacrarum largitionum; though they had each their peculiar præpositus, as at Alexandria, Tyre, &c.— The dyers of London make the 13th company of the city, incorporated under Henry VI. consisting of a master, warden, and livery.— At Paris, and in most of the great cities in France, the dyers are divided into three companies; viz. those of the great dye, du grand & bon teint, who are only to use the best ingredients, and such as strike the surest and most lasting colours.— Dyers of the lesser dye, du petit teint, who are allowed to use the inferior sorts of drugs, which only yield false and fading colours.— And silk, wool, and thread dyers.— All the higher-prized cloths and stuffs are reserved to the dyers of the first sort: those of less value, particularly such as are not rated at above 40 sols the ell in white, are committed to the masters of the petit teint. Blue, red, and yellow, are reserved more peculiarly to those of the grand teint; browns, fallows, and blacks are common to both sorts. As to black, it is begun by the dyers of the grand teint, and finished by those of the lesser.— It seems there is a tradition among dyers, that Jesus Christ was of their profession; which we also find delivered in the gospel of the infancy of Jesus, though on what grounded we know not. But it is hence, the Persian dyers, notwithstanding all their Mahometanism, have chosen Jesus for the patron of their art; insomuch that, among them, a dye-house is called Christ's shop.

DYING *ingredients*, or the materia tinctoria, are best reduced under two heads:—colorata, or those which properly give the colour.— And non-colorata, used to prepare the stuffs for better taking the dye, and to heighten the lustre of the colours.

The colouring ingredients are of three sorts, blue, yellow, and red.— To the first sort belong indigo, woad, weld, wood-wax, and log-wood; to the second, fustic; to the third, madder, brazil, cochineal, kermes, safflower, and sanders.— To which may be added annotto, and young fustic, for orange-colours: lastly, wood soot.

The art of Dying is indebted, for many of its valuable colours, to the vegetable kingdom; and may be much more so, if the world will be at the pains of enquiring into the properties of the plants that grow about the fields. Mr. Jussieu observed, in the drying plants between sheets of paper, in order to the making a hortus siccus in the common way, that some plants tinged the papers with colours the same with those they naturally possess, and others with different ones; and that many plants in drying assumed a colour which was not natural to them. Alkanet, woad, the several sorts of gallium, and some of the species anonis, tinge the papers between which they are dried to a yellowish or reddish colour, because their stalks, or some other parts of them, are of that colour. The common ros solis, or sun-dew, whose leaves are red, tinges the paper red also; and the ros solis of Portugal diffuses this tinge through three or four sheets of paper. The Alpine veronica, though green in itself, leaves its mark in red upon the paper; and many of the common leguminous plants always become black in the drying. The common mercury, which is green, while growing, becomes blue in the drying; and turnsole has the same change, though it is white in its natural state.

One great reason of these changes of colour is, that all paper is impregnated with alum; and this salt may very easily extract, or even alter the colours of plants, whose juices it receives; and in such cases, where the alum is not in sufficient quantity to do this, it is no wonder that it should however so far affect the leaves as to turn them black.

On this principle, Mr. Jussieu attempted, by means of alum, to separate colours from several plants, not known or used at present among the dyers, which might prove serviceable to them. The first experiment made on this occasion proved, that there were many plants not used at present, which afford colours not at all inferior to those in common use. The experiments the same gentleman tried on the drugs used for Dying in the Indies, proved very plainly that they were no way superior in many cases to vegetables of our own growth; and that, in order to have the most lively colours from such substances, it is always necessary to have recourse to some salt.

Among the other drugs used abroad in Dying, there were sent over to France, on this occasion, certain yellow flowers of the radiated kind, which afforded on trial a very beautiful yellow dye; and Mr. Jussieu found, on trying parallel experiments, that there were also yellow flowers in Europe of a like radiated kind, which were capable of affording a like beautiful yellow dye.

The flower which Mr. Jussieu tried these experiments upon, was the common yellow corn marygold, the chrysanthemum segetum of Lobel. This plant flowers in the middle of July, and Mr. Jussieu, drying its flowers between papers at that time of the year, found that they did not lose their colour, as most others do in the operation, but became of a deeper yellow than before. Hence it was easy to judge, that this flower contained a matter proper for colouring; and, decoctions being made of it of different strength, cloths of different kinds dipped into them became tinged to a light pale yellow, and keep this colour after being boiled in fair water. A little alum was after this added to the decoctions, and cloths dipped in these became much more finely dyed, the colour being greatly stronger and more lively. They also imbibed the colour much more speedily from the decoctions; and, on boiling afterwards in water, they lost no part of it, but remained as strongly and as lively tinged as before. This experiment was afterwards tried by a dyer, under whose hands it succeeded much better than before with Jussieu, who was unacquainted with the regular methods of the trade. The decoctions of the flowers gave a sort of sulphur colour; but linen, woollen, and silken things, which had been the day before steeped in alum water, received from this decoction a very beautiful and sufficiently strong yellow. Another decoction of the flowers, made stronger than the first, tinged a woollen cloth to a greenish lemon-colour; and the same decoction gave a bright gold-yellow to silk: and a piece of woollen cloth, before dyed blue with indigo, on dipping it in this decoction, became of a beautiful deep-green. A small quantity of chimney soot added to the decoction made it tinge cloth of a yellowish-brown, and a small quantity of roucou added to the simple decoction produced an olive-yellow.

The mixture of several other drugs, used to be added to the decoctions of the common luteola or dyer's weed to vary its tinge, produced the same changes with the decoction of this flower, and abundantly testified its value and use in the Dying trade. *Mem. Acad. Par.* 1724.

There is therefore great reason to believe, that the art of Dying might be carried to much greater perfection than it is at present, if the attempts to improve it were in proper hands, and the persons employed in it could be enabled to set out with all the knowledge there is at present in regard to its several materials, and their manner of use, as a fund of real facts on which to ground future discoveries. This however seems too difficult to be brought about, for the people who exercise the art generally are acquainted only with a certain set of rules, which though they know not they follow, yet they will not depart from them, and esteem every thing loss of time that can be proposed to them as improvements. They keep their knowledge also a close secret from those who might be expected to improve upon it; and usually, one man trades only in some one part of it, without any knowledge of the rest. Hence the difficulties attending the acquiring a knowledge of the first principles of the art are very discouraging, but they are not unsurmountable. The idea which presents itself most naturally to us, as to the manner in which stuffs are dyed, is, that the colouring particles which swim in the liquor, immediately attach themselves to the surface of the body that is plunged into it, and there adhere in so firm a manner, that there is no removing many of them without wholly taking off the surface of the body. The barely plunging a white substance into a coloured liquor is not however sufficient for the Dying of it in many cases. Indeed, there are only a few colours which will strike with this ease and facility; and the others require that the matter to be dyed should have first received the particles of another fluid, which is in most cases a solution of alum and tartar in common water. And, according to the nature of the colour that is to be given the stuff afterwards, the alum is put in large quantities, or the stuff boiled in the liquor a longer or a shorter time. After boiling in this liquor, a stuff is in the proper condition to receive the greater part of the common colours; but, for blue, stuffs require no preparation at all; and, for scarlet, the liquor in which they are first boiled is made without alum.

The matter of the stuff to be dyed makes it necessary also to change the liquor in which it is boiled, or to vary the ingredients; and the greatest naturalists, without a mechanical knowledge of Dying, would be amazed to see, that if a skain of white wool, and another of white cotton, be plunged together into the scarlet dye, and this even after they have both received the same previous boiling and preparation, the skain of cotton would come out of the liquor as white as it was put in, while the wool comes out tinged of a beautiful fire-colour. The dyer however sees this every day without an admiration of the cause, and never troubling his thoughts about how it is done. He uses it daily, to dye any thing woollen to a scarlet-colour, leaving a part white: in order to which, he knows, there requires no more than that the part, to be left white, should be of cotton.

Mr. du Fay, supposing this to be owing to the cotton's imbibing, much more slowly than the wool, the liquor in which they are both previously boiled to make them receive the colour, as cotton is well known not to take wet so soon as wool, ordered a sort of cloth to be wove, the warp of which was wool, and the woof cotton; and, sending this to the fuller's, the two substances were so well blended together, that it became impossible for the one to receive the impregnation of any liquor without the other. With all these precautions however, the whole came out of the scarlet dye in the same

ſame condition as if nothing had been done, the cotton remaining wholly white, and the wool being marked with fire-colour and white; ſo that it may be eſteemed a certain fact, that the colour of cochineal cannot be given to cotton by the means of acids; the ſame alſo holds good of kermes and gum-lac, both which are uſed inſtead of cochineal to dye in ſcarlet; but neither of theſe, any more than the cochineal, will dye cotton. It is not to be concluded from hence however, that cotton cannot be dyed ſcarlet by thin ſubſtances; the truth is, that it requires a different treatment; and, as wool, to take the ſcarlet dye, requires only to be firſt impregnated with tartar, cotton requires to be firſt impregnated with alum, as wool does, for the generality of other colours. The acid of ſea-ſalt, of vitriol, vinegar, and verjuice, all ſerve to dye wool to a ſcarlet with cochineal, but none of theſe will make it give any tinge to cotton, though alum alone can ſerve.

The ſame dye will give very different colours to the different parts of a cloth, which have been differently prepared. And this gentleman ſhewed before the Academy a piece of cloth, which he had carefully prepared in a different manner in the different parts, which being all plunged together into the dye, when taken out and dried, was found to be of a dirty red in that part where it had not been impregnated with any thing; and in the other parts, where it had been differently impregnated, was found of all the degrees of red, from a pale damaſk roſe-colour to the deepeſt ſcarlet, and this, while it had in every part been dipped an equal time in the ſame dye. This equally holds good of the other colours. And, in theſe experiments, the dirty colours given to ſuch parts of the cloth as have received no previous impregnation, will be waſhed away, and quite carried off, while the others remain in all their perfection.

Another circumſtance very worthy attention in the Dying of ſcarlet is this, that the dye is evidently compoſed of a clear or common water, in which the colouring particles are ſuſpended, and from which it is eaſy to ſuppoſe that they are ſeparated and applied to the ſtuff in Dying. As this is naturally ſuppoſed to be the caſe in regard to all colours, ſo it appears very evidently to be a fact in this, ſince the colouring particles adhere in ſuch quantities to the matter, and ſeparate themſelves ſo readily and perfectly from the water, that after an hour and half's boiling of the dye with the proper quantity of the ſtuff in it, the whole coloured matter ſhall be attached to the ſtuff, and the remaining liquor be only clear water; and what might appear wonderful is, that all the boiling in the world will never diſlodge any of the colour from the ſtuff, or occaſion its being received into the water again.

It might be ſuppoſed that this was wholly owing to the particles of ſalts, which had been imbibed into the ſtuff in its prior preparation; that theſe attracting the particles of the colour to the ſtuff, while the water of the dye had none of them to cauſe ſuch an attraction in it, they did not remain in it. But this appears not to be the caſe, but that the ſtuff will attract the colour, whether it be previouſly prepared, or the preparation and the Dying be all one act; ſince the dyers ſometimes dye ſcarlet at once in this manner, only plunging the ſtuff into a dye made of cochineal, a ſolution of tin mixed in a large quantity of water, with a ſmall quantity of ſal armoniac and cream of tartar. All theſe ingredients are mixed together before the ſtuff is put in, yet, after it has boiled about an hour and half, all the colour is in the ſtuff, and the liquor is become colourleſs as water. The event is the ſame in the dyes made of woad and of indigo for the Dying blue, and indeed in the greater part of other colours; but as the ingredients of theſe are not ſo pure as the cochineal, and there are uſually many heterogeneous particles among them, the liquor does not become ſo wholly colourleſs in theſe, as in the caſe of the ſcarlet. But the dyers, who well know, that ſo long as there is any colour left in the liquor, ſo long the ſtuff will be profited by remaining in it, always take ſmall quantities out of it, and, examining it by pouring it gently down againſt the light, they know when it is that the ſtuff has received all the tincture it can, by there being no more colouring matter ſuſpended in the dye.

Experience ſhews, that all colours do not attach themſelves with equal readineſs to the ſtuff, or remain equally firmly united to it. Woad, indigo, cochineal, kermes, and many other colours, never reach farther than the ſurface of the ſtuff. The liquor of the dye penetrates indeed perfectly through the body of it, but the colouring particles ſtopping at the ſurface become entangled there, and never penetrate, at leaſt, not in any great quantity, to the central part, which remains either quite white, or only very ſlightly tinged. This however only happens to ſuch ſtuffs as are thick, and of a very cloſe texture: others are coloured throughout. And this is only the caſe in regard to ſome dyes, not to all ſorts, ſince moſt of the wood-colours penetrate wholly through the ſtuff, be it ever ſo thick, and colour it equally every-where. Whence it ſeems probable, that the colouring particles of the woods are either more minute and fine, or much more intimately blended with the water, than thoſe of cochineal, indigo, and ſuch others as do not penetrate beyond the ſurface.

It might ſeem ſtrange, that the ſtuffs which are thus readily coloured on the ſurface, ſhould not afterwards, by the continued boiling of the water, have the colouring particles carried farther down into the body, as the water continually penetrates the whole from each ſurface to the center, and might naturally be expected to carry a part of the colouring particles in along with it. But, if we conſider the whole proceſs from the beginning, we find that the colouring particles are ſtrongly attracted by the ſtuff, and ſcarce at all by the water. Whence they almoſt immediately leave the water, and attach themſelves to the firſt part of the ſtuff they come in contact with, which is its ſurface; and, when once fixed there, it is no wonder that the particles of water, ever ſo long paſſing by them, do not attract or take them away from this ſurface, as they muſt do in order to carry them in; ſince we have before had proof, that their attraction to the water is greatly weaker than that to the ſtuff. And the difference between the wool and the cotton, the one receiving, and the other not receiving at all the coloured particles in its natural ſtate, or with the ſame impregnation by means of which the other does, ſeems reſolvable into the ſame principle, that though the attraction in wool be much greater in regard to the coloured particles than that of the water, and therefore it robs the water of them; yet the attraction in cotton being leſs than in water, the colouring particles remain in the water without any tendency to attach themſelves to the cotton.

In Dying, the ingredients uſed for the colours are well known to be of very different kinds. Some of them are ſuch as communicate a colour, which will a long time reſiſt the injuries of the air, and theſe are therefore called the good or ſtanding colours; and there are others which the bare expoſition to the air will deſtroy or deface in a very little time; theſe are therefore called the falſe or fading colours. In what manner is the action of the air upon theſe laſt to be explained? Does it take away, or carry off from the ſtuff, the very particles of the colours; or does it only break and deſtroy that beautiful and regular texture of each particle on which the colour depends? The dyers very often have recourſe to ſeveral ingredients, in order to produce one colour; and reaſon ſeems to urge, that one of theſe falſe or fading colours might be rendered laſting by mixing it with a permanent one: the dyers are alſo of this opinion. But it is nevertheleſs an erroneous one; for repeated experiments have proved, that one of theſe falſe colours fades as ſoon, when it is mixed with a ſtanding or laſting colour, as when it is uſed alone. There are but few colours on which this experiment can be tried, ſo as to come to a regular deciſion. One of the principal is the mixing a blue and a yellow, for the producing a green. In this experiment, if the blue and the yellow be both ſtanding or permanent colours, the ſtuff will perfectly hold its colours, and ſucceed alike, whether it be dyed firſt blue, and afterwards yellow; or firſt yellow, and afterwards blue. But, if one of the two colours be a falſe or fading colour, it is found that the green produced by the mixture will not ſtand, though the other be ever ſo good or permanent a colour.

There is a ſhorter way of trying the permanence of many colours of this kind, than that of expoſing them to the air, ſince in boiling only five minutes in a pint of water, in which there has been diſſolved half an ounce of alum, they will loſe as much colour as they would have done by being expoſed two days to the air in ſummer. Some colours require different methods of trial, but this ſerves for almoſt all. The ſhades of blue, yellow, red and green, purple and green, are the fineſt colours to experiment theſe things upon, as the ſame previous preparation or impregnation of the ſtuff ſerves for both, and both depend upon blue for their baſis, the purple being made of blue and red, and the green of blue and yellow.

It ſhould not ſeem ſurpriſing, if the ſtuff be firſt dipped into a dye of a ſtanding blue, and afterwards into a fading red or yellow, to turn it green or purple, that the action of the air, or boiling in alum water, ſhould carry off thoſe falſe colours, which had only been applied to the ſtuff, after it was before ſaturated with a ſtanding colour. But it might be expected, that when the ſtuff was firſt impregnated with them, and afterwards had the blue added upon them, that either the blue muſt be the colour that went off, or that they muſt all remain: but, in effect, nothing of this difference is found, but the blue remains, while the fading colours go off, however, or in whatever manner or order, they are applied. *Mem. Acad. Scienc. Par.* 1737.

The non-colouring ingredients are,— Certain reſtringent or binding materials, as galls, ſumac, alder bark, pomegranate peel, walnut rinds, and roots, ſapling bark, and crab-tree bark.— Certain ſalts, as alum, argol, ſalt-petre, ſal armoniac, pot-aſhes, lime, and urine.— Liquors, as well-water, river-water, aqua-vitæ, vinegar, lemon-juice, aqua-fortis, honey, and melaſſes.—Gums, as tragacanth, arabic, maſtic, and ſanguis draconis.— Smectics, or abſterſives, as ſoap, fullers-earth, linſeed-oil, ox-gall, &c.— Metals, as ſteel-filings, ſlippe, and pewter, to which add copperas, verdigreaſe, antimony, litharge, and arſenic.— Laſtly, bran, wheat-flower, yolks of eggs, leaven, cumin-ſeed, fenugreek-ſeed, argaric, and ſenna.

Of moſt of theſe ingredients ſome account may be found under their reſpective articles in the courſe of this book; but, with regard to their uſe and effect in Dying, it will be neceſſary to conſider them more particularly, and to bring together in one view.

Among the non-colouring drugs, then, from the mineral kingdom come, 1. Copperas, ſteel-filings, and ſlippe, the ſtuff found in the troughs of old grind-ſtones whereon edge-tools have been ground, which are uſed for all true or Spaniſh blacks, though not for the Flanders blacks.— 2. Pewter diſſolved in aqua-fortis, uſed for the new ſcarlet or Bow-dye.— 3. Litharge, though not owned or allowed, is uſed to add weight to the dyed ſilks. 4. Antimony uſed chiefly for the ſame purpoſe, though it alſo contains a tingent ſulphur, which by precipitation, &c. affords a great variety of colours.— 5. Arſenic uſed in Dying crimſon, on pretence of giving a luſtre.— 6. Verdigreaſe, uſed by linen-dyers, in their yellow and green colours.— 7. Alum.— 8. Bran and bran-water, whoſe flower, entering the pores of the ſtuff, levigates its ſurface, and thus renders the colour laid on it more beautiful; much as woods, to be gilded, are firſt ſmoothed over with white colours.— 9. Saltpetre, uſed chiefly in aqua-fortis, in the Bow-dye, to brighten colours by back boiling; for which purpoſe, 10. Argol is more commonly uſed.— 11. Lime or calk, uſed in the working of blue-fats.

Non-colouring ingredients of the animal kind, are,— 1. Honey.— 2. Yolks of eggs.— 3. Ox-gall: though this, and the two laſt, are only uſed by a few particular dyers to ſcowr, promote fermentation, and increaſe weight.— 4. Stale urine; uſed as a lixivium to ſcowr, alſo to help the fermenting, and heating of woad; though it is alſo uſed in the blue-fats inſtead of lime: in reality, as it diſcharges the yellow, wherewith blue and moſt greens are compounded, it is uſed to ſpend weld withal: yet it is known, that the urine or old mud of piſſing-places will dye a well ſcowred piece of ſilver of a golden colour; it being with this (not Bath water, as imagined) that the Bath ſixpences, &c. are prepared.

To the claſs of non-colouring ingredients, may alſo be added water, by dyers called white-liquor, which is of two ſorts.— 1. Well-water uſed in reds, and in other colours wanting reſtringency, as well as in Dying ſtuffs of a looſe contexture, as calico, fuſtian, and the ſeveral ſpecies of cottons: but naught for blues, and making yellows and greens look ruſty.— 2. River-water, ſofter and ſweeter than the former, and diſſolving ſoap better, uſed in moſt caſes by the dyers, for waſhing, rinſing, &c. their cloths after Dying.— 3. Liquor abſolutely ſo called, which is bran-liquor, made of one part bran, and fine river-water, boiled an hour, and put in a leaden ciſtern to ſettle: four or five days in ſummer will turn it too ſour, and unfit for uſe: its office is to contribute to the holding of the colour: it is known, that ſtarch, which is only the flower of bran, makes a clinging paſte, which will conglutinate paper, though not wood or metals. Accordingly, bran-liquors are uſed to mealy Dying ſtuffs, as to madder, which is rendered clammy and glutinous by being boiled in bran-water, and thus made to ſtick better to the villi of the ſtuff dyed.— 4. Gums, tragacanth, arabic, maſtic, and ſanguis draconis, are uſed in Dying ſilk, chiefly to give it a gloſſineſs, which may make it ſeem finer, as well as ſtiffer, and to increaſe its weight.

For the colouring ingredients, colorantia colorata, we have,— 1. Iron and ſteel, or what is made from them, which, we have obſerved, are uſed in Dying blacks; though how they contribute thereto is not ſo obvious: we know that green oaken boards become black by the friction of a ſaw; a green ſour apple, cut with a knife, turns of the ſame colour; the white greaſe wherewith the wheels of coaches are anointed, becomes likewiſe black, by means of the iron boxes wherewith the nave is lined, and the friction between the nave and the axle-tree; and that an oaken ſtick becomes black by a violent friction againſt other wood in a turning lath; and the black colour on earthen-ware is given with ſcalings of iron vitrified. From all which it ſeems to follow, that the buſineſs of blacking lies in the iron, and particularly in its uſtulation or friction. Be this as it will, copperas, the moſt uſeful ingredient for Dying black, is the ſalt of the pyrites wherewith old iron is incorporated. And, wherever this is uſed, ſome of the aſtringents are to accompany it.— 2. Red-wood chopped, and ground in a mill, is uſed for Dying cloth, rugs, &c. of the coarſer ſort. Its tincture, which is a ſort of brick-colour, is got out by long boiling it with galls, and the cloth along with it. It ſtands better than brazil.— 3. Brazil, chopped alſo, and ground, dyes a pink-colour, or carnation neareſt approaching cochineal: it it uſed with alum; with pot-aſhes it alſo ſerves for purples. It eaſily ſtains.— 4. Madder gives a colour near approaching the Bow-dye, or new ſcarlet: thoſe called baſtard-ſcarlets are dyed with it. It endures much boiling, and is uſed both with alum and argol, and holds well: the brighteſt dyes with madder are made by over-dying the ſtuff, and then diſcharging part of it by back-boiling in argol. It is uſed with bran-water inſtead of white liquor.— 5. Cochineal, uſed with bran-liquor in a pewter furnace, with aqua-fortis, gives the dye called among us, though improperly, ſcarlet in grain. Any acid takes off the intenſe redneſs of this colour, and turns it towards an orange, or flame-colour. With this colour the Spaniſh leather and wool, uſed by ladies, are dyed.— 6. Annotto gives an orange-colour, eſpecially to ſilks, linens, and cottons; for it does not penetrate cloth: it is uſed with pot-aſhes.— 7. Weld, by the help of pot-aſhes, yields a deep lemon-colour, though it is uſed to give all ſorts of yellows.— 8. Wood-wax, or green-wood, called alſo geniſta tinctoria, and the dyers-weed, has the like effect as weld, though its uſe is chiefly confined to coarſe cloths. It is ſet with pot-aſhes, or urine.— 9. Fuſtic is of two ſorts, young and old.— The former, chopped and ground, yields a kind of reddiſh orange-colour: the latter, a hair-colour, diſtant ſeveral degrees of yellow from the former. It ſpends with or without ſalts, works either hot or cold, and holds firm.— 10. Wood-ſoot, containing not only a colour, but a ſalt, needs nothing to extract its dye, or make it ſtrike on the ſtuff. The natural colour it yields is that of honey, but it is the foundation of many other colours on wool, and cloth only.— 11. Woad ground, or chopped with a mill for the purpoſe, is made up into balls, which being broken, and ſtrewed on lime or urine, is uſed with pot-aſhes, or ſea-weed, and gives a laſting blue. The lime, or calk, accelerates the fermentation of the woad, which in three or four days will work like a guile of beer, and be covered with a greeniſh froth or flower. An intenſe woad colour is almoſt black, that is, is of a damſon-colour. It is the foundation of ſo many colours, in its different degrees or ſhades, that the dyers have a ſcale whereby to compute the lightneſs and depth of this colour.— 12. Indigo is of the like nature, and uſed for the ſame purpoſe as woad, only that it is ſtronger.— 13. Logwood, chopped and ground, yields a purpliſh-blue: it may be uſed with alum: formerly it was of ill repute, as a moſt falſe and fading colour: but, ſince it has been uſed with galls, it is leſs complained of. The Dying materials are generally applied in decoctions made in water, more or leſs ſtrong, according to the occaſion; ſometimes by only dipping the ſtuff in the vat of dye; ſometimes by boiling it therein; and ſometimes by leaving it a day or more to ſteep.— For the alum, in Dying ſilks, it is always applied cold, in which ſtate alone it contributes to the brightneſs of the dye.

The art of Dying may be divided into as many branches as there are different colours to be communicated, and ſorts of different ſtuffs to be ſubjects of it.

Dying *of cloths, ſerges, druggets, and other woollen manufactures.*— For black, in cloths and ſtuffs of price, it is begun with a ſtrong decoction of woad and indigo, which give a deep blue; after which, the ſtuffs, being boiled with alum and tartar, or pot-aſhes, are to be maddered with common madder; then dyed black with Aleppo galls, copperas, and ſumac; and finiſhed by back-boiling in weld.— Scarlet is dyed with kermes and cochineal, with which may alſo be uſed agaric and arſenic.— Crimſon ſcarlet is given with cochineal-meſtich, aqua-fortis, ſal armoniac, ſublimate, and ſpirit of wine.— Violet-ſcarlet, purple, amaranth, and panſy-ſcarlet, are given with woad, cochineal, indigo, braziletto, brazil, and orchal.— For common reds, pure madder is uſed, without other ingredients.—Crimſon-reds, carnations, flame and peach-colours, are dyed, according to their ſeveral hues, with cochineal-meſtich, without madder, or the like.—Crimſon-red is prepared with Roman alum, and finiſhed with cochineal.— Peach colour muſt be back-boiled a little with galls and copperas, or the like.— Orange-aurora or golden-yellow, brick-colour, and onion-peel-colour, are given with woad and madder, tempered according to their reſpective ſhades. For blues, the dark are given with a ſtrong tincture of woad: the brighter, with the ſame liquor, as it weakens in working.—Dark-browns, minims, and tan-colours, are given with woad, weaker in decoction than for black, with alum and pot-aſhes; after which, they are maddered higher than black: for tan-colours, a little cochineal is added.—Pearl-colours are given with galls and copperas; ſome are begun with walnut-tree roots, and finiſhed with the former; though, to make them more ſerviceable, they did them in a weak tincture of cochineal.— Greens are begun with woad, and finiſhed with weld.— Pale yellows, lemon-colour, and ſulphur-colour, are given with weld only.— Olive-colours of all degrees are firſt put in green, and taken down again with ſoot, more or leſs, according to the ſhade required.— Feuille-mort, hair-colour, muſk, and cinnamon-colour, are given with weld and madder.— Nacarat, or bright orange-red, is given with weld and goats hair, boiled with pot-aſhes. Fuſtic here is forbid, as a falſe colour.

Dying *of wools for tapeſtry*, is performed after the ſame manner as cloths, excepting blacks, which are only to be woaded, and then put in black, as above.

Black wools for cloths and ſerges may be begun with walnut-tree root, and walnut rinds, and finiſhed by dipping in a vat of black.

Dying *of ſilks*, is begun by boiling them with ſoap, &c. then ſcowring and waſhing them out in the river, and ſteeping them in alum-water cold.— For crimſon they ſcowr them a ſecond time before putting them in the cochineal vat.

Red-crimſon is dyed with pure cochineal-meſtich, adding galls,

galls, turmeric, arsenic, and tartar, all put together in a copper of fair water almost boiling: with these the silk is to be boiled an hour and a half; after which, it is suffered to stand in the liquor till next day.—Violet-crimson is also given with pure cochineal, arsenic, tartar, and galls; but the galls in less proportion than in the former. When taken out, it is to be well washed, and put in a vat of indigo.— Cinnamon-crimson is begun like the violet, but finished by back-boiling, if too bright, with copperas; if dark, with a dip in indigo.— Light-blues are given in a back of indigo.— Sky-blues are begun with orchal, and finished with indigo. For citron-colours, the silk is first alumed, then welded, with a little indigo.—Pale-yellows, after aluming, are dyed in weld alone.— Pale and brown aurora's, after aluming, are welded strongly, then taken down with rocou dissolved with pot-ashes.— Flame-colour is begun with rocou, then alumed, and dipped in a vat or two of brazil.— Carnation, and rose-colours, are first alumed, then dipped in brazil.— Cinnamon-colour, after aluming, is dipped in brazil and braziletto.— Lead-colour is given with fustic, or with weld, braziletto, galls, and copperas. But the galls, on these and other occasions, are not to be used, which increases the weight to the damage of the purchaser; for which reason, it is punished in France as a fraud: in reality, few but black silks need galls.

Black silks, of the coarser sort, are begun by scowring them with soap, as for other colours: which done, they are washed out, wrung, and boiled an hour in old galls, where they are left to stand a day or two; after which they are washed again with fair water, wrung, and put in another vat of new and fine galls; then washed and wrung again, and finished in a vat of black.— Fine black silks are only put once into galls, viz. the new and fine sort, which has only boiled an hour; then they are washed, and wrung out, and dipped thrice in black, to be afterwards brought down by back-boiling with soap.

DYING *of thread*, is begun with scowring it in lye of good ashes; after which it is wrung, rinsed out in river-water, and wrung again.— For a bright-blue, it is given with braziletto and indigo.— Bright-green is first dyed blue, then back-boiled with braziletto and verdeter, and lastly woaded.—For a dark-green it is given like the former, only darkening more before woading.—Lemon, or pale yellow, is given with weld, mixed with rocou.— Orange and isabella, with fustic, weld, and rocou.— Red, both bright and dark, with flame-colour, &c. are given with brazil, either alone, or with a mixture of rocou.— Violet, dry rose, and amaranth, are given with brazil, taken down with indigo.— Feulemort, and olive-colour, are given with galls and copperas, taken down with weld, rocou, or fustic.— Black is given with galls and copperas, taken down and finished with braziletto wood.

DYING *of hats*, is done with braziletto, galls, copperas, verdigrease, dissolved and boiled in a copper capable of receiving, besides the liquor, twelve dozen of hats on their blocks, or moulds. Here the hats are suffered to boil some time; after which, they are taken out, and suffered to stand and cool; then dipped again; and thus alternately, oftener or seldomer, as the stuff is of a nature to take the dye with more or less difficulty.

Proof of DYES.— There are divers ways of proving the truth of Dyes, or examining the justness and legitimacy of their composition.— To discover whether a cloth have been duly treated by the dyer, and the proper foundation laid, a white spot, by the French called rosette, of the bigness of a shilling, ought to be left; besides a white stripe between the cloth and the list.

Farther proof is had by boiling the dyed stuff in water, with other ingredients different according to the quality of the Dye to be proved. If the colour sustain the test, i. e. do not discharge at all, or very little, so that the water is not tinctured by it, the Dye is pronounced good: otherwise, false.

Proof of the DYES *of Silks.*— For red-crimson the proof is made by boiling the silk with an an equal weight of alum.— For scarlet-crimson, it is boiled with soap almost of the weight of the silk.— For violet-crimson, with alum of equal weight with the silk, or with citron-juice, about a pint to a pound of silk.— These ingredients are to be mixed, and put in fair water, when it begins to boil; after which, the silks are also to be put in, and after boiling the whole for half a quarter of an hour, if the Dye be false, the liquor or the red-crimson will be violet, in case it had been dyed with orchal, or very red, if with brazil.— That of crimson-scarlet, if rocou have been used, will become of an aurora colour, or, if brazil have been used, red.— And that of violet-crimson, if brazil or orchal have been used, will be of a colour bordering on red.— On the contrary, if the three sorts of crimson be truly dyed, their liquors will discover very little alteration.

A still surer way to discover whether crimson silks have been rightly dyed, is by boiling a piece of standard dyed crimson silk, kept for that purpose at Dyers-hall, after the same manner, and then comparing the tinctures of the two liquors.

To discover whether other colours have been dyed with galls, the silk is put in fair boiling water, with pot-ashes, or soap, nearly of the weight of the silk; after some time, it is taken out; upon which, if it have been dyed with galls, the colour will be all vanished, and nothing but that of the galls left, which is a sort of feulemort, or wood colour.

The dying of silk with galls may also be detected by putting it in boiling water, with a gallon of citron juice; being taken out, and washed in cold water, and then dipped in a black dye, if galls have been used, it will turn black; if not, it will be of a brown-bread colour.

To discover whether black silk have been overdosed with galls, steel filings, or slippe, it is boiled in fair water, with twice its weight of soap: if it be loaden with galls, it will turn reddish, otherwise it will keep its colour.

To discover whether black cloth have been first woaded, and maddered; a sample of it, and, at the same time, a sample of standard black, kept for that purpose by the dyers company, is to be taken; and then as much Roman alum as is equal in weight to both, together with a like weight of pot-ashes, is to be put over the fire in a pan of bran water: when it begins to boil, the two samples to be put in, and after half an hour to be taken out and compared. — The piece which has only been woaded will be found bluish, with somewhat of a dull green; if it have both woaded and maddered, it will be of a tan or minim colour; and, if it have been neither woaded, nor maddered, its colour will be dunnish, between yellow and fallow.

For cloths dyed of a minim colour, the proof is to be made after the same manner as that of blacks.

To know whether scarlet or crimson cloth have been dyed with pure cochineal, they are to be boiled with an ounce of alum to a pound of cloth.

For cloths of other colours, the proof is to be made in the same manner as that of blacks and minims.

Theory of DYING. — We cannot better close this article, than with some general deductions, which may throw a little necessary light on the theory of Dying. As,

1. That all the materials, which of themselves give colour, are either red, yellow, or blue; so that out of them, and the primitive fundamental colour, white, all that great variety, which we see in dyed stuffs, arises. — 2. That few of the colouring materials (as cochineal, soot, wood-wax, or woad) are, in their outward and first appearance, of the same colour, which, by the slightest solutions in the weakest menstrua, they dye upon cloth, silk, &c. 3. That many of the colouring materials will not yield their colours without much grinding, steeping, boiling, fermenting, or corrosion by powerful menstrua; as red-wood, weld, woad, annotto, &c.— 4. That many of the said colouring materials will of themselves give no colouring at all, as copperas, or galls, or with much disadvantage, unless the cloth, or other stuff to be dyed, be first covered or incrustated, as it were, with some other matter, though colourless, aforehand; as madder, weld, and brazil, with alum. — 5. That some of the colouring materials, by the help of other colourless ones, strike different colours from what they would alone, and of themselves; as cochineal and brazil. — 6. That some colours, as madder, indigo, and woad, by reiterated tinctures, will at last become black. — 7. That, though green be the most frequent and common of natural colours, yet there is no simple ingredient, which is now used alone, to dye green with upon any material; sap-green, the condensed juice of the rhamnus berry, being the nearest; and this only used by country people. —8. There is no black thing in use which dyes black; though both the coal and soot of most things burnt, or scorched, be of that colour; and the blacker, by how much the matter, before it was burnt, was whiter, as in the famous instance of ivory black. —9. The tincture of some dying stuffs will fade even with lying, or with the air, or will stain even with water; but very much with wine, vinegar, urine, &c.— 10. Some of the dyers materials are used to bind and strengthen a colour; some to brighten it; some to give lustre to the stuff; some to discharge and take off the colour, either in whole, or in part; and some, out of fraud, to make the material dyed, if costly, to be heavier. — 11. Some Dying ingredients, or drugs, by the coarseness of their bodies, make the thread of the dyed stuff seem coarser; and some, by shrinking them, smaller; and some, by levigating their asperities, finer.— 12. Many of the same colours are dyed upon different stuffs with different materials; as red-wood used in cloth, not in silks; annotto in silks, not in cloth; so that they may be dyed at several prices. — 13. Scowring, and washing of stuffs to be dyed, is to be done with appropriate materials; as sometimes with ox-galls, sometimes with fullers earth, sometimes with soap: this latter being pernicious in some cases, where pot-ashes will stain or alter the colour. — 14. Where great quantities of stuffs are to be dyed together, or where they are to be done with great speed, and where the pieces are very long, broad, thick, &c. they are to be differently handled, both in respect to the vessels and ingredients. — 15. In some colours and stuffs the tingent liquor must be boiling; in other cases bloodwarm, in some it may be cold. — 16. Some tingent liquors are fitted for use by long keeping; and in some the virtue wears away by the same.— 17. Some colours, or stuffs, are best dyed by reiterated dippings

pings ever into the fame liquor at feveral intervals of time; and fome by continuing longer, and others leffer whiles therein.— 18. In fome cafes, the matter of the veffel wherein the liquors are heated, and the tinctures prepared, muft be regarded; as that the kettles be pewter for Bow-dye.— 19. Little regard is had how much liquor is ufed in proportion to the dying drugs; the liquor being rather adjufted to the bulk of the ftuff, as the veffels are to the breadth of the fame; the quantity of Dying drugs being proportioned to the colour higher or lower, and to the ftuffs both; as likewife the falts are to the Dying drugs. Concerning the weight which colours give to filks, for in them it is moft taken notice of, as being fold by weight, and being a commodity of great price; it is obferved, that one pound of raw filk lofes four ounces by wafhing out the gums and natural fordes. — That the fame fcowred filk may be raifed to above thirty ounces from the remaining twelve, if it be dyed black, with certain materials. That the reafon why black colour may be dyed the heavieft is, that all ponderous drugs may be dyed black, being all of colours lighter than it; whereas, there feem to be few or no materials wherewith to increafe the weight of filk, which will confift with fair light colours; and perhaps white arfenic to carnations, is the only inftance. Of things ufeful in Dying, efpecially black, nothing increafes weight fo much as galls; by means whereof black filks recover the weight which they loft by wafhing out their gum: Nor is it counted extraordinary, that blacks fhould gain about four or fix ounces in the Dying upon each pound. — Next to galls, old fuftic increafes the weight about one half in twelve. —Madder about an ounce.—Weld half an ounce.—The blue fat, in deep blues of the fifth ftall, adds no confiderable weight. —Neither do logwood, cochineal, or annotto; nor even copperas of itfelf, where galls are not.—Slippe adds much to the weight, and gives a deeper black than copperas, which affords a good excufe for the dyers that ufe it.

Dying *of leather, fkins*, &c.—Blue is given by fteeping the fubject a day in urine and indigo, then boiling it with alum: or it may be given by tempering the indigo with red-wine, and wafhing the fkins therewith. Red is given by wafhing the fkins, and laying them two hours in galls; then wringing them out; dipping them in a liquor made with liguftrum, alum, and verdigreafe in water; and laftly, in a dye made of brazil-wood boiled with lye.—Purple is given by wetting the fkins with a folution of roche alum in warm water, and, when dry again, rubbing them with the hand with a decoction of log-wood in cold water. — Green is given by fmeering the skin with fap-green and alum-water boiled: to darken the colour, a little more indigo may be added. — Dark-green is alfo given with fteel filings and fal armoniac fteeped in urine till foft, then fmeered over the skin; which is to be dried in the fhade.— Sky-colour is given with indigo fteeped in boiling water, and the next morning warmed and fmeered over the skin. — Yellow, by fmeering the skin over with aloes and linfeed oil diffolved and ftrained: or by infufing it in weld. — Orange-colour is given by fmeering with fuftic berries boiled in alum-water: or, for a deep orange, with turmeric.

Dying, *or ftaining of wood, for inlaying, vaneering*, &c.— Red is done by boiling the wood in water and alum; then taking it out, adding brazil to the liquor, and giving the wood another boil in it.—Black, by brufhing it over with log-wood boiled in vinegar, hot; then wafhing it over with a decoction of galls and copperas, till it be of the hue required.— Any other colour may be given by fqueefing out the moifture of horfe-dung thro' a fieve, mixing it with diffolved roche alum and gum arabic; and to the whole adding green, blue, or any other colour defigned: after ftanding two or three days, pear-tree, or other wood, cut to the thicknefs of half a crown, is put into the liquor boiling hot, and fuffered to remain till it be fufficiently coloured.

Dying *of bone, horn, or ivory*. — Black is performed by fteeping brafs in aqua-fortis till it be turned green: with this the bone, &c. is to be wafhed once, or twice; then put in a decoction of log-wood and water, warm.—Green is begun by boiling the bone, &c. in alum-water; then with verdigreafe, fal armoniac and white-wine vinegar; keeping it hot therein till fufficiently green.—Red is begun by boiling it in alum-water, and finifhed by decoction in a liquor compounded of quicklime fteeped in rain-water, ftrained, and to every pint an ounce of brazil-wood added: the bone, &c. to be boiled herein till fufficiently red.

E.

EAR *of fishes*.—All the cetaceous fishes have external meatus auditorii, or passages for hearing; but other fish have nothing of these external appearances, and seem neither to be intended by nature to make any sounds, or to hear any. Though, sound being a tremulation in the air, it may be felt by them as motion, though not distinguished as sound. It may easily be proved, that they do not hear our voices in speaking, by walking near the side of a pond or river well stored with fish about the edges; if the body and its shadow be kept out of their sight, they will never start at the voice.

Yet, how far fishes are deaf and dumb, seems a question not yet perfectly decided.

EAR, in gardening, a name given to seminal leaves of plants, or those two green and succulent leaves which first appear from the seed, and are varied different in all respects from those which follow:

EAR-*shell*, auris marina, in natural history, the name of a genus of shell-fish, the characters of which are these: it consists only of one shell, or valve, and is of a flatted shape, in some measure resembling that of the human Ear, and has an extremely wide mouth, or aperture, at its base, the widest of that of all shells, except only the patella or limpet, which is all mouth below. *Plate* XVII. *fig.* 14.

EARTH, in geography (*Dict.*)—In the terraqueous globe we distinguish three parts, or regions, viz. 1. The external part, or crust, which is that from which vegetables arise, and animals are nourished. 2. The middle, or intermediate part, which is possessed by fossils, extending further than human labour ever yet penetrated. 3. The internal, or central part, which is unknown to us, though by many authors supposed of a magnetic nature; by others, a mass, or sphere of fire; by others, an abyss, or collection of waters, surrounded by the strata of Earth; and, by others, a hollow empty space, inhabited by animals, who have their sun, moon, plants, and other conveniencies within the same. Others divide the body of the globe into two parts, viz. the external part, which they call the cortex, including the whole depth or mass of the strata of the Earth: and the internal, which they call the nucleus, being of a different nature from the former, and possessed by fire, water, or the like.

The external part of the globe either exhibits inequalities, as mountains and vallies; or it is plain and level; or dug in channels, fissures, beds, &c. for rivers, lakes, seas, &c.

These inequalities in the face of the Earth are by most naturalists supposed to have arose from a rupture, or subversion of the Earth, by the force either of the subterraneous fires or waters. The Earth, in its natural and original state, Des Cartes, and after him Burnet, Steno, Woodward, Whiston, and others, suppose to have been perfectly round, smooth, and equable; and account for its present rude and irregular form, principally from the great deluge.

In the external, or cortical part of the Earth, we meet with various strata, which are supposed to be the sediments of various floods, the waters whereof being replete with matters of divers kinds, as they are dried up, or oozed through, deposited these different matters, which in time hardened into strata of stone, sand, coal, clay, &c.

Dr. Woodward has considered the business of strata with great attention, viz. their order, number, situation with respect to the horizon, depth, intersections, fissures, colour, consistence, &c. and ascribes the origin and formation of them all to the great flood, or cataclysmus. At that terrible revolution, he supposes all the terrestrial bodies of every kind to have been dissolved and mixed with the waters, and sustained therein, so as only to constitute one common mass therewith. This mass of terrestrial particles, intermixed with water, he supposes to have been at length precipitated to the bottom, and that, according to the laws of gravity, the heaviest sinking first, and the lighter in their order. By such means were the strata formed, whereof the Earth consists, which, attaining their solidity and hardness by degrees, have continued so ever since. These sediments he further concludes to have been at first all parallel and concentrical, and the surface of the Earth, formed thereby, perfectly smooth and regular: but, in course of time, divers changes happening from earthquakes, volcano's, &c. the order and regularity of the strata was disturbed and broke, and the surface of the Earth, by such means, brought to the irregular form in which it now appears.

EARTHS, in natural history, are the various species and kinds of earthy matter found in digging, or lodged on the surface of the terraqueous globe. These are either simple, or composed of entirely similar particles; or compound, having a mixture of heterogeneous ones, as sand, or the like, among them.

Earths are defined to be friable, opake, insipid bodies; not inflammable; vitrifiable by extreme heat, diffusible in water, and separable from it by filtration.

The simple Earths are divided into two orders, and under those into five genera. Of the first order are those Earths which are naturally moist, of smooth surfaces, and of a firmer texture; and of the second are those which are naturally dry, of rough, dusty, surfaces, and of a looser texture. Of the first of these orders there are three genera, the boles, the clays, and the marles; and of the second there are two, the ochres and the tripelas. The several distinguishing characters of which are these.

Of the first order: 1. Boles are Earths moderately coherent, penderous, soft, not stiff, or viscid, but, in some degree, ductile, while moist, composed of fine particles, smooth to the touch, easily breaking between the fingers, readily diffusible in water, and freely and easily subsiding from it. See BOLE.

2. Clays are Earths firmly coherent, weighty, and compact, very stiff and viscid, ductile to a great degree while moist, smooth to the touch, not easily breaking between the fingers, nor easily diffusible in water, and, when mixed in it, not readily subsiding from it.

3. Marles are Earths, but slightly coherent, not ductile, stiff, or viscid, while most, most easily diffusible in, and disunited by water, and by it reduced to a soft, loose, incoherent mass.

Of the second order are, 1. Ochres. These are Earths slightly coherent, composed of fine, smooth, soft, argillaceous particles, rough to the touch, and readily diffusible in water.

2. Tripelas are Earths firmly coherent, composed of fine, but hard, particles, and not readily diffusible in water.

The compound Earths are two; the loams, composed of clay and sand; and the moulds, composed of earthy and putrified vegetable and animal matters.

Magnetism of the EARTH. The notion of the magnetism of the Earth was started by Gilbert; and Mr. Boyle supposes magnetic effluvia moving from one pole to the other. See Works abr. Vol. I.

Dr. Knight also thinks, the Earth may be considered as a great load-stone, whose magnetical parts are disposed in a very irregular manner; and that the south pole of the Earth is analogous to the north pole in magnets, that is, the pole by which the magnetical stream enters.

He observes, that all the phænomena attending the direction of the needle, in different parts of the Earth, in great measure correspond with what happens to a needle, when placed upon a large terella; if we make allowances for the different dispositions of the magnetical parts, with respect to each other, and consider the south pole of the Earth to be a north pole, with regard to magnetism. The Earth might become magnetical by the iron ores it contains, for all iron ores are capable of magnetism. It is true, the globe might notwithstanding have remained unmagnetical, unless some cause had existed capable of making that repellent matter producing magnetism move in a stream through the Earth.

Now the doctor thinks that such a cause does exist. For, if the Earth revolves round the sun in an ellipsis, and the south pole of the Earth is directed towards the sun, at the time of its descent towards it, a stream of repellent matter will thereby be made to enter at the south pole, and come out at the north. And he suggests, that the Earth's being in its perihelion in winter, may be one reason why magnetism is stronger in this season than in the summer.

The cause here assigned for the Earth's magnetism must continue, and perhaps improve it from year to year. Hence the doctor thinks it probable, that the Earth's magnetism has been improving ever since the creation, and that this may be one reason, why the use of the compass was not discovered sooner. See Dr. *Knight's attempt to demonstrate, that all the phænomena in nature may be explained by attraction and repulsion.*

EARTH *of dew*, an Earth much valued by many of the chymical experimenters, and prepared in the following manner: a large quantity of dew is to be collected, and set in a wooden vessel, in a cool shady place, covered with a canvas, to keep out

out duft and flies; there will in time come on a putrefaction in the liquor. It is fometimes three weeks, fometimes longer firft; during the time of this putrefaction, certain films are daily formed on the furface of the liquor, and thefe falling down to the bottom, one after the other, form, by degrees, a fediment of a fort of mud. This is to be thrown away, and the dew, when feparated from it, is to be filtred clear, and evaporated to a drynefs; the remainder is a greyifh Earth, which is the true Earth of dew; this is very light and friable, and is of a foliated ftructure in the mafs, looking like fo many leaves of brown paper, fpread very thin and even over one another. *Phil. Tranf.* N°. 3.

EARTH-*banks*, in hufbandry, &c. are a very common fence about London, and in feveral other parts of England. Where ftones are not to be had cheap, thefe are to be preferred to all other fences, both for foundnefs and lafting.

The beft manner of making them is this: dig up fome turf in a graffy place, a fpit deep, or nearly to the breadth of the fpade, and about four or five inches thick; lay thefe turfs, with the grafs outward, even by a line on one fide, and on the backfide of thefe lay another row of turf, having a foot fpace of folid ground on the outfide, to prevent the bank from flipping in, if it fhould be any ways faulty. On the outfide of this make a ditch, or elfe let the fides be lowered both ways with a flope two feet deep, and there will be no pafture loft by the fence, becaufe it will bear grafs on both fides.

The Earth that is dug out of the ditches, or from the flope, muft be thrown in between the two rows of turf, till the middle is made level with the reft. Then lay on two more rows of turf, in the fame manner; and with more of the earth fill up, and make level as before. Let this method be continued till the bank is raifed four feet high, or more if neceffary, only obferving, that, the higher it is to be carried, the wider the foundation muft be made. As the bank is carried up, the fides muft not be raifed perpendicular, but floping inward both ways, fo that at the top it may be about two feet and a half wide. This fort of fence, when made with lefs care, and faced with clay, is left naked, and ferves very well in fome places; but, when it is thus managed with the turf, the joinings of the feveral pieces are hid in a little time, by the growth of the graffy part of the turf on each fide, and it makes a beautiful fence, of as green and pleafant a colour as the reft of the field.

The great improvement upon this plan is the planting quickfets, or young white-thorn plants, in the middle of the top of the bank. The Earth on each fide of thefe may be raifed up with a fort of wall, and the rain that falls all preferved for the plants. This plenty of water, and depth of fine Earth, makes the young plants grow quicker and more vigoroufly than any other way; and the moft beautiful of all hedges is propagated this way. When this fort of hedges is young, there muft be placed on each fide of it a fhort dry hedge, of about a foot high, to keep the fheep from cropping thefe young plants, but this may be taken away after a little time.

There is one caution neceffary in regard to the making thefe banks, which is, that they muft never be made in a very dry feafon, becaufe, if much rain fhould follow, the Earth of the bank would fwell and burft out, or fpoil the fhape of the bank; but, if this fhould happen, it is eafily enough repaired. This beautiful fence may be made at a fmaller price than thofe unaccuftomed to thefe things may imagine. In good digging ground, where men work for fourteen pence a day, it may be made and planted with quick for two fhillings a pole. It may be made proper for the keeping in of deer, only by the fmall addition of planting, at every eight or ten feet diftance, a poft a little flanting, with a mortife in it; let this ftand about two feet above the bank, and into the mortifes, all along, put a rail made of a bough of any tree; no deer will ever go over this, nor can they creep under it, as they often do, when a pale tumbles down. The quick, on the top of this bank, may be kept clipped, and will grow very thick, and afford the beft fhelter for cattle of any fence in ufe with us. *Mortimer's Hufbandry.*

Compound EARTHS, in natural hiftory, are a clafs of foffil bodies, ufually confounded with the genuine and fimple Earth, as if fubftances of the fame kind, but being of a very different nature and origin. They are foffils compofed of argillaceous and marly particles, feparated and divided by adventitious matter, and never found free from thofe admixtures, or in the ftate of pure fimple marles or clays.

EA'RTHQUAKE. — Jamaica is remarkable for Earthquakes. The inhabitants, Sir Hans Sloane informs us, expect one every year. That author gives us the hiftory of one in 1687: another horrible one, in 1692, is defcribed by feveral anonymous authors. In two minutes time it fhook down and drowned nine tenths of the town of Port-Royal. The houfes funk outright, thirty or forty fathoms deep. The earth, opening, fwallowed up people, and they rofe in other ftreets; fome in the middle of the harbour, and yet were faved; though there were 2000 people loft, and 1000 acres of land funk. All the houfes were thrown down throughout the ifland. One Hopkins had his plantation removed half a mile from its place. Of all wells, from one fathom to fix or feven, the water flew out at the top with a vehement motion. While the houfes, on one fide of the ftreet were fwallowed up, on the other they were thrown on heaps; and the fand in the ftreet rofe like waves in the fea, lifting up every body that ftood on it, and immediately dropping down into pits; and, at the fame inftant, a flood of water, breaking in, rolled them over and over; fome catching hold of beams and rafters, &c. fhips and floops in the harbour were overfet and loft; the Swan frigate particularly, by the motion of the fea, and finking of the wharf, was driven over the tops of many houfes. It was attended with a hollow rumbling noife like that of thunder. In lefs than a minute, three quarters of the houfes, and the ground they ftood on, with the inhabitants, were all funk quite under water; and the little part, left behind, was no better than a heap of rubbifh. The fhake was fo violent, that it threw people down on their knees, or their faces, as they were running about for fhelter. The ground heaved and fwelled like a rolling fea; and feveral houfes, ftill ftanding, were fhuffled and moved fome yards out of their places. A whole ftreet is faid to be twice as broad now as before; and, in many places, the earth would crack, and open, and fhut, quick and faft. Of which openings, two or three hundred might be feen at a time; in fome whereof, the people were fwallowed up; others the clofing earth caught by the middle, and preffed to death; in others, the heads only appeared. The larger openings fwallowed up houfes; and out of fome would iffue whole rivers of waters, fpouted up a great height into the air, and threatening a deluge to that part the Earthquake fpared. The whole was attended with ftenches and offenfive fmells, the noife of falling mountains at a diftance, &c. and the fky, in a minute's time, was turned dull and reddifh, like a glowing oven. Yet, as great a fufferer as Port-Royal was, more houfes were left ftanding therein, than on the whole ifland befide. Scarce a planting-houfe, or fugar-work, was left ftanding in all Jamaica. A great part of them were fwallowed up, houfes, people, trees, and all, at one gape: in lieu of which afterwards, appeared great pools of water, which when dried up left nothing but fand, without any mark that ever tree, or plant, had been thereon. Above twelve miles from fea, the earth gaped and fpouted out, with a prodigious force, vaft quantities of water into the air: yet the greateft violences were among the mountains and rocks; and it is a general opinion, that, the nearer the mountains, the greater the fhake; and that the caufe thereof lay there. Moft of the rivers were ftopped up for twenty-four hours, by the falling of the mountains; till, fwelling up, they made themfelves new tracks and channels, tearing up in their paffage trees, &c. After the great fhake, thofe people who efcaped, got on board fhips in the harbour, where many continued above two months; the fhakes all that time being fo violent, and coming fo thick, fometimes two or three in an hour, accompanied with frightful noifes like a ruffling wind, or a hollow rumbling thunder, with brimftone blafts, that they durft not come afhore. The confequence of the Earthquake was a general ficknefs, from the noifome vapours belched forth, which fwept away above three-thoufand perfons.

EA'RWIGS.—Thefe are very troublefome vermin in a garden, efpecially where carnations are preferved; for they are fo fond of thefe flowers, that, if care is not taken to prevent them, they will entirely deftroy them, by eating off the fweet part at the bottom of the leaves. To prevent which, moft people have ftands erected, which have a bafon of earth or lead round each fupporter, which is conftantly kept filled with water. See the article CARNATION.

Others hang the hollow claws of crabs and lobfters upon fticks in divers parts of the garden, into which thefe vermin get; and, by often fearching them, you will deftroy them without much trouble; which will be of great fervice to your wall-fruit; for thefe are great deftroyers thereof. *Miller's Gard. Dict.*

E'BONY (*Dict.*) — Authors and travellers give very different accounts of the tree that yields the black Ebony: by fome of their defcriptions it fhould be a fort of palm-tree, by others a cytifus, &c. The moft authentic of them is that of M. Flacourt, who refided many years in Madagafcar as governor thereof. He affures us that it grows very high and big; its bark black, and its leaves refembling thofe of our myrtle, of a deep, dusky, green colour.

Tavernier affures us, that the iflanders take care to bury their trees, when cut down, to make them the blacker. F. Plumier mentions another black Ebony tree, difcovered by him at St. Domingo, which he calls *fpartium portulacæ foliis aculeatum ebeni materiæ*. Candia alfo bears a little fhrub, known to the botanifts, under the name of ebenus Cretica.

Pliny and Diofcorides fay, the beft Ebony comes from Ethiopia, and the worft from India; but Theophraftus prefers that of India. Black Ebony is much preferred to the other colours. The beft is a jet black, free of veins and rind, very maffive, aftringent, and of a fharp pungent tafte.

Its rind, infufed in water, is faid to purge pituita, and cure venereal diforders; whence Matthiolus took guaiacum for a fort of Ebony. It yields an agreeable perfume, when laid on the coals: when green, it readily takes fire, from the abundance of its fat. If rubbed againft a ftone, it becomes brown. The Indians make ftatues of their gods, and fcepters for their princes, of this wood. It was firft brought to Rome by Pompey, after his

his fubduing Mithridates. It is now much lefs ufed among us, than anciently, fince the difcovery of fo many ways of giving other hard woods a black colour.

As to green Ebony, befides Madagafcar and St. Maurice, it likewife grows in the Antilles, and efpecially in the ifle of Tobago. The tree that yields it is very bufhy, its leaves fmooth, and of a fine green colour. Beneath its bark is a white rind about two inches thick; all beneath which, to the very heart, is a deep green, approaching towards a black, though, fometimes, ftreaked with yellow veins. Its ufe is not confined to Mofaic work: it is likewife good in dying, as yielding a fine green tincture

As to red Ebony, called alfo grenadilla, we know little of it more than the name.

The cabinet-makers, inlayers, &c. make pear-tree, and other woods, pafs for Ebony, by ebonifing, or giving it the black colour thereof. This fome do, by a few wafhes of a hot decoction of galls, and, when dry, adding writing ink thereon, and polifhing it with a ftiff brufh, and a little hot wax. Others heat, or burn their wood black.

ECHINI'TES, or ECHINITÆ, in natural hiftory, the name given by authors to the foffil fhells of the feveral fpecies of echini marini, and to the ftones formed in them. Of thefe there is almoft an endlefs variety in the foffil world. Many of thofe which we find daily in our chalk-pits are the fame with thofe now known to us in their recent ftate, or living in the fea; but we have numbers of others, of which our imperfect knowledge of the animal world gives us no certain account, in their recent ftate.

ECHINOPHO'RA, in botany, the name of a genus of plants the characters of which are thefe: the flower is of the rofaceous kind, being compofed of feveral petals, arranged in a circular form; and thefe are collected into an umbellated head, and contained in the circuit of one common cup, which finally becomes an unicapfular fruit, containing an oblong feed.

ECHINO'PUS, *globe thiftle*, in botany, the name of a genus of plants, the characters of which are thefe: the flower is of a globofe fhape, and of the flofculous kind, being compofed of a number of flofcules divided into feveral equal fegments at the ends, and placed on the embryo feeds, but each having its peculiar fquamofe cup, which is fixed to the thalamus of the flower; and contains the embryo, when it has ripened into a feed.

E'CHO (*Dict.*)—Echo's are diftinguifhed into divers kinds, viz.

1. Single, which return the voice but once; whereof fome are tonical, which only return a voice when modulated into fome particular mufical tone. Others polyfyllabical, which return many fyllables, words and fentences.

Of this kind is that fine Echo in Woodftock Park, which, Dr. Plott affures us, in the day-time, will return very diftinctly feventeen fyllables, and in the night twenty. See *Nat. Hift. Oxford*.

2. Multiple, or tautological, which return fyllables and words the fame oftentimes repeated.

In Echo's, the place where the fpeaker ftands, is called the centrum phonicum; and the object, or place, that returns the voice, the centrum phonocampticum.

At the fepulchre of Metella, wife of Craffus, was an Echo, which repeated what a man faid, five times. Authors mention a tower at Cyzicus, where the Echo repeated feven times. One of the fineft Echo's we read of is that mentioned by Barthius, in his notes on Statius's Thebais, l. VI. v. 30. which repeated the words a man uttered feventeen times: it was on the banks of the Naha, between Coblents and Bingen. Barthius affures us, he had proved what he writes, and had told feventeen repetitions. And whereas, in common Echo's, the repetition is not heard till fome time after hearing the word fpoke, or the notes fung; in this, the perfon who fpeaks, or fings, is fcarce heard at all; but the repetition moft clearly, and always in furprizing varieties; the Echo feeming fometimes to approach nearer, and fometimes to be further off. Sometimes the voice is heard very diftinctly, and fometimes fcarce at all: one hears only one voice, and another feveral: one hears the Echo on the right, and the other on the left, &c.

Addifon, and other travellers into Italy, mention an Echo in that country, ftill more extraordinary, which will return the found of a piftol fifty-fix times, even though the air be very foggy.

ECLI'PSE (*Dict.*)—The learned M. Segner, profeffor of mathematics at Gottingen, has contrived the following method of reprefenting folar Eclipfes by means of a terreftrial globe.

In order to exhibit any Eclipfe of the fun, a projection in plano of the imaginary arches and circles defcribed on the illuminated hemifphere of the earth is of great ufe: and, if in fuch a projection the fituation of the cities, iflands, &c. on the furface of the earth be inferted, and a circle defcribing the pofition and magnitude of the lunar penumbra, and fome leffer concentric circles be added, thofe parts of the fun which at that time are obferved by the interpofition of the moon, are fhewn at one view, and to what part of the world the Eclipfe is vifible.

But fuch a projection is imperfect, becaufe it cannot exhibit the other phænomena which depend partly on the rotation of the earth, and partly on the motion of the moon; fo that whoever would exhibit all the appearances of an Eclipfe by this method muft draw feveral projections, which will be a work of much labour, and never worth the pains taken about it.

The rotation of the earth, indeed, makes no difference in the parallels or circles of latitude, and their projection is therefore always the fame; but the meridians or circles of longitude are continually changed by the earth's rotation, and confequently the projection of thefe circles and the fituation of places on the globe muft alfo be changed, as far as they depend on them; thefe confiderations induced me to devife a clearer and more concife method of demonftrating the doctrine of Eclipfes.

An artificial globe eafily reprefents an hemifphere illuminated. For, the pole being elevated above the horizon or depreffed beneath it, fo as to render that elevation or depreffion equal to the declination of the fun at the given time, or, which amounts to the fame thing, let the fun's place in the ecliptic be the zenith of the globe, the artificial horizon becomes the terminator of light and fhade, or that which diftinguifhes the opake from the illuminated hemifphere of the earth: and nothing remains to exhibit the illuminated hemifphere, but to turn the globe on its own axis till it obtains that fituation, which the time of day requires.

And thus the globe more eafily and naturally performs what is very difficult to exhibit by projection. From this obfervation, I imagined that all the phænomena of Eclipfes of the fun might be exhibited on a globe, that the lunar penumbra might be projected upon it, and a machine be contrived, by which its pofition might be reprefented for any time, and might be referred to places of the earth drawn on the globe. Invited by the eafe and perfpicuity I apprehended in fuch a demonftration of the nature of Eclipfes, I fet about the following machine defcribed, *plate* XVII. *fig.* 15. which reprefents a common terreftrial globe with the meridian and horary circle rectified. Two wooden brackets A B, *a b*, are fixed to the horizon, the length of each of thefe brackets fomewhat exceeds a femidiameter of the globe. Both the extremities of thefe brackets A C D, *a c*, are fo made that they may take in the horizon, and be fixed at any point of it by fcrews, one of which appears at D.

On the oppofite extremes of the brackets B, *b*, are fixed two wooden columns perpendicular to the horizon B E, *b e*, of an equal height with the femidiameter of the globe and breadth of the brazen meridian, fo that a right line drawn through the fummits of the columns may not touch the meridian.

The columns are covered with circular plates of brafs, perforated with iron axes, firmly connected to the plates of brafs. The lower parts of thefe axes are inferted firmly in the columns, the circular plates are likewife fixed immoveable in a pofition parallel to the horizon of the globe.

The tops of the axes are fmooth and polifhed as well as the plates which receive the brazen wheels E F G, *e f g*, placed on the plates, in fuch a manner, that, however they are moved round the axes, they continually keep parallel to the horizon. The diameters of thefe wheels are about three inches, and their peripheries have each a cavity to receive a thread. The wheel *e f g* is a little lefs than the other E F G, but the machine receives no detriment by this difparity, for nothing particular is marked on *e f g*; it is therefore fimply faftened at *h*, to prevent it from falling off from the axis.

But the other wheel E F G has a circle infcribed on it, divided into degrees, and the index H is fixed on to fhew the number of their parts; which is fixed to the axis in fuch a manner, as to move round it with fome difficulty, but fo that the motion of the wheel may not interrupt the motion of the index, nor the motion of the index interrupt that of the wheel. Therefore, a fmall immoveable round plate is fixed between the index and the wheel; and the index is fo faftened to the axis, that it is preffed on every fide towards that immoveable round plate.

Three brazen radii, *i k*, *i l*, *i m*, are connected at *i*, containing the equal angles *k i l*, *l i m*, *m i k*; at *i* is a very fmall perforation. The radii are elaftic, and as thin as the ftrength required will admit; their length is as near as poffible equal to a fourth part of the diameter of the globe, and this part is applied to the other as a fkeleton to produce the penumbra. Now, the radii have little holes at *l* and *m*, through which a thread is drawn and put round the wheels, as may be feen by *m*; E F G, *g f e l*, the extremes between *l* and *m*, are tied faft: wherefore, the fkeleton, alfo is rendered immoveable at that part of the thread which is included between *e l m* E; the third radius *i k* lies loofe on the part of the thread between *g* G, fo that the wheel E F G, or *e f g*, being turned round the fkeleton, may be moved backward or forward in a right line. By this conftruction of the machine it may be difcovered how many parts of the divifion of the wheel E F G are equal to a diameter of the globe.

The brackets A B, *a b*, are fo difpofed, that, the fkeleton being put in motion, its center *i* would pafs over the diameter of the globe: to this end, the horizon of the globe being placed in a fituation parallel with the horizon of the earth, the plumbline *i n* is let down from the center, to fhew the points of the horizon over which this center would impend. Therefore, the center being brought forward the whole length of the diameter of the globe, the number of the parts of the wheel E F G may be noted, which paffed in the mean time by the index H: and this muft be carefully obferved, becaufe the ufe

of

of it recurs in exhibiting all Eclipses. The following circumstances must be changed according to every particular Eclipse. First, the disk of the penumbra, which I endeavoured to effect in this manner: having found by the tables the semidiameter of the lunar penumbra on the disk of the earth, and the horizontal parallax of the moon, for the Eclipse I designed to exhibit, I reasoned in this manner; as the parallax of the horizontal moon was to the radius of the disk of the penumbra, so the semidiameter of the terrestrial globe, I made use of, must be to a fourth term which expressed the radius of such a penumbra as the size of the globe required.

That radius being divided into six parts (for the smallness of the machine prevented me from dividing it into twelve with convenience) I described concentric circles on thick cap paper, and, according to them, cut the paper into armillæ. I pasted the biggest of these on the skeleton *k l m*, so that the center of the armilla might be congruous to the center of the skeleton; the second armilla I rejected, and pasted the third on the skeleton in the same manner as the first; the fourth I rejected, pasted on the fifth as before, omitting the inner circle, which produced the figure described between *k l m*, the use of which is to shew (every part of the machine being put into the disposition herein after mentioned) the beginning and end of an Eclipse, and the places marked on the globe which are perpendicularly under the exterior margin of the biggest armilla; those parts which are placed under the interior margin of the same armilla exhibit an Eclipse of two digits; those parts which are under the exterior margin of the second armilla, represent an Eclipse four digits, and so on; those parts of the globe which are under the center suffer a total Eclipse; for I thought it sufficient to represent the shade by the center itself, on account of its minuteness.

The machine must be put in this disposition to exhibit every moment or progression of the given Eclipse. Having found by calculation the points of the terminator of light and shade, at which the center of the moon first enters into the earth's disk, and departs out of it again, they are marked on the horizon of the globe, and the brackets A B, *a b*, *fig.* 15. are placed in such a manner that, the wheel E F G being turned round, *i*, the center of the disk of the penumbra *k l m*, may pass over it, which the pendulum *i* shews whether it can or not. Then I find at what time the center of the penumbra is in any remarkable place, to shew where it first enters the disk of the earth, and place the globe in such a manner, with the help of the horary circle, that the part which appears above the horizon may represent the hemisphere of earth at that time enlightened by the sun. Then I turn round the wheel E F G, till the center of the penumbra *i*, at that remarkable place as in our example, becomes perpendicular to the terminator of light and shade; this I call its first position, and set H, the index of the wheel, to the beginning of the division. Thus every part is properly adapted to the time, and will exhibit the phænomena of the Eclipse proposed.

Now, the horary motion of the moon from the sun being taken out of the tables, I infer that, as the parallax of the horizontal moon is to this horary motion of the moon, so the number of the parts of the wheel E F G, which is equal to the semidiameter of the globe, is to a fourth term which shews how many parts are to be drawn through the place of the index to obtain the situation of the disk of the penumbra an hour after or before the time which corresponds to its primary position; the disk being placed in this position, and the globe being turned round upon its axis, the phænomena of the time given will be exhibited.

The positions for any other times are easily obtained, for, the number of the parts of the wheel being divided into half-hours, quarters, and months, a table may be formed only by addition and subtraction, by which it may be shewn how the disk of the penumbra ought to be moved backward or forward to agree with the time. This being completed, the globe need only be turned round according to the time; but the wheel in such a manner, that the index may shew the number ascribed to the time. The first operation is performed more expeditiously by the use of an horary circle which is expressed in the figure, if the hours are marked in retrograde order, accommodated to the motion of the earth round its axis.

We have before observed that the parts of the globe placed perpendicularly under the disk of the penumbra in any position might be discovered by the plumb-line. But these may be seen, at one view, by the solar rays reflected from a plane speculum so disposed that the rays may fall perpendicular to the horizon of the globe, which will project shades on the globe from the disk of the penumbra resembling those penumbræ which the moon projects on the earth, and exhibit the phases of any Eclipse.

ECTRO'PIUM (*Dict.*)—Sometimes this is a simple and original disorder, and sometimes it is only a symptom of some other, as of an inflammation, sarcoma, tumour, or the like. This sometimes owes its original to the contraction of the skin of the eye-lids, by the scar of a wound, ulcer, burn, &c. or to the induration and contraction of the skin, after an inflammation; and sometimes it in a great measure proceeds from the injudicious use of astringent collyriums, or eye-waters.

When the disorder is become inveterate, it is not easily cured; while recent, it is to be attempted by relaxing and elongating the skin of the eye-lid, by the application of emollients, such as the vapours of hot milk, or water, oil of almonds, mucilage of quince seed, and ointment of marsh-mallows. These must be repeated every day, the skin of the eye-lid drawn frequently towards its right position, and, when the patient goes to bed, the eye-lids should be brought together, and restrained in their proper posture by a plaister compress and bandage. But, if all this fail, and the case yet appear not incurable, manual operation must take place.

The operation is performed in the following manner: first, a semilunar incision is to be made in the external skin of the eye-lid, next its tarsus, or cartilaginous margin, making the angles of the incision, downward in the upper lid, and upward in the under, that by this means the skin may be elongated. If it does not appear sufficiently let out by one incision, two or three more may be made, running parallel with the first, and at the distance of a small packthread. When the eye-lid is thus sufficiently elongated, the incision must be dressed first with dry lint stuffed into them, and afterwards with lint, armed with some vulnerary unguent, which will prevent the skin from growing together again, and will occasion new flesh to be formed in the place, which will elongate the skin. Lastly, to forward the extension and cure, a piece of sticking plaister should be fastened to the eye-lid, to keep it extended, and this must be continued till the eye will shut close. When this case has continued from the patient's birth, the cure is very difficult, and it is a yet more hopeless case, when it happens to old people, from a weakness of the orbicular muscle. *Heister's Surgery.*

EDGINGS, in gardening, the series of small, but durable, plants, set round the edges or borders of flower beds, &c. The best and most durable of all plants for this use is box, which, if well planted, and rightly managed, will continue in strength and beauty for many years. The seasons for planting this are the autumn, and very early in the spring. And the best species for this purpose is the dwarf Dutch box. The Edgings of box are now only planted on the sides of orders, next walls, and not, as was some time since the fashion, all round borders or fruit beds, in the middle of gardens, unless they have a gravel walk between them, in which case it serves to keep the borders from washing down on the walks in hard rains, and fouling the gravel.

In the last age, it was also a very common practice to plant borders, or Edgings, of aromatic herbs, as thyme, savory, hyssop, lavender, and the like. But these are all apt to grow woody, and to be in part, or wholly, destroyed in hard winters. Daisies, thrift, or sea july flower, and chamomile, are also used by some for this purpose; but they require yearly transplanting, and a great deal of trouble, else they grow out of form; and these are also subject to perish in very hard seasons. *Miller's Gard. Dict.*

EEL, in ichthyology, the name of a well-known fish.

Though the learned world at this time generally allows, that Eels are produced, like other animals, by parents of their own kind, yet there remain many doubts, about the manner in which this is performed; some allowing the Eels to be like the generality of other animals of different sexes, in the different individuals; and others affirming that they are all hermaphrodites, each having the parts of generation of both sexes. Rondeletius affirms they are of different sexes: and Mr. Allen, who has given a very curious paper concerning them, in our Philosophical Transactions, is of the same opinion; and both say, that the parts of the sexes may be discovered, on a careful inspection, and some found to be males, and others females; but these parts are, in both sexes, they say, buried in a large quantity of fat, and they are of opinion, that hence proceeded the mistake of Aristotle and his followers, who, not being able to find these parts, concluded that they did not exist at all.

Among those who allow the Eels to be produced, like other animals, from animal parents, which have the sexes, some are of opinion that they are viviparous, and others, that they are oviparous; but a gentleman of our nation, Mr. Chartwynd, seems to have determined this great controversy, by observing, that, if the aperture under the belly of the Eel, which looks red in the month of May, be cut at that time, the young Eels will be seen to come forth alive, after the operation. Mr. Allen also affirms them to be viviparous; but his observation, concerning the place of their conception, does not appear analogous to that care and industry of nature, in providing convenient receptacles for the fœtus; neither is it consonant to reason, that, when nature has provided an uterus in all animals, not only the viviparous, but the oviparous, and even in insects, that the Eel and the sword-fish should be without this part, as Bartholine supposes; much less that the guts, which are appointed by nature for the secretion of nourishment, and expulsion of the fæces, and which are in continual motion to answer these purposes, should be destined in one single animal to the reception of a fœtus. This gentleman mentions a slender gland lying near the bowels, and, in all probability, this was the uterus. For Mr. Lewenhoeck, who took much pains in examining this fish, says, that he found an uterus, not only in some,

ſome, but in every Eel he examined, and he therefore concludes Eels to be hermaphrodites; nay, he goes ſo far as to ſuppoſe, that there are no male parts of generation, of the common form of thoſe in other animals; but that the office of theſe is performed by a liquor analogous to the male ſeed of animals, which is contained in certain glands, ſituated on the inſide of the uterus itſelf.

Nature having, in all animals hitherto diſſected, been found to have provided in the females not only an uterus, but alſo two tubes, which, from Fallopius, the perſon who firſt diſcovered them, are called Fallopian tubes, and which ſerve to convey the ovum from the ovary into the uterus, the ſyſtem of Mr. Allen, and thoſe others who ſuppoſe the bowels the ſeat of generation in Eels, is rendered highly improbable, by the want of ſuch parts as theſe. This gentleman obſerves, that he had ſeen the embryo's within the parent Eel, both in the egg and animal ſtate; that the eggs were always found to lie on the outſide of the inteſtines, and the young Eels within them. Now, as we have no idea how theſe embryo's ſhould get within the gut, from an egg on the outſide, any more than how an egg ſhould come in that place, the whole ſyſtem of this gentleman, though favoured by many people, ſeems built on ſo bad a foundation, as not to merit any longer the countenance of the world. It is probable, that all his obſervations were founded upon errors, for it is a very common caſe to find Eels ſubject to worms in their guts, ſuch as we have, and all the kinds that we are ſubject to; ſome of theſe might be eaſily miſtaken by the author of this ſyſtem for embryo Eels; and poſſibly the eggs he deſcribes on the outſides of the bowels, might be no other than ſmall lumps of fat.

The fine ſilver Eel may be catched with many ſorts of bait, and with great eaſe to the fiſher. Powdered beef is the very beſt bait for many places; next after this are lob-worms, minnows, or other ſmall fiſh, and, in the place of theſe, chickens guts, and even fiſh garbage will do. The Eel, for the ſix winter months, remains conſtantly buried in mud, and even in warmer weather this fiſh ſeldom appears above the bottom by day light, ſo that night is the beſt time for fiſhing for it. The hooks may be baited, and thrown into the water at night, and the ends of the lines faſtened to the ſhore; and one general line may have a great many other ſhorter ones, with each its hook tied to it, depending on it. When theſe are laid in over night, they may be left to themſelves afterwards; and, when they are taken up in the morning, the Eels will be found hung. A very good method for large Eels is this: take five or ſix lines, each of them about ſixteen yards long, and at every two yards ſpace make a nooſe, and at every one of theſe nooſes hang on a hook, faſtened to a ſhort line of ſtrong ſilk; ſome uſe wire, but ſilk will anſwer the purpoſe, and give the fiſh leſs ſuſpicion; bait the hooks with miller's thumbs, loaches, minnows, and ſmall gudgeons; let the long line be drawn quite acroſs the deepeſt part of the brook or river, and the two ends faſtened down, with a peg driven into the ground on each ſide: theſe are to be laid in at night, and the ſportſman muſt either ſit up and watch them, or elſe be up very early to take them up, for otherwiſe many of the Eels, which were hung, will be got away again; and what is moſt provoking is, that thoſe are the largeſt which thus eſcape.

With proper management and attendance there will ſeldom fail being three or four Eels on each line. When there are very large Eels in any place, the beſt bait is a moderate-ſized roach: this muſt be faſtened to a ſtrong ſingle night line, and the hook muſt be hid in the mouth of the bait.

Eels have been obſerved to move directly upwards, and ſo to get over perpendicular obſtacles ſeveral feet above the ſurface of the water. They ſlide thus upwards with as great eaſe, ſeemingly, as if they had been going along the level ground. *See Phil. Tranſ.* Numb. 482.

EEL *Pout*, in ichthyology, the Engliſh name of the muſtela fluviatilis, a fiſh of the gadus kind, according to Artedi, and diſtinguiſhed from the others by the name of the bearded gadus, with two fins on the back, and with both jaws of the ſame length.

This fiſh is caught in the Trent, and many other of our rivers, and in ſome places called a barbot.

EFFLU'VIA (*Dict.*)—Some bodies are found to emit Effluvia for a great number of years, without any conſiderable loſs, either as to bulk or weight; as magnets, electrical bodies, ambers, and divers odorous bodies, the tenuity of whoſe emanant corpuſcles is incredible: not but that the loſs they ſuſtain by the continual emiſſion of Effluvia, may be made up to them by the reception of other ſimilar Effluvia of the ſame kinds of bodies, diffuſed through the air.

It is added, that theſe Effluvia are emitted in manner of radii, rays, in orbem, and that the circumference or bound of the activity of the radiation exhibits the ſame figure as is that of the radiant. This the aſtronomers ſufficiently prove, from the ratio of the refraction of the atmoſphere.

That Effluvia may conſiderably operate upon, and have great effects on bodies within the ſphere of their activity, is proved by Mr. Boyle, in an expreſs treatiſe on the ſubtility of Effluvia; where he ſhews, 1. That the number of corpuſcles, emitted by way of Effluvia, is immenſely great. 2. That they are of a very penetrating nature. 3. That they move with vaſt celerity, and in all manner of directions. 4. That there is frequently a very wonderful congruity, or incongruity, in the bulk and ſhape of theſe Effluvia, with the pores of the bodies they penetrate into and act upon. 5. That in animal and organical bodies, particularly, theſe Effluvia may excite great motions of one part of the frame upon another, and thereby produce very conſiderable changes in the œconomy. Laſtly, that they have ſometimes a power of procuring aſſiſtance in their operations from the more catholic agents of the univerſe, ſuch as gravity, light, magnetiſm, the preſſure of the atmoſphere, &c.

That Effluvia are emitted to very great diſtances, we have a notable proof in this: that our wines grow turbid in the hogſhead, preciſely at the ſame time when the grapes are at their maturity in other remote countries, whence the wine was imported. Beſide, that odoriferous Effluvia are, in many caſes, perceived at the diſtance of many leagues. Again, that the generality of Effluvia retain the proper colour, ſmell, taſte, and other properties, and effects of the bodies whence they proceed, and this even after they have paſſed through the pores of other ſolid bodies, we have abundant proof. Thus, magnetical Effluvia penetrate all, even the moſt ſolid bodies, without any change of their nature, or loſs of force. And the ſame we ſee confirmed in ſympathetic inks, and powders, the ſagacity of blood-hounds, &c.

The wonderful extenſion of Effluvia, and the ſmall diminution of the body they iſſue from, is one of the ſtrangeſt problems in phyſics. Mr. Boyle refers the doctrine of Effluvia to ſeveral heads, as to the ſtrange extenſibility of ſome bodies, while their parts yet remain tangible; the multitude of viſible corpuſcles that may be afforded by a ſmall quantity of matter; the ſmallneſs of the pores at which the Effluvia of ſome bodies will get in; and finally the great quantity of ſpace that may be filled as to ſenſe by a ſmall quantity of matter, where rarified or diſperſed. The efficacy of ſeveral Effluvia, and their acting on one another, is a ſecond thing as obſervable in regard to them. This is done by either the great quantity of corpuſcles emitted, or their penetrating or pervading nature, or elſe by their celerity, or other modification of their motion, or by the congruity or incongruity of their bulk and ſhape to the pores of the bodies they are to act upon; or by the motions of one part upon another, which they excite or occaſion in the body they work upon, according to its ſtructure; and finally by the fitneſs and powers which they have to make themſelves be acted upon by the more catholic agents of the univerſe, which then aſſiſt them in their working.

The determinate natures of Effluvia, according to the principal inſtances we have of them, are reducible to theſe three heads: 1. That, theſe Effluvia being, by condenſation, or otherwiſe, re-united, they appear to be of the ſame nature with the body that emitted them. 2. Their determinate nature may be ſometimes diſcovered by the difference that may be obſerved in their ſenſible qualities, foraſmuch as thoſe Effluvia which are endowed with them proceed from the ſame ſort of bodies, and yet, thoſe afforded by one kind of bodies being in many caſes manifeſtly different from thoſe which fly off from another, this evident diſparity in their exhalation argues, that they retain diſtinct natures, according to the nature of each body from which they proceed. 3. We may diſcover this different nature of Effluvia from their effects upon other bodies than the organs of our ſenſes, conſidering that the effects, which certain bodies produce in others by their Effluvia, being conſtant and determinate, and always different from thoſe which other agents produce by their emiſſions on the ſame or other ſubjects, the diſtinct nature of the corpuſcles, emitted on this occaſion, may be ſufficiently judged of, were it only from this. *Boyle on Effluvia.*

EFT, or EFF, in zoology, the name of a creature very common in all parts of England, and called alſo the newt, and the ſwift, and by others the common lizard, lacertus vulgaris. The beak of this creature is oval and obtuſe, its back of a ruſty iron colour; its feet have each five toes, and are armed with very ſharp though ſmall claws. That toe which is in the place of the fore finger with us is the longeſt of all, and that which anſwers to our thumb is placed lower. *Ray's Syn. Quad.*

EGGS *of flies.* After the congreſs with the male, the female fly is ſeldom ſo much as twenty-four hours before ſhe begins to depoſit her Eggs on ſome ſubſtance proper to give nouriſhment to the worms that are to be produced from them.

Theſe Eggs in general are white and oblong, but there are ſome of them which are ſingular, and vary from this form. The deſcription of one ſpecies of theſe may give an idea of the reſt, and it may not be improper to take, for this purpoſe, thoſe of the Eggs of the fly found on hog dung, and on other ſuch matters. This fly is of the claſs of the great blue fleſh fly, but differs from it in many particulars. Its body is more round, and a little hollowed on the belly ſide, eſpecially that of the male. The hinder end of the male is bent alſo into a ſort of hook. The wings croſs one another on the body, and exceed it in length. The male is yellow, often of a very beautiful, and ſomewhat reddiſh yellow. This colour is principally owing to a multitude of hairs with which the body is covered. The corcelet is of a paler yellow than the body,

body, and has some slight tinge of brown with it. Is has only a number of black hairs on it, fewer, and placed more distant than those of the body. The female has much fewer hairs, and is browner than the male.

The Eggs are but a little time in hatching, and the growth, and all the changes of the animal, take up but a little time. The creature is found to make its way out of the upper part of the Egg, and it is not more than three weeks from the laying the Egg that is taken up, before the creature is seen in form of a perfect fly, if a female, and ready to deposit her's.

On the stalks of the common meadow grasses, there are also frequently found the Eggs of flies deposited in great numbers. These, examined by the microscope, have all the form of small snow white boats, or rather of small ships, with the decks standing up above their sides. The places where they are lodged, shew evidently the care of the creature which laid them; the fly is not known, but they always produce a small white worm, with a variable head, and two hooks.

On other stalks of grass, one may often see also yellow spots and blotches, which may naturally pass with an incurious observer for maladies of the plants; but, when examined with the microscope, all these appear to be, in reality, clusters of Eggs of the same boat-fashioned form, and amassed in different numbers; sometimes also they are formed perfect and whole, and sometimes with their ends eaten. These last are such Eggs from which the worms have made their way. These worms are white, and have a variable head, armed with two hooks, but their changes are not known. *Reaumur, Hist. Insect.*

EGGS *of gnats*. There are few creatures in the winged kingdom more prolific than the gnat. Its whole series of changes, from the Egg to the perfect animal, is usually accomplished in three weeks, or a month, and there are commonly seven generations of them in a year, in each of which every female is the parent of two or three hundred young ones, if all the Eggs come to good. These Eggs are arranged by the animal in the form of a small boat, and each separate Egg is of the shape of a nine-pin; the thicker ends of these are placed downwards, they are all firmly joined to one another by their middles, and their narrower, or pointed parts, stand upward, and make the upper surface of the boat of the Eggs, as it were, rough or prickly.

When these Eggs are examined singly by the microscope, they appear not exactly of the nine-pin shape; the larger end is rounded, and terminated by a short neck, the end of which is bordered with a ridge which makes a kind of mouth. The neck of each of these is sunk within the water on which the boat swims, for it is necessary that it should keep on the surface, since, if wholly submerged, the worms could never be hatched.

The arrangement of these Eggs, in such nice and exact order, is a thing very worthy our admiration, and which cannot have been effected, but by the utmost care and caution in the creature, while in the act of laying them. It is only in the morning hours that the gnats are to be found laying their Eggs, and then they will be frequently found about the surfaces of waters, as are in a proper condition to give support to their young. The female gnat here places herself on a small stick, the fragment of a leaf, or any other such matter usually near the water's edge, and places her body in such a manner, that the last ring but one touches the surface of the water; the last ring of all, where there is the passage for the Eggs, is turned upward, and every Egg is thrust out vertically, and the creature, when it is almost disengaged, applies it against the sides of the already formed cluster, to which it readily adheres, by means of a mucilaginous sticking matter with which it is naturally covered, like the Eggs of many other insects.

The greatest difficulty to the creature is the placing the first laid Eggs in a proper position to receive the rest, and sustain themselves and them in a proper direction; these she, with great precautions, places exactly by means of her hinder legs, and, when a sufficient number of them are thus arranged together, the rest is easy, they serving as a support to all the following. *Reaumur's Hist. Insect.*

EGRA *Salt*, Egranum sal, a name given by Hoffman, and other writers, to a purging salt, extracted from the waters of Egra by evaporation. The waters of this place are in great esteem for many diseases, and are, by Hoffman himself, in some repects, preferred to the Pyrmont, as containing less ochre and calcarious earth. The salt is wholly of the nature of Glauber's salt, as is also that of many other springs thereabouts, and even in our own country; the nitrum calcarium of Dr. Lister being plainly the same with this, or Glauber's salt, produced in the bowels of the earth by a mixture of a vitriolic acid with that alkaline earth, which is the basis of sea salt. This salt, or one analogous to it, is found also concreted into a solid form in the earth in many places. There are accounts of it in the Memoirs of the Paris Academy, in Spain, in France, and in some parts of the East; and, in England, we have earth which contains it. *Hoffman.*

ELATE'RIUM, in botany, *the wild cucumber*. — This plant has several rough stalks, which creep upon the ground, whose leaves are set on long hairy foot-stalks; they are pretty large, greenish above, and hoary underneath, somewhat triangular, and indented about the hedges, rough and hairy. The flowers grow on the rudiment of the fruit, being much smaller than the flowers of the garden cucumbers, of one single pale yellow leaf, cut into five parts. The fruit is as big as a large olive, covered, all over, with harmless prickles, and full of a pulpy juice, containing several brown oval seeds, which, when ripe, upon handling, or gently pressing, will squirt forth at the end with great violence. It is sown in gardens, flowers in July, and the fruit is ripe in September.

It may be propagated by sowing the seeds in the spring of the year in an open warm border; and, when the plants are come up, they may be transplanted into an open bed or borders, about six or eight feet distance from each other; for the vines will spread very far, especially if the ground is good, in which they are planted; these produce their fruit in autumn, which if you suffer to fall off, and emit their seeds, will afford a plentiful supply of plants, without any farther care. The roots of these plants will abide some years. *Miller's Gard. Dict.*

In order to render the preparations of this plant more mild and gentle, Mr. Boulduc has been at incredible pains, and, in the course of his experiments, found that this plant has scarcely any sulphureous principles; because brandy and spirit of wine hardly act upon it at all, and because the principles they draw from it are only salts, dissolved and carried off, not by the sulphur of these menstruums, but by the phlegm they always retain. The wild cucumber, then, contains only saline parts, in which its virtues consist: and, as it is a strong purgative, we may, from this circumstance, conclude, that salts are as properly purgatives as sulphurs, though this quality is not so generally ascribed to the former as to the latter.

Mr. Boulduc was convinced, that juices obtained by expression have less virtue than decoctions and infusions. In the former of these processes, we leave, as useless, a mass, which is not, in reality, so; and which contains principles of the plant, the union of which with the others would be necessary, either to correct or augment their qualities. By the latter of these processes, that is, decoction or infusion, every principle is equally drawn out; and, even though the compound substance should be peccant with respect to strength and acrimony, the principles united and mixed, drawn from it, are such as were most easily disengaged, and, at the same time, most mild and gentle.

After trying an incredible number of experiments, sometimes on all, and sometimes only on some of the parts of this plant, Mr. Boulduc, at last, fell upon a method of preparing, from the dry root, a simple decoction, or extract, preferable to what can be obtained from all the other parts, and which he has found, from experience, to be a very mild, and, at the same time, a very powerful hydragogue. The dose is from twenty-four to thirty grains, in conjunction with a few grains of mechoacan or rhubarb, and salt of wormwood, incorporated with extract of juniper.

As the cucumbers, produced by this plant, do not ripen all at once, they must be gathered immediately before the precise moment of their perfect maturity, because soon after they would fall, and spread their seeds, which would render them useless. Mr. Boulduc thinks, that the method of preparing the Elaterium used among the antients was highly difficult; and positively affirms, that it was lost a long time ago. This art he has attempted to recover, and, by preserving every thing that was essential and important in it, has found the means of preparing an Elaterium, not only as good, but apparently better than that of the antients; since six grains of it purge very well, and without violence. It must be exhibited in conjunction with some powder of rhubarb, and some alcaline salt.

But the most simple elaterium is that which he made, when he imagined, that most of the good vegetable remedies come, as it were, prepared from the hands of nature. Accordingly he dried the wild cucumber very well, and reduced it, together with its seeds, to a powder, which he found a very good hydragogue. *Hist. de la Acad. Royale, An.* 1719.

ELEA'TICS, a sect of philosophers of Elea, founded by Xenophanes, a Colophonian. He held all things to be incomprehensible, but withal maintained many dogmatical assertions. He held that God is one, incorporeal, eternal, all sight, and all hearing, no way resembling man: that this God is all things; that whatsoever is, is eternal; that there are infinite worlds, and those immutable and eternal; that there are four elements; that the stars are certain clouds, set on fire when they rise, and extinguished when they set; that all comets, falling stars, and the like, are clouds, kindled by motion; that the sun is a fiery cloud, extinguished in its eclipses; that the moon is a close, compact, and habitable cloud; that there are many suns and moons in the several climates of the earth; that the sun promotes generation, but the moon contributes nothing to it; that the sun goes forward in infinitum, but to us seems to move circularly by reason of the great distance; that the clouds are a vapour drawn up by the sun; that the earth was first founded and rooted, as it were, in an infinite depth; that the soul is a spirit; and that all divination is false, &c.

ELECTRI'CITY (*Dict.*)—The effects of lightning and those of of Electricity appear very similar. Lightning has been known to strike people blind, the electrical shock has had the same effect on animals. Animals have been killed by both. The mariner's compass has sometimes lost its virtue by lightning; and by Mr. Franklin's experiments it appears, that polarity may be given and reversed by Electricity. The late Mr. Stephen Gray observed several years ago, that the electrical seemed to be of the same nature with that of thunder and lightning. Others have since been of the same opinion. And indeed it appears, from various experiments, that the flame of Electricity has been justly called by Mr. Franklin, a mimic lightning, since it blinds and kills animals, and melts metals, &c. like natural lightning.

This analogy is now farther confirmed by the discovery made in France, in consequence of Mr. Franklin's hypothesis, of being able, by a proper apparatus, to collect the Electricity from the atmosphere during a thunder storm. For a pointed bar of iron, 40 feet high, having been placed upon an electrical body, and a stormy cloud having passed over the place where the bar stood, those that were appointed to observe it drew near, and attracted from it sparks of fire, perceiving the same kind of commotions as in the common electrical experiments. The like effect followed, when a bar of iron 99 feet high was placed upon a cake of resin, two feet square and two inches thick. For a stormy cloud having passed over the bar, where it remained half an hour, sparks were drawn from the bar. These were the first experiments made in France, and they have been sufficiently varied and verified since; so that it seems now certain, 1. That a bar of iron, pointed or not, is electrifed during a storm. 2. That a vertical or horizontal situation is equally fitting for these experiments. 3. That even wood is electrifed. 4. That by these means a man may be sufficiently electrifed to set fire to spirit of wine with his finger, and repeat almost all the usual experiments of artificial Electricity; for such may that which is excited by friction be denominated.

It is, however, to be remarked, that these phænomena are attended with irregularities, and do not always succeed perfectly. Sometimes simple clouds, without thunder or lightning, produce more Electricity, than when there is loud thunder. Sometimes the Electricity does not shew itself but where there is lightning: in other cases, the Electricity which seemed dissipated during the rain, began again as soon as the rain ceased, although the thunder was very distant.

Mr. Franklin has contrived a very ingenious and easy way of trying experiments of this kind by means of an electrical kite, made of a large thin silk handkerchief, extended and fastened at the four corners to two slight strips of cedar, of sufficient length for this purpose. This kite, being accommodated with a tail, loop, and string, will rise in the air like those of paper. To the top of the upright stick of the cross is to be fixed a very sharp-pointed wire, rising a foot or more above the wood. To the end of the twine, next the hand, is to be tied a silk ribband; and where the twine and silk join, a key may be fastened. The kite, is to be raised when a thunder gust appears to be coming on, and as soon as the thunder-clouds come over the kite, the pointed wire will draw the electric fire from them, and the kite with all the twine will be electrified; and the loose filaments of the twine will stand out every way, and be attracted by an approaching finger. When the rain has wet the kite and twine, so that it can conduct the electric fire freely, it will stream out plentifully from the key, on the approach of a man's knuckle. At this key the phial may be charged; and from electric fire thus obtained spirits may be kindled, and all the other electrical experiments be performed, which are usually done by the help of a rubbed glass globe or tube, and the sameness of the electric matter with that of lightning may thereby be completely demonstrated.

The electrical virtue having, in some cases, accelerated and facilitated the motion of liquids through capillary tubes, the Abbé Nollet was led to suppose, that the electrical effluvia might also contribute to accelerate the growth of vegetables, and to increase the perspiration of animals, and the experiments made by that gentleman seem to support his opinion; though objections have arisen, as to what he has advanced with respect to the acceleration of the motion of fluids through capillary tubes or syphons: for Mr. Ellicott seems to have proved, that this acceleration is not barely owing to the fluids being electrified, but that other circumstances are necessary, in order to produce this effect. Mr. Ellicott observes, that if a vessel of water is hung to the prime conductor, having a syphon in it of so small a bore that the water will be discharged from it only in drops, on the water's becoming electrical by means of the machine, it will immediately run in a stream, and continue to do so, till the water is all discharged, provided the sphere is continued in motion. And the true reason of the water's running in a stream in this case seems to be, that so long as the machine is in motion, there is a constant succession of the electric effluvia excited, which visibly run off from the end of the prime conductor in a stream; and as they are in like manner carried off from all bodies hung to it, those effluvia which run off from the end of the syphon, being strongly attracted by the water, carry so much of it along with them, as to make it run in a constant stream.

Mr. Watson has given us a particular account of several curious phænomena of Electricity in vacuo in the Philosophical Transactions, Vol. XLVII. p. 362, seq. The electrical effluvia, in their passage through an exhausted glass tube, of almost three inches in diameter, afford a most agreeable spectacle in a darkened room. We may observe, not as in the open air, brushes or pencils of rays an inch or two in length, but coruscations extending the whole length of the tube, that is, in his experiment, thirty-two inches, and of a bright silver hue. These did not immediately diverge, as in the open air, but frequently, from a base apparently flat, divided themselves into less and less ramifications, and resembled very much the most lively coruscation of the aurora borealis. At other times, when the tube has been exhausted in the most perfect manner, the Electricity has been seen to pass between two brass plates, contrived so, that they might be placed at different distances from each other in one continued stream, of the same dimensions throughout its whole length.

If the exhausted tube be made part of the circuit before mentioned in Muschenbroek's experiment, at the instant of explosion, a mass of very bright embodied fire may be seen jumping from one of the brass plates in the tube to the other. But this is observed not to take place, when one of the plates is farther distant from the other than ten inches. If the distance be greater, the fire begins to diverge, and lose part of its force; and this force diminishes in proportion to its divergency, which is nearly as the distance of the two plates.

But, though the vacuum here employed greatly exceeded that which is usually made by common air-pumps, yet it was far from being perfect. These experiments were therefore tried with a Torricellian vacuum, very ingeniously contrived by Lord Charles Cavendish. The apparatus consisted of a cylindrical glass tube of about three-tenths of an inch in diameter, and of seven feet and an half in length, bent in such a manner, that thirty inches of each of its extremities were nearly straight, and parallel to each other, from which an arch sprung, which was likewise of thirty inches. This tube was carefully filled with mercury; and each of its extremities being put into its bason of mercury, so much of the mercury ran out, until, as in the common barometrical tubes, it was in equilibrio with the atmosphere. Each of the basons containing the mercury was of wood, and was supported by a cylindrical glass of about four inches in diameter, and six inches in length; and these glasses were fastened to the bottom of a square wooden frame, so contrived, as that to its top was suspended, by silk lines, the tube filled with mercury before mentioned; so that the whole of this apparatus, without inconvenience, might be moved together. The Torricellian vacuum then occupied a space of about thirty inches. In making the experiment, when the room was darkened, a wire from the prime conductor of the common electrical machine communicated with one of the basons of mercury, and, any non-electric touching the other bason, while the machine was in motion, the Electricity pervaded the vacuum in a continued arch of lambent flame, and as far as the eye could follow it, without the least divergency.

It is to be observed, that upon admitting a very small quantity of air into the exhausted tube, the phænomena disappear; not so much from the small quantity of air admitted, as from the vapours which insinuated themselves therewith. For these phænomena have been visible, though in a less perfect degree, when a much larger quantity of air was left in the receiver, by omitting to exhaust it as much as possible.

If the electrifying machine, and the man who turns the wheel thereof, are supported by electrics per se; and if a piece of wire be connected with the brass cap covering the upper extremity of the exhausted tube, or to the end of the long brass rod, by the sliding of which through a box of oiled leather, the upper brass plate may be moved in the tube; and if the other end of the wire be fastened to any part of the frame of the electrifying machine; when this is put in motion, the electrical coruscations may be seen to pass, as before, from one of the brass plates contained in the tube to the other, and to continue, unless the air insinuates itself, as long as the machine is in motion. If, under these circumstances, the hand of a person standing on the floor is brought near the sides of the glass, the coruscations will direct themselves that way in a great variety of curious forms.

This experiment, in which the Electricity is seen pushing itself on through the vacuum by its own elasticity, is considered by Mr. Watson as an experimentum crucis of the truth of his doctrine hereafter mentioned.

It may be observed in all these experiments, that a vacuum does not conduct Electricity so perfectly as metals or water. For, in the last experiment, a person standing upon the floor,

floor, and applying his finger to the upper brass cap of the tube, receives a smart stroke; and, in the former, snaps of fire may be drawn from the prime conductor. These are arguments of some degree of accumulation, while the Electricity is passing through the vacuum; since nothing of this kind happens when metals, standing upon the ground, touch the prime conductor.

Laws, &c. of ELECTRICITY.—Mr. Ellicott, from carefully observing the various phænomena of Electricity, thinks that the following conclusions, or general laws, may be justly deduced from the phænomena.

1. That these remarkable phænomena are produced by means of effluvia; which, in exciting the electrical body, are put into motion, and separated from it.

2. That the particles composing these effluvia strongly repel each other.

3. That there is a mutual attraction between these particles and all other bodies whatsoever.

That there are effluvia emitted from the tube when rubbed, and which surround it as an atmosphere, is evident from that offensive smell arising from them, from that sensation on the hands or face, when the tube is brought near either of them, and from those sparks of light, on a still nearer approach of the finger to it.

That the particles of these effluvia repel each other, is proved by the cork balls, and the fibres of the feather repelling each other, when impregnated with them; and by the leaf-gold being repelled by the tube, and not returning to it again, until by coming near, or touching some non-electric body, the effluvia are drawn off from it. From this property it is, that these effluvia expand themselves with so great a velocity, whenever they are separated from the electric body; and, as they are likewise capable of being greatly condensed, may we not from hence justly conclude they are elastic?

That there is a mutual attraction between these effluvia and most other bodies, appears from their collecting from the tube such quantities thereof, as to endue them with the same properties with the tube itself, as is proved from several of the experiments above-mentioned.

These principles being admitted, it will follow, that, the greater difference there is in the quantity of electrical effluvia in any two bodies, the stronger will be their attraction. For, if the effluvia in each are equal, instead of attracting, they will repel each other; and in proportion as the quantity of electric matter is drawn from one of the bodies, will the attraction between them increase, and consequently be strongest, when any one of them has all the electrical matter drawn from it.

The particles of these effluvia are so exceeding small, as easily to pervade the pores of glass, as is evident, in that a feather, or any light bodies inclosed in a glass ball hermetically sealed, will be put in motion on the excited tube's being brought near the outside of it: and it has been generally thought that they pass through the pores of the densest bodies, and several experiments render this supposition not improbable, though none of them are quite conclusive.

Mr. Ellicott then proceeds to shew, in a very ingenious manner, how, from these principles, the phænomena of some of the more remarkable experiments of Electricity may be accounted for. But as what he says cannot, with justice to his reasonings, be abridged, we must refer the curious to his essays before quoted; only adding, that we have seen a manuscript of his, where he endeavours to account for the experiment of Muschenbroek on these principles, in a manner that makes us wish to see the rest of his experiments, observations, and reasonings on this subject published.

Mr. Watson has endeavoured to prove, that Electricity is not furnished from the glasses employed in the experiments, nor from the circumambient air. He thinks that Electricity is the effect of a very subtile and elastic fluid, occupying all bodies in contact with the terraqueous globe, and that everywhere in its natural state it is of the same degree of density; and that glass, and other bodies, which are called electrics per se, have the power of taking this fluid from one body, and conveying it to another, in a quantity sufficient to be obvious to all our senses; and that under certain circumstances, it is possible to render the Electricity in some bodies more rare than it naturally is, and, by communicating this to other bodies, to give them an additional quantity, and make their Electricity more dense; and that these bodies will thus continue until their natural quantity is restored to each; that is, by those which have lost part of theirs, acquiring what they have lost, and by those, to which more has been communicated, parting with their additional quantity. Both one and the other of these is, from the elasticity of the electric matter, attempted to be done from the nearest non-electric; and when the air is moist, this is soon accomplished by the circumambient vapours, which here may be considered as preventing, in a very great degree, our attempts to insulate non-electric bodies.

Mr. Watson's system naturally leads him to ask, by what denomination shall we call this extraordinary power? From its effects in these operations shall we call it Electricity? From its being a principle neither generated nor destroyed; from its being every-where and always present, and in readiness to shew itself in its effects, though latent and unobserved, till by some process it is produced into action, and rendered visible; from its penetrating the densest and hardest bodies, and its uniting itself to them; and from its immense velocity; shall we, with Theophrastus, Boerhaave, Niewentiit, s'Gravesande, and other philosophers, call it elementary fire? Or shall we, from its containing the substance of light and fire, and from the extreme smallness of its parts, as passing through most bodies we are acquainted with, denominate it, with Homberg and the chemists, the chemical sulphureous principle, which, according to the doctrines of these gentlemen, is universally disseminated? Whatever we call it, it seems certain, that this power has many surprising properties, and cannot but be of great moment in the system of the universe.

ELECTRO'METER, an instrument contrived to measure the force of electricity.

M. d'Arcy, in the Memoirs of the Royal Academy of Sciences at Paris, has given us the following curious Electrometer.

Plate XX. *fig.* 5. is a large vessel A B containing a glass bottle C D called the philosophical egg: at the extremity of the neck of this bottle is fitted on the rod V, perfectly cylindrical, one line in diameter and twelve inches long. The vessel A B is covered again at the top with a plate of brass H which fits close upon it; this plate has a large perforation at its center, and so has the vessel, that the rod may pass through at liberty. At the upper extremity of the rod is the small circular plate of brass L, fourteen lines one sixth diameter. The vessel A B being full of water, the egg is immersed to a certain depth, which ought to be such, that the instrument being at rest, that is, not electrified, the lower extremity of the egg may be as near as possible to the bottom of the vessel without touching it. That the egg and rod may always be in a vertical situation, the egg is ballasted with mercury, by which means, the center of gravity being very low, the whole keeps itself perpendicular to the horizon, and proves by the least possible motion of the egg, from its balance, that if it were not confined, it would go towards the sides of the vessels, and swim sometimes on one side and sometimes on the other; wherefore it was necessary to determine it to a center in the following manner. On the plate H are fixed fine silver wires in the form of a cross, like those in micrometers; this cross is formed by double wires, which leave a small square space in the center of the plate, which being larger than the diameter of the rod, permits it to ascend and descend between the wires without any sensible friction, and yet restrain it from erring from its center: and this singular phænomenon arises, when the whole machine is strongly electrified, the rod keeps in the middle of the wires almost without touching them, because, being electrified as well as they are, it avoids them continually.

After this description of the instrument, it is easy to conceive its use, especially if we attend to this known principle in hydrostatics, that a body immersed in water swims on the surface or sinks in it, in proportion as a volume of water, equal to that it possesses, is lighter or heavier than the body itself; from this principle it follows, that a volume of water equal to that of the egg, and that part of the rod immersed in the water when the whole is at rest, was equal to the egg, the little plate, and all the rod: consequently, if the whole be elevated one inch, the power which will sustain it at this height, will sustain a weight equal to a volume of water of the thickness of the rod, and an inch above; because the volume of water which the egg and rod then possess, is lessened by this quantity. If, therefore, different powers suspend it at 1, 2, 3, and 4 inches, &c. in height above the point of rest, these powers will be, with regard to each other, as these numbers, double, triple, quadruple, &c. You will see in a moment that electricity produces the same effect upon the Electrometer, that is, it performs the function of a power which would suspend it at 1, 2, 3, and 4 inches, &c. above its point of rest; and, consequently, that by means of this instrument we may estimate all its different degrees of force. Let us suppose, for example, the whole machine composed of the vessel A B, the egg, &c. placed like that in *fig.* 6, on a recipient of glass or any other electric per se. Electrify the vessel A B, the rod V and plate L will become electrified also. Now it is admitted that all electrical bodies repel each other; thus the little plate L and the rod V, being repelled by the great plate H, will necessarily rise more or less in proportion to the strength or weakness of the electricity. Electricity, therefore, will, as I have said before, perform the function of a power, that will suspend the instrument to a certain elevation; but as these powers are proportional to the elevations of the instrument above its equilibrium, or point of rest, these elevations also will be in proportion to the different degrees of the force of electricity: this is therefore a true Electrometer. But this instrument is of much more extensive use than barely this; for it may be employed in a great number of electrical experiments, to determine the laws of attraction,

traction, repulsion, transmission, &c. in electrical bodies: discoveries equally important with that of mensurating the electrical force.

Method of using the ELECTROMETER.—As electrical bodies have this inconvenience, that they cannot be approached, without destroying their electricity, it is evident, that, if we come so near the Electrometer as to judge of its motions with exactness, we should destroy its electricity. This reason determined us, after a number of attempts, to make our observations in the following manner: we place a great lanthorn with a large wax candle, in a part of the room which projects its light through a hole on the Electrometers I, K (we have not drawn the lanthorn in the plate, for fear it might have caused some confusion, and have therefore only exhibited the stream of light) behind these Electrometers is a very solid frame Q, all the part X is wood, but it may be of any opaque matter. In this frame are cut two rectangles or windows filled with glasses, on which are marked very exact divisions with strong Indian ink.

This frame is so disposed that the projection of the Electrometers may fall upon the glasses, and the extremity of the rod D, being made in the form of a cone, projects a very nice shadow. Now, as these glasses are transparent, the observator, placed behind in F, sees, in the most distinct manner, all the different elevations of the Electrometer, and can therefore judge of all its variations with the utmost exactness: for, the plane of the square being perpendicular to the horizon, and Electrometer rising and falling in a parallel plane, the elevations and depressions of the shadows are always correspondent to those of the Electrometers. The chains M serve to conduct the electricity from the bar of iron or any other electrified body to the Electrometers: the square Q, instead of two windows, may have but one, that being sufficient for the Electrometer: but we must at the same time make our observations on the instrument with which we made the experiments, and the Electrometer too, to be assured that the electricity is always equal, which cannot be done without comparing their shadows very accurately. The construction of the Electrometer shews, it has all the essentials to an instrument of this kind.

1. As the electrical force is very weak, the instrument must be very nice and sensible of the least impression: therefore the weight of eight grains laid on the little plate makes it sink above four inches.

2. As the electrical force is very subject to alterations, the instrument must be so contrived as to exhibit all its variations; a thousand experiments have convinced us that the least alteration, in the force of electricity, immediately affects this Electrometer. It is in short universal, for the true Electrometer is the cylindrical rod V, which determines the quantity of electrical power by the number of its parts raised above the point of rest: now it is not difficult to procure a cylindrical rod of a line diameter. It is true the diameter of the little plate L and its distance to H, the point of rest, may cause some differences in the repulsion; but it is easy to observe all these proportions, so that any one may construct an Electrometer, which will be operated upon, like ours, by the same power of electricity: this property seems to me one of the most remarkable in our instrument, like that of M. Reaumur's thermometer, which all Europe has admired. As I have said our Electrometer might be used as an instrument, it may be proper to give some account of the experiments we have made. In order to discover whether electricity is in proportion to the bulk or surface of bodies, we applied ourselves in the manner following: the instrument E served for an Electrometer, the other I was designed to make the experiment on, above this last was suspended perpendicularly, at the distance of ten inches, a cap or portion of the sphere PS; this cap was of hammered iron, very thin, and of a very regular figure; it received its electricity from the electrical bar by a brass wire, and, being suspended on silk, preserved it. The chain in *fig.* 6. extends to both instruments, but in this experiment it only communicated with the Electrometer, so that the instrument was not electrified. One person made his observation on the square of the height of the Electrometer caused by the electricity, another observed the elevation of the instrument; and several repeated experiments confirmed us in the opinion that the elevation of the instrument was in proportion to the force of the electricity, and this we found to answer exactly, after having repeated the experiment above fifty times. We afterwards poured mercury into this cap till it increased the weight sixty times, and found no sensible alteration in the experiment: this seems to shew that the attraction of electrical bodies is in proportion to their surfaces; but this is a mattter of doubt, for the fire and sparks drawn from an electrical body may observe some other law. Certain it is that a piece of any metal must be of a certain thickness to extract shining sparks from, otherwise you only procure such a kind of fire as is extracted from electrified wood of any thickness; yet the sparks we extract from the middle of a plate of iron are very strong; and those extracted from the cap, either with or without mercury, seemed to have no difference. We have, in short, found by a multitude of experiments, that the gravity or levity of a body neither increase nor diminish its electricity.

I shall add another experiment we made to try whether an electrical body always transmitted the same quantity of electricity, of whatever volume it was. Every thing being disposed as in *fig.* 6, except that the instrument with which we made our experiment, instead of communicating with the iron bar by a chain, had a communication with it by a very fine iron wire; we electrified the bar of iron, and made our observations on the Electrometer and the instrument: we afterwards substituted a much thicker wire in the room of the fine one, repeated the experiment, but did not find the least difference in the result, though it was performed several times with wires of all the different sizes, that could be procured.

The objections to our Electrometer are of three kinds, its certainty, universality, and the method of making use of it. It may be asked in the first place, whether the egg immersed in water be not more or less repelled by the bottom of the vessel, which would affect the Electrometer, without any alteration in the electricity? I answer that a body totally immersed in a fluid receives no motion from electricity, and this is a fact confirmed by experiments. 2. It may be asked whether the bodies which transmit the electricity to the Electrometer, may not act differently on the Electrometer? The experiment I have produced of wires of different magnitudes transmitting the same quantity of electricity sufficiently proves electricity to have the property of fluids, which always endeavour to preserve a plain surface, whatever are the canals of their communication. Besides, it follows from this property, that the least change of electricity, in a body composing the mass of those which are electrical, equally influences the whole mass; which solves another objection that might be made against the vessels of glass on which we support our Electrometer: it may be said, that, being more or less dry, they might lose their electricity, and the Electrometer sink, though there was no alteration in the electrical bodies themselves: but the last property I have mentioned proves, that electricity, like a fluid, endeavours to preserve an even surface, and is therefore acted upon equally; and this is supported by a number of experiments.

It may in the last place be objected, that the instrument, notwithstanding all I have said about it, is too coarse to be affected so nicely, and that we are therefore apt to draw false consequences from it; but the following experiment will shew this objection intirely groundless.

The iron bar which receives the electricity of the globe was placed at the distance of above twenty inches from it; a communication was made afterwards between this bar and the Electrometer: and, the chamber being made very dark, we began to electrify. The electricity which the bar received by this method was so weak that we could scarce be sensible whether it was electrified or not, by trying to draw sparks from it; and what were drawn, were so weak, they scarce deserved the name, notwithstanding which, our Electrometer which had a communication with the iron bar rose above a degree. This sufficiently demonstrates the nicety of the instrument and how easily it is acted upon; this too might, if there was occasion, be still increased by lessening the diameter of the rod.

The strongest objection against the universality of our instrument is the different density of water in different climates: but I answer, if a rod be made which will descend four inches with the weight of eight grains, the Electrometer will be as correct as ours. It may be objected, that in a hot country such a rod might be more repelled, because it would be bigger than ours; but, as the rod is only repelled in proportion to its circumference, the difference can scarce be perceivable.

It may be imagined that different positions of the Electrometer, with regard to the frame and lanthorn, may change the apparent ascent or descent, but a very simple experiment will bring these to a certainty. Your Electrometer, &c. being placed as before directed, load the little plate with eight grains, and see how many degrees that will make the Electrometer descend upon the frame; the sum of these degrees, compared with the sum of the degrees which the same weight would have made another Electrometer, on which the same experiment had been made, pass through, will give their exact proportion. *Mem. de la Acad. Royale*, 1749.

ELEOSA'CCHARUM (*Dict.*)—After the chemists had shewn physicians, that the spirit residing in essential oils contained, in a small volume, all the particular virtues of the plants; physicians prudently reflected, that they had hence an excellent instrument in their art; but the unctuous tenacity of the oil still prevented its being used with safety, because these oils, being extremely sharp, and, by their tenacity, remaining fixed to one part, occasioned inflammations. Hence they began to think of a method of rendering these oils miscible with water, and uniformly conveying their intire virtues to the places intended; and this they found might be affected by the means of sugar.

Grind, therefore, an ounce of dry loaf sugar to an impalpable

ble powder, in a glass mortar, with a glass pestle; and, by degrees, add thereto a drachm of any essential oil, or half a drachm, if the oil be very tenacious; and continue rubbing them together, till all the oil is perfectly mixed, and drank into the sugar. The oil, in this operation, usually diffuses a fragrancy to a great distance; the operation, therefore, should be performed quick, and the mortar be covered with a cloth, surrounding the pestle. If a little fresh white of an egg be added in the grinding, and mixed in with the sugar and oil, the oil thus becomes more easily miscible; but the mixture will not thus keep so long, without turning rancid. And thus sugar, which is a very pure soap, or a true essential oily salt, divides the glutinous tenacity of the oil, interposes itself betwixt the principles thereof, unites them closely with itself, and makes an extemporaneous soap; which may thus be commodiously diluted with water, for medicinal uses: for though this mixture is not so perfect as in an actual soap, or true essential salt, yet it suffices for use; nor is there reason to apprehend any inconvenience from the sugar, in this preparation; for sugar is unjustly said to be unwholesome, as there are no proofs extant thereof. On the contrary, it is a wonderful salt, that perfectly mixes with water, and ferments therewith into wine: and yet, what is exceedingly suprising, it appears oleaginous, and perfectly inflammable in the fire; whence it is known to consist of oil and salt.

If these Eleosacchara be well prepared, dried, and put into clean glasses, exactly closed with glass stoppers, they may long be preserved perfect; and, in this manner, very effectual medicines might be commodiously carried from place to place, and, upon occasion, be directly used on a journey, by adding a little of the Eleosaccharum to a glass of wine. An Eleosaccharum might, also, be made, by grinding an essential oil with a fixed alcaline salt; by which means, also, a kind of soap is obtained: but alcalies thus destroy the grateful properties of the essential oils, and change their natural tastes and odours. Such Eleosacchara, also, would presently resolve in the air, and thence be easily spoiled. By the former method, therefore, physicians may prepare an excellent medicine, rich in virtues: for, if the Eleosaccharum of mint be dissolved in distilled mint-water, then strengthened with the addition of the spirit of mint, and the mixture sweetened with the syrup of the same plant, the whole virtues of mint may thus be obtained.

Remarks.

Hence appears the saponaceous property of sugar, which fits it for breaking and dividing the bodies of oils, as if they were in a manner fermented with sugar; and, at the same time, it does not diminish, but rather improves, the particular virtue of these oils: whence the ancients, who were unacquainted with sugar, mixed oils with honey, for the like purpose. And hence we learn the virtue of sugar in the body; where, being diluted with the natural juices, it affords a saponaceous lixivium, which, by the force of circulation, dissolves unctuous and viscous substances: whence it does not generate, but dissolves phlegm; nor does it increase the bile, nor turn into it, but opens, thins, and divides it; though, by dissolving the oils too much, it may occasion leanness; as, by attenuating too much, it produces a weakness and relaxation of the parts, and is, therefore, often found prejudicial in the rickets and the scurvy. In the mean time, this production of nature and art is, as we above observed, very singular and extraordinary; for it intirely dissolves in water, melts in fire, shoots like a perfect salt into perfect crystals, is manifestly fixed, and, if distilled in close vessels, affords an acid penetrating spirit: in an open fire it becomes wholly inflammable; it is fermentable, and thus convertible into strong wine, which will afford alcohol; and, lastly, it may be converted into sharp vinegar. If it be called a salt, we may ask how it comes to be inflammable in the fire: if an oil, how it comes to crystallize? If an essential salt, how it comes to ferment? So that, perhaps, in all nature there is no other body found, in which all these properties conspire. *Boerhaave's Chemistry.*

ELEPHANT (*Dict.*)—The Elephant is said to have four venters, and lungs four times as big as an ox. His genital member is like that of a horse, but less; and the testicles lie inward about the reins. The fore legs are much longer than the hind legs, of short joints, and of equal bigness, both above and beneath the knees; the ancle-bones are very low; he bends his hind legs as a man when he sits, but not both together, and so, leaning on one side, sleeps most commonly against a tree. Their feet are round like horses, and as broad as a bushel, having five distinct toes upon each foot, which are very little cloven, but without nails. They are for the most part of a mouse colour, or darkish brown. See *Plate* XXII. *fig.* 6.

Taming of ELEPHANTS. The method of taking and taming this creature, in the island of Ceylon, is as follows: the natives pitch upon a proper place for a warren, or park, which is broad at the entrance, and grows narrow farther in, till, at the end, it is so narrow, that an elephant cannot turn himself, and it runs on of this narrowness so far, that twenty elephants may stand in it one behind another. When the inclosure of this warren is finished, all the people of the neighbouring places assemble, and make a circumference round the woods, where they know there are elephants, which takes in, perhaps, sixty miles. The men now stand at twenty-five yards distance, and kindle fires between them, and make all the noise they can, by shouting, blowing horns, beating drums, and the like, and, by degrees, approach nearer and nearer the warren. The elephants run from the fires and noise, and consequently can go no where but towards the warren; the men, who every way surround them, except on the warren side, follow upon them in this manner, till they come together, and make a ring, and the Elephants are driven into the inclosure. When these creatures perceive that they are thus taken, they make resistance, and often turn upon the men; but there are always near the warren fences of poles, lying flat upon the ground, which the hunters need only raise up, and they keep in the prey, so that they can neither escape, nor injure them; they then pursue the Elephants with fire-brands, and drive them into the narrow part where they cannot turn.

They are, from this place, taken one by one, and led to the stable, each between two tame Elephants bred for that purpose, the points of whose long teeth are cut; and these, if the wild Elephant be troublesome, will lay hold of his trunk with theirs, and beat him with their teeth. A man, sitting upon each of the tame Elephants, directs them by a staff with a hook at the end, with which he occasionally touches their heads, and orders them, as he pleases, without bridle, or any other furniture. When they are brought into the stable, they are led between two posts, with stakes put athwart before their breasts, and under their bellies, and are so tied that they cannot stir, nor lie down upon the ground; for, if permitted to lie down, they would become sorrowful, refuse to eat, and in some time die. They are here fed with the trunks of plantains, a food they much delight in; and, when they have been kept thus about six weeks, they become tame enough for sale. If not sold at that time, they feed them about six weeks longer with cocoa leaves, and they are, at the end of that time, perfectly tame as a spaniel, and will eat grass with the oxen in the fields. *Philos. Trans.* N°. 277.

The Elephants of Ceylon have been so long hunted, that they now know man for their mortal enemy, and seldom fail to seize upon and kill him, whenever they meet him; but if a man lie upon the ground, and pretend to be dead, they never meddle with him. Several people have, in this island, lain asleep while Elephants passed by them, and some have only pretended sleep, and a perfect stillness has always been found to preserve them, even though the creature came up to examine them.

ELIXIR (*Dict.*)—ELIXIR *of aloes*, a name given, in the late London Dispensatory, to the medicine commonly known by the name of Elixir proprietatis, which is there also ordered to be made in the following manner: take tincture of myrrh, a quart; powder of aloes, and fine saffron, of each three ounces; digest them a due time, and then press off the tincture, and filtre it for use. *Pemberton's London Dispensatory.*

ELIXIR *paregoricum*, a name given, in the late London Dispensatory, to the Elixir asthmaticum of Quincey; which is there ordered to be made thus:

Take flower of benjamin, and strained opium, of each a drachm; camphire, two scruples; essential oil of aniseeds, half a drachm; rectified spirit of wine, a quart; digest all together a proper time, and then strain off the spirit. *Pemberton's London Dispensatory.*

ELLIPSIS *in grammar* (*Dict.*)—F. Bossu considers the Ellipsis, as a way of disguising sentences, by suppressing the word which should make the particular application, and leaving the whole in a kind of ingenious ambiguity.

Thus, the Trojans, in Virgil, being reduced by Turnus to the last extremity, and ready to be destroyed, spy Æneas coming to assist them: upon which the poet says, Spes addita suscitat iras. Which expression signifies either, in particular, that the hope they conceive retrieves and augments their courage: or in general, that the hope of assistance at hand naturally raises courage, and gives new strength.

If the poet had added a word, and said, Ollis spes addita suscitat iras, the passage had been expresly restrained to the first sense; and had ceased to be a sentence, and commenced only the application of a sentence. The suppression of that word makes it a sentence in form.

This that excellent critic looks on as one of the finesses of the Latin tongue; wherein it had vastly the advantage of the modern tongues. *Trait. du Poeme de Epique.*

ELM-TREE, *ulmus*, in botany, a genus of trees whose characters are;

The flower consists of one leaf, which is shaped like a bell, having many stamina, or threads, in the center: from the bottom arises the pointal, which afterwards becomes a membranaceous or leafy fruit, almost heart-shaped; in the middle of which is placed a pear-shaped seed vessel, containing one seed, for the most part of the same shape.

These trees are very proper to plant in hedge-rows, upon the borders of fields, where they will thrive much better than, when planted in a wood, or close plantation; and their shade will not be very injurious to whatever grows under them; but, when

when these trees are transplanted out upon banks after this manner, the banks should be well wrought and cleared from all other roots, otherwise the plants, being taken from a better soil, will not make much progress in these places. About Michaelmas will be a good time for this work, for the reasons before assigned; but when they are planted, there should be some stakes fixed in by them, to which they should be fastened, to prevent their being displaced by the winds; and part of their heads should be taken off, before they are planted, which will also be of use in preventing their being easily overturned by winds; but by no means should their leading shoot be stopped; nor their branches too closely cut off; for, if there are not some shoots left on to draw and attract the sap, they will be in danger of miscarrying.

These trees are also proper to plant at a distance from a garden or building, to break the violence of winds; for which purpose there is not any tree more useful; for they may be trained up in form of an hedge, keeping them cut every year; which will cause them to grow very close and handsome, to the height of forty or fifty feet, and be a great protection against the fury of winds: but they should not be planted too near a garden, where fruit trees, or other plants, are placed; because the roots of the Elm run superficially near the top of the ground to a great distance, and will intermix with the roots of the other trees, and deprive them of nourishment. Nor should they be planted near gravel or grass walks, which are designed to be well kept; because the roots will run into them, and send forth suckers in great plenty; which will deface the walks, and render them unsightly.

But, for large gardens, where shade is required, there is scarce any tree so proper for that purpose, being easy to remove, when grown to a considerable size; so that a person who is willing to have his plantations for shade in a short time, may procure trees of one foot circumference in their trunk, which will be in no danger of succeeding, provided they are removed with care. And these will take root, and grow again, almost as well as young plants, which is what few other sorts of trees will do; but then they should be such trees as have been thus regularly trained up in a nursery, and have good roots, and not such as are taken out of hedge-rows, as is by some practised, which seldom rise with any tolerable roots, and consequently often miscarry; and this has been the occasion of so many plantations of these trees failing; for although some of them may live a few years, yet few of them are of long duration, and they rarely increase much in their stems, but frequently grow hollow, their heart decaying first; so that they are supported only by their bark or shell, for a few years, and the first severe winter, or very dry summer, they are generally destroyed.

In planting of these trees, great care should be taken not to bury their roots too deep; which is very injurious to them, especially if they are planted on a moist loam or clay; in which case, if the clay is near the surface, it will be the best way to raise the ground in an hill, where each tree is to be planted, which will advance their roots above the surface of the ground, so that they will not be in danger of rotting in winter with moisture.

When these trees are propagated by suckers taken from the foot of old trees, they are commonly laid into the ground very close in beds, where, in dry weather, they may be frequently watered, to encourage their putting out roots. In these beds they are left two years; by which time, those that live, will be well rooted, though a great many of them generally die; then they should be transplanted into the nursery.

There are some who raise the witch Elm from seeds, which it generally produces in great plenty, and are ripe in April. These should be sown upon a bed of fresh loamy earth, and gently covered; in dry weather they should be watered, and if the bed is shaded from the violent heat of the sun, it will be of great service to the seeds, for I always observe the plants to come up better in the shade, than when exposed to the sun. When the plants come up, they should be carefully cleared from weeds; and after they have stood two years in the seed bed, they will be fit to plant out into the nursery.

Sometimes the common English Elm will produce seed; but it is not so constantly fruitful as the witch Elm, which seldom fails to produce great quantities, when they have arrived to due maturity; which seeds will fall to the ground, and when they light upon a spot which is not disturbed, the plants will come up in great plenty.

The timber of the common English Elm is generally preferred to the rest; though that of the witch Elm is often as good, and is the largest tree, when planted on a kindly soil; but the Dutch Elm affords the worst timber, and never will grow to the stature of either of the other sorts; so that this should not be cultivated for the timber; therefore the best way to be sure of the kinds which a person would chuse to propagate, is to have a nursery of stools, in order to furnish layers; for when they are grubbed up from hedge-rows, there will often be many sorts intermixed, especially if the people who go about to gather them, furnish them; because they take them indifferently, wherever they can procure them; so that when they are planted out thus blended together, there will be a considerable difference in their growths, which will deface the plantation.

Mr. Dodart, in a discourse made before the Paris academy, on the great fecundity of vegetables, and their prodigious increase, chose this tree as an example of it. He observed an Elm of about six inches diameter in the body, and about twenty feet high to the branches; he ordered one of the branches to be cut off, and, without reckoning the seeds which had been shaken off by the blows of the weapon, or lost by the fall, he counted the rest only which remained on. This branch was about eight feet long, and on this there were 16450 seeds. Counting in a very moderate way, there must be reckoned, at least, ten such branches as this, on an Elm of that growth. The product of these ten branches will be then 164500 seeds.

All the branches which are shorter than eight feet, on the same tree, taken together, on a most moderate computation, must be allowed to make a surface more than double that of these ten branches. The product of this surface of the short branches, therefore, will be 329000.

An Elm may very reasonably be supposed to live a hundred years, and as the Elm, here mentioned, was but of twelve years growth, it cannot be supposed, in that state, to be yet arrived at its middle degree of fertility in seeds; therefore the smallest addition that can be made to the 329000, will bring it to at least 330000, for the mean yearly product of seeds of the tree; and to know what is the whole product of an Elm in seeds, according to this computation, this sum must be multiplied by a hundred, the number of years of the duration of the tree. Thus the smallest amount will be thirty-three millions of seeds, produced by an Elm originally raised from one single seed. *Hist. Acad. Par.* 1700.

This, however, is no more than the natural produce of the tree, in its wild state; we all know very well, that proper management will make trees yield abundantly more fruit than they naturally would. Thus, if this Elm, at a proper stage of its growth, had been lopped off at the head, it would have pushed out infinitely more numerous branches; and a set of these would have appeared in a circle round the trunk, at about half an inch from the place where it was cut off, and this would have been the case in whatever part, or at whatever height, it had been cut. All the trunk of the tree, from the ground up to the beginning of the natural eruption of the branches, being then full of these rudiments of branches, placed in circles, and separated by circular spaces of about half an inch deep, composes so many circles of branches, or rudiments of branches, as there are half inches in measure from the ground up to the first natural rudiments; all these rudiments are formed, therefore, all ready to appear in form of complete branches, and all contain, in miniature, their proportion of seeds, and any circle of them may be made to shoot out and appear, by only cutting off the trunk just above them; these are all, therefore, to be allowed really to exist, and all to be brought into the account of the providence of nature, in the fecundity of the tree, as all are formed and provided for it. There are therefore evidently contained, in the Elm, so many times thirty-three millions of seeds, as there are half inches in twenty feet, which was its measure from the ground to the first branches: that is to say, this tree contains actually in itself 15840000000 rudiments of seeds, or has so many bodies inclosed in itself, by each, or any one of which, it is capable of multiplying its species, and of producing so great and astonishing a number of trees. The imagination is startled at being conducted to so amazing a scene by reason.

What are we to think then of the immensity of the works of the great Creator of the universe, when we consider that every one of these seeds contains in itself a tree, loaded with an equal number of seeds, and each of those another tree, loaded in the same manner, and so on, beyond the utmost extent of our capacity; and that consequently here is a geometrical proportion, or progression of increase, the first term of which is 1, the second 15840000000, the third the square of that number, the fourth the cube, and so on to infinity. Reason and imagination are lost together in the immensity of such a calculation? *Mem. Acad. Par.* 1700.

E'LOHA, in scripture, the singular of Elohi, one of the names of God.

E'LOHI, Eloi, or Elohim, in scripture, one of the names of God. But it is to be observed, that angels, princes, great men, judges, and even false gods, are sometimes called by this name. The sequel of the discourse is what assists us in judging rightly concerning the true meaning of this word. It is the same as Eloha. One is the singular, the other the plural. Nevertheless Elohim is often construed in the singular number, particularly when the true God is spoken of; but when false gods are spoken of, it is construed rather in the plural. *Calmet. Diction. Bibl.*

E'LVERS, an English name for a small sort of eels, caught in some parts of the kingdom, particularly about Gloucester and Tewksbury. These are, in reality, young congers, or sea eels. They get up into rivers, while very small. They are taken in prodigious numbers in the rivers, in dark nights, and

and are esteemed a very delicate food. *Willughby's Hist. Pisc.*

E'LUL, one of the Hebrew months, answering pretty near to our August. There are but nine and twenty days in it. It is the twelfth month of the civil year, and the sixth of the ecclesiastical. Upon the seventh or ninth day of this month the Jews fast, in memory of what happened after the return of those who went to view the promised land.

ELUTRIA'TION, in metallurgy, is the separating the lighter matters from the mixed ores of metals, by means of great quantities of fair water. Solid bodies, not dissoluble in water, are by this operation separated from each other by water very well stirred, so that the lighter and the finer parts are carried away with the water, and the heavier and more solid remain at the bottom of the vessels.

ELYCRY'SUM, in botany, the name of a large genus of plants, the characters of which are these: the flower is of the flosculous kind, being composed of several small floscules, divided into segments, arranged in a stillated form at the ends; these stand on the embryo fruit, and are contained in a common scaly husk or cup, which is of a very glossy and splendid appearance, and of a gold or silver colour, or of some other gaudy tinge. The embryo's finally ripen into seeds, winged with down.

E'MERALD *Colour*, in the glass trade.—The way of giving this beautiful dye to glass is this: in the pots of melted metal, made of pulverine, and without manganese, when the matter is well purified, put a little crocus martis calcined with vinegar. About three ounces of this crocus is enough for a hundred weight of glass; let it stand till thoroughly mixed, then put in to every hundred weight of metal two pounds of calcined brass; this must be added at six different times, letting the metal stand two hours every time. When this is all in, make a proof of the metal, and, if it have any bluishness, add more crocus martis, a small quantity at a time. When the whole is of a fine leek green, let it stand twenty-four hours to mix thoroughly, and then work it. *Neri's Art of Glass.*

EME'RUS, *scorpion sena*, in botany, a genus of plants, whose characters are:

It hath leaves like those of the colutea: the flowers are papilionaceous: the pods are slender, and contain two or three cylindrical-shaped seeds in each.

These shrubs are easily propagated by sowing their seeds, which they commonly produce in great plenty, in March, upon a bed of light sandy earth, observing to keep the bed clear from weeds; and in very dry weather you must often refresh the bed with water, which should be given carefully, lest the seeds should be washed out of the ground by hasty watering. When the plants are come up, you must continue the same care; and the Michaelmas following, if your plants have thriven well, you may draw out the largest; which may be transplanted into a nursery, at three feet distance row from row, and one foot asunder in the rows. This will give room to those plants which are left to grow in the seed bed; in which place they may remain another year, when they will also be fit to transplant into a nursery; where they should be trained up in the manner you design them to grow, either in round heads, or in rude plants. In one or two years more they will be fit to plant out, where they are to remain for good: in doing of which you should be careful, in taking them up, not to break or wound their roots: nor should they remain too long in the nursery before they are transplanted: for they are subject to shoot downright roots, which, when cut off, oftentimes prove the death of the tree. In all other respects it must be treated like other flowering shrubs; amongst which, this is commonly sold at the nurseries. It delights in a dry soil, and may also be propagated by laying down the tender branches; which will take root in about a year's time, and may then be transplanted into a nursery, and managed in the same manner as the seedlings. *Miller's Gard. Dict.*

EMMENAGO'GA, (*Dict.*)—Under this term the great Hoffman also included those medicines which excite a flux of blood from the hæmorrhoidal veins; as the roots of birthwort, zedoary, and the five aperient roots; the herbs mugwort, calamint, feverfew, penyroyal, baum, savin, polium montanum, rue, marjoram, rosemary, wall-flowers, saffron, bay-berries, juniper-berries; the gums bdellium, myrrh, galbanum and amber: among purgative substances, aloes, rhubarb, and bryony; as also aromatics, and animal salts; castor, and chalybeated preparations, which excel all others of the mineral and chymical kind.

The more these excretions are subservient to life and health, the more it were to be wished, with Hippocrates, that we had certain and efficacious medicines for regulating them, and by that means preventing and curing several very terrible disorders. But as these excretions are principally the work of nature, and, in women, appear, return, and end, at certain periods; but are neither incident to all women, nor so periodical as the menses; and as a certain redundance of blood, together with a certain state of the vessels of the anus and uterus, disposed to a spontaneous evacuation, are requisite, in order to these discharges; and as these evacuations may be obstructed, or totally destroyed, by various causes; it must of course be a difficult task to fall upon effectual means of restoring these evacuations when stopped, or enlarging them when impaired; neither of which ends can ever be obtained without knowing the cause from which the misfortune proceeds.

But, supposing that there is a redundance of blood, the principal cause of this evacution; supposing, also, that the vessels of the uterus and anus are so disposed, that they may be distended by a large quantity of blood flowing to them, and be capable of discharging this blood; yet, if the excretions are not duly carried on, either on account of obstructions, or spasmodic constrictions of the small lateral vessels of the arteries, in consequence of which, the blood does not circulate naturally, or on account of a diminution of the spirituous principle of the blood, and the elastic contractile force of the heart and arteries; then the above enumerated medicines afford the desired relief: for the capillary vessels are excellently opened, and obstructions removed, by the five aperient roots, birthwort, rhubarb, bryony, and wall-flowers, especially if exhibited, by way of decoction, with some saline stimulus, such as borax. This intention is also excellently answered by the gums exhibited with aloes, and other purgatives, in the form of pills. The small and capillary ducts, when spasmodically constricted, or preternaturally contracted, are excellently relaxed and opened by mugwort, which is of a demulcent nature, as also by yarrow, saffron, and castor. In order to restore the spirituous principle of the blood, strengthen the solids, and confirm the tone of the fibres and vessels, such corroboratives are to be used, as operate by their fine volatile and oleous salt; among which we may reckon all aromatics, myrrh, the berries of the bay and juniper-trees, rosemary, penyroyal, baum, savory, savin, wall-flowers, calamint, amber, filings of steel, chaly beate tinctures, and volatile oleous salts.

When the evacuation is impaired, or rendered slow, by a redundance of blood which too powerfully resists the elasticity of the vessels, the emmenagogues already mentioned, especially those of the hotter kind, are by no means to be exhibited; for by these the blood is thrown into violent commotions, and a train of formidable symptoms are frequently brought on. In this case, therefore, venesection in the feet is to be recommended, since, by means of that alone, these salutary and critical evacuations are often happily restored.

Nor are the emmenagogues already enumerated proper, in cases where there is a deficiency of blood, and laudable juices, as in persons recovering from the shock of a disease, those whose primæ viæ are stuffed with viscid sordes, or those the villous coats of whose stomachs are lined with a viscid mucus, and by that means digestion and chylification unduly carried on. In cases of this nature, the principal intention of the physician ought to be, not only the regeneration of a good and laudable blood by nutritive gelatinous substances, and broths, easily convertible into blood and juices; but also, if necessary, the restitution of the digestion and elaboration of the chyle by emetics, gentle purgatives of a saline aperient nature, and bitter stomachics.

These evacuations are frequently stopped by obstructions and infarctions of the vascular substance of the anus in men, and the internal part of the uterus and vagina in women; in consequence of which, they admit no blood, however strongly propelled to them. In these cases forcing medicines are not only superfluous, but pernicious, unless the indurated and infarcted vessels are previously relaxed and softened by proper medicines. And this intention can neither be more speedily nor efficaciously answered, than by baths, or fomentations, or vapour baths, so contrived, that a vessel full of warm water, impregnated with mugwort, penyroyal, and chamomile flowers, may be placed under the abdomen in such a manner, that the steam may ascend and penetrate into the uterus and adjacent parts. This is to be done in a warm room, with the patient's body well covered; and, in order to keep the water warm, red-hot flints are now and then to be put into it. Frictions of the legs and thighs with warm cloths, especially after bathing with sweet water, also contribute very much to the production of this effect.

But, in those disorders arising from a suppression, a defect, or irregularity of the menses, or hæmorrhoidal discharge, nothing is more certain, safe, and effectual, than a prudent use of mineral waters, especially the mild Caroline springs for internal, and those of Toeplitz for external use, since by these all the intentions of cure are excellently answered; for, by drinking the former of these waters, the viscid humours are attenuated and evacuated, and the obstructions of the capillary vessels removed, whilst by bathing in the Toeplitz waters, which are highly light, and destitute of a constructing earthy principle, the structure of the parts is removed, and the vessels so enlarged, as readily to admit the blood, and again discharge it.

As in medicine it is a difficult task to keep the menstrual discharges in a due and natural order, so it is still more difficult to manage the hæmorrhoidal, when a large quantity of blood attempts its discharge by the veins of the anus, but does not find them disposed for its evacuation; but the discharges of this kind are, among all other substances, most

most powerfully promoted by pills prepared of aloes, which, by their highly subtile, resinous, and sulphureous particles, not only excite a violent orgasm in the whole mass of blood and humours, but also, by stimulating the coats of the colon and rectum, by their tenacious, viscid, and resinous particles, excite a greater afflux of blood to these parts: yet, when the blood, after it has arrived here, cannot make its way through the vessels, it partly protrudes them, like so many turbercles accompanied with pain; and partly, stagnating between the nervous coats of the intestines, and pressing them, produces violent inflations, spasms, and other terrible disorders of the abdomen. *Frederic Hoffman.*

E'MPIS, in natural history, the name given, by authors, to a large species of gnat, found about rivers and ponds; it is distinguished from all the other kinds, by a circle of white passing round the middle of its body.

EMPLA'STER (*Dict.*)—No part of the apparatus for dressing is of more importance than plaisters; the nature of which is so well known, that it would be ridiculous to attempt a definition of them. There are various and almost innumerable kinds of plaisters; the most considerable of which, together with their composition and preparation, are found in the several dispensatories; but especially in the Pharmacopœia Augustana, the London Dispensatory, that of Brandenburg, and Lemery's Pharmacopée Universelle. Most of these plaisters are spread upon linen cloth, leather, or silk, according to the different conditions of wounds, and the various states of patients. When plaisters are to be applied to hairy parts of the body, those parts are previously to be shaved, that the plaister may adhere more firmly, and be removed more easily and with less pain to the patient. But, that they may be still more commodiously applied, their form is to be adapted to that of the particular part, for whose relief they are intended.

The bulk, as well as the figure, of plaisters, is various; for their largeness ought always to correspond to the wound, or part affected. As for the use of plaisters, it is found to be very various and extensive; for they not only serve to retain balsams, ointments, lint, tents, and other applications, to wounds, but also contribute very effectually to generate pus, to digest and maturate tumors, to conglutinate and cure wounds, to unite fractured bones, to heal burns, to alleviate pains, and to corroborate such parts of the body as are weak and infirm.

It is to be remarked, that the best way of giving a plaister a good consistence is a prejudice to many intentions; and that is done with litharge, or minium, and oil; for, when these are boiled, so as to incorporate, they make a body very suitable for this form, but when they are opposite in virtues to the warmer gums, which are frequently mixed with them. The other way, therefore, of giving a consistence to this form, either with wax, resin, or pitch, may be preferable as to intention or efficacy; but these also have their inconveniencies in other respects; for those plaisters which take in much wax, are difficult to spread, because, when warm, they are not glutinous enough to stick well. Resin likewise is troublesome to spread, and, where it abounds, sticks too much; and pitch of any kind, especially when joined with turpentine, though made into a hard consistence, yet will not hold its form in rolls, but run flat, as is commonly observed in the emplastrum cephalicum and adhæsivum; for which reason they are frequently confined in bladders.

In the prescription of extemporaneous plaisters, the greatest regard is to be had to that particular consistence which the part can most conveniently bear, whereupon the application is to be made. Thus plaisters to the breast and stomach, especially in the intentions of emollient or discutients, should be yielding and soft, as the officinal emplastrum stomachicum magistrale; but to the loins, or any of the limbs, where warm discutients and strengtheners are to be applied, an higher and more adhesive consistence is to be sought for. The emollient plaisters likewise should be laid on thick, and frequently repeated, if the symptoms continue; because their better parts are soon spent. Discutients also, applied to hard tumors, require repetition; but the strengtheners, which are on purpose contrived of a strong adhesive consistence, are permitted to lie on, till they grow dry, and come off spontaneously. In some flatulent tumors, where a plaister alone does not prevail, they are at intervals taken off, and discutient fomentations or lotions made use of; such as are composed of bitters, carminatives, and take in lixivial salts, or alcaline spirits.

EMPLA'STRUM *attrahens*, the drawing plaister, a plaister ordered, in the late London Pharmacopœia, to supply the place of the melilot plaister, in the dressing of blisters. The college are satisfied that the herb is of no sort of use in the composition, and that very gross abuses are practised to give the green colour to the plaister; for which reason they have ordered the plaister to be now made in this manner: take yellow resin, and yellow wax, of each three pounds; tried mutton suet, one pound; melt all together, and strain, while it is hot. *Pemberton's Lond. Disp.*

EMPLASTRUM *commune*, a name given, in the new London Pharmacopœia, to what has been long called diachylon plaister. The apothecaries had been long used to make this by a shorter way than was prescribed them, and the college has now authorized that method, ordering it to be made of only a gallon of oil of olives, and five pounds of litharge, boiled together with about a quart of water, to keep them from burning till they are perfectly mixed, and have the consistence of a plaister. *Pemberton's Lond. Disp.*

EMPLASTRUM *ex ammoniaco cum mercurio*, a form of medicine, in the late London Dispensatory, ordered to be prepared in the following manner:

Take gum ammoniacum strained, a pound; quicksilver, three ounces; simple balsam of sulphur, a drachm. Rub the quicksilver with the balsam of sulphur, till it no longer appears; then add, by degrees, the gum ammoniac melted, and almost cooled again, and make the whole into a plaister. *Pemb. Lond. Disp.*

EMPLASTRUM *roborans*, the strengthening plaister, a form prescribed in the London Dispensatory, and ordered to be made thus: take of the common plaister two pounds, of frankincense half a pound, of dragon's blood three ounces; melt the plaister, and then add to it the other ingredients in powder. *Pemberton's Lond. Disp.*

EMPYE'MA (*Dict.*)—When matter or pus is collected in the cavity of the breast, betwixt the lungs and the pleura, the disorder is called an Empyema.

This is properly enough an Empyema; but the matter may happen, also, to be collected in the duplicatures of the mediastinum.

The disorder above-mentioned supposes a previous purulent abscess within the breast; which, breaking, discharges, its contents into the cavity of the thorax.

These abscesses are seated, first, in the lungs; and are caused either by inflammations, ruptures of the vessels, or considerable obstructions by substances not easily resolvable.

Secondly, in the pleura, arising either from an inflammation, a slight wound healed too precipitately externally, a contusion, or rupture of the membrane.

Thirdly, in the diaphragm, when an unresolved inflammation of this part suppurates, and breaks on that side next the breast.

Fourthly, in the mediastinum, when that part is, in like manner, inflamed.

Fifthly, in the pericardium, after an inflammation thereof.

An Empyema may be prognosticated from an inflammation of any of the parts above-mentioned, which has not been resolved by means of coction, revulsion, a crisis, or medicines; but which terminates with a shivering, a fever which increases in the evening, a wandering heat, a sense of weight on the part, a difficulty of breathing, loss of appetite, and thirst.

An Empyema is known to be formed, first, from a duration of such a disorder, as is mentioned above, for twenty days, without a due expurgation by expectoration.

Secondly, by the discontinuance of the signs of an abscess in any of the before-mentioned parts.

Thirdly, from a new pain, together with a difficulty of breathing, and discharge of saliva, which soon after cease.

Fourthly, from a dry cough, a weight on the diaphragm, an impossibility of lying on one of the sides, a noise made by the fluctuating pus or matter upon motion, a slow fever, redness of the cheeks, hollowness of the eyes, heat at the extremities of the fingers, incurvation of the nails, and tumor of the abdomen.

The consequences of the rupture of an abscess or vomica, so as to form an Empyema, are, first, a continual accumulation of pus or matter from the ulcer, not yet healed, nor deterged.

Secondly, a continual agitation, a degeneracy, fœtidness, putrefaction, and attenuation of the pus or matter, thus confined in a warm and moist place.

Thirdly, a difficult elevation of the diaphragm, and extension of the lungs: hence respiration is rendered short, difficult, and not easily performed, unless in an erect posture; danger of suffocation when the patient lies down, which, however, it is not possible for him to do on the unaffected side; a perpetual dry cough and anxiety.

Fourthly, a maceration, corrosion, and consequent tabid state of the lungs, pleura, diaphragm, mediastinum, pericardium, and of the heart itself; a hectic fever, attended with a small and quick pulse; redness of the cheeks; perpetual thirst; utter loss of appetite; extreme weakness and faintings.

Fifthly, hence an unfitness of all the fluids for nutrition, circulation, secretion, and excretion, whence a consumption and atrophy, a resolution of the fibres, a putrefaction of the liquids, and their discharge through the corroded lungs; or a sanious and fatal diarrhœa, with nocturnal sweats after sleep, pustules on the face, incurvation of the nails, a shining yellowness of the skin, and an Hippocratic countenance.

The operation for the Empyema generally implies an artificial opening made into the cavity of the thorax, by which we evacuate any fluid that lies there extravasated, and is become dangerous by its weight and quantity. The fluids described as necessary to be voided by this operation, are blood, matter, and water.

When

When blood is the fluid, ſuppoſed to require evacuation by this method, it is always extravaſated through ſome wound of the veſſels of the lungs or thorax, and, being diſcharged in great quantities on the diaphragm, is ſaid to oppreſs reſpiration till let out by ſome convenient perforation, made in the moſt depending part of that cavity, which is the only kind of perforation into the thorax, diſtinguiſhed by the name of the operation for the Empyema: but, though this opening is univerſally recommended in the caſe here ſtated, yet we meet with few or no examples, where it has been practiſed for a mere extravaſation of blood; and I ſhould think it can hardly ever be adviſeable on this account: for, if we perform it immediately after the accident, and during the hæmorrhage, the opening made at the bottom of the thorax might probably make way for a dangerous effuſion of blood, which perhaps would otherwiſe be choked up and ſtopped for want of a ready iſſue; and, if we wait till the hæmorrhage ceaſes, it becomes needleſs, becauſe the blood not only, for the moſt part, finds ſome vent for the external wound, if left open, but is conſtantly ſpit up by the trachea; ſo that, had we no farther proofs of this abſorbent power in the lungs, we might from hence be perſuaded of the probability of its being more ſafely carried off ſo, than by any artificial opening we can poſſibly contrive in the thorax.

Or if it be thought that the extravaſated blood, being coagulated in the thorax, cannot be taken up by the veſſels of the lungs, yet, even in that caſe, the operation uſually practiſed will not anſwer the purpoſe; for, beſides the poſſibility of the lungs adhering to the pleura in the place of inciſion, which would abſolutely prevent any advantage from it, the depth and narrowneſs of the orifice, and its height above the diaphragm, on which the congealed blood is ſuppoſed to lie, will make the ſucceſs at beſt very precarious.

To empty the thorax, in a rupture of any veſſels which open into it, bleeding is very neceſſary, which not only ſtops the hæmorrhage, by abating the force of the circulation; but likewiſe, by unloading the veſſels of their contents, makes them more fit to receive the extravaſated fluid by abſorption: gentle evacuations and pectorals are alſo very ſerviceable, and a low diet is abſolutely neceſſary.

The rules laid down in ſome books for diſtinguiſhing if a wound penetrates, have led practitioners into miſchievous methods, by adviſing them to examine theſe wounds with the probe, or, for more certainty, the finger; which if rudely uſed ſometimes even tear into the thorax, always force or preſs the parts too much, and often ſeparate the lungs from the pleura, when they happen to adhere; all which violences will produce abſceſſes there, eſpecially if the part be afterwards dreſſed with large tents, or filled with any active injection, both which were formerly applied with a view to deterge the cavity of the wound, but now ſeem to be exploded in favour of more ſuperficial dreſſings, the advantage of which method, in my opinion, cannot be too much inculcated.

But what I have here advanced concerning the excellence of ſuperficial applications, without dilating the wound, to make way for the iſſue of the blood or ſucceeding matter, muſt be conſidered with regard to punctures or inciſions by ſharp inſtruments, not followed with a great diſcharge: for, where the wound is made by fire arms, the method of practice muſt be ſometimes altered; becauſe not only ſloughs and great ſuppurations enſue, but very often pieces of the ſhirt or coat are carried in with the bullet, which will perhaps require an enlargement of the wound, in order to be freely diſcharged; though, even upon this account, there will be no occaſion to make an opening at the bottom of the thorax, ſince the mere dilatation of the wound will more readily give vent to the pus and extraneous bodies, than an orifice made lower; becauſe the lungs, being inflamed by the wound, will generally adhere to the pleura, and break off the communication between the abſceſs and the cavity below it. In dreſſing the dilated wound, care muſt be taken to apply the doſſils with ſuch preſſure only, as ſhall be ſufficient to keep open the external orifice; and not to croud them into the thorax, ſo as to lock up that matter, which the very deſign of dilatation is to give a diſcharge to.

The ſecond circumſtance in which this operation takes place, is a rupture of matter from the pleura, mediaſtinum, or lungs, into the cavity of the thorax, where accumulating it at length proves fatal for want of a diſcharge. It is true that the caſe occurs but very ſeldom, where the operation is neceſſary; becauſe, in moſt abſceſſes of the thorax, the matter is uſually ſpit up as faſt as it is generated, and in the diſſection of ſuch, who have died of this ſpecies of conſumption, we rarely find much extravaſated pus in the cavity, though a great portion of the lungs is deſtroyed: however, as I have intimated, there are a few examples which require the operation, and theſe may be diſtinguiſhed by the following ſymptoms. The patient is obliged to lie upon the diſeaſed ſide, or, in caſe there is matter in both cavities of the thorax, on his back; becauſe the mediaſtinum can ſeldom ſupport the weight of the incumbent fluid, without ſuffering great pain; but this rule is not certain, it ſometimes happening that the patient can lie with eaſe on that ſide, where there is no fluid. Another ſymptom of extravaſated matter, is an evident undulation of it, ſo that in certain motions it may be heard to quaſh. For the moſt part too, upon careful enquiry, an œdema, or at leaſt a thickening of ſome portion of the intercoſtal muſcles, will be diſcovered. And, laſtly, if there be much fluid, it will be attended with a preternatural expanſion of that ſide of the cheſt, where it lies. When therefore theſe ſigns appear after a previous pleuretic or pulmonary diſorder, and the caſe has been attended with the ſymptoms of a ſuppuration, it is moſt probably owing to a collection of matter; though the patient will alſo labour under a continual low fever, and a particular anxiety from the load of fluid.

I have here deſcribed the abſceſs as breaking into the cavity of the thorax; but, generally ſpeaking, in any inflammation of the pleura or lungs, an adheſion of both enſues; in conſequence of which, nature finds a diſcharge outwardly, it being moſt frequent for abſceſſes of the pleura and intercoſtal muſcles, and not uncommon even for abſceſſes of the lungs, to break externally. In caſe of an adheſion, no farther operation is required than opening the tumor, when ſuppurated, with a lancet; and, if the diſcharge is ſo great as to forbid the healing the external ulcer, it may be kept open with a hollow tent; by which manner of treatment many have lived a long time with a running fiſtula.

The laſt ſort of fluid, ſaid to require iſſue from this operation, is water, which however very ſeldom collects in ſuch manner as to become the proper ſubject of the operation; for, if the dropſy of the thorax is complicated with an anaſarca, or even aſcites, it is certainly improper; and indeed it can hardly ever take place, but where the diſtemper is ſingle, and takes its riſe from the ſame ſort of diſorder in the lymphatics of the pleura, as the hydrocele does from thoſe of the tunica vaginalis. The ſymptoms of this dropſy are, a ſmall cough without ſpitting, a little ſlow fever from the diſturbance of reſpiration; ſometimes too the water, by a ſudden jerk, may be heard to ſquaſh, and, generally ſpeaking, its weight upon the diaphragm and mediaſtinum are ſo troubleſome as to oblige the patient to ſtoop forward when in an erect poſture, and to turn upon the affected ſide when he lies down; for the ſame reaſon, when there is water in both cavities of the thorax, he is forced to lie on his back.

The manner of operating, whether it be for the diſcharge of matter or water, is to pitch upon the moſt depending part of the thorax, which ſome have ſuppoſed to be between the eighth and ninth rib, and others, between the ninth and tenth, at ſuch a diſtance from the vertebræ, that the depth of the fleſh may not be an impediment to the perforation: this diſtance is determined to be about a hand's-breadth; and here with a knife, ſciſſars, or trocar, we are ordered to make the perforation; but, in doing it, there are a great many difficulties: in fat perſons, it is not eaſy to count the ribs, and the wound will be very deep, and troubleſome to make; it is hardly poſſible to eſcape wounding the intercoſtal artery, which runs in this place between the ribs; or, if you avoid it, by cutting cloſe to one of the ribs, a caries of the bone will follow from the preſſure of the tent employed afterwards: again, the inflammation of the wound may poſſibly affect the diaphragm, which is ſuppoſed almoſt contiguous to it, and this may prove of very ill conſequence; ſo that upon the whole, without any farther recital of objections to the Empyema thus performed, it cannot appear an adviſeable operation. But if the only advantage, propoſed by this ſituation of the wound, is from its dependency; the purpoſe of diſcharging the fluid will be as well anſwered, by an opening between the ſixth and ſeventh rib, halfway from the ſternum towards the ſpine; which, by laying ourſelves down, becomes in effect as depending an orifice, as the other in ſitting up; and, by opening in this manner, we avoid all the inconveniences in the other method: for, in this part of the thorax, there is very little depth of muſcles; the artery lies concealed under the rib; and the diaphragm is at a great diſtance; ſo that none of thoſe miſchiefs can enſue I have ſuppoſed in the other method; which conſequently will give it the preference. The opening is beſt made with a knife, and ſhould be about an inch long through the ſkin, and half an inch through the ſubjacent muſcles: though, to make the inciſion with leſs riſk of wounding the lungs, it may be adviſeable to dilate it with the blunt-pointed knife after having made a ſmall puncture with a common knife. If it ſhould be objected, that the fluid cannot be diſcharged by this orifice, while we are erect, whereas, by making it in the lower part of the thorax, it will be continually draining; I think it may be anſwered, that, after it is once emptied, it will hardly in twelve hours be generated in greater quantity than what will lie upon the diaphragm below the opening made even by that operation, and conſequently cannot be more readily diſcharged by one orifice, than the other. The treatment of the wound will be according to the nature of the diſcharge; if, after a few days, there appears no drain, you may let the orifice heal up; but, if it continues, it may be kept open with a ſhort ſilver cannula, till ſuch times as an alteration, in that circumſtance, will give us leave to cicatrize with ſafety. *Sharp's Surgery.*

ENA'MEL (*Dict.*) — The workers in Enamel muſt be very cautious of the good or bad qualities of the oil of ſpike they employ to mix their colours with. It is a thing very ſubject to adulterations.

adulterations. Sometimes with ſpirit of wine; ſometimes with oil of turpentine. In the firſt caſe it wants body, as there is uſually too much ſpirit added; and, in the latter, the ſmoak of the turpentine, when heated, ſpoils the colours. A ſmall mixture of ſpirit of wine does well; and the beſt method, for the nice artificer, is to refine the oil, and afterwards add to it ſuch a quantity of ſpirit as is found beſt.

The common matter, which is the baſis of all Enamels, is thus made: take fine lead, thirty pounds; fine tin, thirty-three pounds; calcine theſe together in a kiln, then ſift them; boil this powder in water, in clean earthen veſſels, and pour off the water, which will carry with it the finer part of the calx; put freſh water on the remainder, boil it again, and pour off in the ſame manner; do this ſo long as the water will carry off with it any part of the calx. Recalcine the remaining matter, and waſh off its finer part in the ſame manner again; then evaporate all the waters, which have waſhed off the finer calx, and keep the fire low, towards the end of the operation, that the calx may not be waſted; this will be found, at the bottom, of an extreme fineneſs.

Take of cryſtal frit, made with tarſo, and this fine calx, each fifty pounds; white ſalt of tartar, eight ounces; powder and ſift theſe, and mix them well. Put this mixture into a new earthen pot, give it a fire for ten hours, then powder it, and keep it in a dry covered place. *Neri's Art of Glaſs.*

Azure ENAMEL. To make this, take of the common matter of Enamels, four pounds; zaffer prepared, two ounces; braſs thrice calcined, forty-eight grains. Mix all theſe well together, and melt them in the furnace in the uſual way. *Neri's Art of Glaſs.*

Black ENAMEL. To make the black Enamel, take of the common matter of Enamels, four pounds; tartar, four ounces; mangane e, two ounces. Grind and mix theſe powders well with the matter of the Enamel, then ſet them in a furnace in a large pot; when melted and refined, caſt them into water, and, putting them again into the furnace, let them refine. *Neri's Art of Glaſs.*

Green ENAMEL. To make this, take of the common matter of Enamels, four pounds; melt it, and caſt it into water, return it again to the furnace, and, when purified, add of braſs, thrice calcined, two ounces, crocus martis, made with vinegar, forty-eight grains. Mix theſe firſt in fine powder, and put this in at three ſeveral times; when all is well incorporated, take it from the fire. *Neri's Art of Glaſs.*

Milk-white ENAMEL. To make this uſeful colour in Enamels requires no more than this: take the common matter of Enamels, ſix pounds; mangane e prepared, forty-eight grains; melt them in the furnace, caſt the whole into water, and afterwards return it again into the furnace, and, when refined, uſe it. *Neri's Art of Glaſs.*

Purple ENAMEL. To make this, take of the common matter of Enamels, ſix pounds; of manganeſe, three ounces; braſs, thrice calcined, ſix ounces; mix all well together, and ſet them in a furnace, let them refine, then caſt them into water, return the matter to the furnace again, and, when thoroughly melted, take it out for uſe. *Neri's Art of Glaſs.*

This mixture, with a ſmaller proportion of braſs, makes the red Enamel.

Violet-coloured Enamel. The method of making the violet-coloured Enamel is this: take of the common matter of Enamels, ſix pounds; of manganeſe prepared, three ounces; of thrice calcined braſs, forty-eight grains; mix the two powders well together, then mix the whole, put them into the furnace, and, when refined, caſt them into water, return the matter again to the furnace, and, when refined, take it out. *Neri's Art of Glaſs.*

Yellow ENAMEL. To make this, take of the common matter of Enamels, ſix pounds; of tartar, three ounces; of manganeſe, ſeventy-two grains; mix all well together, and put them into the furnace, in a large pot; when refined, caſt them into water, then return them to the furnace again, and, when melted, take it out for uſe. *Neri's Art of Glaſs.*

ENCAU'STUM *Sacrum*, a name given, by many authors, to that fine red colour, uſed for illuminating the capital letters in ſome old manuſcripts. The Latin writers have got a way of calling all thoſe liquid paints, which may be uſed by means of a pen, by the general name of atramenta, and we call them inks. Thus the tincture of logwood, or brazil-wood, is called red ink; the tincture of fuſtic, brown ink; and the ſolution of gamboge, yellow ink. The Greeks expreſſed ink by the word melan, which ſignifies only black; and the atramentum of the Latins is as plainly derived from atrum, ſignifying alſo black. The Greeks kept ſtrictly to this ſenſe of the word, and acknowledged only two kinds of ink, the graphicon, and the burſodepſicum; the firſt uſed in writing, and the other in dreſſing of leather. Some ſuppoſe that they mentioned a third kind, under the name of melan Indicon, which many have been idle enough to imagine the ſame that we call by the name of Indian ink; but they have uſed the word melan not as the ſubſtantive, or the name of ink, but as an adjective, expreſſing deep blue, as Theophraſtus uſes it, ſpeaking of the deep blue of the fine ſapphire, and others of the violet. This red colour, uſed in the illuminations, was never called ink by the Greeks. Procopius calls it baphe, ſome have called it coccus, and ſome cinnabar. It is ſaid that it was made of the purple colour, extracted from the murex, or purple fiſh, with ſome other additions. It is to be obſerved, that however well this colour, when laid on the parchment, or paper, might reſemble the colours of enamel, yet, it was as improper to call it Encauſtum, which ſignifies a colour burnt in, as in enamelling, as it would have been to have called it atramentum, or ink.

ENCU'RECK, in natural hiſtory, a venomous inſect, found in Perſia, and ſuppoſed, by ſome, to be a kind of tarantula. It neither ſtings nor bites, but lets fall its venom like a drop of water, which cauſes inſufferable pain in the part for a time, and afterwards ſo profound a ſleep, that, we are told, nothing can raiſe the patient from it, but cruſhing one of thoſe creatures on the part affected. It is nevertheleſs ſaid, that the ſheep eat theſe inſects without damage. *Olearius.*

ENDI'VIA *marina*, ſea endive, in natural hiſtory, the name of a ſpecies of ſea plant, deſcribed by count Marſigli: there are two ſpecies of it, the one having broad and jagged leaves, reſembling thoſe of the vine, the other much narrower. This laſt kind grows on ſtones, ſhells, pieces of wood, or any other ſubſtances, accidentally found at the bottom of the ſea. It ſeldom grows in very deep water, and thrives beſt in places where the ſea is calm and quiet. It is of a duſky greeniſh colour, variegated in ſome places with yellow. It exactly reſembles the ſhape of the endive common in our gardens, and its leaves are cut and fringed in the ſame manner; but they are of ſo tender a ſubſtance, that a ſlight touch deſtroys them; they are indeed tender and more delicate than any other known plant, either of the ſea or land. When this plant is examined by the microſcope, its ſurface is found to be compoſed of a great number of eminencies, and cavities, or little holes, between and among them; and, when the leaves are cut tranſverſely, there are ſeen a great number of glandules in them. *Marſigli, Hiſt. de la Mer.*

E'NGINE (*Dict.*)—The following Engine for raiſing water by fire is an improvement of Savary's conſtruction (given under this article in the Dictionary) to render it capable of working itſelf, invented by Mr. De Moura of Portugal, F. R. S.

This Engine conſiſts of a receiver, a ſteam, and an injection-cock; a ſuction and a forcing-pipe, each furniſhed with a valve; together with a boiler, which, on account of its bulk and weight, was not ſent with the reſt; but, as it may be of the common globular ſhape, and having nothing particular in its conſtruction, a deſcription of it will not be neceſſary, as alſo, the reſt of theſe parts already mentioned being eſſential to every machine of this kind, a further account of them may be diſpenſed with. What is peculiar to this Engine, is a float within the receiver, compoſed of a light ball of copper, which is not looſe therein, but faſtened to the end of an arm, which is made to riſe and fall by the float, while the other end of the arm is faſtened to an axis; and, conſequently, as the float moves up and down, the axis is turned round one way, or the other. This axis is made conical, and paſſes through a conical ſocket; which laſt is ſoldered to the ſide of the receiver. Upon one of the ends of the axis, which projects beyond the ſocket, is fitted a ſecond arm, which is alſo moved backward and forward by the axis, as the float riſes and falls. By theſe means, the riſing and falling of the ſurface of the water within the receiver communicates a correſpondent motion to the outſide, in order to give proper motions to the reſt of the geer, which regulates the opening and ſhutting of the ſteam and injection-cocks; and ſerves the ſame purpoſe as the plug-frame, &c. in Newcomen's Engine. The particular conſtruction, and relation of thoſe pieces, will better appear by the figure and references, than can be done by a general deſcription.

A B, *plate* XVII. *fig.* 11. an arm, which is faſtened to *a b*, a conical axis, which goes through a conical ſocket in C, a triangular piece ſoldered to the receiver. This piece has this ſhape to give liberty to the arm to riſe and fall, that carries the float on the inſide. D E, is a ſmall ciſtern, ſoldered to the receiver, which, being kept full of water, keeps the axis and ſocket air-tight. This ciſtern is conſtantly kept full of water, by means of a ſmall leakage through the wooden peg *c*, which follows the pack-thread *c d* to the ciſtern.

e, Is a ſmall weight to counterpoiſe the float within.

f, Is a ſlider; which, being ſet nearer to, or farther from, the axis, will riſe, or fall, a greater or leſſer ſpace, as may be required; and is faſtened by the ſcrew *g*. This ſlider is furniſhed with a turn-about, *h i*, which is alſo faſtened by a ſcrew and nut at the end *i*, and ſerves to adjuſt the length of F G G H, a chain, which gives motion, by means of the ſhorter chain *k l*, to I K L, the balance, which opens and ſhuts the cocks; and moves upon the ſmall axis L.

G G, are two pullies ſupported by two arms, that are faſtened to the ſide of the receiver, and give the chain a proper direction in order to move the balance.

M N, is the ſteam-cock; the end N being ſuppoſed to be detached from a pipe that gives it communication with the boiler.

O, is the injection-cock, whoſe key is turned by the arm O *m*.

P Q, is the injection-pipe, communicating between the forcing-pipe above the valve, and the top of the receiver.

R S, is the arm, by which the key of the steam-cock is worked.

I K, two rollers annexed to the balance, which, by striking upon the arm R S, open and shut the steam-cock, as the balance is moved backward and forward.

R *n o*, is the steam-cock's key-tail, which is furnished with two small rollers, *n o*, which open and shut the injection-cock, by acting upon the arm O *m*, in such a manner, that, when the steam-cock is opened, the injection is shut, and vice versa.

T, is a bell of advice, which, moving along with the balance, continues to ring as long as the Engine is at work.

V, is a cock, which serves to discharge the air from the receiver, and is opened by hand, when necessary.

W, is a weight sufficient to raise the balance to a perpendicular posture, when it is inclined to the right, and also, to overcome the friction of the float, axis, pullies, chain, &c.

To put the Engine in motion, press down the arm A B, which will bring the balance over to the right side, and in its motion will open the steam-cock, and shut the injection; set open the cock at V, that the air may be discharged by the entrance of the steam into the receiver. This being done, shut that cock, and let go the arm; the weight W will bring over the balance to the left, and in its motion shut the steam-cock, and open the injection; this, presently condensing the steam into water, in a great measure, leaves a vacuum in the receiver. Things remain in this situation, till the pressure of the atmosphere has caused the water to mount through the suction-pipe into the receiver, where, as its surface rises, it causes the float to ascend; and, depressing the arm A B, raises the balance till it has passed the perpendicular; and, in its descent, which is done by its own gravity, the roller K lays hold of the arm R S, again opens the steam-cock, and shuts the injection. The receiver being now almost filled with water, the balance cannot return, till the surface of the water therein subsides, and suffers the float to descend. This is performed by the elasticity of the steam, which, at the same time that it fills the receiver, drives out the water through the forcing-pipe; and, when the surface is descended so low, as to suffer the weight W to bring the balance beyond the perpendicular towards the left, it then falls of its own accord, and, in falling, the roller I lays hold of the arm R S, shuts the steam-cock, and opens the injection, as before.

When the Engine is desired to be stopped, observe, when the balance lies to the right, to turn round the arm O *m* of the injection-cock, so that the tail of the steam-cock may miss it in the next motion; so that, at the same time that the receiver is filled with steam, and the steam-cock shut, the injection not being opened, the motion will stop for want thereof. *Phil. Trans.* Vol. XLVII.

ENGLISH *Tongue* (*Dict.*) — Mr. Welstead is of opinion, that the English language is not capable of a much greater perfection, than it has already attained; we have trafficked, he observes, with every country for the enriching it: the ancients and moderns have both contributed to the giving it splendor and magnificence; the fairest cyons that could be had from the gardens of France and Italy, have been grafted on our old stocks, to refine the savageness of the breed; we have laid aside most of our harsh, antique words, and retained few but those of good sound and energy: the most beautiful polish is at length given our tongue that it will bear, without destroying and altering the very basis and ground-work of it: its Teutonic rust is worn away, and little or nothing is wanting, either of copiousness, or harmony. He goes on to argue the maturity and perfection of the English from another very extensive principle, viz. by comparing the time and circumstances of the improvements, made since the first refiners of it, with those of the Greek, Latin, French, and other tongues, that confessedly have risen to their height.

Every civilized nation, that author thinks, has its classical age; and he suggests, that the English are not far from it. So that what remains to be done for the English tongue, should not be to advance, but to fix it where it is, and prevent its declining. There is in effect a point of perfection, which when a language has once arrived at, it cannot exceed, though it may degenerate from it; and thus it happened to the two finest languages the world has known.

It may seem odd to talk of fixing so unstable a thing as language: the Greek liturgies of St. Basil and St. Chrysostom, still used in that church, the one for solemn, the other for common days, have been a long time unintelligible to the people: so much is the vulgar Greek degenerated from its original purity! Polybius testifies, that the articles of truce between the Romans and Carthaginians could scarce be understood by the most learned Roman antiquaries, 350 years after the time of their making. In effect, from the days of Romulus, to those of Julius Cæsar, the Latin was perpetually changing; and what was wrote three hundred years before Tully, was as unintelligible in his time, as the English and French of the same period are now: and these two have changed as much since William the Conqueror, in about 700 years, as the Latin appears to have done in the like term.

Whether our language will decline as fast as the Roman did, may admit of some doubt; there being many circumstances in the affairs of the nation, which contributed to that corruption, that may not, in all probability, find place among us. — The French, for these fifty years past, has been polishing as much as it will bear; and appears to be now declining, by the natural inconstancy of that people, and the affectation of some late authors to introduce cant words, which is the most ruinous corruption in any language. But, without some such consideration, there does not seem any absolute necessity, why a language should be perpetually changing.

We find examples to the contrary: from Homer to Plutarch, are above a thousand years; and so long, at least, Dr. Swift thinks, we may allow the purity of the Greek: the Grecians spread their colonies round all the coasts and islands of Asia minor and the Ægean sea, where the language was preserved entire for many ages after they themselves became provinces to Rome, and were over-run by the barbarous nations. The Chinese have books in their language above 2000 years old; neither have the frequent conquests of the Tartars been able to alter it. And the German, Spanish, and Italian, have admitted few or no changes for some ages past.

On such considerations, that author moved the then prime minister, the earl of Oxford, to establish a society, or academy, for the settling, and ascertaining, the purity of our tongue; to set a mark on the improprieties which custom has made familiar, to throw out vicious phrases and words, to correct others, and perhaps retrieve some others now grown obsolete, and to adjust the orthography, pointing, &c.

Without some such means, he complains, that the fame any writer can expect will be so short and scanty, as by no means to be a sufficient motive to call forth and engage a man to exert his genius. Our language is chiefly confined to these two islands; and it is hard our authors fame should be limited in time as well as place. Were it not for the bible and common-prayer, we should hardly have been able to understand any thing written a hundred years ago.

It is a melancholy reflection, that Petrarch still speaks good Italian; whereas Chaucer, who lived a hundred years later, is not to be understood without a Saxon and French glossary. And what security has Pope himself, while things continue on their present footing, that he shall not in a like space of time become as obsolete as Chaucer is?

Grammars and dictionaries, with whatever care and judgment they are composed, will prove but a feeble stay to a fleeting language, unless they have some extraordinary sanction and authority. And, what is to be lamented, such writings have contributed to the corruption almost as much as the perfection of our tongue.

ENGRA'VING *on precious stones*, is the representing of figures, or devices, in relievo or indented, on divers kinds of hard polished stones.

The art of Engraving on precious stones is one of those wherein the ancients excelled; there being divers antique agats, cornelians, and onyx's, which surpass any thing of that kind the moderns have produced. Pyrgoteles among the Greeks, and Dioscorides under the first emperors of Rome, are the most eminent Engravers we read of: the former was so esteemed by Alexander, that he forbad any body else to engrave his head: and Augustus's head, engraven by the latter, was found so beautiful, that the succeeding emperors chose it for their seal.

All the polite arts having been buried under the ruins of the Roman empire, the art of Engraving on stones met the same fate. It was retrieved in Italy, at the beginning of the fifteenth century; when one John of Florence, and after him Dominic of Milan, performed works of this kind no way to be despised. From that time, such sculptures became common enough in Europe, and particularly in Germany, whence great numbers were sent into other countries; but they came short of the beauty of those of the ancients; especially those on precious stones; for, as to those on crystal, the Germans, and, after their example, the French, &c. have succeeded well enough.

In this branch of Engraving, they make use either of the diamond, or emery. — The diamond, which is the hardest, and most perfect of all precious stones, is only cut by itself, or with its own matter.

The first thing is to cement two rough diamonds to the ends of two sticks, big enough to hold them steady by, in the hands; and to rub or grind them against each other, till they be brought to the figure desired. The dust, or powder, rubbed off, serves afterwards to polish them; which is performed with a kind of mill, that turns a wheel of soft iron.

The diamond is fixed in a brass dish, and thus applied to the wheel, which is covered with diamond dust, mixed up with oil of olives: and, when the diamond is to be cut facet-wise, they apply first one face, then another, to the wheel.

Rubies, sapphires, and topazes, are cut and formed the same way, on a copper wheel; and polished with tripoli, diluted in water.

As to rubies, emeralds, hyacinths, amethysts, garnets, agats, and other of the softer stones, they are cut on a leaden wheel, moistened with emery and water; and polished with tripoli, on a pewter-wheel. Lapis, opal, &c. are polished on a wooden wheel.

To fashion and engrave vases of agat, crystal, lapis, or the like,

like, they have a kind of lathe, like that of the pewterers; excepting, that whereas the latter is to hold the veſſels, which are to be wrought with proper tools; the former generally holds the tools, which are turned by a wheel, and the veſſel held to them to be cut and engraved, either in relievo, or otherwiſe; remembering, from time to time, to moiſten the tools with diamond duſt and oil; or, at leaſt, emery and water.

To engrave figures or devices on any of theſe ſtones, when poliſhed, ſuch as medals, or ſeals, &c. they uſe a little iron wheel, the two ends of whoſe axes are received within two pieces of iron placed upright, as in the turner's lathe, to be brought cloſer, or ſet further apart, at pleaſure. At one end of one of the axes, are fitted the proper tools, being kept tight by a ſcrew. Laſtly, the wheel is turned by the foot; and the ſtone applied by the hand to the tool; and thus ſhifted and conducted, as occaſion requires.

The tools are generally of iron, ſometimes of braſs. As to their form it is various, but generally bears ſome reſemblance to chiſſels, gouges, &c. ſome have ſmall round heads like buttons, others, like ferrels, to take the pieces out; others flat, &c. Theſe tools are not applied directly againſt the ſtone, but, as it were, ſidewiſe; thus wearing, and as it were, grinding off the ſubſtance. And ſtill, whether it be figures, or letters, or characters, the manner of application is the ſame. The tools, as above obſerved, are to be frequently moiſtened with diamond duſt, and oil of olives. When the ſtone is engraven, they poliſh it on a wheel of bruſhes, made of hogs briſtles, with tripoli. For the larger and leſs delicate works, they have copper, or pewter tools, on purpoſe to poliſh the ground, or plain parts, with tripoli, &c. which they apply after the ſame manner, as thoſe wherewith the graving is performed.

ENGRAVING *on ſteel*, is chiefly employed in cutting punches, matrices, and dies, proper for ſtriking coins, medals, and counters. See the article COINING in the Dictionary.

The methods of Engraving, with the inſtruments, &c. are the ſame for coins, as for medals and counters: all the difference conſiſts in their greater or leſs relievo; the relievo of coins being much leſs conſiderable than that of medals; and that of counters ſtill leſs than that of coins.

The engraver in ſteel uſually begins with punches, or punchions, which are in relievo, and ſerve for making the creux, or cavities of the matrices, and dies. Though, ſometimes, he begins immediately with the creux; but it is only when the intended work is to be cut very ſhallow. The firſt thing is to deſign his figures; then he moulds them in white wax, of the ſize and depth required; and from this wax he graves his punch.

This punch is a piece of ſteel, or at leaſt of iron and ſteel mixed; on which, before they temper or harden it, the intended figure, whether a head, or a reverſe, is cut, or carved in relievo. The inſtruments uſed in this graving in relievo, which are much the ſame as thoſe wherewith the finiſhing of the work in creux is effected, are of ſteel. The principal are gravers of divers kinds, chiſſels, flatters, &c. when the punch is finiſhed, they give it a very high temper, that it may the better bear the blows of the hammer, wherewith it is ſtruck, to give the impreſſion to the matrice.

What they call matrice, or matrix, is a piece of good ſteel of a cubic form, called alſo a die; whereon the relievo of the punch is ſtruck in creux. It is called matrix, becauſe, in the cavities or indentures thereof, the coins, or medals, ſeem formed, or generated, as animals are in the matrix of their mother.

To ſoften this ſteel, that it may more eaſily take the impreſſions of the punch, they make it red-hot; and, after ſtriking the punch thereon in this ſtate, they proceed to touch up or finiſh the ſtrokes and lines, where, by reaſon of their fineneſs, or the too great relievo, they are any thing defective, with ſome of the tools abovementioned.

The figure thus finiſhed, they proceed to engrave the reſt of the medal, as the mouldings of the border, the engrailed ring, letters, &c. All which, particularly the letters, and graining, or engrailment, are performed with little ſteel punches, well tempered, and very ſharp. Add, that as they ſometimes make uſe of punchions, to engrave the creux of the matrix; ſo, on ſome occaſions, they make uſe of the creux of the matrix, to engrave the relievo of the punch.

To ſee and judge of the Engraving in creux, divers means have been deviſed to take the impreſſions therefrom, as the work proceeds. Sometimes they make uſe of a compoſition of common wax, turpentine, and lamp black; which, always retaining its ſoftneſs, eaſily takes the impreſſion of the part of the graving it is applied to. But, this only ſerving to ſhew the work piece-meal, they have had recourſe to other ways, to ſhew the whole figure. The firſt, by pouring melted lead on a piece of paper, and clapping the matrice thereon: the ſecond, with melted ſulphur, managed the ſame way: and the third, proper only where the graving is ſhallow, by laying a piece of ſoft paper on the graving, and over the paper a leaf of lead; when, giving two or three blows with a hammer on the lead, the paper takes the impreſſion of the work.

When the matrix is quite finiſhed, they temper it, rub it well with pumice-ſtone, and clean out the ſtone again with a hair-bruſh; and, laſtly, poliſh it with oil and emery. In this condition it is fit for the mill, to be uſed to ſtrike coins and medals.

ENNEAHÆ'DRIA *, in natural hiſtory, the name of a genus of ſpars.

* The word is derived from the Greek ἐννέα, nine, and ἕδρα, a ſide.

The bodies of this genus are ſpars, compoſed of nine planes, in a triagonal column, terminated at each end by a triagonal pyramid.

ENNEA'NDRIA *, in botany, a claſs of plants, with hermaphrodite flowers, and nine ſtamina, or male parts, in each.

* The word is derived from the Greek ἐννέα, nine, and ἀνήρ, male.

The plants of this claſs are the bay-tree, rhubarb, &c.

ENNE'RIS, in the ancient ſhip-building, a name given to thoſe gallies, or veſſels, which hold nine tiers of rowers.

ENRI'CHING *Plants*, a term uſed, by the Engliſh farmers, to expreſs ſuch plants as are found to do good to land, rather than to exhauſt it, and in conſequence of which the ſame piece of land will produce a good crop of corn, though it would, without the aſſiſtance of their having been planted on it, have yielded a very poor one. The myſtery of this difference between plants, ſome of which are found to burn up, that is, impoveriſh land, while others enrich it, and leave it fitter for ſucceeding crops than they found it, had been long a perplexing thing to account for. Though it was eaſy to conceive that ſome plants mighty exhauſt the earth more, and others leſs, yet, it was hard to conceive, while all exhauſted it in ſome degree, how any could leave it better than they found it; but this was at length explained by Mr. Tull. This author, having obſerved, that breaking the earth, by digging, or horſe-hoeing, between the plants, gave them great increaſe, found that it was this practice that enriched the earth, and that, while corn and ſuch plants as ſtand cloſe, and cannot be hoed between, impoveriſh the ground, and ſuffer no means of enriching it again to be uſed, there were ſome other things, the crops of which, being planted thinner, gave room to the earth to be plowed, dug, or hoed between, and that theſe were the plants which were called the Enriching kind, by the farmers; and the whole ſecret lay in this, that the hoeing, plowing, or otherways breaking the earth between them, in order to kill the weeds, enriched the ground greatly more, in proportion, than theſe plants exhauſted it; and the conſequence was, that, though they had thriven very well, yet, the earth was left richer than before, notwithſtanding all that they had imbibed from it. See his *Horſe-hoeing Huſbandry*. On this obſervation, this excellent author ſeems to have founded the ſyſtem of what he calls horſe-hoeing huſbandry, concerning which he has written a large and uſeful treatiſe. He found that this ſtirring up of the earth enriched it ſo greatly, that, where it was uſed in a proper manner, the kind of plant need not be changed, but that the ſame earth would yield a ſucceſſive ſeries of crops of the ſame plant, and that even without dunging, or ever lying fallow, and every crop for a long time would be better than the former ones. The method of ſowing, to this purpoſe, is not by ſcattering the corn with the hand, but ſowing it in rows, and leaving large intervals between, the naked earth of which might be turned up by the hoe. *Tull's Horſe-hoeing Huſbandry.*

ENTA'LIUM, *the pipe-ſhell*, in the materia medica, a ſhell of the ſame genus with the dentalia, being a ſpecies of the tubuli marini. It is frequent in the Eaſt-Indies, and ſometimes is found on our own ſhores. The virtues aſcribed to it are the ſame with thoſe of the dentalium; but neither of them have any title to more than thoſe of alkaline abſorbents, like the other teſtaceous powders.

The modern Italians call all ſtones, metals, woods, cut in with lines or figures, or barely channelled, entaglia; from whence, and from the nearneſs of the word dentalium, the learned and ingenious Dr. Liſter conjectures the name Entalium to have its original. *Dale.*

ENTHU'SIASM (*Dict.*) — Mr. De Piles is of opinion that Enthuſiaſm contains the ſublime, as the trunk of a plant does the branches.

This is the Enthuſiaſm felt in poetry, oratory, muſic, painting, ſculpture, &c. But this Enthuſiaſm which belongs to the works of art, is very different from that attributed to the ſibyls and prieſteſſes of the oracles, and heathen gods; which was little elſe but fanaticiſm, and conſiſted principally in grimace, and contortions of the body.

There is a degree of aſſent, ſays Mr. Locke, which, with ſome men, has the ſame authority, as either faith or reaſon; and that is Enthuſiaſm; which, laying by reaſon, would ſet up revelation without it; whereby, in effect, it takes away both reaſon and revelation, and ſubſtitutes, in the room of it, the ungrounded fancies of a man's own brain, and aſſumes them for a foundation both of opinion and conduct.

Immediate revelation being a much eaſier way for men to eſtabliſh their opinions, and regulate their conduct by, than the tedious labour of ſtrict reaſoning; it is no wonder, that ſome have been very apt to pretend to it, eſpecially in ſuch of their opinions and actions as they cannot account for by the ordinary methods of knowledge, and principles of reaſon.

Hence we ſee, that, in all ages, men, in whom melancholy has mixed with devotion; or whoſe conceit of themſelves has raiſed them into an opinion of greater familiarity with God,

 than

than is allowed others; have often flattered themselves with the persuasion of an immediate intercourse with the Deity, and frequent communications from the divine spirit.

Their minds being thus prepared, whatever groundless opinion comes to settle itself strongly upon their fancies, is an illumination from the spirit of God; and, whatsoever odd action they find in themselves an inclination to do, that impulse is concluded to be a call, or direction, from heaven, and must be obeyed. This we take to be properly Enthusiasm, which, though rising from the conceit of a warm or overweening brain, works, where it once gets footing, more powerfully on the persuasions and actions of men, than either reason, or revelation, or both together; men being most forwardly obedient to the impulses they receive from themselves.

When men are once got into this way of immediate revelation, of illumination without search, and certainty without proof, reason is lost upon them; they are above it: they see the light infused into their understandings, and they cannot be mistaken; like the light of bright sun-shine, it shews itself, and needs no other proof but its own evidence: they feel the hand of God moving them within, and the impulses of the spirit, and cannot be mistaken in what they feel.—But, of this seeing and feeling, is it a perception of an inclination to do something, or of the spirit of God moving that inclination? These are two very different perceptions, and should be carefully distinguished.

If they know the thing to be a truth, they must do it, either by its own self-evidence, or by the rational proofs that make it out to be so: if they know it to be a truth, either of these two ways, they in vain suppose it to be a revelation: for thus all truths, of what kind soever, that men uninspired are enlightened with, come into their minds. If they say, they know it to be true, because it is a revelation from God, the reason is good; but then it will be demanded, how they know it to be a revelation from God? If they say, by the light it brings with it; they should consider, whether this be saying any more, than that it is a revelation, because they believe it to be true; for all the light they speak of, is but a strong persuasion of their own minds, that it is a truth; which is a very unsafe ground to proceed on, either in our tenets or actions. True light in the mind is nothing else but the evidence of the truth of any proposition: and, if it be not self-evident, all the light it can have, is from the clearness of those proofs upon which it is received.

God, when he makes the prophet, doth not unmake the man: he leaves his faculties in their natural state, to enable him to judge of his inspirations, whether they be of divine original, or no. If he would have us assent to the truth of any proposition, he either evidences that truth by the usual methods of natural reason, or else makes it known to be a truth which he would have us assent to by his authority; and convinces us, that it is from him, by some marks, which reason cannot be mistaken in. The holy men of old, who had revelations from God, had something else besides internal light of assurance in their own minds, to testify to them, that it was from God. They had outward signs to convince them, of the author of those revelations. And, when they were to convince others, they had a power given them to justify the truth of their commission from heaven; and by visible signs to assert the divine authority of the message they were sent with. Moses saw the bush burn without being consumed, and heard a voice out of it. God, by another miracle, of his rod turned into a serpent, assured him likewise of a power to testify his mission, by the same miracle repeated before them to whom he was sent.

ENTRO'CHUS, in natural history, the name of a genus of fossils, of a very regular figure and structure, supposed, by many authors, to be lapides sui generis, and stones in their native state. They are, however, in reality, the fossil remains of some marine animal, probably either of the echinus, or of the star fish kind, filled, like the fossil species of the echini, with a plated spar. Our imperfect knowledge in the animal history has not yet been able to ascertain to what creature they really belong; but their analogy with the other animal remains, found in the fossil world, plainly evince, that they are of that origin. They are cylindric columns, usually about an inch in length, and are made up of a number of round joints, like so many small wheels, or segments of cylinders. These joints, when found separate, and naturally loose, as they sometimes are, are called trochitæ. They are all striated, from the center to the circumference, and have a cavity in their middle, which is sometimes found empty, but more frequently filled up with various matter, of the nature of the stratum, in which they have lain, or of other of the native fossil substances.

Some of the Yorkshire Entrochi are swelled or tumid in the middle, and go off tapering to each end, and some others resemble the lapides Judaici. These, however, are true Entrochi: They are jointed in the same manner with the rest, and consist of a small stalk, or pedicle, formed of three or four joints, and on this an oval body is placed, broken off at both ends. Some of these have also been the natural summits or fastigia of the bodies, for they have a little jointed button on the top, hollow, and not seeming to have been divided, or broken off from any thing else. *Phil. Transf.* N°. 100.

The hollows of the Entrochi are usually filled up with earthy or stony matter, but sometimes with another smaller Entrochus, so that they resemble a pair of screws, one nicely fitted into the other, and the one making a sort of pith to the other, and having gone regularly through its whole length.

ENTROCHO-*asteriæ*, in natural history, the name given by authors to a peculiar kind of Entrochus, differing from the common kind, in having a stellar cavity, instead of a round one, in its center.

ENTROCHUS *pyramidalis*, a name given, by some of the writers of natural history, to the ortho-ceratites, or tubulus marinus concameratus, a species of shell-fish, not known to us in its recent state, but very common in the stones brought over from Sweden for pavements.

ENTROCHUS *ramosus*, in natural history, the name of a fossil body, the several parts of which resemble the Entrochi; but, as they are joined together in this body, when perfect, they shew themselves in their proper light, and a sight of them, in this state, is sufficient to explode the opinion, advanced by some persons, of the Entrochi being of a vegetable nature, or, as they have pleased to call them, rock plants.

E'PERON, in natural history, *the spur-shell*, so called from its resembling, in some degree, the rowel of a spur. It is a species of snail, of the round mouthed kind, or class of the cochleæ lunares; all its volutæ are surrounded with double rows of prickles.

EPE'RVIERS, in natural history, a name given, by the French authors, to a class of butterflies, which make the sixth in Reaumur's method.

EPHE'DRA, *sea-grape*, in botany, a genus of plants whose characters are:

The root is perennial: the plant has the appearance of a shrub; and the stalks, branches, and leaves, resemble those of horsetail. The flower is male; has no petals, but consists of testiculated stamina, growing on a thin substance, the congestion of which furnishes the floscule with a sort of calyx: these are the flowers which grow on the male or hermaphrodite plant. The fruit, which either grows on another part of the same plant, or on another plant which bears no flowers, is a red juicy berry; consists of a pair of squamous or scaly substances, laid across, upon a pair of others like them, and upon that a third, and over this a fourth pair, in like order as the first and second, the series gradually increasing from the least and lowest scales to the uppermost and greatest, which in a bifid cleft, a little gaping, contains two smooth oval seeds, gibbous on the back part, and flat on the other, and covered with a coriaceous membrane. *Boerhaave.*

EPHE'MERA (*Dict.*)— This fever is, properly, an attempt of nature to ease herself of a load of a plethora, either by an absolute discharge of part of the blood by an hæmorrhage, or, by resolving it into serum, and expelling it in that form, the secretory and excretory motions, being increased beyond their natural degree. The diary fever, properly so called, lasts only twenty-four hours; but this differs in nothing, except the time of its duration, from the ephemeron plurium dierum, which commonly lasts four days. To this it is to be added, that some authors have called the sudor Anglicus Ephemera maligna, diary fever, as it generally destroyed the patient in the space of one day.

The simple diary fever usually seizes the patient without any preceding shivering, and immediately is attended with a degree of heat of the flesh, which continues the same without intermission or exacerbation, till the close. This is usually not very violent, and is always attended with pains in the head, sometimes heavy and dull, sometimes pulsative and very acute. Such persons as fall into this fever, from drinking large draughts of cold liquors while they are hot, as is very frequently the case, always have a pain in the right hypochondrium. The face is red, and inflated in this disease, and there is a lassitude and weariness in all the limbs; the pulse is strong and quick, the urine is of a deep orange colour, and deposits a reddish sediment.

Method of treatment. When the peculiar disposition of the blood, and other accidents, render this fever worse than it naturally would be, the proper course is to attemperate the violent emotions of the blood with nitrous, and the fixed antimonial medicines, and occasionally, with the gentle acids, such as lemon juice, and the like: And indeed, in all cases of this kind, the frequent use of warm and weak liquors, with lemon juice among them, is highly to be commended. The free eruption of the sweat, by which nature attempts to ease herself of the disease, is to be promoted by the gentle sudorifics; nitre, crab's eyes, and a small quantity of the juice of lemons, just enough to saturate the alkali of the crab's eyes, prove an excellent medicine, to be repeated in small doses every three or four hours; and, towards night, the sudorifics should be joined to these, such as the contrayerva root, or the like. And when it is over, there should be given a few doses of some gentle purge, as an infusion of rhubarb and sena, or the like. Bleeding is unnecessary in this fever. *Juncker's Consp. Med.*

EPHE'MERON (*Dict.*)—This insect is found about the mouths of the Rhine, and some other rivers in Germany, and seems a sort of middle species between the May fly, common with us, and bred from the cadew worm, and the libella, or dragon fly. It has four wings, two long, and two short; two short horns,

six

six legs, and two very long straight hairs, issuing from the tail. They are seen flying about the surface of the water, about Midsummer, for three days, and no longer; they eat nothing, and their only business is to drop their eggs on the surface of the water, after they have copulated. These eggs, sinking to the bottom, produce a sort of worms, or maggots; these soon hollow themselves cavities in the clay, where they remain three years, growing every year about an inch in length. When the worm is come to its full growth, it rises to the surface of the water, about six o'clock in the morning, and there issues from it this fly, which lays its eggs, and dies about six o'clock the same night; so that the life of the creature, in the fly state, is only about twelve hours. *Swammerdam. Hist. Inf.*

EPICERA'STICA, ἐπικεραστικά, from κεράννυμι, to mix, or attemperate. Medicines which attemperate or obtund the acrimony of the humours, and mitigate the uneasy sensation of the parts thence arising. Among medicines of this kind, are reckoned emollient roots; as those of the marsh-mallow, mallow, and liquorice.

The leaves of mallows, water-lily, the large house-leek, purslane, and lettuce.

The seeds of barley decorticated, white henbane, lettuce, flax, white poppy, and rue.

The fruits, jubebs, raisins, sweet apples, sweet prunes, sebestens, sweet almonds, and pine-nuts.

Among juices and liquors; almond-milk, starch, barley-water, pinguious broths, the milk of the sow-thistle, cremor of ptisan, and the juices of the leaves of night-shade, and winter-cherry.

Among the parts of animals; the whites of eggs, butter, milk of all kinds, whey; the head and the feet of a calf, and also a sheep's head, and broths prepared of them; jellies of hartshorn and ivory.

Among mucilages; the seed of fleawort, quinces, of the seed and root of marsh-mallows; of the seed of flax, mallows, and of the root of borrage.

Among oils; oil of olives, violets, sweet almonds, expressed oils of the seed of gourd, white henbane, and white poppy.

Among ointments; the unguentum rosatum and unguentum album camphoratum.

Among syrups; the syrups of violets, of apples, of marshmallows, of Fernelius, of liquorice, jubebs, poppies, and of purslane.

Among the various shop preparations; the pulp of cassia, diacodium, diapenidium, sugar of violets, julap of violets, honey of violets. *Morellus, de Materia Medica.*

EPIDE'MIC (*Dict.*)—Pertinent to the present subject are the observations of the celebrated Boerhaave, on epidemical diseases: we must remark, says this author, that though every particular disease of the fluids, in various epidemical constitutions, appear, to unattentive observers, the same with regard to their names, signs, and their consequences in some measure, yet the same diseases, appearing in one epidemical constitution, differ exceedingly from those produced in another, with respect to their obscure natures; their appearances not observable, except by the judicious; the various times of their increase, state, coction, crisis, effect, event, and method to be pursued for the cure. Hence it is evident, that they require a different administration of the non-naturals, different treatment and medicines: this variety, however, in epidemical distempers, is so obscure, that physicians have not yet been able to deduce it from any abuse of the non-naturals: and yet there are many circumstances which make it highly probable, that the causes reside in the air, but depend more upon the inexplicable variety of exhalations contained therein, which, by their mixture with the fluids of the body, or their stimulus, injure the human machine, than upon any change in the sensible qualities thereof. But it is very surprizing, that these epidemical disorders should be principally propagated by contagion, received from one by another person unaffected.

Upon the invasion of any unknown epidemical distemper, the physician will receive some information with respect to the cure: first, by reducing the distemper to some more known species, which it most resembles.

Secondly, by observing its tendency at the vernal and autumnal equinoxes, at which seasons it is generally most prevalent.

Thirdly, by attending to the spontaneous phænomena, which precede, accompany, or follow, the death or recovery of the patient, and the better or worse state of the disorder.

Fourthly, by diligently remarking the benefit or injury received, from whatever the patients are unavoidably obliged to do; whatever is taken into; or discharged out of, the body.

Fifthly, by comparing the cases of a great many patients labouring under the distemper at the same time.

Sixthly, by abstaining from all remedies which are dubious, which exagitate and induce a considerable change in the humours, and thereby obscure the genius of the disease.

From these circumstances, duly attended to, the curative indication arises.

EPIME'DIUM, *barren-wort*, in botany, a genus of plants whose characters are:

The leaves are like those of ivy, and grow three on the top of each branch: the stalk is divided into three branches at each joint, and the triple division is continued in the subdivisions: the calyx is composed of four leaves: the flower consists of four petals, which are tubulated and hollowed into blind canals, and furnished with four stamina: the ovary is seated in the bottom of the calyx, and is furnished with an erect tube or pointal, which becomes an unicapsular bivalve pod, containing round flat seeds. *Boerhaave, Index alter.*

EPI'PHORA (*Dict.*)—Some confound this disorder with a fistula lachrymalis, but improperly; since, in the latter, pure tears are not discharged, but tears, mixed with a purulent matter, flowing from a latent ulcer in the saccus lachrymalis. But, that we may the more easily and accurately discover the nature of both these disorders, we shall, as briefly as possible, exhibit the state, figure, and situation, of the lachrymal ducts or passages. In *Plate* XX. *fig.* 7. the letters *a a* represent the puncta lachrymalia in the eye-lids; and *b*, the caruncula lachrymalis. *Fig.* 8 and 9, represent the ductus lachrymalis of both eyes intire, separate, and in such a state as they pass from the eye-lids to the nostrils. The letters *a a* exhibit the saccus lachrymalis; *b b*, the puncta lachrymalia, with their ducts or small tubes, *c c c c*, running off to the saccus lachrymalis. The letters *d d* represent the nasal duct; and *e e*, its mouth, opening in the nostrils. *Fig.* 10. represents the communication of these ducts with the eyes; *a a*, the puncta lachymalia; *b*, the caruncula lachrymalis, *c c*, the ducts running from the puncta lachrymalia to the saccus lachrymalis *d*; *e*, the nasal duct; and *f*, its extremity, opening into the nostrils.

This disorder may arise from various causes; for whatever prevents the course of the humours from the eye through the puncta lachrymalia and nasal duct to the nostrils, produces an Epiphora, or weeping eye; for, so long as the eye or lachrymal duct are sound and intire, that liquor discharged from the glandula lachrymalis, for moistening and cleansing the eye, insensibly drops through the puncta lachrymalia, the saccus lachrymalis, and the nasal duct, into the nostrils. A weeping eye, or the oculus lachrymans, is produced:

First, when any tumor, or tubercle, such as an encanthis, appears in the greater canthus, or that which is next to the nose, and disorders the puncta lachrymalia.

Secondly, when, after an exulceration, burn, or any other misfortune of the eye-lids, the puncta lachrymalia are closed up and obstructed.

Thirdly, when the nasal duct is either obstructed, or totally conglutinated; for, when the saccus lachrymalis is so full, that no more can enter therein, it must necessarily happen, that the humours, continually discharged in large quantities from the glandula lachrymalis, must run down the cheeks. The nasal duct is generally obstructed, when it is either filled with a thick, viscid, and glutinous matter, or when just by the nostrils it is affected with an inflammation capable of conglutinating it.

Fourthly, an Epiphora may be produced by a polypus, a caruncle, or fleshy excrescence of the nose; for these substances obstruct and compass the ductus lachrymalis nasalis.

Fifthly, this disorder may arise from a fistula lachrymalis.

Sixthly, from an inversion of the eye-lids, or that species of disorder called ectropium.

Seventhly, from an erosion or defect of the caruncula lachrymalis.

Eighthly and lastly, from a wound of the lachrymal ducts, and their agglutination by a bad cicatrice.

The prognostics, and method of cure, in this disorder, are various, according to the different causes from which it may possibly proceed; for, if a tumor of the large canthus, a polypus of the nose, a distortion of the eye-lids, or a fistula lachrymalis, should produce an Epiphora, or weeping eye, the disorder cannot be removed, till its respective causes are taken away. When the Epiphora arises from a conglutination of the puncta lachrymalia, we ought carefuly to examine, whether their ducts *c c*, in *fig.* 8 and 9, are totally conglutinated, or whether their mouths, *b b* are only closed up by a slender cuticle; for, when the ducts of the puncta lachrymalia are totally conglutinated, either by some internal cause, or cicatrices formed after wounds or burns of the lachrymal ducts, there remain little or no hopes of a cure. But, if a slender cuticle should only block up the ducts of the puncta lachrymalia, which sometimes happens, the most proper method is cautiously to perforate that cuticle with a needle, and then to pass a hog's bristle, or a piece of slender silver wire, anointed with oil of eggs, into the perforations. Various wires for this purpose are represented by *fig.* 11, 12, and 13, *Plate* XX. and these measures must be persisted in, till the mouths of the perforations are so effectually indurated as to prevent a future conglutination.

But if, in this disorder, the puncta lachrymalia are sound, and sufficiently pervious, the nasal duct must necessarily be obstructed. And this obstruction, when proceeding from a glutinous matter, which, by long continuance, is not preternaturally indurated, is very often capable of being removed. For this purpose the patient is frequently every day to be laid upon his back, and have resolvent liquors dropped into the greater

greater canthus; then the ſaccus lachrymalis is carefully to be compreſſed with the fingers, leſt the humours, by remaining long in it, ſhould contract a certain acrimony, corrode the lachrymal ducts, and gradually produce a fiſtula lachrymalis. Among the reſolvent medicines ſuited to this intention, the moſt conſiderable are eſſence of aloes, prepared with the aqua ophthalmica; eſſence of the gall of the eel-pout; prepared nearly in the ſame manner; warm infuſions of the herbs hyſſop and Paul's betony; mineral waters ſuch as thoſe of Wiſboden, the Caroline ſprings, thoſe of Emſer, the Selteran, the Sedlitz, and other waters of a like nature, or any ophthalmic waters, to be frequently dropped warm into the eye, with an admixture of a ſmall portion of mineral ſalt, obtained from the abovementioned waters. Beſides theſe, it is expedient ſometimes to draw up the noſtrils an errhine, or mild ſternutatory, prepared of marjoram, lilies of the valley, marum, and other herbs of a like quality. Spirit of hartſhorn, or ſal ammoniac, may alſo be applied to the noſtrils. If all theſe medicines ſhould prove ineffectual, it will be expedient to uſe that new method of cure in a fiſtula lachrymalis, recommended by Anel, in which a certain ſlender ſilver probe, like thoſe repreſented in *Plate* XX. *fig.* 11, 12, and 13, is cautiouſly and dexterouſly paſſed to the noſtrils through the ſuperior punctum lachrymale, the ſaccus lachrymalis, and the lachrymal duct of the noſe. But, in performing this operation, the ſituation and ſtructure of the lachrymal ducts muſt be carefully adverted to; the operator's eye muſt be quick and diſcerning, his hand ſteady, and well accuſtomed to the niceſt chirurgical operations; otherwiſe he will hardly ſucceed in the operation. This method ought to be perſiſted in for ſome days; and every morning and evening, after introducing the ſilver probe or wire now mentioned, a ſmall quantity of the above recommended liquors is, by means of the ſmall ſyringe, repreſented in *Plate* XX. *fig.* 14, to be injected into the inferior punctum lachrymale, in order to cleanſe the lachrymal ducts, leſt the paſſage of the tears to the noſtrils ſhould again be obſtructed. When this ſpecies of diſorder continues long, it generally degenerates into a fiſtula lachrymalis, and is to be treated as ſuch. When an Epiphora ariſes from a total want of the caruncula lachrymalis, all attempts of relief are unſucceſsful; becauſe that gland cannot be reſtored. *Heiſter. Chirurg.*

EPIPLO'CELE (*Dict.*)— There have been a few inſtances where ſo great a quantity of the omentum has fallen into the ſcrotum, that, by drawing the ſtomach and bowels downwards, it has excited vomiting, and inflammations, in which caſe the operation of opening the ſcrotum is neceſſary: it is neceſſary alſo the rings of the muſcles ſhould be dilated, or otherwiſe, though you have taken away ſome of the mortified part of the omentum, the reſt that is out of its place, and ſtrangled in the perforation, will gangrene alſo. What I have here deſcribed as an inducement to the operation, ſhould, by the experience I have had, be the only one. There are a great many people, who are ſo uneaſy with ruptures, though they are not painful, that a little encouragement from ſurgeons of character will make them ſubmit to any means of cure; but, as I have ſeen two or three patients, who were in every reſpect hale and ſtrong, die a very few days after the operation, the event, though very ſurpriſing, ſhould be a leſſon, never to recommend this method of treating an Epiplocele, unleſs it is attended with inflammation, &c. *Sharp's Surgery.*

E'PITHEM (*Dict.*)— There are three kinds of Epithems; firſt, the liquid; ſecondly, the dry, or ſolid; and, thirdly, thoſe of the ſoft and poultice kind. The two former retain the general name of Epithem, and the latter is called cataplaſm, poultice, or malagma.

A liquid Epithem, called alſo ſometimes, a fomentation, is a medicated liquor, either ſimple or compound, applied either cold or hot, by the intervention of a proper vehicle, to the ſurface of the body; and calculated either for inducing ſuch a change on it, or the ſubjacents parts, as the intention of the phyſician ſhall require.

The liquors for theſe intentions may be water, milk, wine, vinegar, ſpirit of wine, liquid juices, oil, or urine, either ſimple by themſelves, or variouſly prepared, and mixed either with each other, or with other officinal and extemporaneous medicines, of whatever conſiſtence, ſuch as diſtilled waters of all kinds, vinegars, infuſed oils, decoctions, aromatic ſpirits, tinctures, eſſences, ſaline liquors, lixiviums, forge-water, lime-water, and, eſpecially, infuſions and decoctions prepared from theſe and other proper materials, expreſſed juices, emulſions, and mixtures of various kinds.

The choice of the phyſician, with reſpect to proper materials, is to be directed by the nature of the part to be changed, or to which the application is made, the malignant or benign nature of the ſymptoms, and the particular quality of the liquor to be uſed.

The ſame cautions are to be uſed in the management of theſe, as in that of ſuch forms for internal uſe: only, as in the former caſe, it is not neceſſary we ſhould regard the taſte, the ſmell, or the colour of the medicines; ſo, for this reaſon, we are to omit the ſugars and ſyrups uſed for correcting internal remedies.

A pretty thick conſiſtence is no diſadvantage to liquid Epithems, though, at the ſame time, when a deep penetration into the part affected is required, thoſe of a leſs thick conſiſtence are, when all other circumſtances are alike, to be preferred.

As a change of the part only to which the application is immediately made, is not always intended, but, ſometimes, alſo, of the viſcera and organs lying under it; ſo the ſubſtances moſt proper for applications of this kind are thoſe, whoſe virtues conſiſt in their volatile, highly fine, and penetrating principles, eſpecially when a change of the internal parts is intended: for this reaſon, ſubſtances of an earthy or ſtony nature, aſtringents, and materials of an inſpiſſating nature, can poſſibly be of no ſervice for this purpoſe; ſince, in conſequence of their thickneſs, they either cannot be abſorbed, or, by bracing up the mouths of the pores, prevent their own ingreſs. But, perhaps, better effects may be produced by adding ſome penetrating aromatic, or ſpirit, to gentle aſtringents.

It is alſo to be carefully conſidered, whether the nature of the part, to which the application is immediately to be made, is ſuch, as, without being injured, is capable of bearing the liquor, whether oil, water, ſpirits, or acrid fluids; leſt, whilſt we do ſervice to one part, we ſhould injure or hurt another.

EPU'LIS, ἐπουλὶς, from ἐπὶ upon, and οὖλα, the gums, a ſpecies of tubercles growing on the gums, of which there are two kinds; for ſome are intirely without pain, whilſt others afflict the patient in a moſt terrible manner, becauſe they are of a malignant nature, and gradually degenerate into a cancer: tubercles of this kind are alſo in ſome meaſure diſtinguiſhed from each other by their different bulks and conditions; ſince ſome are as big as a large nut, and others no bigger than a ſmall one; ſome hard, others ſoft; ſome have a ſlender, and others a larger and broader root: when theſe tubercles are of the large kind, they not only diſtend and deform the jaws, but alſo prove a conſiderable obſtruction to maſtication and ſpeech, for which reaſon they require a ſpeedy and expeditious cure: now, no method of cure is more expeditious, than a total extirpation of theſe caruncles, as is uſual in other tubercles of a like nature: when, therefore, the roots are ſmall, a thread is carefully to be paſſed about them, with which they are to be tied pretty tight: but, when the inferior part of the tubercle is pretty large, the uſe of ſome gently corroſive medicine is proper; and this intention is excellently anſwered, by oil of tartar per deliquium, or a ſolution of ſal ammoniac. But in caſes of this nature we are abſolutely to abſtain from the more draſtic and poiſonous corroſives, ſince, for the moſt part, they not only excite violent inflammations, and exulcerations of the mouth, but may alſo produce the death of the patient, if they ſhould happen to be unfortunately ſwallowed: for this reaſon, in caſes where the milder corroſives are not ſufficient, it is more expedient and ſafe to ſeek the means of relief from the knife, whilſt theſe caruncles, being laid hold of by a pair of forceps, or a ſmall hook, are to be extirpated and cut out, either by the knife or a pair of ſciſſars: but this is to be done cautiouſly, leſt, by cutting out the whole ſubſtance of the gum at the ſame time, a caries ſhould be excited in the denudated bones of the jaw. The diſcharge of the blood is to be permitted for ſome time; but, if it ſhould continue too long, in order to ſtop it more eaſily, and cleanſe the blood out of the mouth, it is highly proper to make the patient often waſh his mouth with warm wine, eſpecially of the red and aſtringent kind, or with oxycrate, mixed with a little alum, till he has ſpit out all the blood: when the diſcharge of the blood is ſtopped, the wound is to be daily anointed, till healed, with oil of myrrh per deliquium, or eſſence of myrrh mixed with honey of roſes. If any part of the tubercle ſhould remain, or if it ſhould begin to appear afreſh, it is with all expedition to be conſumed by the corroſives already mentioned, or by blue vitriol, or any other corroſive medicine; or it may be again extirpated by means of the ſciſſars or knife. The actual cautery is by ſome recommended in caſes of this nature, and inſtances of cures happily performed by it alledged; but it is not only incommodious to apply, but alſo excites intolerable pain; it is however to be uſed when the tubercle cannot be repreſſed by other means. Meckren, in his twenty-eighth obſervation, gives us a ſingular inſtance of a cure of this diſorder, together with the deſcription of a knife, accommodated to this purpoſe. Scultetus, in his thirty-fifth obſervation, informs us, that, by means of a forceps uſed in eradicating polypuſes, he happily extirpated a caruncle of this kind, adhering to the gum of the anterior teeth, hard by the palate. Some years ago, I myſelf ſays Heiſter, ſaw ſuch a caruncle in the palate of a monk, behind the dentes inciſores; but, becauſe his miſfortune was complicated with a ſpina ventoſa in the bones of the palate, and becauſe he would not ſubmit to the uſe of the actual cautery, the caruncle could not be totally removed; but the patient, gradually loſing his ſtrength, at laſt died. *Heiſter. Chirurg.*

EQUA'TION (*Dict.*)— Dr. Halley's method for the ſolution of Equations is thus: let the root z of any Equation be taken equal to $a \pm e$; where a is ſuppoſed to be taken near to the true value. Then from the quantity $a \pm e$ let all the powers of z, found in the propoſed Equation, be formed; and to theſe

let

let their respective coefficients be prefixed. Let the power to be resolved be subducted from the sum of the parts of the first column, where e is not found; and let the difference be $\pm b$, then take the sum of all the coefficients of e in the second column, which call s: and having added all the coefficients of ee, the sum of which is called t; the root sought, z, will, in a rational form, $= a \pm \frac{sb}{ss \pm tb}$; and, in an irrational form, $= a \frac{\mp \frac{1}{2} S \mp \sqrt{\frac{1}{4} ss + bt}}{t}$.

For instance, let it be proposed to find a root of the Equation $z^4 - 3zz + 75z = 10000$, where 10000 is the resolvend.

For a first supposition let $a = 10$; we shall therefore have the Equation

$$z^4 = a^4 \pm 4a^3e + 6a^2ee \pm 4ae^3 + e^4$$
$$-dzz = da^2 \pm dae - dee$$
$$+cz = +ca \pm ce$$
$$= 10000 \pm 4000e + 600ee \pm 40e^3 + e^4$$
$$-300 \pm 600e - 3e$$
$$+750 \pm e\,75e$$
$$-10000$$

$$+450 \mp \underset{s}{4015}e + \underset{t}{597}ee \mp \underset{u}{40}e^3 + e^4 = 0.$$

The signs + and — with respect to e and e^3 are left doubtful, till it be known whether e be affirmative or negative; in which there is some difficulty, as in Equations having several roots, the homogenea comparationis, as they are called, are often increased by diminishing a, and on the contrary diminished by increasing a. But the sign of e is determined by the sign of the quantity b; for, the resolvend being subtracted from the homogeneum formed from a, the sign of se, and, therefore, of the parts prevailing in its composition, will always be contrary to the sign of the difference b. Hence it will appear whether e be affirmative or negative, or whether a has been assumed greater or less than the true root. But e is always equal to $\frac{\frac{1}{2}s - \sqrt{\frac{1}{4}ss - bt}}{t}$, as often as b and t have the same sign; but, when they are connected with different signs, e becomes $= \frac{\sqrt{\frac{1}{4}ss + bt} - \frac{1}{2}s}{t}$. After that e has been found to be negative, e, e^3, e^5, &c. must be made negative in the affirmative members of the Equation, and affirmative in the negative members, that is, they must be writ with a contrary sign: but if e be affirmative, then must e, e^3, e^5, &c. be affirmative in the affirmative members, and negative in the negative.

In the proposed example we have 10450 instead of the resolvend 10000, or $b = +450$; from whence it appears, that a was taken greater than the true root, and, consequently, that e is negative. Hence the Equation becomes $10450 - 4015e + 597ee - 4e^3 + e^4 = 10000$; that is, $450 - 4015e + 597ee = 0$. Therefore, $450 = 4015e - 597ee$, or $b = se - tee$; the root of which is $e = \frac{\frac{1}{2}s - \sqrt{\frac{1}{4}ss - bt}}{t}$, or $\frac{s}{2t} - \sqrt{\frac{ss}{4tt} - \frac{b}{t}}$, that is, in the present case, $e = \frac{2007\frac{1}{2} - \sqrt{3761406-}}{597}$, from whence the approximated root is found to be $= 9.886$. Now, this root being taken for a second supposition, and the operation being repeated, we shall have $a + e = z = 9.8862603936495$, which is very exact, scarcely exceeding the truth by above 2, in the last figure.

This is sufficient to give a notion of Dr. Halley's method: those who desire more examples, and farther instructions, may consult the the Philosophical Transactions, N°. 210, or Lowthorp's Abridg. vol. I, p. 85.

EQUATION *of the center (Dict.)*— This Equation not being constant, there is a place in the planet's orbit where it is greatest. Hence several questions in astronomy arises; as, what is the greatest Equation for every planet? To what mean anomaly does this Equation correspond? Also, as the greatest Equation is determined by the excentricity of the planet's orbit, it may be reciprocally requisite to determine the excentricity by the greatest Equation.

The rigorous solutions of these questions being no where extant, Mr. Euler has enquired into them, in Mem. de la Acad. de Berlin, Tom. II, p. 225. Where he solves the following problems.

1. To find the true and mean anomaly, corresponding to the planet's mean distance from the sun; that is, when the planet is in the extremity of the conjugate axis of its orbit.

2. The excentricity of a planet being given, to find the excentric anomaly corresponding to the greatest Equation.

3. The excentricity being given, to find the mean anomaly corresponding to the greatest Equation.

4. From the same data to find the true anomaly corresponding to this Equation.

5. From the same data to find the greatest Equation.

6. The greatest Equation being given, to find the excentricity. Mr. Euler observes, that this problem is very difficult, and that it can only be solved by approximation and tentatively, in the manner he mentions. But, if the excentricity be not great, it may be then found directly from the greatest Equation. Thus, if the greatest Equation $= m$, and the excentricity $= n$, then

$$m = 2n + \frac{11}{48}n^3 + \frac{899}{5120}n^5 +, \&c.$$

Whence, by conversion,

$$n = \tfrac{1}{2}m - \frac{11}{768}m^3 - \frac{587}{2^{10}.15}m^5 -, \&c.$$

Where the greatest Equation m must be expressed in parts of the radius, which may be done by converting the angle m into seconds, and adding 4.6855749 to the logarithm of the resulting number; for this will be the logarithm of the number m.

The mean anomaly to which this greatest Equation corresponds, will be, $x = 90° + \frac{5}{8}m - \frac{5}{2^9.3}m^3 - \frac{1}{2^9.5}m^5 -$, &c.

Whence, if to 90° we add $\frac{5}{8}$ of the greatest Equation, we shall sufficiently approximate to this mean anomaly.

Mr. Euler gives us a table, in which may be found the greatest Equations, the excentric and mean anomalies, corresponding to these greatest Equations, for every hundredth part of unity, which he supposes equal to the greatest excentricity, or when the distance of the foci and the transverse axis become infinite. The last column of his table also gives us the logarithm of that distance of the planet from the sun, where its Equation is greatest. By the help of this table, any excentricity being given, we may find the greatest corresponding Equation, by interpolation. But the principal use of the table is, to determine the excentricity when the greatest Equation is known, and Mr. Euler thinks the question insoluble without this help.

EQUISE'TUM, *marsh horsetail*, in botany, a genus of plants whose characters are:

The root is very creeping: the leaves are round, hollow, and articulated by a pyxidated insertion, or after the manner of boxes, a less within a greater: the flower has no petals, is stamineous or thready, has a fungiform or mushroom-like head, and is male in one plant. The fruit consists of black rough grains, growing close together on the plant, which bears no flowers.

The great horsetail has many hollow, whitish-green, smooth, and neatly channeled round stalks, having many joints at some distance one from another, the uppermost being always set-in or articulated in that next under it: they grow to be a foot and a half, or two feet high, taper, and scarce half an inch thick: They are surrounded, at every joint, with a great number of long, very slender, rough leaves, which, like the stalks, are jointed one within another, and stand so thick, that the whole stalk appears like a horse's tail: early in the spring, before the stalks come up, there arise from the root several short stalks, without leaves, but jointed as the others, having at their tops a brownish round head like the top of an asparagus, in which lies the seed: the root is long and slender, full of joints, and spreading much. It grows in ditches and marshy grounds.

Horsetail is restringent, drying, and binding; good to stop bleeding in wounds, and all hæmorrhages in any part of the body, redundant catamenia, and the fluor albus, for ulcerations in the kidneys or bladder, and is useful in all kinds of ruptures. *Miller's Bot. Off.*

Horsetail has an herby saltish taste; it is detersive, and gives hardly any tincture of red to blue paper: its salt seems to resemble that of coral; but it is mixed with a little sal ammoniac and sulphur: by the chemical analysis, it affords several acid liquors, a little oil, a great deal of earth, no concreted volatile salt, but a little urinous spirit: its fixed salt does not easily dissolve in the air, neither does it give an orange colour to the solution of corrosive sublimate. *Martyn's Tournefort.*

Frederick Hoffman recommends a decoction or infusion, by way of tea, made of this plant, as excellent in the stone; and Fuller gives a decoction thereof, intended against ulcers of the bladder.

E'QUUS, in natural history, the horse. See the article HORSE.

ERE'TRIA *Terra*, *Eretrian earth*, in the materia medica, the name of a very peculiar kind of bole, dug in the Negropont, near the ancient Eretria, and once in great use as an astringent and a sudorific.

The grey, or genuine Eretrian earth, is a fine and pure greyish-white earth, moderately heavy, naturally of a smooth surface, of a friable texture, easily crumbling to pieces between the fingers, but not staining the skin in handling; it sticks firmly to the tongue, but melts into a butter-like substance in the mouth; it burns to a perfect snow white, and effervesces violently with aqua-fortis. But what abundantly distinguishes it from all other earths, is, that, if a little wetted and drawn over a plate of brass or copper, so as to mark a line, the mark will, a little after, appear bluish.

ERI'CA, *common heath*, in botany, a genus of plants whose characters are:

The leaves are small and ever-green, monopetalous, bell-shaped, naked, and often shaped like a pitcher. The ovary in the bottom of the flower becomes a roundish fruit, gaping in four places, divided into four cells full of small seeds, and covered with the lower part of the flower as with a calyx.

The flower of this plant is of a very singular structure. It is a little bell prolonged and double. The outer one, which is the longest, is formed by four petals, encompassing the other, which seems to be monopetalous, open only at the fore part, and cut into four equal segments. The cavity of this inner one is filled with eight chives, disposed round a pointal, which does not exceed the thickness of a middling pin's head, and is raised with eight rounded ribs, and surrounded by a style, terminated with a button, which usually juts out of the flower. These parts are sustained by a little empalement, like a cup, cut to the very base into four equal parts. This double flower is purple, as is also the style; but the chives are white.

The decoction of heath is diuretic. Clusius affirms, that Rondeletius, the famous professor of physic at Montpelier, used the oil of its flowers for tetters, with a great deal of success. Tabernæmontanus says, that it is a specific for these sorts of diseases; and that a fomentation, with the flowers of heath, eases the pain of the gout. For the same disease they prepare a vapour bath, with its leaves and flowers. *Martin's Tournefort.*

ERMI'NEUM *Animal*, the ermin, or creature whose skin is the ermin, so much esteemed as a fine furr.

This creature is properly a species of weasel, and is called by Mr. Ray, and other authors, mustela candida, the white weasel. It is in all respects like the common weasel, and is all over of a pure snow-white, except the tip of the tail, which is of as beautiful a black; and that it has a little yellowish-grey about the eyes, and a mark, or spot, of the same colour, on the head, another on the shoulders, and a third near the tail. Its colour is, however, very different in degree and elegance, according to the season of the year. It is frequent about rivers, and in meadows, in those countries which produce it, and feeds on moles, mice, and other small animals. *Ray's Syn. Quad.*

ERU'CA, *wild rocket*, in botany, a genus of plants, whose characters are:

The pod is full of roundish seeds, and the plant has a particular taste, and a particular fœtid smell above all others.

This rocket has a long white root, with many fibres at the bottom; from which arise a great many striated stalks a foot or two high, full of narrow, long, and deeply laciniated leaves. The flowers are pretty large and yellow, of four leaves a-piece, which are succeeded by long, narrow, angular pods, full of small, hot, bitterish seed. The whole plant has an ungrateful, fœtid smell. It grows frequently upon old walls, as on the walls of the city of London, in great plenty, flowering great part of the summer.

This rocket is hot and dry, and much of the nature of the following; but is very rarely used in physic. *Miller's Bot. Off.*

This plant is of a state altogether acrid and burning, mixed at last with a little bitterness; it gives a pretty deep tincture of red to the blue paper, and its smell resembles that of fœtid oils rectified over quicklime; which makes us believe, that it contains a salt very acrid, which in some measure resembles the sal ammoniac, mixed with a great deal of fœtid oil and earth.

Thus it is no wonder, that the plant, of which we are speaking, should be aperitive, incisive, and diuretic. Matthiolus affirms, that, being boiled with a little sugar, it is good for the cough in children, which is generally occasioned by glutinous matters, irritated in the bronchia and vesicles of the lungs. *Martyn's Tournefort.*

ERUCA, *garden-rocket*.—The common garden-rocket has a slender white woody root, of a hot biting taste; the leaves somewhat resemble mustard in shape, but are much smoother; the stalks grow to be two or three feet high, cloathed with lesser leaves, having on their tops many flowers of a whitish yellow colour, full of dark purple veins; the seed vessels, which succeed them, are long, slender, and smooth, parted in two by a thin membrane, and opening at the sides when the seed is ripe, which is very small, of a reddish yellow colour, and a roundish shape, and hot taste. It is sown in gardens, and the seed is ripe in July.

Rocket is eaten frequently among other herbs as a sallad, though many people dislike it for its strong ungrateful smell; it has the name of a provocative, and exciter to venery, and is likewise a good diuretic. Matthiolus commends the leaves, boiled with sugar, to be given to children for a cough: I suppose he means, that they should be made into a syrup. Camerarius says, that an equal part of the powder of rocket and cumin seed is a mighty preservative against an apoplexy. *Miller's Bot. Off.*

ERU'CÆ *aquaticæ*, water caterpillars. It might seem incredible that there is any such creature as a caterpillar, whose natural habitation is under water; but experience and observation prove that there are such, and that they feed on the water plants as regularly as the common kinds do on those at land. These are not named at random, like many of the aquatic animals of the larger kinds, the sea-wolf, and the sea-horse, &c. which might as well be called any thing else as wolves and horses; but they are properly what they are called, and do not respire in the manner of the fish tribe, but by thin stigmata, as other caterpillars. Mr. Reaumur, in his observations, met with two species of these; the one upon the potamogiton, or pond-weed; the other upon the lenticula, or duck-meat. These are both very industrious animals; but, the first being much the larger, its operations are more easily distinguished.

This, though truly an aquatic animal, swims but badly, and does not at all love to wet itself. The parent butterfly lays her egg on a leaf of the potamogiton, and, as soon as the young caterpillar is hatched, it gnaws out a piece of the leaf of a roundish shape. This it carries to another part of the same leaf, and lays it in such a manner, that there may be a hollow between, in which it may lodge. It then fastens down this piece to the larger leaf with silk of its own spinning, only leaving certain holes at which it can put out its head, and get to gnaw any of the leaves that are near. It easily gets out, though the aperture be naturally small, since a little force from its body bends up the upper leaf, and bends down the lower, both being flexile; and when the creature is out, it has a sort of down that defends it from being wetted, and the natural elasticity of the leaves, and of the silk, join the aperture up again, so that no water can get in. The leaves of this kind of plant are also naturally very slippery, and not easily wetted by water. It soon happens, that this habitation becomes too small for the animal, in which case it makes just such another, and after that, at times, several others, each being only made fit for it at the size it is then of. The changes of this creature into the chrysalis and butterfly state are in the common method. The butterfly gets out of a chrysalis which was placed on the surface of the water, the lightness of the animal easily sustains it on the water till its wings are dried, and it then leaves that element never to return to it again. *Mem. Acad. Par.* 1736.

E'RVUM, *bitter vetch*, in botany, a genus of plants whose characters are:

The pods are articulated, undulated on both sides, as if knotted, and full of roundish seeds. The leaves grow by pairs, as if conjugated to a middle rib.

This vetch seldom grows to above a foot and an half, or two feet high; full of weak angular stalks, having many winged tare-like leaves, whose obtuse pinnæ are more numerous and slender. The flowers grow at the setting on of the leaves, singly, in shape like the flower of a tare or vetch, but less, and of a white colour; and are succeeded by small round pods, containing two or three large round white seeds, which swell out the pod, making it appear, as it were, jointed: it grows in Italy, and some parts of France; and flowers in June.

The powder of bitter vetch, mixed with honey, is accounted good to cleanse the lungs of tough phlegm. It is a strong diuretic, and expels the stone and gravel; but, if taken too frequently, it causes bloody urine: it is but seldom used. *Miller's Bot. Off.*

ERY'SIMUM, *hedge mustard*, in botany, a genus of plants whose characters are:

It has a long, thin, slender pod, full of very small round seeds; and it has a peculiar appearance.

The root of hedge mustard is long, whitish, frequently crooked, and full of small fibres. The stalk arises to be a foot and a half, or two feet high, tough, and pliant, branching out, usually, on all sides, like a shrub, or bush. The lower leaves are long and narrow, cut into several jagged segments, set opposite to one another, with one more blunt at the end, and are somewhat hairy; the leaves, which grow on the stalks, have fewer segments, the upper many times but three, appearing like the head of an halbert; the flowers are yellow, very small, and four-leaved, growing thick together at the lower end of the branches; which flowering gradually, and the stalk still extending itself, the spikes of the seed-vessels grow to a great length, being round, sharp-pointed, clapping close to the stalks, and are full of hot biting seed. It grows everywhere, by the way-side, flowering good part of the summer.

Hedge mustard is hot and dry, opening and attenuating, and, by its warming quality, is good to dissolve thick, gross, slimy humours in the lungs, to help a cough, and shortness of breath; and it is particularly recommended against an habitual hoarseness, to recover the voice. Riverius praises a decoction of it, in wine, against the cholic. *Miller's Bot. Off.*

ERYSI'PELAS (*Dict.*)— Heister thinks that the grand intention, in the curing this disorder, must be to dilute the inspissated blood, and break and divide it where it stagnates and is obstructed. Plenty of thin and weak drinks are therefore to be administered, by which a gentle and lasting sweat may be excited, and the testaceous powders, and nitrous medicines, are frequently found also to have great and good effects. If the inflammation be but very slight, it is often cured by external warmth; but, when warmth alone does not prove sufficient, cloths, with the rob of elder spread upon them, are found of great benefit, being laid on the part, and kept on by warm compresses, and the proper bandages. Ointments made of the middle green bark of elder are also very beneficial, and, notwithstanding that many do not approve the practice, yet spirit of wine camphorated, with a mixture of saffron and Venice treacle, are found often of very great service, applied warm with coarfe paper, or with linen rags: and a mixture of lime water and fpirit of wine camphorated often does great fervice. It fometimes happens, that an Eryfipelas comes to fuppuration; and from this generally arife the moft untractable fpreading and eating ulcers. In this cafe, the ulcer is to be carefully cleanfed, and dreffed with ointments of cerufs, red lead, or litharge, and plaifters of the fame ingredients; and muft, at the fame time, take internal remedies to fweeten the blood, fome gentle purges, and a ftrict regimen in regard to diet. *Heifter's Surgery.*

ES'CHATON, in mufic, the difference between the diefis enharmonica and the hyperoche; that is, what remains, after taking the difference between the femitone minor and diefis enharmonica from the latter.

Thus the difference between the femitone minor and the enharmonic diefis is $\frac{25}{24} : \frac{128}{125} = \frac{3125}{3092}$, and this, taken from the diefis, is $\frac{128}{125} : \frac{3125}{3072} = \frac{393216}{390623}$. This interval is about $\frac{53}{100}$ of a comma, as will eafily appear by logarithms.

Mr. Henfling has taken notice of this interval. He calls it Efchaton, from its being the leaft and laft interval that occurs in his fyftem.

ESPA'LIERS, (*Dict.*) — Efpaliers of fruit trees are commonly planted to furround the quarters of a kitchen garden; for which purpofe they are of admirable ufe and beauty: for, by laying out the walks of this garden regularly, which are bounded on each fide by thefe hedges, when they are handfomely managed, they have a wonderful effect in fheltering the kitchen plants in the quarters, and alfo fkreening them from the fight of perfons in the walks; fo that a kitchen garden, well laid out in this manner, and regularly managed, will be equal to the fineft parterre for beauty.

The trees chiefly planted for Efpaliers are apples, pears, and fome plums; but the two former are moftly ufed: fome plant Efpaliers of apples grafted upon paradife ftocks; but thefe, being of a fhort duration, are not fo proper for this purpofe; therefore I fhould rather advife the having them upon crab ftocks, or (if in fmall gardens, where the trees cannot be allowed to grow fo high) upon what the gardeners call the Dutch ftock; which will caufe them to bear much fooner, and prevent their growing too luxuriant.

In chufing the trees for an Efpalier, endeavour, as near as poffible, to plant the feveral forts which are nearly of the fame growth in one line, that the Efpalier may be the more regular, and of an equal height, which greatly adds to their beauty; for, if you plant trees which fhoot very unequally in the fame line, it will be impoffible to make the Efpalier regular: befides, the diftance the trees are to be planted muft be directed hereby; for fome trees, viz. thofe of a larger growth, fhould be planted twenty-five or thirty feet afunder; whereas thofe of fmaller growth need not be above fixteen or eighteen feet diftance from each other.

The width of the walks between thefe Efpaliers fhould (in a large garden) be fourteen or fixteen feet at leaft; and, if they are defigned to be carried up pretty high, the diftance fhould be greater, that each fide may receive the advantage of the fun and air, which is abfolutely neceffary, if you would have the fruit well tafted. And, if your ground is fo fituated, that you are at full liberty which way to make the Efpaliers, I would advife the placing the lines from the eaft a little inclining to the fouth, and toward the weft a little inclining to the north, that the fun may fhine between the rows in the morning and evening, when it is low; for in the middle of the day, when the fun is advanced far above the horizon, it will fhine over the tops of the Efpaliers, and reach the furface of the earth about their roots; which is a matter of more confequence than many people are aware of.

The forts of apples proper for Efpaliers are the golden pippin, nonpareil, rennette grife, aromatic pippin, Holland pippin, French pippin, Wheeler's ruffet, Pile's ruffet, with feveral others. The feafon for planting, and the method of pruning and training thefe trees, you will fee under the articles of APPLES and PRUNING.

The forts of pears proper for an Efpalier are fummer and autumn fruits; for fome of the winter pears feldom fucceed well in an Efpalier. Thefe trees, if defigned for a ftrong moift foil, fhould be upon quince ftocks; but, if for a dry foil, upon free ftocks. Their diftance of planting muft alfo be regulated by the growth of the trees, which are more unequal in pears than apples, and fhould therefore be more carefully examined before they are planted. As for thofe pears upon free ftocks, the diftance fhould never be lefs than twenty-five feet for moderate-growing trees; but, for vigorous fhooters, the fpace of thirty or five and thirty feet is little enough, efpecially if the foil be ftrong, in which cafe they fhould be planted at a greater diftance. The particular forts of pears I would recommend for an Efpalier, are the jargonelle, blanquette, poir fans peau, fummer boncretien, Hambden's burgamot, poir du prince, autumn burgamot, l'ambrette, gros roufelet, chaumontelle, beurre du roy, le marquifs, creffane, with many others of lefs note, always remembering, that thofe pears which are of the melting kind, will do better in Efpaliers than the breaking pears, which feldom ripen well on Efpaliers: you fhould alfo be careful of the ftocks thefe are grafted on, for, if the breaking pears are grafted on quince ftocks, the fruit will be ftony. As to the method of planting, fee the article PEAR; and, for pruning and managing, fee PRUNING.

I fhall now give directions for making the Efpalier, to which the trees are to be trained: but this I would not have done until the third year after the trees are planted; for, while they are young, it will be fufficient to drive a few fhort ftakes into the ground on each fide of the trees, to which the branches fhould be faftened in an horizontal pofition, as they are produced; which ftakes may be placed nearer, or at a farther diftance, according as the fhoots produced may require, and will be fufficient for the three firft years; for, fhould you frame the Efpalier the firft year the trees are planted, the poles would rot before the Efpalier is covered. The cheapeft method to make thefe Efpaliers is with afh poles, of which you fhould have two forts; one of the largeft fize, which contains thirteen poles in a bundle, and the other fize thofe of half a hundred; the firft or largeft fize poles fhould be cut about feven feet and an half long; thefe are intended for upright ftakes, and muft be fharpened at the largeft end, that they may, with more eafe, be driven into the ground; thefe fhould be placed at a foot diftance from each other in a direct line, and of an equal height, about fix feet above ground; then you fhould nail a row of ftraight flender poles along upon the tops of the upright ftakes, which will keep them exactly even, and continue to crofs the ftakes with the fmaller poles, and the tops which were cut off from the larger ones, at about nine inches diftance, row from row, from the top to the bottom of the ftakes. Thefe rows of poles fhould be faftened with wire, and the largeft end of the poles fhould be nailed to the upright ftakes, which will fecure the Efpalier almoft as long as the poles will endure; whereas, if your faftening is not ftrong, the poles will be continually difplaced with every ftrong wind. When your Efpalier is thus framed, you muft faften the branches of the trees thereto, either with fmall ofier twigs, or fome fuch binding, obferving to train them in an horizontal pofition, and at equal diftances; being careful not to crofs any of the branches, nor to lay them in too thick: the diftance I would allow for the branches of pears and apples, fhould be proportioned according to the fize of their fruit; fuch of them whofe fruit is large, as the fummer boncretien, monfieur John, and beurre du roy pears, and the rennet guife, Holland pippin, French pippin, and other large apples, fhould have their branches fix or eight inches diftance at leaft; and to thofe of leffer growth four or five inches will be fufficient. But for further directions I fhall refer to the articles of the feveral fruits; as alfo that of PRUNING, where the particulars will be fufficiently explained.

But, befides this fort of Efpalier made with poles, there is another fort that is by many people preferred; which is framed with fquare timbers cut to any fize, according to the ftrength thereof, or the expence the owner is willing to go to; thefe, though they appear more fightly, when well fixed and painted, are not of longer duration than one of the former, provided it is well made, and the poles are ftrong which are fet upright; nor will they anfwer the purpofe better, though they are vaftly more expenfive; for the greateft beauty confifts in the difpofing the branches of the tree, which, efpecially in fummer, when the leaves are on, will intirely hide from the fight the frame of the Efpalier: therefore all expence in erecting thefe is needlefs, farther than making provifion to fecure the branches of the trees in a regular order.

Fruit-trees thus planted, and well managed, are much preferable to thofe trained up in any other figure, upon feveral accounts: as, firft, thefe take up very little room in a garden, fo as to be hurtful to the plants which grow in the quarters; and, fecondly, the fruit upon thefe are better tafted than thofe which grow upon dwarfs, the fun and air having freer accefs to every part of the tree, whereby the dampnefs arifing from the ground is fooner diffipated; which is of fingular advantage to fruit-trees. *Miller's Gard. Dict.*

ETRU'SCA *Terra*, in the materia medica, a kind of bole of which there are two fpecies, the white and the red; thefe are called, by many authors, the terra figillata alba & rubra magni ducis, as they are brought to us fealed with different impreffions.

The white Tufcan earth is a denfe and compact fubftance of a dull deadifh white, which in drying acquires fome degree of yellownefs; it is of a fmooth furface, and does not ftain the fingers in handling. It is not eafily broken, and but flightly adheres to the tongue, and freely melts into a fubftance like butter in the mouth. It makes a flight effervefcence with acid menftruums.

The red Tufcan earth is an impure bole, very heavy and of a fomewhat lax texture, and of a pale red colour. It is naturally of a fmooth furface, breaks eafily between the fingers, and is apt to ftain the hands; it adheres ftrongly to the tongue, and melts freely in the mouth, and has a ftrongly aftringent tafte, but leaves a fandy harfhnefs between the teeth. It makes no effervefcence with acid menftrua. Thefe are the characters by which both thefe earths may be known from others of the fame colour; they are both dug in feveral parts

parts of Italy, particularly in the neighbourhood of Florence: they are kept in the shops there, and prescribed with success in fevers of many kinds, and in diarrhoeas, dysenteries, and the like cases. *Hill's Hist. of Fossils.*

EVAPORA'TION (*Dict.*)—The Evaporation of fluids is generally supposed an effect of heat, but experience proves that cold which is just a contrary cause is able also to produce the same effect, and that in a very considerable degree; the Evaporations of liquors in the severest frosts being at least equal to those when the air is in that degree which we call temperate. An ounce of water by weight being set out at six in the evening to freeze, Mr. Gauteron found that by eight o'clock the next morning, it was reduced to a solid lump of ice, and had lost twenty-four grains in weight; and, this ice being thawed into water with all possible caution, the water weighed twelve grains less than the ice. The same experiment repeated several times always gave the same phænomenon, only in different degrees; the loss of quantity being always greater, as the weather was more severe, or the wind higher. This effect is also different in different fluids. This gentleman set out to freeze at the same time an ounce of common water, the same quantity of nut oil, the same of brandy, the same of oil of turpentine, and the same of mercury. The water froze almost immediately and lost six grains in weight; and the oil of nuts in the same time lost eight grains; the brandy and the oil of turpentine lost twelve grains each; but the oils of olives and the mercury seemed rather to have increased than diminished in weight. The next morning, the loss of the water was thirty-six grains; that of the nut oil was forty grains, though it had not been frozen; and the loss of the brandy and oil of turpentine was fifty-four grains each, though neither had been at all frozen; the mercury and oil of olives remained as before. The greater cold and more rough winds always increased the Evaporation, and the lesser cold and calmer weather made it less. Water, when reduced to the state of ice, does not cease to evaporate: for this ice of an ounce of water had lost thirty-six grains from eight o'clock in the morning to three in the afternoon, and thirty-six more between that and eight at night; and during the night the Evaporation had not been continued in any less degree, and, upon the whole, an ounce of ice was found to lose by Evaporation a hundred grains in twenty-four hours.

EUO'NYMUS, *the spindle-tree*, in botany, a genus of plants whose characters are;

The calyx is monophyllous, and quinquefid, or quadrifid; the flower rosaceous, tetrapetalous, and sometimes pentapetalous, and furnished with four or five stamina. The ovary in the bottom of the calyx is furnished with a bifid tube, or pointal, and becomes an angulous, membranaceous fruit, divided into four or five cells, full of oblong seeds. *Boerhaave, Index alter, Part II.*

They say its fruit purges both upwards and downwards: the peasants make use of the powder of its fruit, to kill lice; or else wash their hair with the decoction of its seeds. *Martyn's Tournefort.*

It grows frequently in the hedges, and flowers in May. The fruit is in use, but of a noxious quality, and not to be taken inwardly without danger; externally used, it is an emollient and resolvent, kills lice, and deterges furfuraceuos heads. *Dale.*

EUPATORIOPHA'LACRON, *naked-headed agrimony*, in botany, a genus of plants whose characters are:

It is a corymbiferous plant, which in some species has radiated flowers, whose flowers are hermaphrodite, and the half-florets are female; but, in other species, the flowers are produced in a disk, and are for the most part hermaphrodite. The ovaries have naked heads, and are placed on a woolly placenta. All these parts are contained in a flower-cup, which is divided into many parts to the placenta. To these notes must be added, the leaves growing opposite on the branches.

EUPATO'RIUM, *hemp agrimony*, in botany, a genus of plant, whose characters are:

Its root is fibrous and perennial; the leaves grow two, three, or four together at intervals; the calyx is long, smooth, and scaly. The flowers form an umbella, furnished with many long bifid capillaments, or threads.

This species of Eupatorium has a spreading stringy root; from which arise reddish square stalks, two or three feet high, somewhat woolly, having at each joint two leaves, divided into three long narrow serrated hemp-like sections, green above, and whitish underneath. The flowers grow on the tops of the stalks in clusters, umbelwise, each being somewhat slender and naked, composed of several fistular flowers, of a purple colour, divided into five parts at the top, and passing away into down. It grows by rivers and ditch-sides, and flowers in July.

Schroder commends this as a very good vulnerary plant, used inwardly, but especially outwardly, useful to correct an ill habit of body, and cure coughs and catarrhs; though Gesner, upon trial, found the root to be a strong purger. It is but seldom used. *Miller's Bot. Off.*

EUPHRA'SIA, *eye-bright*, in botany, a genus of plants, the characters of which are these:

The leaves are small, conjugated, roundish, and serrated; the the flower monopetalous, anomalous, personated, bilabiated, the upper lip erect and multifid; the lower divided into three parts, each bifid; the fruit is an oblong bicapsular pod.

Eye-bright has a small woody root, full of fibres, from which springs, usually, one stalk, branched out into several smaller, somewhat of a reddish brown colour. The leaves are small, set on by pairs, opposite, without foot-stalks, hard, and veiny, roundish but indented at the ends.

The flowers grow at the tops, among the leaves, small and white, and gaping or galeated, with a yellow spot in the middle, and several black stripes running lengthways; after the flowers are fallen, come small, long, flattish seed-vessels containing very small seed. Eye-bright grows in fields and commons, and flowers in July. The whole plant is used.

This plant is famous for all disorders and distempers of the eyes, especially for dimness of sight, and to strengthen it when weak and decayed, either given in the juice, or a decoction of the powder of the leaves. A powder made of two ounces of eye-bright, and half an ounce of mace, is very much commended for the same purposes, especially after proper evacuations.

Some commend it as good against the jaundice. *Miller's Botan. Offic.*

It is very bitter, and gives a faint tincture of red to the blue paper; which makes us conjecture, that the sal ammoniac, though involved in a great deal of oil and earth, may predominate in this plant. It dissolves the humours, disposes them to circulate, and carry off the obstructing particles. Every body agrees, that it clears, strengthens, and even restores the sight. The powder is given from one drachm to three, in a glass of fennel, or vervain-water. The use of the conserve, alone, or mixed with worm-wood-leaves, continued for a long time, is good for the same purposes. Arnaldus de Villa nova, in his treatise concerning Medicinal Wines, very much commends that of eye-bright. In vintage-time they put this plant in must, and drink it, when it is well clarified. Pena and Lobel prefer the use of the powder to the wine: they affirm that one of their friends in Switzerland, who had but a slight defluxion in his eyes, had like to have lost his sight by drinking eye-bright wine, for three months. *Martyn's Tournefort.*

EXCHA'NGE.—Under this article, in the Dictionary, we have given an account of the trade of money carried on between one place and another by means of bills of Exchange; but there is another kind of Exchange extremely worth our notice and consideration, and this is a negociation by which one merchant transfers to another whatever effects he has in a foreign country, at a price agreed on.

We must particularly remark two things in the transaction of this affair, the transfer, and the value of the transfer.

The transfer is made by a mercantile contract called a letter of Exchange, which intimates the effects thereby ceded or granted.

The value of this transfer is a compensation of the value between one country and another: this they call the value of Exchange; this is divided into par and course of Exchange or currency.

An exact equality of the money of one country to that of another is the par of the value of Exchange.

When the circumstances of commerce alter the par of this compensation, the variations which result from these circumstances make and determine the course or value of Exchange.

The value of Exchange may be defined, in general, a present compensation of the coins of two countries, in proportion to their reciprocal debts.

To render what has been said more perspicuous, it will be necessary to consider Exchange in different views, and all its parts. We shall consider Exchange as a transfer which one merchant makes to another of effects he has in foreign parts, the nature, end, and consequences of it: and then explain the origin of the value of Exchange, or compensation of coins, its essence, par, currency, the propriety of this currency, and the commerce that results from it.

The first commerce among men was transacted by way of Exchange. Trade grew more extensive, and mutual wants increased with the number of commodities. Every nation soon found they had fewer commodities to exchange, than they had necessities to relieve: or, what they had to barter, was not wanted by the nation with which they trafficked. To supply their wants, and remove this inconvenience, they had recourse to some certain pieces to represent the value of merchandises.

That these pieces might be durable and capable of being divided into parts of different value without loss, they fixed upon metals, and those the most rare, to make the transfer more easy and commodious.

Gold, silver, and copper, became the mediums of buying and selling: different quantities of these metals, in every state, had a value in proportion to their weight and fineness, which every government imposed arbitrarily; every legislator stamped these bits of metal with what impression he pleased, and these pieces were called monies.

As commerce extended itself, mutual debts multiplied, by which means the transfer of these metals, in lieu of merchandises, became difficult, and men were driven to find out some method of representing monies by signs.

Every country buys in, and sells out, merchandises, and consequently fequently becomes both at once debtor and creditor: to pay these reciprocal debts, they concluded it fufficient to transfer the reciprocal credits between two countries mutually, or even between feveral countries that correfponded together. It was therefore agreed, that monies fhould be reprefented by an order which the creditor fhould give in writing to the debtor, to pay the value to the order of the bearer.

The multiplicity of reciprocal debts is therefore the origin of Exchange, confidered as the transfer that one merchant makes to another of the effects he has in a foreign country.

As Exchange fuppofes a reciprocal debet, its nature confifts in the Exchange of this debet: if the debet were not reciprocal, the negociation of Exchange would be impracticable, and the payment for the merchandifes muft neceffarily be made by a transfer of money.

The end and defign of Exchange is, confequently, to avoid the rifk, and fave the expence of transferring money.

The confequence is, that bills of Exchange reprefent money fo effectually, that there is no difference between the one and the other. An example will fet thefe propofitions in a clearer light.

Let us fuppofe Peter of London debtor to Paul of Paris for goods received, and, at the fame time, that Anthony of Paris has bought of James of London goods of an equal value: if the two creditors, Paul of Paris and James of London, exchange their debtors, a transfer of money is needlefs. Let Peter of London pay to James of London the fum he owes to Paul of Paris, and let James for the faid fum transfer to him, by an order in writing, that which he has at Paris in the hands of Anthony. Peter, the proprietor of this order, will transfer it to Paul his creditor at Paris, and Paul, on prefenting it to Anthony, will receive cafh for it.

If no merchant of Paris had owed money in London, Peter would have been under the neceffity of fending over money to Paris to pay his debt: or, if James had fold, at Paris, only to half the value that Peter was indebted there, the half of Peter's debt would have been acquitted, the other half by fending over the fpecie.

It is evident, therefore, that Exchange fuppofes reciprocal debts, that without them it could not exift, and that it confifts in the Exchange of the debtors.

The example propofed proves alfo, that the object, end, and defign of Exchange, is to fpare the hazard and expence of transferring money. Let us fuppofe the debt between the two 100l. and value the rifk and charges on merchandife in trade at 40 l. it is plain each muft pay 110l. inftead of 100 l. without an Exchange of debtors.

The confequence is alfo completely demonftrated by this example, for the bill of Exchange drawn by James of London, or Anthony of Paris, was fo effectually the fign of money, that Paul of Paris, to whom it was fent, has actually received 100 l. on prefenting it.

The part of Exchange we have defined, the transfer which one merchant makes to another of effects which he has in a foreign country, is applied to the reprefentation of metals ftamped or coined: the fecond part or value of Exchange is applied to the thing reprefented.

When gold, filver, and copper were introduced into trade to be the medium of commerce, and were converted into money of a certain denomination and weight, the coins took their denomination from their weight, that is, as among the French, the livre or pound was a pound weight of filver.

The neceffity or difhonefty of men leffened the weight of every piece of money, which, notwithftanding, retained its former denomination.

Thus, there is in all countries a real and ideal money. Ideal monies are preferved in accounts for the fake of convenience; the alterations that have happened in money, have been different, in different countries: the proportion of the weight being not always equal, no more than the intrinfic value, the denomination is often different: fuch is the origin of the comparifon we muft make of thefe monies to exchange, compenfate, or weigh them one againft another.

The greater or leffer occafion we have for this Exchange, the eafe or difficulty with which it is tranfacted, the contingencies and charges, have a value in trade, and this value has an influence which we ought to confider in the eftimation of money.

Therefore, their compenfation or value in Exchange contains two proportions, which we muft examine.

Thefe proportions conftitute its effence; for, if the monies of all countries were of the fame real value, of the fame denomination and weight, in fhort, if the particular contingencies were not eftimated in commerce, there could be no difference in current coin, and, confequently, no compenfation to make; a bill of Exchange would be fimply the reprefentation of a certain weight of filver or gold.

A bill of Exchange on Paris for 100 livres would be equivalent to 100 l. in London, which on this fuppofition are real and exactly equal.

But, in fact, the difference between the real coins of England and France, and the contingencies of commerce, will have an influence on the quantity of money of the one country, to be paid for a quantity of money of the other.

Of thefe two proportions, that, which refults from the mixture of the metals coined, is the moft effential, and the neceffary bafis of compenfation or the price of Exchange.

To find the juft proportion of the mixture of metals in both coins, we muft know the weight, the finenefs, and ideal value of each, with the greateft exactnefs; and the proportion of the weights made ufe of in each country for the weight of metals.

Silver coined in France is of the fame finenefs, as filver coined in England, that is, to 11 penny-weights fine 2 penny-weights alloy.

The pound fterling is ideal money, or a collective name which contains within its value feveral pieces of real coin; as crowns, half-crowns, fhillings, &c.

The crowns weigh each one ounce, three penny-weights, thirteen grains; the ounce Troy confifts of no more than 480 grains, therefore, the crown of 565 grains, and is worth 60 pence, or 5 fhillings.

In France, there are two forts of crowns (écus) the écu or crown in Exchange and accounts, always valued at 60 fols, or 3 livres Tournois, values equally ideal.

The fecond fort of écus or crowns, are real pieces of filver current; they are of the fame ftandard as Englifh money of the fame denomination; 16 $\frac{3}{4}$ make a marc which weighs 8 ounces, reckoning 576 grains to the ounce; they pafs current for 60 fols, but are intrinfically worth no more than 56 fols and $\frac{1}{4}$; the marc is 46 livres, 18 fols.

This difference arifes from the contingent expences of coinage, mixture, &c.

This being prefuppofed, we muft compare their weight and value, to know the proportion of the French to the Englifh crown in value.

938 Sous are the value of a marc of France, = to 8 ounces French.

The ounce of France = to 576 grains.

565 Grains, the weight of a crown, = to 60 pence fterling.

Intrinfic value = to 56 d. $\frac{1}{4}$, the intrinfic value of the écu current.

The proportion, 29 pence $\frac{1}{2}$.

The number found of 29 d. $\frac{1}{2}$ fterling, is the juft proportion of the comparifon of thefe two monies, or the par of the price of Exchange; that is, the French crown of the intrinfic value of 56 fous 6 deniers at London, is worth 29 d. $\frac{1}{2}$ fterling, but the écu in accounts of 3 livres, or 60 fous Tournois, reprefenting the real crown, its value muft be the fame.

The weight and ftandard of money evidently fix its comparative value with other money, and the proportion that indicates what quantity of the one is equivalent to the other, is the par of the price of Exchange.

We have hitherto only confidered the real par of Exchange as it relates to filver coin, becaufe that is more commonly circulated; but we fhall run into a very great error, if we form our ideas of the benefit a nation receives by Exchange, on this foot only.

It is very well known, that, befides the uniform and general proportion in all countries, between the degrees of finenefs of gold and filver, there is a particular value in every ftate fet upon thefe metals, which is regulated by the quantity that ftate circulates.

The French louis d'or and our guinea are of the fame finenefs; the guinea weighs 156 grains, and is worth 21 fhillings, or 252 pence fterling: the louis d'or weighs 153 grains, and confequently is worth 247 pence $\frac{1}{7}$ Englifh; now in France 8 écus are change for a louis d'or, the écu we have demonftrated to be worth no more than 29 d. $\frac{1}{2}$ eight times which fum amounts to no more than 236 pence fterling, yet, thefe eight crowns, reprefented by a louis d'or, are apparently worth 247 pence $\frac{1}{7}$ fterling. The difference is 4 pence $\frac{1}{7}$ fterling, and it is evident, that, if this be divided among the écus in Exchange of the louis d'or, each écu muft be valued at 30 pence $\frac{1}{10}$ fterling, inftead of 29 pence $\frac{1}{2}$.

This difference arifes from this caufe: in France, they give 153 grains of gold for 2216 grains of filver, the weight of eight crowns, which fettles a proportional value between thefe metals in the ratio of 1 to 14 $\frac{7}{15}$. In England we give 156 grains of gold for 21 fhillings, each fhilling weighs 113 grains, and they in all amount to 2373 grains, which is in the proportion of 1 to 15 $\frac{1}{5}$.

Wherefore, if a Frenchman pays cafh in England, it will be to his advantage to pay it in gold; but it is the intereft of an Englifh-man to pay cafh in filver in France; becaufe the guinea is worth no more than 22 livres, 14 fous, 7 den. French, whereas twenty-one fhillings, the value of a guinea, weigh 2373 grains, and are worth 24 livres, 2 fous, 10 den.

Different contingencies alter the price of Exchange from the real par: and, as thefe accidents have an infinite variety, the alteration of the equality is continually floating up and down; this alteration is called the courfe of Exchange.

The caufes of the alteration of the par of Exchange, are the alteration of public credit, and the abundance or fcarcity of credits of one country upon another.

A variation in the current coin is an example of the variation which the lofs of public credit makes in the par of Exchange; although, at the very inftant this change was made in the current coin, a new real par of Exchange commenced, yet, the public credit declining, on account of the uncertainty of the property and the ſpecie not circulating, what repreſents the ſpecie muſt of courſe be under its value.

The ſecond cauſe of the alteration of the par of Exchange, is the abundance or ſcarcity of credits of one country upon another; and this abundance or ſcarcity proceed in general from two cauſes.

One is the neceſſity that obliges the body politic of a ſtate to tranſport large ſums into foreign countries, as in caſe of a war.

The other lies in the proportion of the current mutual debts of private perſons in each ſtate.

The private perſons of two nations may contract two kinds of reciprocal debts.

The inequality of reciprocal ſales will form a firſt kind of debts.

If one of the two nations has a great deal of money at lower intereſt than the other, the rich private perſons in the former nation will buy up all the public ſecurities of the other, becauſe they will receive more intereſt for their money: the product of this intereſt, which muſt be paid every year, forms a ſecond ſpecies of debts: this may be looked upon as the product of a commerce, becauſe the national funds are negociated; and, if you obſerve attentively, this is not a matter of ſpeculation only; in this caſe and ſeveral others, money is the merchandiſe, and thus theſe two debts belong properly to what is called the balance of trade, and will occaſion an abundance or ſcarcity of the credits of one country upon another. See BALANCE *of trade*.

When two nations would ſettle the balance of their commerce, that is, pay their reciprocal debts, they have recourſe to the Exchange of debtors; but, if the reciprocal debts are not equal, the Exchange of debtors will only pay a part of theſe debts, the ſurpluſage or balance of trade muſt be paid in ſpecie.

The deſign and intention of Exchange is to ſave the expence and hazard of tranſporting money; conſequently, every private perſon, before he determines on this method of trade, will ſeek credits on the country where he ſtands indebted.

Theſe credits will be dear in proportion to the difficulty of acquiring them, and conſequently, to have the preference, we are obliged to pay above their real value; if the credits are eaſy to come at, we ſhall pay under their value.

Let us ſuppoſe the merchants of Paris owe the manufacturers of Rouen 20,000 livres, and that the manufacturers of Rouen owe the bankers of Paris 10,000 livres; to ſatisfy theſe demands, we muſt make a bill of Exchange for the 10,000 livres, the reciprocal debts between Paris and Rouen, and ſend the other 10,000 livres from Paris to Rouen.

Let us rate the charge and hazard of ſending this ſum at five livres per m. Every merchant in Paris will try to ſave this expence, and will ſeek to purchaſe a credit of a 1000 livres on Rouen; but as theſe credits are ſcarce, and difficult to procure, he will gladly give 1004 livres for a draught of 1000 livres on Rouen, and ſave one livre per m. thus the ſcarcity of bills of Exchange on Rouen will lower the price of this Exchange four livres per m. under par.

It is proper to obſerve, that the riſe and fall of Exchange is always underſtood of the country on which we draw. Exchange is low, when this country pays leſs real value for the bill, than it coſt the purchaſer: Exchange is high, when this country pays more real value for the draught, than it coſt the purchaſer.

The par of Exchange between London and Paris is at 29 ½ d. per écu of three livres; if the Exchange at London drops to 29 pence, London will pay beneath the intrinſic value of the écu; if the Exchange riſes to 30 pence per écu, London will pay above its real value.

To reſume the foregoing example, it has been ſhewn from the ſcarcity of credit on Rouen, a merchant at Paris is obliged to pay 1004 livres for a draught, to receive 1000 livres at Rouen.

Juſt the reverſe of this is the caſe of Rouen; credits on Paris are frequent and numerous; the manufacturers of Rouen who owe money at Paris, will give orders to the banker of Paris to draw upon them, becauſe they know that, for 1000 livres on Rouen, they ſhall pay 1004 livres at Paris: or, if you offer them draughts on Paris, they will purchaſe them at the ſame præmium as the draughts on Rouen are at Paris, which will raiſe the Exchange in favour of Rouen to four livres per m. which will therefore pay no more than 996 livres. When the reciprocal debts are paid, Paris muſt ſend to Rouen the remainder of the balance in ſpecie. But in the mean time it is clear, that, in the payment of the reciprocal debts, Rouen pays 1000 livres with 996, and Paris pays 1004 livres for 1000.

If Exchange ſubſiſts long on this foot between theſe two cities, it is evident, that Paris owes more to Rouen, than Rouen owes to Paris.

From whence we may conclude, that the courſe of Exchange indicates which ſide the balance of commerce inclines to.

We have already ſeen that the par of the price of Exchange is the compenſation of the monies of two countries; this compenſation is made uncertain by ſeveral accidents, and is therefore only momentaneous: its courſe indicates which ſide the balance of commerce inclines to; thus the price of Exchange is a momentaneous compenſation of the monies of two countries in proportion to their reciprocal debts.

As the nature of the accidents in trade which alter the par of the compenſation of monies, or price of Exchange, continually varies, the courſe or price of Exchange varies with theſe accidents.

The fluctuation of the courſe of Exchange has two effects. Firſt, it makes a daily uncertainty what quantity of money one ſtate muſt pay to another for ſuch a quantity of money of another ſtate. Secondly, it occaſions a trade of money by repreſenting the ſpecie by bills of Exchange.

When the quantity of money which one ſtate gives in compenſation for ſuch a quantity of money in another ſtate, is undetermined from one week to another: it follows that of theſe two ſtates one propoſes a certain, the other an uncertain value; becauſe every proportion ſuppoſes an unity as the common meaſure of both the terms of this proportion, and which ſerves to value it by.

Let us ſuppoſe that London to-day gives thirty pence ſterling for an ecu of Paris, it is certain Paris will always accept thirty pence for an écu, but it is uncertain whether London will continue to give ſo much. In terms of Exchange, this is called giving the certain or uncertain.

If the quantities were certain on both ſides, there would be no variation in the par of Exchange, and conſequently no courſe of Exchange.

This difference is introduced into every country; according to the different method of keeping their accounts; they fix a quantity, the valuation of which ſerves for a ſecond term, to find the value of another quantity of the ſame kind as the firſt. As, for example, if one écu or French crown be worth thirty pence ſterling, what are 100 worth at the ſame rate? Thus, between two places, one ought always to propoſe a certain quantity of its money, for an uncertain quantity which the other ſhall give it.

But, while one place gives the certain to one other place, it ſometimes gives the uncertain to a third. Paris gives the certain to London, that is, an écu to have from 29 pence halfpenny to 33 pence ſterling: but Paris receives from Cadiz a piaſtre for an uncertain quantity of ſous from 75 to 80 per piaſtre, as the accidents of commerce ſettle the value.

The ſecond effect of the fluctuation of the courſe of Exchange, is a trade of money carried on by repreſenting the ſpecie by bills of Exchange.

The merchant or banker is continually attentive to every alteration in the courſe of the price of Exchange, between the different places that have a mutual correſpondence; he compares theſe changes with each other, and conſiders what is the reſult; he ſeeks into the cauſe of them, to foreſee their conſequences, and by theſe means is enabled to make the moſt of his credits. But this is not the ſole object which ought to employ the views of the merchant; before he ſells his credits in any place, he ought to conſider the profit or loſs there will be in withdrawing his effects from this place; if the courſe of the price of Exchange is not in favour of the place of his reſidence, he will ſeek ſome other methods more lucrative, and his money will be returned by different channels. The knowledge of this trade conſiſts therefore in laying hold on all the advantageous inequalities of the par of Exchange, which offer between two cities, and theſe two cities and others: for, if five places of trade differ between each other in the ſame proportion with regard to the par of Exchange, no gain can be made by this commerce with them, the intereſt of money and expence of commiſſion would turn to nett loſs. This reciprocal equality between the courſe of the price of Exchange of ſeveral places is called the political par.

If we agree about this parity

$$a = b$$
$$b = c$$
$$c = a$$

It is certain that, a, b, &c. being equal quantities, there can ariſe no benefit by exchanging one with the other, which correſponds with the real par of the price of Exchange; let us ſuppoſe now

$$a = b$$
$$b = c$$
$$c = a + d$$

Here the parity is deſtroyed, we muſt Exchange b with c, which will give $a + d$: now, we have ſuppoſed $a = b$, therefore, the profit of this Exchange will be d. This difference correſponds with the inequalities of the courſe of Exchange between two or more places: the parity will be re-eſtabliſhed, if theſe quantities are increaſed equally

$$a + d = b + d$$
$$b + d = c + d$$
$$c + d = a + d;$$

This parity correſponds to the political par of the price of Exchange or equality of its courſe among ſeveral places.

The parity will be altered again, if

$$a + d = b + d$$
$$b + d = c + d$$
$$c + d = a + d + f;$$

In this caſe the Exchange muſt be made as before, and the

profit

profit of $b + d$ will be f; if, cæteris paribus, $a + d - f = c + d$, and we Exchange these two quantities, it is evident the proprietor of $c + d$ will receive less the quantity f: therefore, to avoid this loss, he will Exchange $c + d$ with $b + d$, which is equal to the quantity $a + d$.

The operation of Exchange consists in changing quantities one for another; he that is forced to Exchange a quantity for another quantity less than his own, seeks a third that may be equal to his, and reputed equal to that for which he is forced to make the Exchange, to prevent his own loss; he that deals in this commerce, endeavours to Exchange lesser for greater quantities, and his gain is consequently the excess of the quantity which different Exchanges have procured him, in his own country, on the quantity he has furnished abroad.

This commerce is not lucrative, unless it be more beneficial than putting the money out to interest at home; from whence follows this consequence, that those people among whom the interest of money is lowest, must have the balance of this trade against another nation which pays higher interest for money.

If the people which pay the lowest interest have plenty of money, an intercourse of this trade must be very prejudicial to the other people, and the latter cannot bring foreign wealth into their dominions by this method.

This trade does not principally tend to increase the quantity of money in a nation, but is more connected with the political springs of government, and requires more refined judgment than any other. It results from the continual variations in the price of Exchange, on account of the disparity of the mutual debts between different countries; as Exchange itself owes its rise to the multiplicity of mutual debts.

From what has been said on the nature of Exchange, we may draw the following general principles.

1. We shall know whether the general balance of trade has been in favour of a nation for some time, by the mean course of its Exchanges with other nations for the same space of time.

2. Every Excess of the reciprocal debts of two nations or the balance of trade ought to be paid in money, or by credits on a third nation, which is always a loss, because the money that ought to be returned is carried elsewhere.

3. That nation, which is debtor to the balance loses by an Exchange of debtors a part of the profit it might have by sales, besides the money it must part with to satisfy the balance of the mutual debts: and that nation which gives the credit, gains, beside the money, a part of the mutual debt by the Exchange of debtors.

4. If one nation is so much indebted to another, that the debt has effect sufficient to lower the course of Exchange, it will be more beneficial to that nation to export cash in specie, than augment their loss by trading in bills of Exchange.

EXCRE'SCENTIA *faba Bengalensis*, Bengal bean.—It is round, flat, wrinkled, and hollowed in the manner of an umbilicus, large, brown on the outside, and blackish within, of a styptic and astringent taste, and no smell.

It is a powerful astringent, and highly serviceable in repressing all sorts of hæmorrhages, particularly a spitting of blood, moderately incrassating the blood, and shutting the mouths of the veins and arteries, consolidating ruptures, and tempering and allaying acrimonious and corrosive humours.

D. Marloe, who gives the foregoing account of its virtues, was the first, as far as I know, says Dale, who communicated this exotic medicine, with its uses, to the learned world, under the name of faba Bengalensis. Hence some took it for a fruit which comes from Bengal, others for a species of myrobalans, and others again for the flower of the citrine myrobalan; because it is very often found among those fruits. But to me, says Dale, it seems to be a kind of excrescence excited by the puncture of a certain insect, or, more properly, the wounded fruit itself of the citrine myrobalan, which, from the venom of the stroke, assumes this monstrous form. I have very often myself, he says, observed plums deprived of their natural shape by a wound of this nature inflicted by an insect, and rendered hollow, without any stone. *Dale.*

EXCU'TIA *ventriculi*, a name, by modern surgeons, given to that instrument represented in *Plate* XX. *fig.* 1. It is generally made of soft bristles formed into a bundle, and fixed to a flexible brass or iron wire B B B, which may have flaxen or silken thread closely wrapped about it. Authors of very considerable note assert, that this instrument is highly commodious, not only for removing small bones from the fauces, but also for cleansing the stomach. When it is to be used for this latter purpose, they lay down the following directions, as necessary to be observed: a small draught of warm water, or, according to others, of brandy, is to be taken before the instrument is used; since, by this means, the mucus and sordes are the more easily resolved and attenuated in the stomach. Then the Excutia A is to be immersed in some proper liquor, and, by means of the wire BB, gently passed through the œsophagus, as far as the stomach. Then it is to be moved up and down through the fauces, like the sucker of a siphon or pump, but must be soon totally extracted. These authors order the Excutia, and repeated draughts of the above-mentioned liquor, to be used, till no more sordes can be brought away from the stomach. This practice is, according to them, so highly beneficial, that by its means the lives of men may be protracted to an uncommon age, especially if it is repeated every week, every fortnight, or every month. However great the encomiums bestowed on this practice may possibly be, yet, it is certain, we have very few instances of cures happily brought about by its means; since the sense of pain, and the danger of suffocation, attending the use of this instrument, must certainly create a just aversion to it. But these points are at greater length discussed by Wedelius and Teichmeierus, in their Disputationes de Ventriculi Excutia. These authors have also shewn, that this is not altogether an instrument of modern date, but long ago described by some authors. *Heister. Chirurg.*

EXO'MPHALOS (*Dict.*)— This rupture is owing to a protrusion of the intestine, or omentum, or both of them, at the navel, and rarely happens to be the subject of an operation; for, though the case is common, yet most of them are gradually formed from very small beginnings, and, if they do not return into the abdomen upon lying down, in all probability, they adhere without any great inconvenience to the patient, until some time or other an inflammation falls upon the intestines, which soon bring on a mortification and death; unless, by great chance, the mortified part separates from the sound one, leaving its extremity to perform the office of an anus: in this emergency however, I think it adviseable to attempt the reduction, if called in at the beginning, though the universal adhesion of the sac and its contents are a great obstacle to the success: the instance in which it is most likely to answer, is, when the rupture is owing to any strain, or sudden jerk, and is attended with those disorders which follow upon the strangulation of a gut.

In this case, having tried all other means in vain, the operation is absolutely necessary; which may be thus performed: make the incision somewhat above the tumor, on the left side of the navel, through the membrana adiposa; and then emptying the sac of its water, or mortified omentum, dilate the ring with the same crooked knife, conducted on your finger; after this, return the intestines and omentum into the abdomen, and dress the wound without making any ligature, but of the skin only. *Sharp's Surgery.*

EXPE'CTORANTS (*Dict.*)— Among the several species of evacuants, none are, perhaps, of more importance than those which eliminate the viscid lymph secreted from the arterial blood, and remaining in the glands, or rather the glandulous coats and emunctories. But in no part of the body is there a larger secretion of mucous lymph than in the internal ducts of the aspera arteria, and the bronchia of the lungs, which are internally lined with a glandular coat: hence, very often a serous, pituitous, viscid, and, sometimes, a purulent matter, is, in coughing, expectorated, and especially in disorders immediately affecting the lungs, whether of the acute or chronical kind. The medicines which promote this evacuation from the cavity of the thorax are called Expectorants; of which, the most considerable in the vegetable kingdom are, the roots of elecampane, arum, Florentine orris, and liquorice; the herbs Paul's betony, chervil, scabious, mouse-ear, germander, hyssop, and the tarragon; the flowers of violets, mallows, red poppies, and saffron; the seeds of anise and fennel; the bark of sassafras; and, among resinous gums, benjamin and gum ammoniac; among fruits, raisins, figs, jujubes, and pine kernels; honey, liquorice-juice, and oil of sweet almonds; among animal substances, sperma ceti and fats; among mineral substances, sulphur, together with its flowers and milk; among compound substances, the anisated balsam of sulphur, the anisated spirit of sal ammoniac, the lohoch sanum, the syrup prepared of the lungs of a fox, the pectoral elixir, the pectoral balsam of Meibomius, and the asthmatic spirit of Michaeli.

As all substances which promote excretion do not operate in the same manner, since some render the matter moveable, and dispose it for evacuation; others open the emunctories, that it may be separated from the juices; and others stimulate the vessels and ducts to an excretory motion; so Expectorants operate pretty much in the same manner; for, if the humour secreted is thin and acrid, and the ducts and pores of the glands from which it is to be thrown, too much constricted, those substances are most properly exhibited, which soften the passages, obtund the acrimony, and coagulate the too thin and fluid parts of the humours. These intentions are best answered by the juice of liquorice-root, saffron, sperma ceti, the flowers of violets, mallows, and red poppies, cream, oil of sweet almonds, fats of animals, syrup prepared from the lungs of a fox, the syrup of violets, the syrup of white poppies, and the pilulæ de styrace, especially exhibited with some diluting liquor, such as a decoction of oats, or of the shavings of hartshorn, in the form of a jelly. But, when a large quantity of thick and viscid matter is lodged in the bronchia of the lungs, it proves prejudicial to respiration, and when, for this reason, some stimulus to expectoration becomes necessary, the tough and viscid matter is excellently resolved by infusions of Paul's betony, hyssop, scabious, and germander; as, also, by the terra foliata tartari, a solution of crabs eyes, and antimoniated nitre. The nervous coats of the bronchia are stimulated to an excretory motion by a certain acrid, subtile, and oleous principle found in gum ammoniac, and its essence, the anisated ſpirit of ſal ammoniac, myrrh, benjamin, powder of the roots of elecampane, and Florentine orris, flowers, milk, and balſam of ſulphur. When a ſtronger ſtimulus is required, as in a pituitous aſthma, and a ſuffocative catarrh, oxymel of ſquills, or the ſpiritus aſthmaticus of Michaeli, which is prepared of gum ammoniac and the green cryſtals of copper, may be exhibited.

In the exhibition of Expectorants, great caution is to be uſed on account of their different methods of operation; and the phyſician who preſcribes them promiſcuouſly, without any regard to time, or the ſtate and condition of the peccant matter, certainly does more harm than good: hence, when in epidemical coughs, raging in the ſpring and autumn, highly ſtimulating Expectorants are exhibited, before the thin acrid matter is corrected; or, on the contrary, when after the matter is concocted and prepared, emollient and relaxing medicines are exhibited; more harm than good is produced by ſuch pieces of practice.

In coughs of the moiſt and chronical kind, as alſo in a pituitous aſthma, in which large quantities of phlegm fall into the bronchia of the lungs, ſweet ſubſtances, linctuſes, ſyrups, and oleous medicines, weaken the ſtomach, whoſe ſtrength is already too much impaired, diminiſh the appetite, digeſtion, and chylification, and not only promote the generation of more recrementitious matter, and the increaſe of the diſeaſe, but alſo diſpoſe the patient to a cachexy, œdematous tumors, or even a dropſy. In theſe caſes, it is therefore more expedient to uſe balſamic pectorals, which are grateful to the ſtomach, ſuch as the pectoral elixir, the eſſences of myrrh, gum ammoniac, and the tincture of tartar.

Expectorants ought alſo to be cautiouſly uſed in a phthiſis and ſpitting of blood; as alſo in dry coughs, difficulties of breathing, and oppreſſive pains of the breaſt, which rather ariſe from a congeſtion of blood, than matter to be expectorated; ſince, in theſe caſes, Expectorants, either by ſoftening or ſtimulating, augment the congeſtion of blood and humours, inſtead of removing it.

In acute diſorders of the breaſt, ſuch as a legitimate pleuriſy and a peripneumony, Expectorants are alſo to be cautiouſly uſed, eſpecially in the beginning, leſt by their means the inflammatory ſtagnation of the blood ſhould be increaſed. But when theſe diſorders are on the decline, and when the greater part of the inflammation is diſcuſſed, they are very properly and commodiouſly uſed, in order to draw the concocted and viſcid matter out of the pulmonary canals. *Frederic. Hoffman. Medicina Rationalis Syſtematica.*

EXPORTATION (*Dict.*)—The obvious meaſures, requiſite to promote the Exportation of produce and manufactures, may be comprehended under the following particulars:

1. That our lands be cultivated in ſuch quantities, as to render all the neceſſaries and conveniencies of life as cheap as they are in thoſe nations who are ſtruggling to rival and ſupplant us in our commerce and navigation.

2. To this end, that all taxes and incumbrances whatſoever, as ſoon as may be done with ſafety, be taken off from the neceſſaries and conveniencies of life, that our people may work as cheap as thoſe of other nations, and our commodities be carried to foreign markets as cheap as they do, and, if poſſible, better in quality for the price.

3. That reaſonable public encouragement be given to thoſe who ſhall make any capital improvements in huſbandry, farming, and agriculture, &c. ſo as to afford not only our native productions deſirably cheap, but to promote the cultivation of ſuch valuable exotics as our lands will admit of, in order to make merchandize of them to ſome other nations.

4. That all reaſonable public encouragement be given to thoſe who ſhall make any material diſcoveries in the mechanical and manufactural arts, either by improvements in the old commodities, or by the invention of new, whereby general induſtry may be promoted, and our traffic and navigation with foreign countries advanced.

5. That working, mechanical, and manufacturing ſchools be eſtabliſhed for children over the kingdom, in order to prevent ſloth, debauchery, and villainy, by habituating infants from their cradle to honeſt induſtry, and hereby to render labour in general cheap throughout the kingdom.

6. That all meaſures be taken to render the kingdom populous in uſeful artiſts and manufacturers, and ſeamen, more eſpecially in our own natives.

7. That our fiſheries of every kind be promoted to the utmoſt extent which they will admit of, as a nurſery to our ſeamen, as well as for the benefit of our traffic.

8. That we import rather foreign materials for manufactures, than things manufactured.

9. That we prevent the Exportation of ſuch quantities of wool as may injure our own woollen manufactures; and that every meaſure may be uſed to work up the whole of our wool, by the improvement of new kinds of woollen manufactures; as thoſe with wool and ſilk, wool and cotton, wool and linen, wool and hair, &c. and to apply the material of wool to whatever elſe it will admit of, eſpecially in the lieu of any general manufacture, wrought with foreign materials: ſuch, for example, as woollen hats for men, which, doubtleſs, might be properly ſtiffened for the purpoſe; woollen hats for the ladies, woollen wigs for labourers, &c. which not only might become generally faſhionable at home, and in our own plantations among the lower claſs of people, but might, perhaps, be exported in large quantities to other countries. In ſhort, to promote whatever manufactures could be thought of, whereby all the wool produced in Great Britain could be worked up; which ſeems the moſt natural and the moſt effectual way to prevent its being ſent abroad, to the detriment of our woollen manufactory at home.

10. That encouragement be given to thoſe who ſhould be inſtrumental to improve our fineſt wool in certain counties, that it may effectually anſwer the end of Spaniſh wool, ſo that we may have no occaſion to import the ſame from that kingdom; eſpecially ſince they have ſtole away our woollen manufacturers, ſhip-builders, and divers other artizans, in order to raiſe their own trade upon the ruin of our's, if they can.

11. That the produce of ſilk be duly encouraged in thoſe our plantations which may be proper for it, and that our own ſilken manufactures be preferred in our general wear to thoſe of foreigners.

12. That the trade of our colonies and plantations be improved to the utmoſt, ſo that they do not interfere with the commerce of their mother country; but that they be ſo regulated as to enable us to rival our competitors in ſuch branches as they are able to outdo us in.

13. That a ſtanding committee of trade be appointed by parliament, compoſed of perſons well verſed therein, whoſe buſineſs ſhould be conſtantly to conſider the ſtate thereof, and to find out ways and means to improve it; to enquire how the trades we carry on with foreign countries, grow more or leſs profitable; how, and by what means, we are outdone by others in the trades we drive, or hindered from enlarging them; what is neceſſary to be prohibited, both with regard to our exports as well as imports, and for how long time; to hear complaints from our factories abroad, and to correſpond with our miniſters there, in affairs relating to our trade, and to repreſent the reſult of their enquiries to parliament, with their opinion, what courſes may, from time to time, be proper to be taken for its encouragement; and to repreſent what bounties and drawbacks, &c. may be neceſſary for the advancement of particular branches. That this committee enquire into all the improvements that ſhall be made for the benefit of trade, and lay them before parliament; and that ſuch artiſts may be rewarded, at the public expence, according to their merits.

14. That proper treaties of commerce be made with nations, that may prove mutually and laſtingly beneficial.

15. That our merchants who export our product and manufactures, be ſecured in their foreign traffic, and the payment of their cuſtoms made as eaſy to them as poſſible. That good convoys and good cruizers, in time of war, be provided for the ſafety of their ſhipping and merchandizes, to the end that aſſurance may be kept low, and our merchandize come as cheap as poſſible to foreign markets, as well in times of war as peace.

16. That courts merchant be erected in the kingdom, conſiſting of able and experienced traders, for the ſpeedy deciding of all differences between merchants, relating to maritime and other commercial affairs.

EXTENSION *of fractured limbs*, in ſurgery. When the fractured bones maintain their natural ſituation, the ſurgeon has nothing to do but to apply a proper bandage to keep them in it; but, when the fractured parts recede from one another, ſome degree of Extenſion is neceſſary, which muſt always be ſuited to the diſtortion of the limb. The greater diſtance there is between the extremities of the divided parts of the bone, ſo much the ſhorter will the limb become from the natural contraction of the muſcles, and the Extenſion muſt be proportionably the greater; but, in theſe caſes, every thing is to be done tenderly, and with great care. 1. The patient is to be kept very firm and ſteady; the poſture of the body muſt be, in this operation, different, according to the different circumſtances of the caſe; ſometimes ſitting, and ſometimes lying, are the moſt proper. 2. An aſſiſtant muſt ſupport the limb with his hands, both above and below the fractured part. 3. The perſon who holds the lower part of the limb, muſt extend it ſtrongly and equally, till the fractured bone can be replaced; but when the ſurgeon is called at ſome diſtance of time from the accident, and a tumor and inflammations are come on, it is beſt, in ſuch caſe, to defer the Extenſion of the parts till theſe ſymptoms are removed, by letting blood, looſening the bowels, giving the patient large quantities of aqueous fluids, and preſcribing the proper internal remedies for abating inflammations, and fermenting the parts with warm diſcutient decoctions. Theſe applications will uſually ſucceed ſo well as to take down the inflammation, in twenty-four hours, in ſuch a manner, that the Extenſion of the limb may be ſafely attempted; but, when they do not take place ſo ſuddenly, they are to be repeated till they have the deſired effect; and, when the common fomentations fail, the following has often very great and happy ſucceſs: take two or three handfuls of ſcordium, and boil them for about a quarter of an hour in a pint of water, with ſix ounces of rectified ſpirit of wine; afterwards mix

mix with it an ounce of common salt, and half an ounce of salt-petre, and use this to the inflamed fractured limb. To make the proper Extension of a limb, the surgeon must, while it is kept at its proper length by two assistants, direct it with his hands, sometimes a little one way, and sometimes another, putting it into different positions, as the nature of the case shall require, till the parts have recovered their natural situation. This will be known by the remission or absence of pain, and by observing, that the fractured limb is of the same length as the sound one; and, if these signs of success in the operation are wanting, there is great reason to suppose that the operation is as yet ineffectual, and the Extension is to be repeated, or continued, till the bones are evenly and properly replaced. *Heister's Surgery.*

EXTRA'VASATED *blood.* In the contusions, fissures, depressions, fractures, and other accidents of the cranium, one or more of the blood vessels distributed on the dura mater are frequently divided. The blood that is discharged from these vessels greatly oppresses the brain and disturbs its offices, frequently brings on pains and other mischiefs, and often death itself, unless the patient be timely relieved. If the quantity of Extravasated blood be ever so small, it will certainly corrupt, and affect the meninges, and the brain itself, with the same disorder; and from hence will proceed violent inflammations, deliriums, and ulcers, and finally death; and this will frequently be the case, after a violent blow upon the cranium, though the bone should escape without injury. In these injuries of the head, the blood is spilt either between the cranium and the dura mater, or between the dura and pia mater, or between the pia mater and the brain; or, lastly, into the sinuses of the brain. Either of these cases is attended with very great danger, but, the deeper the extravasation happens, so much greater must the danger be. Blood Extravasated in the cavity of the cranium will be discovered from the violence of the symptoms that succeed a blow on the head; as if the patient lies still without sense or motion, if blood flows from the mouth, ears, or nose; if the eyes are much inflamed and swelled; if vomitings succeed; when, upon the remission of these symptoms, the patient complains of a remarkable heaviness of head, sleepiness, vertigo, blindness, spasms, and disorders of this kind. When the quantity of Extravasated blood on these accidents is very considerable, and oppresses the cerebellum, the patient dies upon the spot; but, when it is not in a very large quantity, or does not affect the cerebellum, life still remains, but the symptoms just mentioned come on. In this case, if no fissure or contra-fissure is to be found, nor any external injury on the integuments of the head after a violent blow, it proves very difficult to find in what part of the head the extravasation is seated. It will be proper in this case first to shave the head all over, and then thoroughly to examine it; for, if any part is softer than ordinary, or is enlarged, or red from stagnating blood, it is plain that this is the part that has received the injury. But, if neither this way, nor by enquiry among the persons present at the accident, you can get light into the affair, it will be proper to cover the whole head with an emollient plaister, laying over it medicated bags of herbs, &c. well heated. This application will in a few hours time produce a tumor and softness upon the injured part. Sometimes the patient also, though he lies speechless, and seemingly senseless, will be continually putting his hand to the injured part; and, if either side of the patient has lost sense or motion, and is become paralytic, it is an apparent sign, whatever some might think to the contrary, that the injury has been received on the contrary or sound side. If after accidents of this kind you can discover any wound in the skin, that must be enlarged with the knife till the injury on the cranium, of whatever kind it be, is come at.

When the seat of the injury is discovered, the first intention is to discharge the Extravasated blood, and then to clean the wound, and remove all splinters, or extraneous bodies. Some have recourse on these occasions to the instant use of the trapan; but patients have been often very successfully recovered without it. It is therefore best first to open a vein, and take away as much blood as the strength of the patient will permit; this will take off the impetus of the vessels, and prevent the extravasation of more blood. Prescribe after this a brisk purge to lessen the quantity of the fluids; foment the head with medicated bags, and apply a melilot plaister to it; endeavour to rouse the patient by volatile applications to the nostrils, such as sal volatile, spirit of sal armoniac, or spirit of hartshorn; and give frequently attenuating fluids, such as the decoctions of betony, sage, rosemary, lavender flowers, sassafras, and the like. This method does not immediately produce the desired effect, but is to be continued for some time, and the prescriptions frequently repeated, particularly when the bad symptoms seem by degrees to abate; and, if the patient find relief from the first bleeding, it will be proper to repeat it a second or third time, especially if he be of an athletic constitution. When, notwithstanding this method, the symptoms are found however rather to increase than abate, it will be necessary to make a perforation in the cranium with the trapan, to give a passage for the discharge of the confined grumous blood; and, when there is no finding out the part affected, the skull must be perforated in several parts till the right is found. *Heister's Surg.*

EYE (*Dict.*)—If the humours of the Eye decay by old age, so as by shrinking to make the cornea and coat of the crystalline humour grow flatter than before, the light will not be refracted enough, and for want of a sufficient refraction will not converge to the bottom of the eye, but to some place beyond it; and, by consequence will paint in the eye a confused picture; and, according to the indistinctness of the picture, the object will appear confused. This is the reason of the decay of sight in old men, and shews why their sight is mended by spectacles. For the convex glasses supply the defect of plumpness in the Eye, and by increasing the refractions make the rays converge sooner, so as to convene distinctly at the bottom of the Eye, if the glass has a due degree of convexity.

And the contrary happens in short-sighted men, whose Eyes are too plump. For, the refraction being now too great, the rays converge and convene in those Eyes before they come at the bottom; and, therefore, the vision caused thereby will not be distinct, unless the object be brought so near the Eye as that the place where the converging rays convene may be removed to the bottom; or that the plumpness of the Eye be taken off and the refraction diminished by a concave glass, of a due degree of concavity; or, lastly, that by age the Eye grows flatter till it comes to a due figure. For short-sighted men see remote objects best in old age, and therefore they are accounted to have the most lasting eyes.

In determining the magnitude of pictures upon the retina, only one ray in each pencil need be considered; because, when the picture is distinct, all the rays in any one pencil are collected to one and the same point of the retina. Or, which is much the same, we may suppose the pupil of the Eye contracted to a point: and, for greater simplicity and ease of the imagination, that this point O is a little hole at the center of a dark hollow hemisphere, *Plate* XX. *fig.* 2. admitting only single rays straight through it without any refraction at all. For then the length of these pictures pqr will increase and decrease as the angle pOr does, or as the angle POR does; which I am going to shew to be the property of the natural Eye: and, if the semidiameter Oq, of this hollow hemisphere, be about five eighths of an inch, or if the axis of an human Eye, the pictures of the same objects will always have the same bigness in both sorts of Eyes, very nearly.

The diameters or lengths of the pictures of objects upon the retina are measured by, or proportionable to, the angles which the rays that come from the extremities of the object do make in falling on the Eye, provided those angles be but small. For let two or more objects, *fig.* 3. and ϖx, either parallel or oblique to each other, subtend the same angle POQ, or $\varpi O x$ at O; and, because the particles of light flowing from P and ϖ describe the same line $P\varpi O$, they will be refracted to the same point p upon the retina; and in like manner those that flow from Q and x will be refracted to the same point q; and so the picture pq of the objects PQ, ϖx, which subtend the same angle at O, are the same in magnitude; which was the first thing to be proved.

Now the pictures of objects painted upon the retina of a dead Eye are found by experience to be perfectly well shaped and proportioned in their parts; that is, the proportion of the parts pq, qr, of the whole picture pqr, is the same as that of the parts PQ, QR, of the whole object PQR; and this latter proportion is very nearly the same as that of the angles POQ, QOR, subtended by the parts PQ, QR; and so the proposition is proved, when the objects PQ, QR, are both at the same distance from the Eye. And, since it was shewn just before that the objects PQ and ϖx have the same picture pq, it follows that the proportion of the pictures of the objects ϖx and QR is the same as that of the angles $\varpi O x$, QOR, subtended by them at the Eye.

When an object approaches towards the Eye, the diameter of its picture upon the retina increases in the same proportion as the distance between the Eye and the object decreases; and, on the contrary, it decreases in the same proportion as that distance increases. For the diameter of its picture increases in the same proportion as the angle increases, which the object subtends at the Eye; and this angle, when small, increases in the same proportion as the distance between the Eye and object decreases.

The degree of brightness of the picture of an object painted upon the retina continues the same, at all distances between the Eye and the object; provided none of the rays be stopped by the way, and that the pupil does not alter its aperture. For instance, when the Eye approaches as near again to the object, the picture upon the retina becomes double in length and double in breadth, and consequently quadruple in surface; for the surface would be double, if its length alone or breadth alone was double. The quantity of rays received through the same aperture of the pupil, at half the distance from the object, is also quadruple; and, being equally spread over four times the quantity of surface of the retina, they are just as dense as before, when the object was at twice the distance.

It

It follows then that the faint appearance of remote objects is owing to the opacity of the atmosphere, which hinders part of their light from coming to the Eye. Accordingly we find that the sun, moon, and stars appear very faint, when near the horizon, and brighter continually, as they rise higher; because the tract of vapours, which lies in the way of the rays, is longest and thickest near the horizon; and becomes thinner and shorter, as the objects rise higher, and consequently does less obstruct the passage of the rays.

The sensibility of the Eye, or its power to discern objects without inconvenience, by different quantities of light, is vastly extensive. For instance, the disproportion in the quantities of light, cast upon the horizon by the sun and moon, at any equal altitudes, I find no less than 90 thousand to 1, when the moon is full; or no less than 180 thousand to 1, when the moon is in the quarters. And the proportion between those parts of the lights of the sun and moon, whatever they be, which are reflected to our eyes from the same object by day and by night, can hardly be different from the proportion of the whole lights. Allowing then that the aperture of the pupil may possibly be eight or nine times less by day than by night (that is, about three times less in diameter) yet the proportion in the quantities of day-light and moon-light received by the Eye from the same object, to illuminate a picture of the same bigness, will be no less than twenty thousand to one, when the nights have a middle degree of moon-light; I say no less, because the numbers here given are deduced from a rule, which is built upon this principle, that the moon reflects all the light received from the sun; which cannot be true, by reason of the appearance of very large obscure places in her body; and, in all probability, a great part of the incident light is buried and lost even in the brightest places.

The rule I mentioned is this, day-light is to moon-light as the surface of an hemisphere, whose center is at the eye, to the part of that surface which appears to be possessed by the enlightened part of the moon: so that the whole heavens covered with moons would only make day-light. This will be evident enough from the following considerations, though I invented it another way. Day-light is made by innumerable reflections of the sun's rays from all sorts of bodies, till at last they come to our eyes; for, if this were not so, we we could see nothing in the world, even in the day time, but the sun and stars and self-shining substances. Accordingly we find that day-light is much the same, whether the sun shines out or not, in the place we are in; because his light is reflected to us from a vast quantity of earth, air, and clouds extended all round us, perhaps to a hundred miles or more. So that the absence of the sun's rays from a particular place scarce alters day-light. Another thing is, that the moon by day appears like a cloud in the air of a middle degree of brightness; some appearing duller and some brighter than the moon itself. The rays of the sun being therefore intercepted in the night from all the visible clouds, and being reflected to us by the moon only, it follows, that day-light is to moon-light, as the apparent surfaces of all the visible clouds to the apparent surface of the visible part of the moon, considered as the only cloud which remains enlightened. And these two lights, whatever be the distances of the moon and clouds, are just the same as if those bodies were all placed at any equal distances from us, and composed the surface of an hemisphere, whose parts are the true measures of the parts of the light which comes to us.

A vast disproportion between the lights of the sun and moon appears also by experiments made with burning-glasses; either by refraction of the rays through very broad lenses, or by reflexion from very broad concave-glasses or metals: which, by collecting the rays of the sun into a small round image at the focus, do excite a more violent heat and burn quicker than the hottest wind-furnaces: as appears by their melting and calcining the hardest metals, by vitrifying bricks and stones in much less portions of time than a minute. Yet the rays of the moon, being collected by the same glasses, do not excite the least sensible heat; nor do they sensibly affect the nicest thermometer, when cast upon the ball of it, though the brightness of the light be very sensibly increased. By measuring the breadth of the round image at the focus, and by comparing it with the breadth of the glass itself, it appears that some of these burning-glasses collect the incident rays into a space about two thousand times less than they possessed at their incidence. But by the preceding calculation the light of the full moon must be condensed about 90 thousand times, to make it as dense and as warm as the direct rays of the sun. It is no wonder then that the heat of the moon's rays is not sensible in the focus of the glass, being then even forty or fifty times thinner than the direct rays of the sun. For it is found by experiments made with these glasses, that the degrees of heat are proportionable to the densities of the rays: which being compared with a scale of the degrees of heat and warmth of several natural bodies, determined by Sir Isaac Newton, in the Philosophical Transactions, it appears there is a vast disproportion between the degrees of light which the Eye can bear and be sensible of, and the degrees of its heat which the touch can bear and be sensible of.

Dr. Hook assures us, that the sharpest eye cannot well distinguish any distance in the heavens, suppose a spot of the moon's body, or the distance of two stars, which subtends a less angle at the Eye than half a minute; and that hardly one of a hundred can distinguish it, when it subtends a minute. If the angle be not bigger than this, the two stars appear to the naked Eye, as if they were but one. I have been present at making the experiment, when a friend of mine, who had the best eyes of all the company, could scarce perceive a white circle upon a black ground, or a black circle upon a white ground, or against the sky-light, when it subtended a less angle at the Eye than two thirds of a minute; or, which is the same thing, its distance from the Eye exceeded 5156 times its own diameter: which agrees well enough with Dr. Hook's observation. Hence the diameter of the picture of that circle upon the retina was but the 8000th part of an inch at most; and this may be called a sensible point of the retina. That this point is very small any one may perceive from hence, that the breadth of the finest hair is visible at the length of one's arm. *Smith's Optics.*

Contusion of the EYE. When the Eye is, by any accident, contused, it will be intirely deprived of sight, unless the contusion be slight, or the proper remedies instantly applied. If the Eye have received a very slight contusion, it will be proper to wash it frequently, for the first day, with cold spring water, laying on it linen rags, wet with the same: on the next day it must be rubbed externally with camphorated spirits of wine, and covered up with stuphs wrung out of decoctions, made in wine of eye-bright, speedwell, hyssop, sage, chamomile-flowers, and fennel seeds; but, if these things are not to be had, bolsters dipped in warm wine must be applied, and renewed very often; and, if the patient be of a plethoric habit, bleeding is also necessary. If the contusion of the Eye is so violent, that you can plainly see the extravasated blood through the cornea, and all objects appear red to the patient, a vein must be opened either in the foot or neck, the Eye must be kept continually fomented with warm stuphs, wrung out of the same decoctions as are before mentioned, and the feet must be bathed in warm water two or three times a day, and a few drops of pigeons blood must be, two or three times a day, put into the Eye; and, if all these attempts prove fruitless, you may very probably succeed, by making an opening in the cornea with the lancet. *Heister's Surgery.*

Wounds of the EYE. If the Eye is wounded, but not so as to let out the vitreous or crystalline humour, the wound must be anointed two or three times a day, with a feather, or fine rag, well dipped in the white of an egg, or else in a mucilage made of quince seeds, or of fleawort seeds, in rose water; and, after each dressing, a compress is to be laid on, well saturated with a collyrium, made of the whites of eggs. 2. Two ounces and a half of rose water, half a drachm of oil of roses, and three grains of camphor, well mixed together, and thoroughly shook up every time it is to be used. If the accident is attended with any great degree of inflammation, as is very frequently the case, it will be proper to cover the small compress, first laid over the Eye, with a larger, dipped in warm spirits of wine, with camphor. The bowels must, in this case, be kept open, and the patient blooded, if of a plethoric habit. And, if it happens, that the crystalline humour, or any part of it, sticks in the orifice of the wound, it must, in this case, be pulled out, that it may not bring on a deformity, or worse mischief, to the Eye. *Heister's Surgery.*

Artificial EYE, is an optical machine, where objects are represented after the same manner as in the natural Eye; of considerable use in illustrating the nature and manner of vision.

Its construction is thus: provide two hollow hemispheres of hard, dry wood, well cemented together, to represent the ball of the Eye: let the anterior or fore hemisphere be perforated with a round hole in C (*Plate* XX. *fig.* 4.) to supply the place of a pupil; and therein fit a thin, plane glass, or, which amounts to the same, a concavo-convex glass, to serve for the cornea. In the inside, have a short draw-tube G, with a lens convex on both sides, to do the office of the crystalline therein. In the hind or posterior hemisphere, fit another drawn tube E F, with a plain glass therein, having its inner surface smooth, though not polished, representing the retina and optic nerve.

If now the aperture C be turned towards any object, and the draw-tube F E be gradually pulled out; you will have the object beautifully and strongly represented, in all its colours, on the retina, only in an inverted order.

EYES *of horses*, in the manege, &c. These should be bright, lively, full of fire, pretty large, and full; but not too big, goggling, or staring out of the head. They should also be resolute, bold, and brisk. A horse, to appear well, should look on his object fixedly, with a kind of disdain, and not turn his Eyes another way.

The diseases of the Eyes, in horses, proceed either from a defluxion, or from some external hurt. In the former case, the Eyes are watery, hot, red, and swollen, the distemper advancing by degrees; in the latter, the malady comes speedily to a height, and the skin on the outside of the Eye is peeled off.

If the distemper takes its rise from a rheum, or defluxion, it is is to be conſidered, whether it proceeds from the Eye itſelf, or from another aggrieved part: in the latter caſe, the redreſſing of the part will ſet the Eye free; in the former, it is proper to cool the horſe's blood with an ounce of ſal prunellæ, mingled every day with his bran; and, when it leſſens his appetite, to change it for liver of antimony, till he recovers his ſtomach.

For ſore Eyes, when a ſkin is growing over them, the following receipt is recommended: to the white of an egg add a little fine powdered ſalt; then ſet this on the fire till it be reduced to a powder. This, mixed with a little honey, is to be put into the horſe's Eye with a feather. If it is found inſufficient to eat off the ſkin, the powder alone muſt be blown into the Eye with a quill.

In caſe of a blow on the Eye, take honey, and, having added a ſmall quantity of powder of ginger, put it into the horſe's Eye; or elſe take hog's lard, with oil of roſes and elder, of each an equal quantity; then, having melted them together, anoint the Eye therewith.

Some horſes have naturally tender weeping Eyes, which void a ſharp eating humour; theſe are eaſily cured by waſhing or bathing them every morning and evening with brandy.

EYE *of a tree*, a ſmall pointed knot, to which the leaves ſtick, and from which the ſhoots or ſprigs proceed.

EYE-BROWS *wounded*. In wounds of this part, great care muſt be taken to guard againſt inflammations, leſt the Eye ſhould partake of the injury; all hot and ſharp things muſt be avoided, in eating and drinking, and the patient ſhould be blooded, if plethoric; the wound muſt be dreſſed with vulnerary balſams, and the dreſſings covered with compreſſes, dipped in camphorated ſpirit of wine. If the wound be large, and the Eye-brow intirely divided, it will be neceſſary to uſe the ſuture and dreſs of it, with a vulnerary balſam, covering both eyes, and keeping them as much as poſſible from motion. *Heiſter's Surg.*

EYE-LIDS *wounded*. Wounds, either of the upper or lower Eye-lid, will not readily heal, not ſo much from the thinneſs of the parts, as from the great quantity of fluids, with which the Eye is continually moiſtened. It is neceſſary, therefore, firſt to foment the part with decoctions of chamomile, hyſſop, or eyebright, till the flux of the blood is ſtopped, and the wound well cleanſed; then, if the wound is tranſverſe, it muſt be ſtitched up in the middle with a fine needle, and ſprinkled over afterwards with the powder of comfrey root, gum arabic, or other ſuch medicines, or anointed with balm of Gilead, Peru, or Capivi, laying over theſe applications a plaiſter of diachylon, and tying it up in ſuch a manner, that the Eye may have very little power to move about. If the wound is made lengthways, it will require ſeveral ſtitches, and muſt be dreſſed over them as before. *Heiſter's Surg.*

F.

F.

FABA *Ægyptia*, in natural hiftory, the Egyptian bean, by fome called the Pontic bean, as it is not only copioufly produced in Egypt, but, alfo, in fome marfhy grounds of Afia and Cilicia. It has a very large leaf, a ftalk a cubit long, as thick as one's finger, and a flower whofe colour refembles that of a rofe, and which is as large again as a poppy-flower. But, when the flower falls, it bears fmall pods, almoft refembling little bladders, and in which the bean is fomewhat prominent above its covering, in the form of a bubble. They call it ciborium or cibotium, from the manner of planting it; which is, firft, to lodge it in a moift clod, by way of a cafe or box, which is afterwards immerfed in water. Its root is thicker than that of the common reed. This root is eaten, both raw and boiled, and is called colocafia. The bean itfelf is, alfo, eaten green; but, when dry, becomes black, and in bulk exceeds the Grecian bean. It is of an aftringent quality, and good in diforders of the ftomach. In confequence of its aftringent nature, an infperfion of its flower, inftead of polenta, is highly beneficial to dyfenteric patients, and fuch as labour under the cœliac paffion. This flower is, alfo, ufed by way of poultice: but the hufks made into a decoction, with mulfum, prove more effectual, if three cyathi of the mulfum are exhibited for a dofe. This bean, if boiled in oil of rofes, relieves pains of the ears, if dropped into them; becaufe, in the middle of the bean, there is a green fubftance, highly bitter to the tafte. *Diofcorides*.

The root of this bean, triturated, and made up, with fugar, in form of a preferve, is exhibited for the hæmorrhoids. The juice, extracted from the flowers, ftops immoderate difcharges of the menfes. *Dale* from *Henricus Adrianus Van Rheede*.

FABA *Sti Ignatii*, St. Ignatius's bean, in natural hiftory, a fruit of which Sir Hans Sloane gives us the following account:

It is about the bulk of a nutmeg, and triangular: the fhavings of it, drank in cold water, are highly beneficial for evacuating poifons by vomit, as alfo for the cure of bites inflicted by venomous animals, if, at the fame time, a few of the fame fhavings are applied to the bite: thefe fhavings, alfo, afford great relief, when applied to a part fpafmodically conftricted, and ftop hæmorrhages, when applied to the wounds. In the year 1692, a woman, who had, for a long time, been afflicted with floodings, was reftored to perfect health, by drinking thefe fhavings in fome proper liquor: the fame year, an infant, labouring under an highly intenfe fever, by drinking thefe fhavings, had its diforder forthwith removed in my prefence. They, alfo, afford relief to women in labour, and facilitate their delivery. I myfelf have found from experience, that this bean is of fingular fervice in all kinds of repletion, and crudities of the ftomach, as, alfo, in a dyfentery and tenefmus.

Divide each bean into three parts; and, when there is a neceffity, put one of thefe into the mouth, for a quarter or half a quarter of an hour, fwallowing the faliva difcharged; then drink about two or three ounces of cold water, and the effects of the medicine will be fenfible.

Another manner of ufing this bean is to put it into the concave part of a hard fhell with a little water, and rub it up and down. This water is to be put into a veffel with fome of the fhavings; and the like is to be done, till you have two ounces of the water thus prepared, which is to be taken for a dofe.

When this bean, divided into pieces, is rubbed in the concave part of a fhell, with oil, efpecially that of olives, this oil produces the fame effects with the former preparation, when drank; and is an excellent medicine, when applied to wounds, or members fpafmodically conftricted.

The moft ordinary method of ufing this nut is to put it entire into a little warm water, till the water is rendered bitter; and this infufion is afterwards to be exhibited. Others ufe a little of the powder in fubftance; others fwallow a piece of the bean; and others wear a whole bean, hung about their necks, by way of amulet.

When poifon is fufpected, and in cafes where there is an immoderate and tumultuous conflict of the fpirits, it is to be ufed without any regard to time. In other difeafes, it is to be ufed in a morning fafting. But, when the intention is to vomit, it is moft conveniently exhibited an hour or two after eating: the dofe is half a fcruple, in conjunction with other gentle emetics.

The powder, an infufion, or the oil, of this bean are exhibited in tertian and quartan fevers. It is alfo ufed for provoking urine, the menfes, and fuppreffed labours; for facilitating the birth, expelling the fecundines, the fœtus when dead, and worms; in all which cafes I have found it effectual. It is alfo exhibited in cholics, crudities of the ftomach, an injured concoction, diarrhœas, tenefmus, and obftructions of the liver and fpleen.

It is produced in the Philippine iflands, and thofe adjacent to them; but we are ignorant what kind of plant it grows on; only I learned from Raphael de Roa, a learned Spaniard, who lived long in thefe iflands, that it was a convolvulous plant, twifted itfelf round the talleft trees, and bare a fruit as large as a nutmeg. *Philof. Tranf.*

FACE *of a plant*, a word ufed by Tournefort and many other botanifts, to convey an idea of that general appearance of plants, which fhews a famenefs in thofe of the fame genus, and a diverfity from the other genus's, though not eafily charactered in words, yet very obvious to an eye accuftomed to thefe refearches. Thus all the fpecies of wormwood have the fame general face, by which they may be taken to be fpecies of the fame genus, and fo of many more; nay, in fome cafes, whole genera, and even claffes, have the fame kind of family face, as it may be called, by which they may be known: as the umbelliferous plants, except the perfoliata, and a few other inftances.

It has been attempted by many to make this general face an indicatory note of the virtues of the plant which wears it, and there would certainly be this great advantage in it, if it could be brought to any degree of certainty, that the moft obvious of all diftinctions would be applied to the moft valuable office: but, though an abfolute certainty cannot be arrived at, in an attempt of this kind, yet, allowing for the poffibility of a few exceptions, general conjectures may be made on the following rules, which will rarely fail. The umbelliferous plants before-mentioned make a very large clafs, and it is their general and obvious character to have their feveral flower branches arife from one center, and expand into an umbrella, every one having a tuft of flowers at the end; thefe flowers confift of five leaves, and the feeds are naked and double, and the leaves of the plant are generally deeply divided, as in parfly, carrots, and the like.

The verticillate plants are another clafs, which are eafily known by their general face; their flowers ftanding in ringlets round the ftalks, and being labiated or of fome fuch form. The leaves alfo in moft of thefe plants ftand in pairs, and they have generally an aromatic fmell. As the virtues of the umbelliferæ lie in the roots and feeds, fo do thefe in the hufks of the flowers. It has been a common opinion, that the flowers of thefe plants contained their virtues, but this is erroneous. The flowers of fage are almoft infipid, but the hufks tafte very ftrongly. Thefe plants are, in general, poffeffed of the fame virtues, and are all of a middle degree between the carminatives before-mentioned and the fpices.

The filiquofe plants have alfo the fame general face. Their flowers are compofed of four leaves, and their feeds contained in long pods, or in fhort and thick filiculæ. In thefe plants the feeds are found to contain the principal virtue in fome, and in others the leaves: fome have alfo virtue in their roots, but the flowers of all are neglected.

FA'LCO, *the falcon*, in ornithology, a bird of prey of the hawk kind, much efteemed for its ftrength and activity. There are many fpecies of this bird, but, when the word Falco is ufed fingly without any diftinctive addition, it is meant of that fpecies called, by authors, the Falco peregrinus, from its travelling into different countries, at different feafons of the year.

It has very long and large wings, reaching, when folded, to the tip of the tail. Its fhoulders are very large, its tail very long and ending like the fparrow hawk's in a point, its end being white variegated with orange-coloured ftreaks. Its feet are of a greenifh or bluifh yellow, its neck is long, and its head of a pale dove colour. There is a fpecies of this bird, which are of a much blacker colour on the back, and has been erroneoufly efteemed by fome a different fpecies; probably it is only owing to the difference of age or fex. This bird is caught in in France, Germany, and elsewhere; but it is not well known where it builds. It feeds on ducks, geese, and other large birds. *Ray's Ornithology.*

FALLACIES *in vision*, deceptions of the sight, from the objects appearing, from their situation, different to the sight than what they really are.

Since oblique distances appear longer in proportion as the eye is raised higher, to view them more fully; it follows that, being placed at a distance from a gentle ascent, like the stage at a play-house, or a rising mount at the end of a walk, we shall judge those ascents much longer than if they were level, especially if they be artfully contracted in the remoter parts. For, by not observing, or attending to, the reality of these ascents, we form the same idea of them, as is usually suggested to the mind by a longer level walk with parallel sides. Now, since the rising of the ground, together with a gradual diminution of its breadth, when not observed, do make it seem longer, and consequently less diminished in breadth, than if the same extent was level, with parallel sides; it should follow that a gentle ascent alone, whose sides are parallel, should still widen the appearance of their remoter parts, so as to make the parallel sides appear parallel or even diverging: which is contrary to the common appearance of parallel sides.

The oblique situation of an object seen alone is suggested to the mind by a greater apparent magnitude or a distincter perception of the nearer than of the remoter parts. And consequently, if the object be so remote or so uniform that we are not affected with a sensible difference in those perceptions, we are subject to mistake its position. For an object may appear under the same angle A O D (*Plate* XX. *fig.* 15.) in two oblique positions A D and *a d.*

Hence we sometimes mistake the position of a weather-cock or a flag; and, by taking the nearest end of the sail of a wind-mill for the remotest, we sometimes mistake the course of its circular motion. For if a spectator at O (*fig.* 16.) situated nearly in the plane of the sails produced, imagine the farthest end A of a sail A E to be the nearest, and the real motion of the sails be in the order of the letters A B C D E; when A is moved to B, and the line B O is drawn, cutting the circle A B C D E in D; since he first imagined the end A to be at E, he will not now conceive it at B but at D, and so will imagine the course of the motion to be from E to D; which is contrary to the real motion from A to B. The uncertainty we sometimes find in the course of the motion of a branch or hoop of lighted candles, turned round at a distance, is owing to the same cause: and also that we mistake a convex for a concave surface sometimes with the naked eye, but more frequently in viewing seals and impressions with a convex glass or a double microscope; and hills and vallies in the moon with telescopes, especially if they invert the object: being led into the mistake by an imperfect judgment of the distances of the parts of the objects, and confirmed in it by a contrary position of the shadows cast by a side light.

We are frequently deceived in our estimates of distance by any extraordinary magnitude of objects seen at the end, of it: as, in travelling towards a large city or a castle, or a cathedral-church, or a mountain larger than ordinary, we think they are much nearer than we find them to be on trial. For, since by experience the ideas of certain quantities of known distances are usually annexed to the apparent magnitudes of known objects of a common size, and since the apparent magnitudes of these larger objects at a greater distance are the same as of the smaller at a smaller distance, it is no wonder they suggest the usual idea of smaller distance annexed to more common objects. This is farther evident, because we are ignorant of the nature of the country, and of the inequalities in the ground interposed.

Animals and all small objects seen in vallies, contiguous to large mountains, appear extraordinary small, because we think the mountain is nearer to us than if it was smaller; and we should not be surprised at the smallness of the neighbouring animals, if we thought them farther off: In like manner, when they are placed at the top of the mountain, or upon a large building, and are viewed from below, we think they are extraordinary small for the same reason, and also because we judge the mountain or the building to be lower in proportion than if it was smaller, both because of its extraordinary magnitude and greater obliquity of its higher parts to the visual rays. Dechales tells us that, while he stood at the bottom of a mountain, he once observed a parcel of crows, which at first he thought were higher than the mountain, because, I suppose, they appeared so very small in comparison to it; but he found they spent half an hour in ascending, before they got to the top of it. The part of the monument extant above the tops of the adjoining houses, I am told, is five times longer than the height of the houses, and yet from below that part appears but two or three times longer at most, because of its unusual magnitude and obliquity to the sight.

Aquilonius mentions a Fallacy in distance which he had frequently observed and admired. In a warm summer's morning, when fogs are exhaled from moist ground, we frequently see them very near us in some known place; but, as soon as they are separated from the ground and are going to ascend, they appear so remote, that, says he, I could never have believed they hung over that place, had I not seen them there the moment before. The reason is, they then appear in the manner and direction of other remote clouds in the horizon, whose difference in distance cannot be discerned, for want of some visible surface extended between them; like the surface of the ground, when the rising cloud lay upon it.

It is said to be a common observation made by travellers in the night or the dusk of the evening, that near objects, as trees and houses, are often taken to be very large and remote. The reason may be, that, being unable to discern the quantity o ground interposed, they refer them to the brighter sky in the horizon, and so think they are remoter and consequently larger: as I remember a red coat of arms, upon the top of an iron gate at the end of a walk, was taken for a brick house in the fields beyond it. *Smith's Optics.*

FAMILIA, in natural history, a term used by authors to express a certain order of animals, or other natural productions, agreeing in their principal characters, and containing numerous individuals, not only different from one another, but, that in whole sets, several numbers being to be collected out of the same family, all of which have the family character, and all some subordinate distinction peculiar to that whole number; or, though found in every individual of it, not found in those of any others.

It has been too common to confound the words, class, family, order, &c. in natural history. But the determinate meaning of the word Familia seems to be that larger order of creatures, under which classes and genera are subordinate distinctions. Among the quadrupeds, the several genera of the unguiculated creatures agree one with another in many general characters common to all; and in which they differ from the ungulated animals, which have also their several peculiar characters common to all, and yet different from all those of the others. These naturally constitute certain larger divisions into families, and no one would ever break through these, or bring the cat and the horse into the same family.

In the same manner, in ichthyology, there are several genera of fishes, which agree perfectly in certain common characters, and disagree from all others in them. The bream and the herring, though very different in genus, may yet be brought into the same family, both having many characters in common, as well as many different ones; but no one would ever be for bringing the herring and the whale into the same family. The arrangement of natural bodies into these families, or general and larger classes, is of the utmost use to natural history, when it is properly done, and the divisions are genuine and natural; when otherwise, it is hurtful.

These divisions of animals into families are of two kinds; the one artificial or hypothetical, the other natural. The artificially contrived families, or classes of bodies, are founded on certain accidents of the things under consideration, not made from the parts of the bodies themselves. Of the artificial kind are those distinctions so much in use among the old naturalists, founded on the place of growth and time of flowering of plants, the time and manner of bringing forth in animals, the food of creatures, and their different magnitudes. And to these false foundations for general divisions may be added those founded on the number of certain external parts of the creatures.

The absurdity of the first of these methods is easily seen, since it requires a prior knowledge of the objects, before they come under our consideration. If an unknown plant mineral, or animal, be offered to a naturalist, how is he to inform himself of its time of flowering, its place of production, or its manner of bringing forth its young. And, as this is impossible, it is also impossible that he should ever refer to its family, or trace it out among the individuals of it. As to the latter method of making the number of certain external parts the character of a family, it is easy to see the absurdity of it in regard to the fishes, for the fins of these animals are not always the same in number, in the different species truly and properly belonging to one genus. Thus the pearch, gadus, syngnathus, and many others, have more or fewer fins, in the same genus. These are the errors of the artificial or hypothetical classes and families of natural bodies.

The natural families are liable to no such objections. In these all the genera, referred to the same family, agree perfectly and punctually in their principal parts; the several individuals, of which these families are composed, being reduced into genera, these are to be arranged into their proper classes, according to their natural agreements; and, of these classes, the smaller the number, the easier and plainer will be the whole method. These natural families can be only founded on essential characters, and, in the quadruped kingdom, they are to be taken either from the figures of the hoofs or claws, or from the teeth. In birds, the figure and proportion of the beak is a very proper character; and, in fishes, the figure of the head, and the situation of the tail, are to be considered, and are stable and essential characters. The whole animal world may easily be thus reduced to families, and from these two classes, genera and species, the study of nature rendered much more regular and easy, than it can be by any artificia ldivisions. *Linnæi Faun. Suec. Artedi Ichthyolog.*

FARM (*Dict.*)—It is commonly allowed that a Farm should make

make three rents, as they exprefs it; one for the landlord, one for the charges, and one for the farmer to live upon; but it is very feldom that a Farm will conftantly do this, or is to be maintained at that charge. In a Farm of one hundred pounds a year, if the land is worth twenty fhillings an acre, a hundred pound may defray the charges of it; but, if in a Farm of the fame rent the land be worth but ten fhillings an acre, a hundred and thirty pounds a year muft be allowed for the charges of this, or nearly fo; and two hundred and fifty acres of fuch land muft be reckoned to a farm of a hundred pounds a year, or elfe the farmer will be ruined, if it be not very improveable land.

FAST *Ground*, or *Faft country*, a term ufed by fome of our miners to exprefs what other call the fhelf. In digging, they frequently, after the paffing the feveral ftrata, which have been difturbed, and give proofs of having been toffed about in the water by their irregularity, meet with plain, firm, regular, and folid ftrata, which evidently fhew that they have undergone no change fince their original formation and inftitution. The workmen, who are very good philofophers in this refpect, affign the different ftructure, they thus find in the upper and lower ftrata of the earth, to its juft caufe, that is, the deluge; and determine, that all they find irregular has been wafhed up, and depofited there again in the time of that cataftrophe, but that the fhelf or Faft country is in its natural ftate and pofition. They obferve, in favour of this opinion, that their loads of ore run very irregularly in the irregular ftrata, but fo much more regularly in the fhelf or Faft ground. *Phil. Tranf.* N°. 69.

FA'THER-*Lafher*, in ichthyology, an Englifh name given to a fifh, called by fome authors, though improperly, fcorpæna, and fcorpius marinus. It is properly of the cottus kind, and is named by Artedi, the fmooth cottus without fcales, with feveral fpines upon the head, and with the upper jaw a little longer than the under. It more refembles the fmall fifh we call the bull-head or miller's thumb, than the fcorpæna. *Arted. Gen. Pifc.*

FA'TTENING *of horfes*. The being able to do this fpeedily is one of the greateft arts our dealers have, and indeed one of the greateft niceties of the whole management of that creature. Many methods have been prefcribed, but the following feems moft to be depended on: take elecampane, cimmun feed, tamarifk, and anifeed, of each two ounces; common groundfel, one handful. Boil all thefe very well, with two handfuls of garlic fcraped and cleaned, in a gallon of good ale; ftrain the liquor well off, and give the horfe a quart of it every morning made hot; keep him warm after it. After he has taken this for four or five mornings, he may be turned out to grafs, or kept in the houfe, as the feafon will permit. But, whenever provender is given him, a quantity of a powder is to be prepared of equal parts of cummin feeds and elecampane, and give him half an ounce of it every time, fprinkling it in by degrees, as he eats, that he may not naufeate the whole.

If this method does not fucceed in a fhort time, then take two fpoonfuls of diapente; brew it in a pint of fweet wine, and give it the horfe for three mornings. This will take off any inward ficknefs, and make the other things take effect. After this, feed him with good provender three times a day, that is, after his watering in the morning, after his watering in the evening, and at nine o'clock at night. If he does not eat the provender well and freely, it muft be changed for fome other kind.

If all this does not fucceed, let the horfe be blooded; and then take half a bufhel of coarfe barley meal, put it into a pail full of water, and ftir the whole together very well; then let it fettle by ftanding. Pour off the clear liquor into another veffel, and let him drink it for his common drink, and eat the remainder which falls to the bottom of the pail. If he refufe to eat this alone, there may be fome bran mixed among it. This fhould be given him three times a day, morning, noon, and night. If he does not rightly take to the meal with the bran, fome oats muft be mixed with it, and this will readily bring him to feed on it. But, which ever way is ufed, they muft be by degrees diminifhed in quantity, till at length he is brought to eat the meal alone; for that is the thing that muft fatten him up. Care muft be taken that the barley is ground frefh every day, as it is ufed, for it quickly grows four; and, when this has once been the cafe with one parcel, no art will ever bring the horfe to touch any of it afterwards. Scarce any horfe but will be well fattened by keeping him to this diet for about 20 days. Barley ground in this manner cools and purges the creature; but the greateft efficacy, as to the Fattening him, lies in the water, which by this management takes up all the rich part of the barley into itfelf. When the horfe grows lufty on this diet, it muft be taken from him by degrees, giving him at firft oats once, and barley-meal twice a day; and then oats twice, and the barley-meal once, till he is perfectly weaned from it. In the mean time, he muft have good hay, and he muft not be rid; only it will be proper to walk him gently about an hour or two in the heat of the day. If it be found that the horfe wants a good fmart purging during the time of his continuing in the barely diet, the beft time to give it him, is after the firft eight days, and the following is a very proper fort of phyfic: take of the fineft aloes one ounce, agaric in powder half an ounce, and powder of florentine orris one ounce. Let all thefe be mixed together, and put into a quart of milk warm from the cow. This will work very brifkly; and, after it is over, the ufual diet is to be continued. If horfes of value were to be kept to this diet once a year, it would make them lefs hot and dry, and not fubject to many difeafes which they are troubled with at prefent, and would be particularly ufeful after campaigns and long journies. If the horfe lofes his appetite by this diet, it will be proper to tie a chewing ball to his bit, renewing it fo often, till at length he begins to feed heartily on the barley; for thefe balls at once reftore appetite, and are themfelves of a Fattening nature. *Mortimer's Hufbandry.*

FAVORI'TO, in the Italian mufic, is an epithet given to fuch parts of any compofition as are performed to the greateft advantage. Thus, choro Favorito is a chorus in which are employed the beft voices and inftruments to fing the recitativo's, play the ritornellos', &c. This is otherwife called the little chorus, or choro recitante. *Broff. Muf. Dict.*

FAU'SSE *Chenille*, in natural hiftory, a term ufed by Mr. Reaumur, and others of the French writers, to exprefs a large clafs of worms produced from the eggs of feveral fpecies of four-winged flies.

The Fauffe chenilles are a clafs of animals almoft as numerous as the caterpillar. They are eafily diftinguifhed into feveral genera, according to the different numbers of legs, as thofe with eighteen legs, thofe with twenty, twenty-two, and twenty-four. The Fauffe chenille of the alliaria is of this laft kind. They are of feveral colours, in the different kinds; fome are white, fome brown, others black, but the greateft number of all are green. There are many of a flate colour, or bluifh black variegated with ftreaks and fpots of brown, and other colours. And, befide thefe, there are others variegated on feveral other grounds; in general, however, they are much inferior in beauty to the caterpillars. The colours of thefe infects are however very indiftinct marks to difcern them by, fince they are not permanent, but the creature varies them at different times of its life. Thefe infects, like the true caterpillars, change their fkin feveral times in their lives, and with it they change their colours alfo. The young ones of thefe animals are always much more handfome than thofe more grown; for, at every change of the fkin, there is a lofs of fome of the variegations; and ufually at the laft change they are all gone, and the creature puts on a colour different from any that it had before. This is an obfervation of the accurate Vallifnieri, who gives an inftance of it in a worm caterpillar of the elder. This creature, while young, is of a fine green, with a long ftreak of brown running all the way down the back; but, after the laft change of its fkin, it appears without the ftreak, and all over of a pale yellowifh hue.

Thefe creatures differ from the common caterpillars in their manner of remaining on the leaves of a plant. The caterpillar is always extended at its full length, whether it is eating or not; but the Fauffe chenille, though it extends its body to the full length while eating, always rolls it up into a fpiral when at reft, making feveral circular turns with it, of which the head is at the end of the outermoft, and the tail in the very center of the inner one. They give themfelves various odd contortions, when they are feizing on their food; and it is a very whimfical fight to obferve twenty or thirty of them, in thofe kinds which live in fociety, attacking the different portions of the fame leaf all at once, and each giving its body fome odd turn at the fame time. This is a common fight on the leaves of the ofier; a whitifh green kind being very frequent in large companies on that tree, and often feen thus feeding in covies. It is remarkable, that, as the caterpillar feeds indifferently on every part of the leaf, this animal ufually attacks only the edges. Some fpecies of thefe animals feed only early in the morning, and, as the leaves are then wetted with the dew, they cannot avoid taking in a large quantity of water with their food; in confequence of which, when they are examined afterwards, their bodies are frequently found covered with drops of a thick and vifcous matter of an ill fmell. It feems probable, that the abundant aqueous matter in this cafe finds its way out at thofe numberlefs apertures in the fkin, at which the creature takes in the air: thefe infects, as well as the caterpillars, having very numerous tracheæ.

The generality of the animals of this clafs feed on the leaves of plants and trees, but there are fome which affect other parts of them. There are a fmall fpecies very frequently found living within the young branches of the rofe-tree, which often deftroy that part of the fhrub. Others are found lodged in young pears, apples, and other fruit: They feem to have been placed there, when very young, and always deftroy the fruit, occafioning its falling off from the ftalk before half grown. Some fpecies of them are alfo found on the leaves of trees, which are rendered tumid, and make what are called leaf galls, thefe being often inhabited by animals of this clafs, in particular the leaf galls of the willow. The creature, when it finds the time of its change into the nymph ftate approaching, gives itfelf the trouble of forming a cafe in which it may pafs into that ftate, and remain in it during the deftined time, without being fubject to external injuries. It fpins a web of filk for this purpofe of the fhape of a little egg. This on the outfide fhews nothing remarkable, but when cut open, it is found to be compofed of two different fubftances, at leaft of two fubftances of very different workmanship, though the materials are the same in both. The outer case is reticulated, and formed of very strong threads wove into a loose open net work; but the inner one is formed of extremely fine threads, and those wove into a closer stuff than all that the loom can come up to. The outer strong and coarse web was plainly intended for no other purpose, but for the better defending and preserving them from injuries. And these two distinct cases do not any where adhere to one another, but barely touch; so that, on pulling asunder the outer one between the fingers, the inner one comes out whole. The strength of this exterior shell is extremely necessary, as also the close texture of the inner one, for the defending the inclosed animal in the nymph state from several devouring insects. The ants, in particular, are very fond of these nymphs, and will hunt out the cases wherever they are to be found; and, if they can eat their way through them, are sure to make a meal of the inclosed creature.

The rose worm, or Fausse chenille, is very singular in the manner of its performing this great work. This is a small greenish species often found on the leaves of the rose, and famous for the various odd attitudes into which it twists its body occasionally. It usually carries its tail erect, and often in the shape of the letter S. This species, though green on the sides and belly, is yellowish on the back, variegated with several specks of black or deep brown, from each of which there grows a long hair. This creature, when the time of feeding is over, goes into the ground, in order to spin its double web. The external one is of a reddish brown, and the internal one whitish. These when taken out of the earth are usually fouled with small particles of dirt, so that, to have them in perfection, it is best to keep the animal in a box, where it will spin them perfectly clear. There are some species of this animal that hide themselves in the holes of trees, and in the cavities between the bark and the wood; and these never spin any outer web, but are found inclosed in the fine thin internal one alone. They all, after having passed a proper time in this state, some only a few weeks, others a whole winter, become four-winged flies. The flies produced of these insects are of that kind which have no trunk, but have a strong tooth on each side of the head, which, meeting one with the other in the middle of the mouth, are able to cut any thing to pieces that the creature has occasion to make its way through. The first use of these is the eating a hole through the double web, in which the creature finds itself inclosed at its birth. All the flies of this kind have a general resemblance one to another, and may be known to belong to the same family, though they are very different in colour, and other obvious characters. They are never very handsome, and are all as it were stupid, having very little motion, and standing readily at any time to be caught between the fingers. Their wings always are crossed over the body, and form a sort of raised covering over it; they are not smooth and even, as those of most other flies, but have prominencies and cavities, and seem as if they had been but ill expanded, at the time of the creature's hatching from the nymph state. *Reaumur's Hist. Inf.*

FEE'DING *of fish.* The owner of fish-ponds will find this an article very worthy of his consideration, as the trouble or expence of it are very little, and the profit very great. In a stew, thirty or forty carps may be kept up from October to March, without any other food than what they will find there for themselves. And, by fishing with trammels or flies, it will be proper in March or April to take, from the larger waters, some to replenish the stews; but after this, from March to October, it is necessary to feed them as much as to feed chickens that are cooped up, and it will turn to as good account. The care of doing this is best committed to the gardener, who is always at hand and on the spot; for the regular serving them is of the utmost consequence.

Any sort of grain is good to feed them with, especially pease and malt coarse ground, and grains after brewing, while they are fresh and sweet, are very proper; but it is to be observed, that that one bushel of malt, not brewed, will go as far as two bushels of grains. Chippings or raspings of bread steeped in the droppings of malt liquors, especially of ale, are very good for carp. The quantity of these should be about two quarts a day to thirty carps; and it is better to have it given twice a day, that is, morning and evening, than all at once. Pease or other seeds or grains, boiled and prepared for the food of carp, may be let down into the water on a square board like a trencher, supported by four strings, one at each corner, and with some leads fastened to its bottom to sink it a proper depth; it is to be supported by a pole or otherwise, and it is a very entertaining sight to observe the manner in which they will come all about it, and take off their food.

When large ponds which contain great numbers of fish are to be fed in this manner, it will be some expence to the owner; but on taking out the fish, and observing how they thrive by it, this will be easily borne with.

Grains are the cheapest and most staunch food that can be procured for fish, and, where breweries are near, they are easily had, but even in country places it will be easy to agree with the neighbouring families, who brew, to throw their grains into the pond at a certain price. Carp and tench will be fed like fowls in this manner. Pike also may be fed with eels to fatten them quickly, and with any other fish at other times. Pearch are not at all proper for this sort of management.

FEE'LERS, *antennæ*, in natural history, are the horns, as they are usually called, upon the heads of insects.

FELLI'NG *of timber.* Many circumstances are well known and constantly observed in the Felling of timber for building, which though, to a hasty observer, they might appear trifling, yet prove, on experience, to be of the utmost consequence. One thing observed by Mr. De Buffon, which very greatly increases the solidity and strength of timber, is that the trees, intended to be felled for service, should first be stripped round of their bark, and suffered to stand and die upon the spot before the cutting. The sappy part, or blea of the oak, becomes by this management as hard and firm as the heart, and the real strength and density of the wood has been proved, by many experiments, to be greatly increased by it; nor is this a practice of any detriment to the proprietor, since the remaining stumps of these trees send up their young shoots as vigorously, as if they had been cut down in their natural condition. *Memoires de l' Acad. Scienc. Par.*

When any tree is to be cut down for timber, the first thing to be taken care of is a skilful disbranching such limbs as may endanger it in its fall. Many trees are utterly spoiled for want of a previous care of this kind. In arms of timber that are very great, it is always necessary to chop or sink in them close to the bole, and then, meeting it with downright strokes, it will be severed from the tree without splitting. In Felling the tree, take care always to cut it as close to the ground as possible, unless it is intended to be grubled up; and the doing this is of advantage both to the timber, and to the wood; for timber is never so much valued, if it be known to grow out of old stocks. When an oak is down, the bark is to be stripped off, and set so that it may dry well. Trees that are nine inches girt about a yard from the ground, are commonly reckoned timber trees; but none under this size, because such will be about six inches girt in the girting-place, when the bark is off: the knowledge of this will save the trouble of climbing up to measure them.

The common method of felling timber is as it stands, but the feller is liable to great cheat and imposition in this respect. It is sold either by the load or ton; forty feet is reckoned a ton in some places, and fifty a load; and in others fifty in the ton, and the load is but forty; so that whoever sells timber standing, should mention how many feet he means in the ton or load. The trees, when felled, are measured either by girth or square measure; it is usually reckoned, that forty feet of round timber, or fifty feet of hewn or square timber, weigh the same, that is, twenty-hundred. And this is usually counted a cart load; and, as they seldom strip the bark off from elm, the buyer commonly allows an inch for the bark, which is a great deal more than it comes to; and therefore, if the owner can strip off the bark in the measuring-place, which should be about the middle of the tree, it will be much the better.

Some allow four feet out of every load for ash, and five feet for oak and elm; and, as for the computation of the feet, if it is square measure, the square is taken by a pair of callipers, or by two rules clapped to the side of the tree, measuring the distance between them, and, if the sides are unequal, they add them together, and take half the sum, which they account the true side of the square.

If girth measure be used, they do it by girting the middle of the body of the tree with a line, and taking a quarter part of this girt for the square, measuring the length from the butt end so far forwards, till the tree comes to be but six inches in the girth, that is, twenty-four inches in circumference; and, if the trees have any great boughs which are timber, that is, which hold six inches girth, they measure them by themselves, and then add them to the whole. For the casting up the contents of this, they make use of Gunter's line, upon which, if a pair of compasses be extended from twelve to the number of inches contained in the square, they place one foot of the compasses at the length, and keep the same extent with them; if the square is under twelve inches, the compasses are to be returned twice from twelve, and it will shew the contents. This is the common practice of measuring, and therefore the seller must generally acquiesce in it; it is a very false way, being almost one fifth part less than the whole. *Mortimer's Husbandry.*

FEN *(Dict.)* — What the farmers call Fens or fenny-lands are of two kinds. First, those which are only drowned by upland floods and great rains, and are very large and lie upon the levels, so that the water cannot run off from them, but must be there till the hot weather and winds dry it off: and, secondly, those that are constantly wet, only that in dry times they are shallower covered with water than in others. In draining of these sorts of lands, which is the only means of making them useful to the world, two things are to be considered: first, the laying them perfectly dry, which can only be effected by the making cuts and drains for the carrying off the water from their lowest parts, and thence from the whole; or, secondly, the taking off from the great additional wetting they have from land floods, and long continued rains. The first method makes a perfect cure; the other is only a temporary relief, and makes the lands more serviceable in dry times, and leaves less for the sun to dry up.

Whatever is attempted in regard to the draining of Fens, the lowest

lowest part of the ground is to be found out first, and the overflowing from great rains, and from land-floods, must be provided for, in the carrying off that way; for, should this be neglected, all the labour and cost employed on the other principle would be thrown away. If it is found that this can be done, there must be afterwards be cut a large drain through the middle of the land, and several smaller drains communicating with this.

The great drain must be dug deep enough to drain the whole level, and this, and all the others, must be made the narrowest at the head, and wider all the way to the mouth, where it must be widest of all.

These drains must be all well cleansed from mud and weeds every spring and autumn, and the water from land-floods must be kept from coming in upon these lands, as much as possible, that there may be the less to be drained off; the lower edges of the Fen-land must be for this purpose guarded with banks to turn the water into other channels. In Essex, they have many lands that lie below the high-water mark, and are above the low-water mark, and have land-floods or fleets running through them, which make a sort of small creek. These lands they have a very easy way of draining, though they are naturally very moist, when they first inclose them from the sea; they do it with a bank, which they extend from one side of the land they design to take in to the other, excepting a space that they leave, where the creek or land-floods run into the sea. They then prepare a wooden frame, well planked and of a considerable thickness, fitted to the head of the creek, and capable of shutting it wholly up; in this frame they make several holes, in which are placed wooden troughs, made each of four boards, and suited in size and number to the quantity of water that is to be discharged through them from the land-floods. Each of these trunks is open towards the creek, but on the sea-side it has a door or flap, which opens when the land-flood presses against it, and gives it free passage out; but, when the sea-water is risen to the height of it and presses it, it is shut by the force, and no sea water is let in. When this head is prepared, they let it in, and, stopping up the whole creek, they continue the banks on each side till they meet it: thus all the land-floods are let out at low water, and not a drop of sea water can be admitted, so that the lands are kept dry and useful, which were before rendered useless, by being drowned with salt water at every high-water mark. The fresh water of the creek is thus kept unmixed with the sea water, and therefore affords good drink for the cattle, which is commonly very difficult to be had in this sort of lands, the tides spoiling what fresh waters there are, every time they come up. *Mortimer's Husbandry.*

The wet grounds called Fens in Lincolnshire and elsewhere in England, bring many advantages to the inhabitants of those countries. Fowl and fish are very plentiful in them. The pike and eels are large and easily caught, but they are usually coarse. The duck, mallard, and tail are in such plenty, as is scarce to be conceived; they are taken in decoys, by prodigious flocks at a time. They send these fowl to London from Lincolnshire, twice a week on horse-back, from Michaelmas to Lady-day, and one decoy will furnish twenty dozen, or more, twice a week, for the whole season, in this manner. The decoy-men contract with the people who bring them to London at a certain rate, and they are obliged to take the whole number that is catched off their hands. Two teal are usually reckoned equal to one duck, and six ducks and twelve teal are accounted a dozen of wild-fowl; and the usual market price is about nine shillings, for such a dozen. About Midsummer, when the moulting season is, a great number are destroyed also by the people of the neighbourhoods. The poor birds at this time are neither able to swim nor to fly well; and the people going in with boats among the reeds, where they lie, beat them down with long poles.

A little before Michaelmas, vast flights of these birds arrive at the decoys from other places; they soon grow fat in them, and continue there a prey to the masters or owners, as long as the decoys are unfrozen; but, when they are iced over, they fly away again, and go to the neighbouring seas for food. *Philos. Trans.* N°. 223.

The Fens also abound in a sort of herbage that is very nourishing to cattle: sheep and horses always grow fat upon it. These Fens are common, and the owners of cattle mark them, that they may be known. It is remarkable, that, though all is open, the cattle, used to one particular spot of ground, seldom leave it, but the owner may find them always in or near the same place. The Fens have many large and deep drains. In these the pike and eels grow to a vast size; and they are full of geese which feed on the grass, but these eat rank and muddy, and may even be smelt, as soon as a person comes into a room where they are roasting. But the people have another very great advantage in these, beside the eating them, that is, their feathers and quills; and the produce of these is so great, that the Custom-house books in the town of Boston shew, that there are frequently sent away, in one year, three-hundred bags of feathers, each bag containing a hundred and a half weight. Each pound of feathers brings in the owner two-pence, and it may be thought strange by people unacquainted with these things, but it is a certain truth, that the owners pull them five or six times a year for their feathers, and three times for their quills. Each pulling comes to about a pound, and many people have a thousand geese at a time, or more. They are kept at no charge, except in deep snowy weather, when they are obliged to feed them with corn.

FENCES, in gardening. — In hotter climates than England, where they have not occasion for walls to ripen their fruit, their gardens lie open, where they can have a water Fence, and prospects; or else they bound their gardens with groves, in which are fountains, walks, &c. which are much more pleasing to the sight than a dead wall: but in colder countries, and in England, we are obliged to have walls to shelter and ripen our fruit, although they take away much from the pleasant prospect of the garden.

Since therefore we are under a necessity to have walls to secure our gardens from the injury of winds, as well as for the conveniency of partitions or inclosures, and also to ripen our fruit, brick walls are accounted the best and warmest for fruit: and these walls, being built panel-wise, with pillars at equal distances, will save a great deal of charge, in that the walls may be built thinner, than if they were built plain without these panels; for then it would be necessary to build them thicker everywhere: and, besides, these panels make the walls look the handsomer.

Stone walls are to be preferred to those of brick, especially those of square hewn stones. Those that are made of rough stones, though they are very dry and warm, yet, by reason of their unevenness, are inconvenient, to nail up trees to, except pieces of timber be laid in them, here and there, for that purpose.

But in large gardens it is better to have the prospect open to the pleasure garden; which should be surrounded with a fosse, that from the garden the adjacent country may be viewed; but this must depend on the situation of the place: for, if the prospect from the garden is not good, it had better be shut out from the sight by a wall, or any other Fence, than to be open. As also, when a garden lies near a populous town, and the adjoining grounds are open to the inhabitants; if the garden is open, there will be no walking there in good weather, without being exposed to the views of all passengers; which is very disagreeable.

Where the fosses are made round a garden which is situated in a park, they are extremely proper; because hereby the prospect of the park will be obtained in the garden; which renders those gardens much more agreeable than those which are confined.

In the making these fosses there have been many inventions; but, upon the whole, I have not seen any which are in all respects preferable to those which have an upright wall next the garden; which (where the soil will admit of a deep trench) should be five or six feet high; and, from the foot of this wall, the ground on the outside should rise with a gradual easy slope to the distance of eighteen or twenty feet; and where it can be allowed, if it slopes much farther, it will be easier, and less perceptible; as a ditch to the eye, when viewed at a distance. But, if the ground is naturally wet, so as not to admit a deep fosse, then, in order to make a Fence against cattle, if the wall be four feet high, and slight posts of three feet high are placed just behind the wall, with a small chain carried on from post to post, no cattle or deer will ever attempt to jump against it: therefore it will be a secure Fence against them; and, if these are painted green, they will not be discerned at a distance, and at the same time the chain will secure persons walking in the garden from tumbling over.

In such places where there are no good prospects to be obtained from a garden, it is common to make the inclosure of park paleing; which, if well performed, will last many years, and has a much better appearance than a wall: and this pale may be hid from the sight within, by plantations of shrubs and ever-greens; or there may be a quick hedge planted within the pale, which may be trained up, so as to be an excellent Fence by the time the pales begin to decay.

There are some persons who make stuckade Fences round their gardens to keep out cattle, &c. which, when well made, will answer the purpose of Fences; but this being very expensive in the making, and not of very long duration, has occasioned their not being more commonly in use.

As to Fences round parks, they are generally of paling; which, if well made of winter-fallen oak, will last many years; but a principal thing to be observed, in making these pales, is not to make them too heavy; for, when they are so, their own weight will cause them to decay; therefore, the pales should be cleft thin, and the rails should be cut triangular, to prevent the wet lodging upon them; and the posts should be good, and not placed too far asunder. If these things are observed, one of these pales will last, with a little care, upwards of forty years very well. The common way of making these Fences is, to have every other pale nine or ten inches above the intermediate ones; so that the Fence may be six feet and a half high, which is enough for fallow deer; but, where there are red deer, the Fence should be one foot higher, otherwise they will leap over.

Some inclose their parks with brick walls; and, in countries where stone is cheap, the walls are built with this material; some with, and others without mortar.

A kitchen garden, if rightly contrived, will contain walling enough to afford a supply of such fruits as require the assistance of walls, for any family; and this garden, being situated on one side, and quite out of sight of the house, may be surrounded with walls; which will screen the kitchen garden from the sight of persons in the pleasure garden; and, being locked up, the fruit will be much better preserved than it can be in the public garden: and the having too great a quantity of walling is often the occasion that so many scandalous trees are frequently to be seen in large gardens, where there is not due care observed in their management.

The height of garden walls should be twelve feet; which is a moderate proportion; and, if the soil be good, it may in time be well furnished with bearing wood in every part, especially that part planted with pears, notwithstanding the branches being trained horizontally from the bottom of the walls.

I would recommend the white thorn, the holly, the black thorn, and crab, for outward Fences to a good ground: but I do not approve of the intermixing them.

The white thorn is the best quick to plant; because it is the most common, and may be clipped so as to render it the closest and the hardiest Fence of any other tree; and, being very durable, is preferred to all others for outward Fences; or, for the division of fields, where they are exposed to cattle, &c.

The black thorn, and crabs, make very good Fences, and are to be raised as the white thorn: but, if the kernels of apples or crabs be sown, it is best to sow the pommace with them, and they will come up the sooner, i. e. the first year.

If crab stocks be planted, while young, in the same manner as quick, they make excellent hedges; and so will some sorts of plums.

The holly will make an excellent Fence, and is preferable to all the rest; but it is difficult to be made to grow at first, and is a slow grower; but when once it does grow, it makes amends by its height, strength, and thickness. *Miller's Gard. Dict.*

FENCES, in agriculture. — The inclosures of grounds are in some places made by ditches full of water, and others by walls either of stones alone, or of stones and earth. Where these materials are in plenty, they make very good Fences, but in other places, the common method is by quick hedges. To raise them, a ditch is dug and a bank thrown up, and on this young trees are regularly planted. The white thorn is the best of all trees to plant for a Fence, being a tolerable quick grower, and lasting a long time, and making a very handsome Fence. It will succeed on any soil where a ditch and new bank are made, except it be wholly of gravel or sand; and even in this case it will thrive, if there happen a rainy season after the planting of it.

Some raise it by seeds, and others by young plants; the latter is the most expeditious way, for the seeds lie two years in the ground before they shoot, but they grow very fast after two or three years. Some prepare the haws, or fruit of the white thorn, by tying them up in a hair bag, and soaking them all winter; after this, if they are sown in February or March, they will come up the first year, and grow better than any other way.

Where sets are scarce, it is a good way, when the underwoods are felled, or rather the year before, to sow haws and sloes in them, and they will furnish a supply of young plants for hedges, without doing the woods any harm, because they may be drawn before they come to be too large. The white thorn is also of considerable value in some sort of works; its root becomes very beautifully veined, when old, and elegant boxes and combs are made of it. It is used by some also, in the business of inlaying, and would be more so, if its beauty were more known.

The crab and the sloe tree, or black thorn, come next in value to the white thorn, for quicks for Fences. *Mortimer's Husbandry.*

FERMENTATION (*Dict.*)—Fermentation under the hands of the distiller differs from the common, which is used in the making of profitable malt liquors and wines, as being much more violent, tumultuary, active, and combinatory than that. A large quantity of ferment or yeast is here added, the free air is admitted, and every thing contrived to quicken the operation; whence it is sometimes precipitately finished in the space of two or three days.

This great dispatch has its great inconveniences with regard to the spirit, which hence becomes not only fouler, or much more gross and really terrestrial, than if the liquor had been slowly fermented; but also suffers a diminution in its quantity, from the violent and tumultuary admission, conflict, and constant agitation of the free air in the body, and upon the surface of the liquor; especially if not immediately committed to the still, as soon as the Fermentation is fairly slackened or fully ended.

It is a difficult task to render the business of Fermentation at once perfect and advantageous. To ferment in perfection of necessity requires length of time, proper attendance, and close vessels; besides several particular encheireses and contrivances, which one cannot reasonably expect should be received and practised in the large way of business, on account of the charge: unless it could be made appear, as there is some reason to suspect it may, that the increase in the quantity of spirit (not now to mention the improvement of its quality) might be brought to pay the additional expence: but it requires farther experience to reduce the thing to a certainty. In the mean time, it may not be amiss to try how much of the more perfect art of vinous Fermentation is profitably practicable by the distiller, in the present circumstance of things.

The improvements to be made in this affair will principally regard, (1.) 'The preparation or previous disposition of the fermentable liquor. (2.) The additions tending to the general, or some particular end. (3.) The admission or exclusion of the air. (4.) The regulation of the external heat or cold. And (5.) A suitable degree of rest at last'. When proper regard is had to these particulars, the liquor will have its due course of Fermentation, and thence become fit to yield a pure and copious inflammable spirit by distillation.

It has been long known, that the tincture, solution, or liquor, designed for Fermentation and the still, should be made thin, or very considerably aqueous; as this property not only fits it to ferment readily, but also to yield more of a pure vinous spirit in proportion, and part with it easier in distillation, than if it were richer, more glutinous, or clammy: the gross, foul, viscid, and earthy particles of such glutinous liquors being after Fermentation apt to rise with the boiling heat employed to raise the spirit, which thus of course comes over foul and fœtid. There is another advantage attending this thinness of the liquor, viz. that it will the sooner fall fine, by standing, before Fermentation: whence it may be commodiously drawn off from its fæces, or bottom; which must always, in case of corn, malt, or other mealy substances, be kept out, where the purity of the spirit is consulted.

A certain degree of warmth seems requisite, in the northern climates, to all artificial liquors intended for immediate Fermentation, especially in the winter: but the natural juices of vegetables that have never been inspissated, as that of grapes, and other fruits, when fully ripened, will usually ferment as soon as they are expressed, without any external assistance. But as a certain degree of inspissation prevents all tendency to Fermentation in vegetable juices, otherwise strongly disposed to ferment; so a long continuance or increase of the inspissating heat, especially if it acts immediately, through a metalline or solid body, upon the juice, will destroy its fermenting property; and this the more effectually, as the heat employed approaches to that of scorching, or the degree capable of giving an empyreuma. After the same manner, several experiments make it appear, that there is a certain degree of heat; the continuance, or least increase whereof, proves detrimental, or destructive to Fermentation; as there is another that wonderfully encourages and promotes it. These two degrees of heat ought to be carefully noted and settled by the thermometer, or other more certain method, for philosophical and chemical uses; but for common or œconomical occasions, they may be limited to what we usually understand by a tepid and a fervid heat: a fervid heat is the bane of all vinous Fermentation; as a tepid one, or rather an imperceptible warmth, is the great promoter thereof. In this neutral state therefore, with proper contrivances to preserve and continue it, the liquor is to be put into a suitable vessel for Fermentation; at which time, if it work not of itself, it must be quickened by additions; and, in general, by such things as are properly called ferments.

By ferments is here meant any matter, which, put to a rightly disposed fermentable liquor, will cause it to ferment much sooner and faster, than it would of itself; and thus greatly shorten the operation. Those are called ferments in an abusive sense, which, when added to the fermentable liquor, only correct some fault therein, and thereby fit it to ferment the better, yield the more spirit, or give some particular flavour.

The primary use of ferments, therefore, is to save time, and make dispatch in business, whilst they only occasionally and accidentally give a flavour, or increase the quantity of spirit. And, accordingly, all fermentable liquors may, without the least addition, and only by a proper management of heat, be brought to ferment, more perfectly, though more slowly, than with the assistance of ferments.

These ferments, in general, are the flowers and fæces of all fermentable liquors, generated and thrown up, or deposited, either in the Fermentation itself, or after the operation is finished.

There are two of these procurable in large quantities, and at a moderate expence, viz. beer-yeast and wine-lees; a prudent and artificial management, or use whereof, might render the business of distillation much more facile, certain, and advantageous. It has been esteemed a considerable difficulty and discouragement, in this business, to procure a sufficient stock of these materials, and preserve them, at all times, ready for use. Hence, some have been driven to invent artificial ferments, or to form mixtures, or compounds of particular fermentable ingredients, but with no great success: these usually falling short in their effects, even in comparison of bakers leaven. And indeed whoever has any talent at experiment, in this way, will soon find it much easier, cheaper, and better, in all respects, to preserve the usual and natural ferments, or raise nurseries thereof, than to invent artificial compositions, or good serviceable substitutes for them.

That common yeast may be preserved fresh and perfect, for several months, is matter of experience; and necessity has put people

people upon inventing ſeveral expedients for the purpoſe. The foundation of the thing reſts wholly in dextrouſly freeing the matter of its ſuperfluous moiſture, and bringing it out of a ſemi-fluid ſtate, wherein it is always expoſed to a farther Fermentation, or deſtructive alteration; and thus of courſe runs into what is vulgarly called corruption: at which time, it becomes intolerably fœtid and cadaverous. The method of drying it in the air is ſubject to great inconveniencies, and requires the due obſervance of ſeveral circumſtances, and particular encheireſes, to render it perfect and effectual. The beſt way, in all reſpects, is ſlowly and gradually to preſs it, in a thick, cloſe, and ſtrong canvas bag, after the manner of wine-lees, by the tail-preſs, till at length it comes into a kind of cake; which, though ſoft, will eaſily ſnap, or break dry and brittle betwixt the fingers. And in this ſtate, being well packed up, or cloſely ſecured in a tight caſk, it will long keep uncorrupted, fragrant, and fit for the fineſt uſes.

The ſame method is likewiſe practicable to the ſame advantage in the flowers or yeaſt of wine; which may thus be commodiouſly received from abroad. Or, in defect of theſe flowers, others of equal goodneſs may be raiſed from freſh wine-lees barely by mixing, and ſtirring them into a proper warm liquor: whence the lighter, or more moveable and active parts of the lee, will be thrown to the top, and may be taken off, and preſerved, as above-mentioned, in any quantity that ſhall be deſired.

And hence a facile method of raiſing an inexhauſtible fund, or perpetual ſupply, of the moſt uſeful ferments, may be readily formed, in the way of ſucceſſive generation; ſo as to cut off all future occaſion of complaint, for want of them, in the buſineſs of diſtillation.

It muſt be obſerved, that all ferments abound in eſſential oil, much more than the liquors that produce them; whence they very ſtrongly retain the particular ſcent and flavour of the ſubject. It is therefore requiſite, before the ferment is applied, to conſider what flavour ought to be introduced, or what ſpecies of ferment is beſt ſuited to the liquor. The alteration thus cauſed by ferments is ſo conſiderable, as to determine, or bring over any neutral fermentable liquor, to be of the ſame ſpecies with that which yielded the ferment: which is an obſervation of greater moment, than will preſently be conceived; as opening not only a new ſcene in the buſineſs of diſtillation, but alſo ſome other buſineſſes depending upon Fermentation. The benefit of it does not, however, extend to malt, treated in the common way; nor to any other ſubject but what affords a ſpirit tolerably pure and taſteleſs: as it otherwiſe makes not a ſimple, pure and uniform, but a compound, mixed, and unnatural flavour. How far the fine-ſtiller may apply it, well deſerves his conſideration; and whether our native cyder-ſpirit, crab-ſpirit, &c. which have little flavour of their own, may not, by this artifice, or a little farther improvement of it, be brought nearly, or intirely into the ſtate of ſome highly eſteemed foreign brandies, is recommended to experience.

When the proper ferment is thus pitched upon, ſuitable to the deſign; its quantity, quality, and manner of application, are next to be conſidered.

Its quantity muſt be proportioned to that of the liquor, its tenacity, the degree of flavour it is intended to give, and the diſpatch required in the operation; from which conſiderations, every one will form a rule to himſelf: but, till ſuch a rule is obtained, or in order to obtain it, proper trial will ſhew how much ſuffices for the purpoſe; beginning with a little, and obſerving to add more occaſionally; the weight of the whole being noted before-hand. Treacle is found to require a large proportion of ferment, and even ſometimes needs the aſſiſtance of other additions. Indeed, the manner wherein this inſpiſſated juice is obtained, tends greatly to unfit it for Fermentation. The ſtrength, long continuance, and almoſt immediate contact of the fire in ſugar-making and refining, and the frequent uſe of lime, or other alkaline or terreſtrial bodies, ſo condenſe, indurate, and ſcorch the body of this juice, and abſorb its acid, that one would ſcarce expect it ſhould ferment at all, even with the addition of jalap, or other powerful, ſaline, and acid, or acrid ſtimulators, which tend to break the viſcous and aduſt connexion, or ſtrong combination of its particles.

More circumſpection is neceſſary, with regard to the quality of the ferment, if a pure ſpirit be required; for, in caſe of the leaſt muſtineſs, or corruption, which all ferments have a ſtrong and natural tendency to, unleſs carefully cured and preſerved, it may deeply impreſs itſelf, and communicate a finewy or fœtid, nauſeous and cadaverous ſmell and taſte to the whole body of the liquor and ſpirit. Great care is therefore required, that the ferment be perfectly freſh and fragrant, nor in the leaſt inclinable to acidity, or eagerneſs; which might prevent its riſing, or forming a head, and give the liquor an acetous, inſtead of a vinous tendency.

When thus the proper quantity of a good-conditioned and ſuitable ferment is got ready, it muſt be put to the fermentable liquor in the bare tepid, or ſcarce luke-warm ſtate above-mentioned. The beſt manner of bringing them together, for raiſing the Fermentation quick and ſtrong, ſeems to be this: when the ferment is ſolid, it ſhould be broke into ſmall pieces, and gently thinned, with the hand, or otherwiſe, in a little of the luke-warm liquor. But a complete uniform ſolution ſhould not be here endeavoured; becauſe this would, in ſome meaſure, weaken the power of the ferment, or deſtroy its future efficacy. The whole intended quantity, therefore, being thus looſely mixed with a moderate parcel of the liquor, and kept near the fire, or elſewhere, in a tepid ſtate, free from the too rude commerce of the external air; more of the inſenſibly warm liquor ought, at proper intervals, to be added, till, at length, the whole quantity is well ſet at work together. And thus, by dividing the buſineſs into parts, it may be much more ſpeedily and effectually done, than by attempting it all at once: in which caſe, it is very apt to miſcarry, and require a reparation in the method already deſcribed.

When thus the whole is ſet at work, ſecured in a proper degree of warmth, and kept from a too free intercourſe with the external air; it becomes, as it were, the ſole buſineſs of nature to finiſh the proceſs, and render the liquor fit for the ſtill; and thus the general end of the Fermentation would be anſwered. But during the whole courſe of the operation, there are ſeveral other things that may be added, with ſome particular view; as either to improve the vinoſity, increaſe the quantity of the ſpirit, or give a particular flavour. And ſuch additions may require ſome particular alterations in the general method above ſet down. See ADDITIONS. *Shaw's Eſſay on Diſtillation.*

In order to aſcertain the fermentative quality of animal ſubſtances, Dr. Pringle, in the Appendix to his Obſervations on the Diſeaſes of the Army, has made ſeveral curious experiments: bread and water only ſtood ſeveral days, in a furnace, heated, as uſual, to 100 degrees; but, two drachms of freſh meat being added to double the former quantity of bread, and water in proportion, the mixture began to ferment in a few hours, and continued to do ſo about two days. For the moſt part, the Fermentation was ſo ſtrong that, if the corks had not frequently given way, the phials muſt have burſt. The bread and fleſh which at firſt lay at the bottom, ſoon roſe to the top, and conſtantly, as the air elapſed, let fall ſome particles that had been buoyed up by the fluid; thus a ſediment was formed, reſembling lees, whilſt the lighteſt part, or flowers, remained on the ſurface; but, the Fermentation continuing, theſe alſo ſubſided, and the acid taſte and ſmell of the liquors, after the action ceaſed, was a farther proof of the preceding Fermentation. This change was the more extraordinary, as, when the motion began, the mixture was tending to corruption, and, in effect, in a few hours afterwards, became offenſive; but next day the putrid ſmell abated, and went off before the Fermentation ceaſed.

The doctor made ſeveral other experiments, to the ſame purpoſe, and nearly ſimilar effects; from all which, he thinks it probable that moſt animal ſubſtances, tending to putrefaction, are endowed with a power of raiſing a Fermentation in the farinacea, and even of renewing that action in ſuch as have undergone it before.

The effect of Fermentation therefore is to change putrid ſubſtances to a ſtate of acidity, which they not only retain, but grow ſtill more and more acid. It is obſerved, indeed, that the acid ariſing from Fermentation has ſomething of an auſtere and ſaltiſh taſte, but without any offenſive ſmell. Now, conſidering how much air is generated by Fermentation, it may ſeem ſtrange that the ſame materials, uſed as food, ſhould make ſo little diſturbance in the body. And the difficulty would be the greater, did the ſaliva, as ſome ſuppoſe, promote both Fermentation and putrefaction.

From this theory of Fermentation the doctor accounts for the ſourneſs or acidity of the ſtomach, a diſorder to which many people are ſubject; ſince not only a ſtrong but an auſtere acid may be produced from the food of thoſe who live on fleſh, bread, and water only, as often as the ſtomach is relaxed, or any way diſabled from conveying the whole aliment into the inteſtines; for what is left, having time to undergo a complete Fermentation, is thereby changed into a harſh ſort of vinegar.

Spirits, wines, acids, bitters, aromatics, and the hotter antiſcorbutic plants retard alimentary Fermentation, by their power of correcting putrefaction. However, they may have their ſeveral uſes; ſome for checking immoderate Fermentation, when, by reaſon of a putrid effluvia, or a defect of it, the aliment may ferment too violently; and others, again, for bracing the ſtomach, and fitting it for expelling its contents in due time.

All theſe facts correſpond with digeſtion; for the moſt nouriſhing and digeſtable food, to people in health, conſiſts in a due mixture of animal and vegetable ſubſtances with water: ſcorbutic or putrid habits require acids, wine, or other antiſeptics. An acid, abounding in the ſtomach, is corrected by abſorbents, and, in a want of natural heat, and a debility of the ſtomach, wines, bitters, and warm and acid ſubſtances become neceſſary. *See Pringle's Obſerv. on the Diſeaſes of the Army, Append.*

FERMENTED *Liquors.*—All Fermented liquors abound with with an over-proportion of water; and, if a very conſiderable quantity of it were taken away, they would become not only richer, but more durable, provided that ſo much of the aqueous humidity was retained, as was juſt ſufficient to preſerve the vinous conſiſtence, to keep the ſaline part fluid, and to retain the ſlimy and unctuous parts expanded and mixed among

among the reſt. But as an actual and truly ſaline matter abounds in wine and in vinegar, and that of an acid, auſtere, and tartareous kind; when the ſpirituous part is drawn away, the wine becomes ſurpriſingly more auſtere; and, when a large quantity of the watery part is ſeparated, this ſuperabundant ſaline, tartareous matter coagulates into a cryſtalline form, and either falls to the bottom, or ſticks to the ſides of the caſk. For the ſubtile, oily matter, which makes the ſpirituous part in wine, blunts and takes off from a tartareous acidity, in the ſame manner that the addition of ſpirit of wine blunts, ſheathes, and dulcifies the acid, corroſive parts of ſpirit of nitre, in making the ſpiritus nitri dulcis.

But this tartareous ſalt, abounding alſo with an over-proportion of ſo groſs and unctuous matter, cannot be diſſolved or diluted without a very large proportion of water, which being taken away, it preſently converts into dry and ſolid cryſtals, as is the known caſe of cream of tartar. Hence proceeds the effect before obſerved, that the auſterity and roughneſs of wine are the more preſerved, the more the wine is deprived of its ſpirituous parts. This experiment is familiar in our kitchens, where wine, being burnt or boiled into ſauce, is found to have a much greater degree of auſterity, than the ſauce and wine had before it had undergone the action of the fire, and loſt its ſpirituous part.

When the water is, even by diſtillation, plentifully drawn off from wine, not of a terreſtrial and chalky, but of a tartareous nature, a beautiful tartar will be found to cryſtallize, among the remaining maſs, in a conſiderable proportion. But though this ſuperfluous water, that generally dilutes the wine, and weakens its taſte, might be advantageouſly ſpared from it, and it would then become much more rich and noble, and at the ſame time more ſmooth and ſoft, through the loſs of ſome conſiderable portion of its tartar; yet this ſeparation cannot be effected by diſtillation, becauſe that carries away other parts as well as the water, and damages the whole, by taking off what ought to be the moſt carefully preſerved. The ſpirituous part is the life of all fermented liquors; it keeps the whole together, and in a manner embalms and renders them durable, and not ſubject to corruption; it alſo in a great meaſure gives them that aromatic, refreſhing, and reſtorative virtue, and the beſt effects they have on the human body. Nor is this all, but the intimate and ſubtile union of this ſpirituous part with the reſt is perfectly the ſole and entire cauſe of both the former effects; ſo that it by no means ſuffices to have the ſpirit barely preſent among the other parts, for then it might be drawn off and poured back again, without any damage to the wine; but the eſſential union is here diſſolved by taking it away, and can never be reſtored again by a ſimple re-affuſion. It is therefore deſtructive of the end propoſed thus to break and diſſolve the texture of the wine, and this entirely ſubverts and deſtroys its nature. This inevitably proves the caſe, whenever wine is evaporated or diſtilled, which conſtantly requires a degree of heat capable of raiſing water into vapour; and hence the ſpirituous part, being greatly lighter than the aqueous, flies off together with it, or before it, and the wine is left diſſolved in its texture, and without its ſoul. Upon this, the remaining ſaline unctuous maſs is ſo diſturbed, as no longer to remain connected, but it becomes thick and turbid, and afterwards runs impetuouſly into a kind of corruption attended with acidity and ropineſs. All theſe circumſtances ſhew, that, though the condenſing of wines by taking away their ſuperfluous humidity would be a very deſirable thing, yet it is by no means to be done by evaporation. *Shaw's Eſſay on concentrating Wines.*

FERN, *Filix*, in botany. There are great varieties of this plant, in different parts of the world; but we ſhall only mention two ſpecies, the male and the female.

The leaf of the male Fern is compoſed of other leaves, which adhere to a rib in ſuch a manner, as to have lobes on both ſides, cut into the depth of the main fibre: the fruit reſembles that of polypody.

It grows on the ſhady banks of hedges: the part uſed in medicine is the root, which is thick, blackiſh without, but pale within, fibrous, involved and interwoven with multitudes of appendages, and of a bitter and ſomewhat aſtringent taſte.

The virtues are the ſame as thoſe of the female Fern; but it has a peculiar efficacy againſt the rickets, or reckets. It expels worms and the ſtone; relieves thoſe who labour under an increaſe of the ſpleen. Dioſcorides ſays, that the root drank, or made into an ointment with fat, cures wounds inflicted by arrows. Theophraſtus, Pliny, and Dioſcorides agree, that it cauſes barrenneſs and abortion. Tragus aſſures us, from his own experience, that, when a horſe falls down, and you are puzzled to find the nature of his diſorder, if you put a rib of the root of this plant under his tongue, he will immediately excrete both ways, and riſe up. *Dale, Ray.*

The common female Fern, or brakes, has many large leaves divided into ſeveral branches, beſet with long, narrow, ſtiff pinnulæ, which are moſtly ſmooth about the edges, though ſometimes they are a little indented: The back of theſe, about Midſummer, will be covered round the margins with a great number of duſky brown particles, which are the ſeed: the root is long and thick, ſpreading much in the earth, ſending out ſhoots on every ſide, which makes it hard to be eradicated: It grows but too frequently on commons and heaths, being uſed, in want of fuel, by the country people, for heating their ovens, and other uſes.

The roots only are uſed in medicine, and thoſe but rarely, being commended as very good for worms, eſpecially the flat worm: a kind of pot-aſh is made of the ſtalks and leaves burnt. *Miller's Bot. Off.*

The common female Fern is very miſchievous and troubleſome to the farmers, being very difficult to deſtroy, where it has any depth of ground to root in. Its root will often penetrate to eight feet deep, and, ſpreading a great way, they will riſe again to the ſurface, and ſend up new plants at a conſiderable diſtance. In graſs land the beſt way of deſtroying it is mowing the graſs, three times a year in ſpring, in May, and in Auguſt. Dung and aſhes are very good manure for lands which abound with it, but the beſt of all things, for deſtroying it, is urine. Fern cut up, when the ſap is in it, and laid to rot upon the ground, is a very good manure for land, and will mellow it ſo as to prevent its binding. Trees, planted where Fern grows, are obſerved to thrive very much, even though it be upon a hot gravel; the reaſon of this is, that the Fern ſhades the roots and keeps them moiſt and cool. *Mortimer's Huſb.*

The ſeeds of the ſeveral ſpecies of Fern were wholly unknown to the antients. Swammerdam, in his Biblia Naturæ, claims to himſelf the honour of having firſt diſcovered them; but it appears from Hook's works, that Dr. William Cole ſent an account of the ſeeds of ſeveral of the plants of this kind to that author, in 1669, whereas Swammerdam declares his diſcovery of them to have been in 1673; ſo that it is plain that Dr. Cole's was prior to his by ſome years. Swammerdam is an author of that ſtrict probity, that there is no room to doubt but that he ſpoke what he thought to be true; and it is even poſſible that he might have diſcovered them ſooner than the time he mentions; but, however that be, it appears from the later obſervations of the ingenious Dr. Miles, that his accounts are extremely accurate and juſt. The ſeed-veſſels of the common Fern, the Engliſh and foreign maiden-hairs, the wall-rue, hart's-tongue, and the like plants, are all alike in their general form, their only differences being in the ſize, and their arrangement on the plants. The number or quantity of the ſeeds is very different in different plants, but Mr. Miles obſerves, that, the fewer ſeeds there are in any ſpecies, there is always the more in quantity of a ſort of ſpongy or fungous matter, which forms a kind of tubercle, not unaptly reſembling what is called Jew's-ears, which ſeems a ſubſtance intended for the ſheltering the ſeeds.

In the female Fern and Engliſh maiden-hair, the whole ſurface of the leaf, on the under ſide, ſeems covered with a congeries of ſeeds, ſo that they guard one another, and therefore have leſs occaſion for a covering of fungous matter of this kind; yet even on theſe plants, when the ſeeds are fallen off, there are found ſmall membranes, a little curled, looking as if they had been raiſed with the edge of a fine penknife, from the ſkin of the leaf, not unlike the pieces of ſkin that are raiſed off from the hand, in the trying a penknife or other ſharp inſtrument. In the common male Fern, there are found, at the proper ſeaſon, ſeveral brown ſpots placed in a regular manner; theſe are of a pale brown colour, and are principally compoſed of this fungous matter, the ſeed-veſſels being ſmall and inſerted round it. *Phil. Tranſ.* Numb. 461.

Theſe ſeed-veſſels conſiſt of a ſtalk by which they are inſerted into the leaf; this repreſents an elaſtic cord, and is ſurrounded by a great number of annular ribs, reſembling the cartilages of the aſpera arteria; and indeed nothing in nature ſo exactly reſembles this cord or ſtalk, as the wind-pipe of a ſmall bird. This cord incircles the globular membranous pod wherein the ſeed lies, adhering to it, and dividing it into two hemiſpheres.

The pod is compoſed of a fine whitiſh membrane ſomewhat like that which lines the inſide of a pea-ſhell; the ſeeds are irregular in ſhape, and of a reticulated ſurface. The moſt advantageous way of viewing this is to uſe the common microſcope for opake objects, putting on a ſmall magnifier, and laying the ſeeds with their capſules, &c. as taken from the back of the plant, on a piece of poliſhed ivory. The proper time of the year is in the beginning of September; and then, if the plant be newly gathered, the ſeed-veſſels often burſt, while they are under inſpection, and ſhew a very elegant appearance. The manner of this burſting of the pod, which is the method nature has taken for the ſcattering and diſperſing of the ſeed, is this: the cord becomes extended in ſome one part, and ſoon after breaks aſunder; this by expanding burſts the pod into two parts, and, continuing to expand itſelf, as it departs from a curve, and approaches to a right line, it rends itſelf away from the globular pod, till it be at length wholly diſengaged from it; and then, as there can be no farther reſiſtance given to its expanding, it ſuddenly flies off, with a ſort of jerk, and becomes quite ſtraight at once. By this laſt action the capſules are ſhook, and the ſeeds are diſcharged out of them on the plate of ivory, in the ſame manner as the grains of wheat or barley would be thrown out of a bowl placed

ced on a table, by the shaking of the bowl. This is a beautiful phænomenon in the minute seed-vessel of the Fern, and frequently seen when the seeds are fresh gathered, as then the cords and capsules are green and juicy, and the bursting goes on gradually; but, when they are dry and crisp, there is nothing of this seen, for the bursting is instantaneous, and the seeds are tossed so far by it, that none of them fall within the area taken by the lens. When the pod and cord are but just ripened, they sometimes are twenty minutes in bursting, and the whole method of the process is then distinctly and beautifully seen. This whole mechanism would be seen in a much more perfect and beautiful manner, if it were possible to get off the seed-vessels from the leaves without injuring them in doing it; for the common way, in getting them off, is by rubbing the leaves, and this must necessarily burst a great number of them; in this method they are seen to fly off from the leaves, in form of a fine dust or powder, and often get into the pores of the skin, and become as troublesome, as cow-itch. *Phil. Transf.* Numb. 461.

FERN-*ashes.* The ashes of the common female Fern produce a very singular phænomenon, in the common way of treating them and their salt. If a large quantity of these ashes are procured, and the salt to the quantity of several pounds extracted from them in the common way, it will succeed better than in smaller quantities. The greater part of this salt being dried, if the remainder, which is more moist, be exposed to the air to receive some of the vapours of it, this will soon become fluid, or an oil, as it is very improperly called, by deliquium. The rest of the lixivium, which will be heavy, and of a deep blood red, or claret colour, being set by in a glass vessel unstopped for five or six months, there will be found, at the bottom of the liquor, a very large quantity of salt precipitated to the thickness of about two inches of the bottom of the vessel. The lower part of this will have all the foulness, and appear discoloured; but the upper part will be extremely pure and white. From the surface of this part, there will grow up a number of plants, in appearance standing erect, and at small distances from one another. These are only the last crystallizations of the subsiding or separating salt, but they have a regularity that is very surprising; they vary considerably in size and weight, but are all of the same shape, exactly resembling so many plants of the common unbranched Fern, sending out a great number of regular leaves on each side the stem. These ramifications of the salt will remain many weeks in this perfection, if the vessel be not stirred; but they are so tender, that the least motion destroys them, and they, after this, never will form themselves again. *Phil. Transf.* Numb. 105.

FERN-*oil,* in pottery, a name given, by our merchants who have been in China, to a sort of varnish, which the Chinese use in their porcelain manufactories: it is also called lime-oil, and is a thing so easily made, that it would be worth attempting what might be done with it, in our imitations of the porcelain. They make it in this manner: they take a large quantity of Fern well dried, and, spreading a covering of it over a piece of ground sufficient for the quantity of oil they intend to make, they lay upon this a coat of large lime-stone, newly calcined into lime; on these they sprinkle with the hand a small quantity of water just to slake them. They cover this bed of lime with another of Fern, and soon, till they have raised it to eight or ten feet high; they then set fire to the Fern; this burns away in a little time, and leaves a mixture of the lime and its own ashes. This mixture is laid in the same manner between beds of more Fern, and burnt again. This operation is repeated five or six times. *Observ. sur les Coutum. de l'Asie.*

When the last calcination is finished, the mixture of lime and ashes is carefully gathered up and thrown into large vessels of water, and, with every hundred weight of it, they put in one pound weight of kekio; they stir the whole together, and, when the coarser part has subsided to the bottom, they take off the finer which swims at the top in form of a fine cream, and, putting it into another vessel of water, they let it subside to the bottom by long standing; they then pour off the water, and save the residuum in form of a thick oil.

This they mix with the oil of stone, prepared by powdering and washing in the same manner a particular sort of stones, and, with this, they cover all the vessels that they intend to varnish. The Fern-ashes have a very great share in the advantage that this oil has over our common varnish; and the Chinese tells us, that they once instead of Fern used the wood of a tree, called setki; and they suppose that the superiority of the old porcelain over the present is owing to the use of this tree instead of the Fern; but it is now too scarce among them. The new manufacture which we have at Bristol excels every thing that has been done of the like kind, in the beauty of the varnishing; and it is said, they have found their advantage on an imitation of this, and the Chinese oil of stone. These two oils, as they are called, are always mixed together, and they must be carefully preserved of the same degree of thickness, or else all the varnishing will not be even. *Observ. sur les Coutum. de l'Asie.*

FE'RRET, *viverra.* This creature has but one note in her voice, which is a shrill but small whining cry. The female usually brings forth seven or eight young ones at a time: she carries them in her body forty days; the young ones are blind for a long time after they are littered. When they are tamed, they are to be fed with milk, and with barley bread; they will fast a long time; when they walk, they set up their back, which is otherwise so long, that it would be troublesome to drag it on; when they are touched, they smell very disagreeably; they naturally sleep very much. The Ferret is a bold and audacious animal, and is an enemy to almost all others. It does not eat the flesh of the creature it kills, but sucks their blood.

When the warrener has occasion to use the Ferret to catch rabbits, he first makes a noise in the warren to frighten them all into their holes; then he pitches his nets, and, having muzzled the Ferret that he may not bite the rabbits, he turns him into their holes to frighten them out, and then the dogs drive them into the nets that are set for them.

FERRETS, in glass-making, the irons with which the workman tries the melted metal to see if it be fit to work.

It is also used for those irons which make the ring at the neck of bottles. *Neri's Art of Glass.*

FERRE'TTO, in the glass trade, a substance which serves to colour glass. This is made by a simple calcination of copper, but it serves for several colours. There are two ways of making this; the first is this: take thin plates of copper, and lay them on a layer of powdered brimstone, in the bottom of a crucible; over these lay more brimstone, and over that another layer of the plates, and so on alternately, till the pot is full. Cover the pot, lute it well, place it in a wind furnace, and make a strong fire about it for two hours. When it is taken out and cooled, the copper will be found so calcined, that it may be crumbled to pieces between the fingers, like a friable earth; it will be of a reddish, and in some parts a blackish colour. This must be powdered and sifted fine for use.

The other way is less easy, but it makes a more valuable Ferretto. It is this: make a number of stratifications of plates of copper and powdered vitriol alternately in a crucible, which place in the floor of the glass furnace near the eye, and let it stand there three days; then take it out, and make a new stratification with more fresh vitriol, and calcine it again as before; repeat this operation six times, and a most valuable Ferretto is produced. *Neri's Art of Glass.*

FERRI'FIC *Cause,* a term used by some writers to express that principle, to which what they call production or generation of iron in burnt bodies, in which no iron could be discovered before burning, is owing. It is the general opinion of the present philosophers, that this iron thus discovered in the ashes of plants, and the like burnt substances, really existed there before, and only needed the disunion of the concreted body, to the bringing of its parts together. If this be the case, there is evidently no production of iron in the case, and therefore the term Ferrific is a word without a meaning. Becher, however, in his Supplement to his Physica Subterranea, is of a very different opinion, determining, that the iron is really produced in these cases, during the action of the fire, and that by the transmutation of some other matter into iron; and from this he agrees the possibility of gold-making among chemists by transmuting something else into gold, as some other substance is in this case transmuted into iron.

FE'RULA, *fennel giant,* in botany, a genus of plants, whose characters are:

It has a large, succulent, and milky root; the stalks are fungous, full of pitch, and disposed to take fire. The seeds are very large, oval, and thin; they throw off their involucrum, and, for the most part, turn black, when ripe.

It is sometimes cultivated in the gardens of botanists, and flowers in July. The parts in use are the medullary substance of the stalk, the seeds, and the juice or gum, which is the sagapenum of the shops. *Dale.*

The medulla, or pith, of the green Ferula, being drank, is good for spitting of blood, and the cœliac passion. It is prescribed in wine, for the bite of the viper; and, intruded into the nostrils, stops bleeding of the nose. The seed, drank, relieves under the gripes, and, used in unction with oil, provokes sweat. The stalks, taken as food, cause head-ach; they are usually pickled. The Ferula often produces a stalk three cubits long; its leaves resemble those of fennel, but are much larger and thicker. The sagapenum distils from the stalk, wounded near the root. *Dioscorides, Lib.* ii. *cap.* 91.

FEVE, in natural history, a name first given to the chrysalis of the silk-worm, and from thence to all chrysalises of the butterfly kind; in which sense it is now received and used with the most accurate writers, and made a synonymous term with the words chrysalis and aurelia.

Choleric FEVER, in medicine, the name of a Fever, called also by some a bilious Fever, and by others a causus; though the generality of writers distinguish the cholerica febris from the causus. All bilious Fevers are properly species of acute Fevers, and owe their origin to distemperatures of the bile, at times when the aliments are in a state of fermentation in the stomach and intestines.

The causus is distinguished from the cholerica febris, properly so called, by its being ever much more violent and dangerous, and

and by the excretions which attend it: for, in the choleric Fever, the vitiated gall and bilious excretions are always plentifully voided, sometimes upward, sometimes downward, and sometimes both ways. In the causus, the matter is more usually detained in the body, and rarely voided otherwise than by vomiting, and that usually only in small quantities, and in the beginning of the distemper.

Signs of it. The general signs of the cholerica febris and causus are a remarkable anxiety, and frequent complaints about the breast, as of a straitness and painful heat. A violent heat on the inside of the mouth, and insatiable and intolerable thirst, trembling and convulsive motions of the joints, and violent deliriums. Dryness of the mouth and tongue are often so terrible in this disease, that the skin cracks with it; and often the whites of the eyes, sometimes the whole body becomes yellowish. The peculiar and appropriated symptoms of a cholerica febris, strictly so called, are an universal languor and debility of the limbs.

A severe shivering first seizes the patient, and is soon succeeded by a very violent heat, and raging pain in the head; and, after the two first days, there usually are very terrible strainings and reachings to vomit. The matter brought up at these times is caustic, acrid, and bilious, and inflames and even ulcerates the fauces; and, if voided upon a stone floor, effervesces violently. If this vomiting abates, there immediately comes on a diarrhœa attended with a tenesmus, occasioned by the irritation of this sharp matter in the rectum. Faintings also are very frequent in this disease, especially where the vomitings do not bring up a sufficient quantity of the offending matter. The peculiar and appropriated signs of the causus, strictly so called, are these: a violent and insatiable thirst, greater than that in any other Fever. The bowels are always bound, and it is but very seldom that there is any tendency to vomit. The urine is reddish and turbid, and, after standing some time, deposits a red sediment. Often there is a sensible pain and soreness in the præcordia, so that the patient cannot bear the least touch upon the breast; and usually, in the course of the disease, there are faintings and violent convulsions.

Persons most subject to this disease are such as eat largely, and drink heavy and imperfectly fermented liquors after it. The cholerica febris, properly so called, is most frequent with those of a cholerico-sanguineous habit, and such as feed on high-seasoned meats, and drink abundance of wine or other strong liquors; and is often brought on such persons, by their falling into violent passions after a full meal. The causus peculiarly attacks the people of melancholic habits, who are much inclined to passion, but suppress it, and who are naturally costive.

Method of cure. The cure of these diseases consists in the mitigating the violent sharpness of the humour, and promoting its evacuation; and, finally, in abating the burning heat brought on by it. The utmost endeavours are first to be made to correct and alter the morbific matter. To this purpose, the several preparations of nitre, with the testaceous powders and mucilaginous ptisans, with small mixtures of lemon-juice, and frequent draughts of cooling and diluting liquors, are to be given moderately warm. If the costiveness be too violent, clysters of broth must be injected, with the addition of a little oil and salt; and, if necessary, small doses of rhubarb. To quell the febrile heat and emotion of the blood, the mistura simplex may be given with great success; and there is often a sensible good effect from the application of rags, wetted in camphorated spirit of wine, to the pit of the stomach. After the morbific matter is evacuated, the reachings to vomit may be allayed by gentle opiates. All hot medicines change the bilious Fevers into inflammatory ones, and the common sudorifics drive the morbific matter into the blood, and usually bring on almost immediate discolourings of the skin, like those of the jaundice. Bleeding, though performed ever so early in the disease, seldom does any good, except only in remarkable plethoric habits. *Junker's Consp. Med.*

FIBRA'RIÆ, in natural history, the name of a class of fossil bodies, the greatest part of which have been very improperly called, by the writers of fossils, fibrose talcs, they being of a very different substance and structure of parts from the talcs, and having none of their distinguishing characters.

The word is derived from the Latin *fibra*, a fibre, or filament, these bodies being all composed of arrangements of parallel filaments of fibres.

The Fibrariæ, in general, are fossils composed of parallel filaments usually remaining so distinct as to preserve in the whole masses of a thread-like texture, but sometimes uniting so as to form plates or flakes, resembling those of the talcs in external figure. They are bright, and in some degree transparent; not giving fire with steel, nor fermenting with, or soluble in acid menstrua. *Hill's Hist. of Foss.*

FI'BROSE *roots*, those which consist wholly of small fibres, such as the roots of the meadow-grass, pinks, and several other flowers. When a Fibrose root penetrates straight into the ground, it is called perpendicular; when it creeps under the surface, horizontal; when somewhat thick, it is called fleshy; when very thin, capillary; when it runs all the way undivided, simple; when divided, or when it sends off smaller roots, branched; when its surface is covered with extremely short and fine fibres, hairy.

FICOI'DES, in botany, a genus of plants, whose characters are:

The whole plant is succulent, and has the appearance of housleek: the leaves are conjugated, or grow opposite by pairs: the calyx surrounds the extreme margin of the ovary; is of a carneous or fleshy substance, and pentaphyllous or pentaphylloidal: the flower is polypetalous, very minutely divided, and springing from the top of the capsule: the ovary produces five reflected tubes, and becomes first a succulent, afterwards a fungous fruit, divided into five or more cells, like little pods full of numerous minute seeds.

Boerhaave, in his Index alter Plantarum, enumerates fifty-three species of this plant; which, in the Historia Plantarum attributed to him, are said to be of an emollient quality, and to have the other virtues of the sedum or housleek. The fruit is eatable, and a good part of the food of the Hottentots.

FIELD-*book*, in surveying, a book used for setting down angles, distances, and other things, remarkable in taking surveys.

The pages of the Field-book may be conveniently divided into five columns. In the middle column, the angles at the several stations taken by the theodolite are to be entered, with the distances from the stations. The distances taken by the off-set staff, on either side of the station line, are to be entered into the columns on either side of the middle column, according to their position with respect to that line. The names or characters of the objects, with proper remarks, may be entered in the columns on either side of these last mentioned. *Treat. Pract. Geom.*

FIE'LDFARE, in zoology, the English name of a bird of the thrush kind, called by authors turdus pilaris. It is larger than the common thrush, and is of a bluish grey colour on the neck; the head is spotted with black, and the shoulders and back are a yellowish brown, variegated with black; the throat is variegated with black and yellow; the lower part of the belly is white and but a little spotted; and on each side of the neck, and near each eye, it has a large black spot; those on the neck are on its lower part near the insertions of the wings; its wing-feathers are variegated with black, white, and a yellowish brown, and the tail is of a bluish black, with some variegations of black and white.

It is a bird of passage, and visits us in England towards the end of autumn in vast flocks, and leaves us in spring; it is not certainly known where they breed. They feed on berries, particularly those of the holly, and are a well-tasted bird. *Ray's Ornith.*

FIE'LD-FORT.— *Plate* XXXI, *fig.* 6. in the Dictionary, represents an irregular Field-fort; such as are thrown up by an army, when they besiege a place.

FIG (*Dict.*)— *Method of cultivating* FIG-TREES.— These trees are always planted as standards, in all warm countries; but in England they are generally planted against walls, there being but few standard Fig-trees, at present, in the English gardens: however, since the fruit is found to ripen well upon the standards, and the crop of Figs is often greater upon them, than upon those trees against walls, it may in time become the general practice to plant them either in standards or espaliers: the latter, I think, will succeed best in England, if they were managed as in Germany; where they untie the Fig-trees from the espalier, and lay them down, covering them from the frost with straw or litter; which prevents their shoots being injured by the frost; and this covering is taken away gradually in the spring, and not wholly removed until all the danger of frost is over: by which management, they generally have a very great crop of Figs; whereas, in England, where the trees grow against warm walls, if the spring proves warm, the young Figs are pushed out early; and the cold, which frequently returns in April and May, causes the greatest part of the fruit to drop off, so that our crop of Figs is generally more uncertain, than most other sort of fruit; and it frequently happens, that trees which are planted against north and east aspected walls, produce a greater quantity of fruit in England, than those which are planted against south and south-east aspects; which must happen from the latter putting out their fruit so much earlier in the spring than the former: and, if there happen cold frosty nights, after the Figs are come out, which is frequently the case in this country, the forwardest of the Figs are generally so injured as to drop off from the trees soon after. In Italy, and the other warm countries, this first crop of Figs is little regarded, being few in number; for it is the second crop of Figs which are produced from the shoots of the same year, which is their principal crop; but these rarely ripen in England; nor are there above three or four sorts which ever ripen their second crop, let the summer prove ever so good; therefore it is the first crop which we must attend to in England: so that, when these trees are growing against the best aspected walls, it will be a good method to loosen them from the wall in the autumn; and, after having divested the branches of all the latter fruit, to lay the branches down from the wall, fastening them together in small bundles, so that they may be tied to stakes, to keep

keep them from lying upon the ground; the damp whereof, when covered in frosty weather, might cause them to grow mouldy: and hereby they will be secured from being broken by the wind. When they are thus managed in the autumn, if the winter should prove very severe, the branches may be easily covered with peas-haulm, straw, or any other light covering, which will guard the tender fruit-bearing branches from the injury of frost: and, when the weather is mild, the covering must be removed, otherwise the Figs will come out too early; for the intention of this management is to keep them as backward as possible: then in the spring, when the Figs are beginning to push out, the trees may be fastened up to the wall again. By this management, I have seen very good crops of Figs produced in two or three places.

I have also seen great crops of Figs in some particular gardens, after very sharp winters, when they have, in general, failed in other places, by covering up the trees with reeds made into panels, and fixed up against the walls.

In the pruning of Fig-trees, the branches must never be shortened; because the fruit are all produced at the upper part of the shoots; so, if these are cut off, there can be no fruit expected; besides, the branches are very apt to die after the knife: so that, when the branches are too close together, the best way is to cut off all the naked branches quite to the bottom, leaving those which are best furnished with lateral branches at a proper distance from each other; which should not be nearer than a foot; and, when they are well furnished with lateral branches, if they are laid four or five inches farther asunder, it will be better.

The best season for pruning of Fig-trees is in autumn, because, at that time, the branches are not so full of sap; so they will not bleed so much, as when they are pruned in the spring; and, at this season, the branches should be divested of all the autumnal Figs; and, the sooner this is done, when the leaves begin to fall off, the better will the young shoots resist the cold of the winter. There are some seasons so cold and moist that the young shoots of the Fig-trees will not harden, but are soft and full of juice: when this happens, there is little hope of a crop of Figs the succeeding year; for the first frost in the autumn will kill the upper part of these shoots, for a considerable length downwards: whenever this happens, it is the best way to cut off all the decayed part of the shoots, which will prevent the infection from destroying all the lower part of the branches; and, by this method, I have seen a moderate crop of Figs put out from the lower part of the shoots, where, if the shoots had not been injured, there would have been no fruit produced; because it is chiefly from the four or five uppermost joints of the shoots that the fruit comes out: and it is for this reason, that as many of the short lateral branches should be preserved as possible, those being the most productive of fruit; for, where the long straight shoots are fastened up, there will be no fruit, but at their extremities; so that all the lower part of the trees will be naked, if there is not a particular regard had to supply young shoots in every part of the trees.

Those trees which are laid down from the walls or espaliers, should not be fastened up again until the end of March, for the reasons before given; and those against walls may remain for some time longer: and, when the large shoots of these are nailed up, if the small lateral branches are thrust behind these, to keep them close to the wall, it will secure the young Figs from being injured by the morning frosts: and, when this danger is over, they may be brought forward to their natural position again: during the summer-season these trees will require no pruning, but the branches are often blown down by wind; therefore, whenever this happens, they should immediately be fastened up again, otherwise they will be in danger of breaking; for, the leaves of these trees being very large and stiff, the wind has great power on them; so that, where the branches are not well secured, they are frequently torn down.

Those trees which are planted against espaliers, may be protected from the injury of frost in the spring, by placing reeds on each side the espalier, which may be taken down every day, and put up again at night; but this need not be practised in warm weather, but only at such times as there are cold winds and frosty mornings: and, although there is some trouble and expence attending this management, yet the plentiful crop of Figs, which may be this way obtained, will sufficiently recompense for both: the best way of making this covering is, to fasten the reeds with rope-yarn, in such a manner, as that it may be rolled up like a mat; so that the whole may with great facility be put up, or taken down: and, if these reeds are carefully rolled up, after the season for using them is over, and put up in a dry shed, they will last several years.

There are several persons, who of late have planted Fig-trees in standards, which have succeeded very well: this practice was revived, by observing some old standard Fig-trees in some gardens, which had been growing many years, and generally produced a much greater plenty of fruit than any of those trees which were growing against warm walls: indeed, the standard Fig-trees are in much greater danger of having their branches killed by severe frost; but in mild winters they generally do better than those against walls; so that, where these trees can be covered in very hard winters, there will always be plenty of fruit; and these may be covered by fastening as many of the branches together, as can be conveniently brought into a bundle; and winding some hay-bands, straw, peas-haulm, or any such light covering as can be readily procured; which in the spring may be gradually taken off, so as not to expose the shoots all at once to the open air; and, if there is some such light covering laid round the stems, and upon the surface of the ground about their roots, it will more effectually secure them from the danger of frost; but, when this is practised, great care should be taken, that no mice or rats harbour in this covering; for these will eat off the bark from their shoots, and kill them: and I have often observed, those trees which were against walls, have suffered greatly from these vermin, by having many of their largest branches disbarked near the ground, which has absolutely killed them: and it is in the winter that these vermin do this mischief to them; therefore they should be carefully watched at that season.

The common blue and white Figs, which are the sorts that have been the most generally cultivated in England, are not so proper to plant for standards, as some other sorts which have been lately introduced; for they are much tenderer, and are often killed almost to the root, when some of the other sorts, which have been growing in the same situation, have received very little injury from the frost: indeed, the white sort is generally a great bearer, and the fruit is very sweet; but, to those palates which are accustomed to Figs, that sort is not much in esteem, from its want of flavour. *Miller's Gard. Dict.*

FIG *insect*, in natural history, a name given by the English to the creature called by the French, after Mr. Reaumur, the faux puceron, or false puceron, from its very much resembling the puceron in external appearance, but extremely different from it, when nearly examined. These insects are, when at their full growth, of the bigness of the head of a pin of the largest size, but there are usually found among them several that are smaller, down to such as are scarce perceivable to the naked eye. They are found in great plenty on the back or under sides of the leaves of the Fig-tree, but they never are seen in clusters like the pucerons; twenty or thirty being the greatest number usually found on one leaf, and these scattered in different parts of it. These animals, though of the same general figure with the pucerons, yet are of so very different a nature, that they are all of them become at length winged insects, none remaining naked, as great part of the pucerons do; and they are not in a condition to multiply or bring forth young in this state, but must pass first through their transformation into the fly, like that to whose eggs they owed their origin.

FIGURES *on China ware*. There are several very different ways of making the Figures we see on the China ware, and, according to the method used, they have a very different appearance; but none of them are difficult. The common Figures which we see, are traced with a pencil dipped in the colours prepared of stones and earths, washed to fineness by water, and afterwards dried, and then blended with gum-water for use in the common way. The common blue is our smalt, and the finer blue a stone they call leao; the reddish is calcined copperas; and the green a preparation of the scoriæ of copper. These will all mix with gum-water, and spread from the pencil; and the only care to be taken in regard to them is, to make the powder very fine. The miniature paintings, as they are called, on the blue China, are thus done: the vessel is plunged all over into the common blue, made into a soft paste or varnish with water; this gives the whole vessel a coat of blue, and the workman takes a fine needle fitted into a proper handle, and with the point of this, he pricks out his Figures, every touch leaving behind a small white spot, which is owing to the taking off the blue where the point touched it; after this is finished, and the whole is dry, the vessel is varnished over, and the Figures appear painted in miniature under the surface.

The elevated or embossed Figures of beasts and flowers which we see on China, are done in a much easier manner, than would naturally be imagined. The artist carves these first with a burin on the surface of the vessel, while yet soft; after this he cuts away the substance about the Figures, and they appear elevated in any degree that he pleases. These are painted by the common hands employed in this work, and, when dry, are varnished over; and the effect is very elegant, while the means are not at all to be discovered.

The most beautiful of all China, in the judgment of many, is that which is all white, but has Figures within the surface; these appear very neat and distinct, though the surface is perfectly smooth. They are made of a whiter matter than the rest, called boache (which see) and, when these are laid on in this white, and covered with the common varnish, they are seen through it, and are of a different white both from the varnish and the substance of the China. *Observations sur les Coutumes de l'Asie.*

FIGURED *stones*, in natural history, a name given by some writers to those fossil bodies which are found in the shape of shells and other parts of animals. Disputes among the learned have

have never run higher on any subject, than on the origin of these stones; some have declared them to be all of marine origin at first, and that they were brought to the places where we find them in this fossil state, at the time of the universal deluge, and have been since altered in the nature of stones, by long lying in the earth, in the way of waters impregnated with stony particles, which they have deposited in them, after entering their substance in their passage through the earth.

Others are of opinion, that these bodies, though resembling ever so exactly the sea fishes, yet never were in the sea at all: but that the first semina of the sea shells, corals, and other substances, being carried by the sea water through the subterranean passages into all parts of the earth, even into the highest mountains, have been there left in vast numbers, and, growing there among stony matter, have arrived at their true bulk and figure, but in a stony substance.

FILA'GO, *common cudweed*, in botany, a genus of plants whose characters are:

The calyx is squamose, and neither shining nor specious: the floscules are divided or cut in form of a star: the broken parts end in ductile filaments.

The common cudweed grows to be near a foot high, usually with one woolly stalk, having several long, narrow, crumpled, sharp-pointed, whitish leaves, set pretty close to the stalk: on the top of the branches grow round globules or heads, composed of a great number of small naked flowers set together in clusters; and from the middle of these, on both sides, spring smaller branches, over-topping them three or four inches, bearing at the ends the like, but smaller heads of flowers; whence it is called herb impious, from the younger heads over-topping those from whence they had their original. The heads pass away into down, holding very small seed: the root is small, woody, and perishing yearly: it grows in dry barren places, and often in fallow fields.

Cudweed is drying and binding, and accounted good for all sorts of hæmorrhages and fluxes. It is given to cattle that have lost the ruminating faculty, and is therefore called cudweed. It is rarely used. *Miller's Bot. Off.*

FILIPE'NDULA, *dropwort*, in botany, a genus of plants whose characters are:

The root is fibrous and perennial, with glandulous bulbs fastened to it: the leaves are finely jagged, like those of millefoil: the calyx is monophyllous, denticulated, and divided into six or seven segments, which are retroflected, or bent backwards: the flowers are hexapetalous or heptapetalous, loosely disposed in panicles on long stalks, which are almost naked: the stamina are numerous, and situated on the reflected margin of the calyx: the fruit is generally round, and contains many seeds compacted together, each of them furnished with its tube.

The Filipendula is styptic, sweet-smelling, glutinous, of a taste a little saltish, and gives a pretty deep-red tincture to blue paper: the root gives it a pretty strong one: it is styptic, and a little bitter. This plant contains a salt, approaching to that of alum; but it is mixed with a great deal of sulphur; for by chymical analysis we obtain from it a great deal of acid earth and oil. All authors agree that it is very diuretic and aperitive. Tabernæmontanus, after Sylvaticus, Simon Januensis, Bayrus, and Lobel, recommend it for the epilepsy; and Mercator and Prevotius for the dysentery. *Martyn's Tournefort.*

FI'LTRUM, in natural history, the name of a stone much used in the eastern parts of the world, and sometimes with us, for the filtrating water intended for drinking. The Japonese are extremely fond of this stone, and impute their uninterrupted health, and particularly their being always free from the stone and gravel, to their drinking the water thus cleared of all its heterogeneous and mischievous particles. The people of this and many other places, thereabout, have a settled opinion, that most diseases arise from impurities of water, and are well assured, that these impurities are all lodged in this stone filtre, and left behind by the water in its passage.

The manner of using the stone is this: they form a sort of mortars with very thick bottoms, out of the largest pieces of it, and the water is poured into these, and, the stone being of a very lax and spongy texture, it soon makes its way through, and is received into a vessel placed underneath for that purpose. Some say, that the stone itself is a kind of marine fungus; that it is soft, while in the water, and grows to the sides of rocks in some part of the gulf of of Mexico, at the depth of a hundred ells, from whence it is with the utmost difficulty got up; and that it hardens into stone, as soon as it comes into the air.

This seems a fabulous account, however, only propagated to countenance the high price it bears. Whatever be its origin in Mexico, we are well assured, that there are other places where it is to be had on much easier terms, than by fetching it from the deep bottoms of the sea. We are at present acquainted with two kinds of it: the one black, resembling the common black slate, with which we cover houses; and the other grey, and of a tophus structure. We have also stones which may be applied to this purpose, in many parts of Europe; and, in all probability, every species of those which are porous, and of the tophus kind, will do. The osteocolla, used in the shops as a medicine, will perfectly well answer that purpose; and, if one of the tubes of this be stopped at the bottom, and then filled with water, it will be seen immediately making its way through it on all sides. The incrustations on vegetable and other substances, in springs, are all formed of a matter very analogous to the osteocolla, that is, of a coarse terrene spar. And, if a piece of any of these be hollowed at the top, and water put into it, it will be seen to fall out at the bottom in form of a little shower of rain; this might give some countenance to the Mexican story of their Filtrum being formed under water. As the spar is contained in all water, so that of the sea, as well as of rivers and springs, may form itself into a sort of fungous masses, against the sides and edges of the rocks; but it is not probable that it should be found at such depths. On observing the great density and firmness of the sparry concretions in springs, which yet suffer water to pervade their texture so very readily, Dr. Vater, to whom we owe this account, was induced to try the common coarse stone used in building houses to this purpose; and a mortar, being made of this, was found to let the water through, as well as the Mexican stone. The water first passed through this mortar had an earthy taste from some of the loose matter of the stone, which it dislodged in its passing through; but this is also the case in the Mexican, and all other kinds of filtring stones, and it goes off in all, after a few times using. It being found therefore an easy thing for use to have our water filtred in the same manner that the Japonese have, it remains to try, whether it will have those salutary effects, which the people of that part of the world give it; and this seems not to be imagined from reason and analogy. We very well know that water is frequently impregnated with saline particles, and that it also frequently dissolves by this means earthy and other matters, which it otherwise could not do. But we also know, that salts dissolved in water are not to be separated by filtration; and it is equally certain; that earthy, sparry, and other matter, that is suspended in water, when clear, will in like manner pass through the filtre with it. We daily see, that the solid bodies of metals, when perfectly dissolved in proper menstruums, pass through the filtre of paper with those menstruums; and, if afterwards something be added to the solution to weaken the force of the menstruum, so that it can no longer suspend so much of those heavy bodies, then the liquors become turbid, and the disunited particles of the metal will, on a second filtration, be left in the paper. It seems evident fr m this, that it is not the fineness of the filtre, but the state in which heterogeneous substances are suspended in fluids, which is the occasion of their passing through with them, or separating from and remaining behind them. It is in vain to say, that filtres of stone can stop the earthy and sparry particles of water, though filtres of paper cannot; since we every day see in caverns in the earth, that the water which oozes through the hardest rocks, forms stony icicles or stalactitæ, before it falls to the bottom. Upon the whole, we are happy enough to have no occasion for filtring stones, since our springs and rivers afford us waters already pure enough to our hands; and, in places where this is not the case, it is always possible to save rain water, which will keep a long time, with proper management, and is much purer than all the art in the world can make such as has once been foul. *Valentini Musæum Musæorum.*

FI'MBRIATED (*Dict.*)—This figure in heraldry is represented, *Plate* XXV. *fig.* 16, in the Dictionary.

FINE-*stiller*, in the distillery. That branch of the art which is employed on the distilling the spirit from treacle or other preparations or recrements of sugar, is called fine-stilling, by way of distinction from malt-stilling; and the person who exercises this part of the trade is called a Fine-stiller.

The operation in procuring the spirit from sugar is the same with that used in making the malt spirit; a wash of the saccharine matter being made with water from treacle, &c. and fermented with yeast. It is usual to add, in this case, however, a considerable quantity of malt, and sometimes powdered julap, to the fermenting backs. The malt accelerates the fermentation, and makes the spirit come out the cheaper; and the jalap prevents the rise of any musty head on the surface of the fermenting liquor, so as to leave a greater opportunity for the free access of the air, and thus to shorten the work, by turning the foamy, into a hissing fermentation. *Shaw's Lect.*

FI'NERY, in the iron works, is one of the two forges, at which they hammer the sow iron. In order to make the wrought iron, they first hammer a piece of a proper size gently at this forge, and, by degrees, bring it, after it has been hammered into a square bar or bloom, into what they call an anc-ory; which is the same mass hammered smaller in the middle, and there reduced to the shape the whole is to be brought to, at the chosery or other forges. *Ray's English Words.*

Carious FI'NGERS. The Fingers, when carious or affected by a spina ventosa, are to be amputated three ways: 1. By a strong pair of scissars or sharp-edged pincers. 2. By a chissel struck by a leaden mallet, by which they are separated at one blow; or, lastly, by dividing the next found joint with a scalpel, and drawing back a part of the skin to wrap over the stump,

ſtump, that it may heal the ſooner; and this is the beſt method of all, as by this you are in no fear about any ſplinters of the bone being left.

Fractured FINGERS. When one or more of the bones in the Fingers are broke, the ſurgeon's buſineſs is carefully to replace what has been removed, and to roll up the Finger a little way with a narrow bandage, and then to bind it firmly to the next ſound Finger. But it is much more proper, when the Finger is maſhed, ſo as to give no hope of a good cure, to take it off at once.

Luxated FINGERS. The bones of the Fingers and thumbs are liable to luxations of each of their articulations, and that in ſeveral directions; but theſe are accidents not only eaſily diſcovered, but very eaſily remedied alſo; for, the ligaments being not very robuſt, the fat and muſcles thin, and the ſinuſes of the articulations ſhallow, the extenſion is very eaſy, and the reduction of them into their former places not leſs ſo. The beſt method is, to extend ſufficiently the Finger with one hand, and to replace the luxated bone at the ſame time with the other, and to retain it ſo by a proper bandage. *Heiſter's Surgery.*

FI'NING *of wines.* The uſual method of Fining down wines, ſo as to render them expeditiouſly bright, clear, and fit for uſe, is this: take an ounce of iſinglaſs, beat it into thin ſhreds with a hammer, and diſſolve it by boiling, in a pint of water; this, when cold, becomes a ſtiff jelly. Whiſk up ſome of this jelly into a froth with a little of the wine intended to be fined, then ſtir it well among the reſt in the caſk, and bung down tight; by this means the wine will become bright in eight or ten days. *Shaw's Lectures.*

This method, however, is found to be beſt ſuited to the white wine; for the red ones, the wine-coopers commonly uſe the whites of eggs beat up to a froth, and mixed in the ſame manner with their wines. The method by which theſe viſcous bodies act in the operation is this: they entangle themſelves among the flying lee or light fæculencies, that float in the wine, and thus, forming a maſs ſpecifically heavier than the wine, they ſink through the body thereof like a net; carrying down all the foulneſs it meets in the way to the bottom; but, when the wine is extremely rich, ſo that its ſpecific gravity is greater than that of the maſs formed by the ingredients uſed in Fining, and the dregs or lee, this maſs then riſes upward, and floats at the ſurface of the wine, which will in this caſe alſo draw off fine.

FINO'CHIA, in gardening, the name of a plant which has of late years been introduced into the Engliſh gardens, and cultivated as a ſallad herb. It is a ſpecies of fennel, and is called by authors fœniculum dulce Azoricum. The ſweet fennel of the Azores iſlands. It is a high delicacy with ſome in England, though in general it is not liked; it ſeems, however, to be gaining more and more ground among us, and probably will in a little more time be a commonly eſteemed herb. The culture of it is this:

Good ſeeds muſt be firſt procured from Italy, for thoſe of Engliſh ripening are very apt to degenerate. In February ſome of theſe ſhould be ſowed for the firſt crop, on a light dry ſoil, and in a warm ſituation. The manner of ſowing theſe ſeeds is firſt to rake the bed very ſmooth, then draw a ſmall rill along it; and in this ſcatter them pretty thin; for the plants are not to ſtand nearer than ſix inches to one another; cover this with half an inch of earth, and, at the diſtance of ſixteen inches, make another rill, and ſo on throughout the bed. In about a month the plants will come up, and they muſt be then cleared of weeds, and cut up to four inches diſtance; a month after this, they muſt be thinned to ſix or ſeven inches diſtance; the ſtalks will now begin to ſwell to a large bulk juſt above the ground; this part muſt be earthed up in the manner of celeri, about a fortnight before it is uſed, which will make it eat very tender and criſp.

A ſecond crop ſhould be ſown three weeks after the firſt; and in that manner till July; every three weeks or a month a new crop ſhould be ſown, to keep a conſtant ſupply for the table.

The crops ſown in the hotter weather ſhould be watered and ſhaded from the great heats. *Miller's Gard. Dict.*

FIR-*tree, abies,* in botany, a genus of trees whoſe characters are:

It is ever-green, the leaves are ſingle, and for the moſt part produced on every ſide the branches; the male flowers or catkins are placed at remote diſtances from the fruit on the ſame tree; the ſeeds are produced in cones, which are ſquamoſe.

The difference between theſe and the pines is, the latter having two or more leaves produced out of the ſheath or cover.

Theſe trees are all raiſed from ſeeds taken out of their polyſpermous cones. The way to get out the ſeeds is, either by expoſing the cones to a gentle fire, or by ſoaking them all night in water, which will cauſe their ſquamoſe cells to open, and readily emit their ſeeds. The former method is the beſt, provided they are not expoſed to too great heat. But this ought not to be done until you are ready to ſow them; which is beſt performed in the beginning of March.

Theſe plants ſhould be all raiſed in a nurſery, where they may be protected from the birds; otherwiſe they will be in danger of being deſtroyed, when they firſt come up: for, as they bring up the huſk of the ſeed on the top of the plant, the birds in picking off the huſk will break off the plant, whereby a whole bed may be loſt in a few hours, if they are not carefully guarded from them.

The beſt time of ſowing theſe ſeeds is about the latter end of March, or the beginning of April, on a bed of light earth, covering the ſeeds about half an inch deep with the ſame ſort of earth. If this bed is netted over to keep off the birds, it will be a ſecure method to prevent them from deſtroying the young plants at their firſt coming out of the ground; at which time the plants ſhould be ſcreened from the ſun in the middle of the day, by covering the beds with mats; becauſe too much ſun frequently deſtroys theſe plants, when they are young. In this bed the plants ſhould remain until the following ſpring, when there ſhould be a number of beds prepared in the nurſery to receive theſe ſeedling plants; and the beginning of April they ſhould be tranſplanted into the beds, at the diſtance of ſix inches row from row, and at three inches aſunder in the rows. In removing theſe plants, they ſhould be very carefully raiſed up with a trowel, ſo as not to break off the fibres of their roots; and they ſhould be kept as little time out of the ground as poſſible; and, during the time they are out, their roots ſhould be covered, to prevent the wind from drying their fibres: and, in planting, the earth ſhould be preſſed cloſe to the roots of the plants, to prevent the air from penetrating the ground to the roots of the plants. If the ſeaſon ſhould prove dry, it will be proper to water the plants every week once or twice, according to the warmth of the weather; and the beds ſhould be covered with mats, to ſcreen the plants from the ſun, and drying winds, until they have taken good root; after which time they will require no farther care, but to keep them clear from weeds. In theſe beds the plants may remain two years; at the end of which they ſhould be tranſplanted into an open ſpot of ground; for their roots will in that time meet quite over the beds. This ground ſhould be well trenched and cleared from the roots of all bad weeds, and made level to receive the plants, which ſhould be tranſplanted about the beginning of April, juſt before they begin to ſhoot; and, if it ſhould prove moiſt weather, it will be of great advantage to the growing of the plants. In removing them out of the beds, there ſhould be great care taken, not to tear off or injure their roots; nor ſhould too many of the plants be taken up at one time; but rather plant them as faſt as they are taken up, that they may be as little time out of the ground as poſſible; for the drying winds which uſually happen at this ſeaſon, will greatly injure the roots of theſe plants, if they are much expoſed thereto.

The diſtance which theſe plants ſhould be placed in this nurſery, ſhould be four feet row from row, and two feet aſunder in the rows. This diſtance may by ſome perſons be thought too great; but if they conſider how their roots ſpread in the ground, as alſo, that, when they are planted nearer together, it will be very difficult to take up the plants again without cutting and tearing off their roots, eſpecially if they are not all taken up clean at the ſame time; theſe conſiderations will have greater weight than that of the loſs of a little ground, with thoſe perſons who have a regard to the future welfare of the plants. In planting of the plants, it will be the better way to draw a line acroſs the ground, and to dig out a trench of a foot wide thereby, into which the plants may be placed at the diſtance of two feet aſunder; then fill the earth into the trench, covering the roots of the plants with the fineſt part of it, ſcattering it carefully between the roots; and, when the whole trench is filled in, preſs the earth gently down with your feet; but by no means tread it too hard, eſpecially if the ground is ſtrong, or apt to bind too cloſe.

When the plants are planted, if the ſeaſon ſhould prove dry, they ſhould be watered, to ſettle the earth to their roots; and if this is repeated three or four times, if the ſeaſon ſhould continue dry, it will greatly promote their taking new root, and ſecure them from the injuries of the drying winds. In this nurſery the plants may remain two or three years, according to the growth they ſhall have made; and, during this time, the ground between the plants ſhould be conſtantly kept clean from weeds, and dug between the rows every ſpring; in doing of which, care muſt be taken not to cut or injure the roots of the plants: this is all the culture they will require during their continuance in the nurſery. And, when they are tranſplanted into the places where they are to remain, the neceſſary care to be taken is, in taking them up, not to injure or cut off their roots, and let them be as little time out of the ground as poſſible; and, when they are out, to guard their roots from the drying winds. The ſureſt time for removing of theſe trees is about the beginning of April; though they may, and often are removed with ſucceſs at Michaelmas, yet the ſpring is the more ſure ſeaſon, eſpecially in moiſt land.

Moſt of the kinds of Firs may be removed at the height of ſix or ſeven feet; but thoſe of two feet high are much better, and will in a few years get the better of thoſe taller trees: therefore I would not adviſe the tranſplanting of theſe trees, when they are much above two feet high, eſpecially if they have stood long in the nursery unremoved; for then their roots will have extended themselves to a great distance, which will be cut in taking of them out of the ground; and, where great amputation is used either to the roots or branches of these trees, the quantity of turpentine, which commonly issues from these wounds, will greatly weaken the trees. There is also another advantage in planting of these trees small, which is that of not requiring staking to secure them from not being blown down by strong winds, which in tall trees is a great trouble and expence: and whoever will give themselves the pains to observe, how much trees of two feet high exceed in growth those which are removed of much higher growth, will, I am sure, be convinced of the truth of what I have above said.

These trees are chiefly cultivated for ever-green plantations in gardens and parks, where, by their perpetual verdure, they have a singular beauty in winter; and in summer they are not without some beauty, by the contrast there is between them and the other woods, by the different shades of green. But, as neither of the sorts of Firs are equal to the Scotch pine in the goodness of the timber, these are not so profitable for large plantations, which are designed for improvement more than beauty. *Miller's Gard. Dict.*

FIRE (*Dict.*)— The learned and ingenious Dr. Knight has endeavoured to account for the phænomena of heat and Fire, by the vibratory motion of a repellent fluid. See HEAT.

The sparks of Fire which are produced by striking flint against steel, are of the number of those things which custom, by rendering the phænomenon familiar, has diverted our attention from the cause.

The striking Fire in this manner has probably been as old as the knowledge of steel; and, since the microscope has been familiar among us, it has been discovered, that these sparks are so many spherical balls of iron detached by the blow from the mass, and rendered by the heat a sort of scoriæ. Kemp de Kenvyck, a very ingenious chemist, proposed it as a problem worthy the attempts of the curious to solve, and proposed the whole in those words: When a flint and steel are struck together, if the sparks are received on a white paper, they are found to be round masses, which, examined by the microscope, are found to be melted and scorified or vitrified iron, which will no longer answer to the magnet. It is therefore demanded, 1. Which of the two instruments contributes most to this change in the iron? 2. What substance it is that is employed to this purpose? 3. In what manner the operation is performed; and, 4. Why, if iron be used instead of steel, the sparks are very few or none, when with steel they are so many?

These questions have appeared almost unanswerable, because people scarce knew how to conceive, that iron which requires so long continued and so violent a Fire to put it in fusion, could, by means only of a slight blow, be not only melted, but destroyed as it were. The most eminent person of the time declined engaging in the attempt, and Mr. Muschenbroek, from whom a solution was expected by many, at length referred the whole to Mr. de Reaumur, who had some time before published a treatise on iron and steel, and was therefore judged to have most considered the metal in both those states.

This gentleman accepted the task, and attempted the solution of the problem by resolving these questions: 1. By what means the iron is in this act converted into scoriæ? 2. By what method it can be so destroyed? 3. How it comes not only to be reduced to scoriæ, but to be in a state of fusion, and truly rendered liquid; and, 4. Why iron gives less as well as fewer sparks on collision with flint than steel does? The nature of iron is well enough known for us to be assured it contains a large portion of inflammable matter, and that it is never ductile, but while it has a quantity of that inflammable matter in it; and that, when that is wholly taken from it, it becomes friable, and is reduced to a sort of scoriæ, analogous to common vitrified matters.

What much conduces to the explication of the grand problem, is, that this inflammable matter contained in iron is very easily separated, when iron is heated in an open Fire; which is evidently seen, in that it is impossible to heat a bar of iron in a smith's forge so much as to make it ready for working or joining with another bar, without reducing its whole surface to scoriæ, or a friable matter which is all thrown off from the bar by the blows of the hammer.

The smaller and thinner a piece of iron is, the more easily is it reduced to scoriæ; and it is easy to conceive from hence, that, in pieces extremely small, there requires no more than the once thoroughly heating them to reduce the whole to scoriæ; and it is easily proved by experiment, that the flame of a candle, being applied to a fine small piece of filings of steel, will soon make it red-hot, and that, if it be then suffered to cool and laid on a white paper, it will be found much to resemble the sparks thrown off by the flint and steel, and will be reduced to scoriæ, and be friable under the nail, like a piece of charcoal.

It appears then, that there requires but an instant of time to give a red heat to a small particle of iron; and also, that, when that heat has been given, the particle must have lost that inflammable matter which caused its ductility, and consequently must be reduced to scoriæ; and hence it appears not wonderful, that the very small piece or particle of steel which is struck off by the flint, should be divested of its inflammable matter, and, with it, of its ductility, by keeping red-hot in the open air, only so long as it was in falling from the steel to the paper that is placed to receive it. The extreme smallness of the particle gives power to so short a heat to destroy its inflammable matter, in which its ductility consists; and therefore to reduce it to a matter no longer ductile, that is, into scoriæ; and we find, that, if a parcel of fine steel filings be dropped thro' the flame of a lamp driven into a horizontal direction by the blast of a blow-pipe, they will, in the instant of their passing through that flame, sparkle, and become ignited, and, if they are received on a white paper placed underneath, the smallest particles will be found round and friable, reduced to scoriæ, no way differing from the little globules of scorified steel, which are struck off from the flint and steel in giving Fire by their collision. When we have occasion to melt larger parcels of steel or iron, we are obliged to have recourse to such substances to mix with them as will replace with increase that inflammable matter which the Fire drives off: the substances of this kind are common sulphur, orpiment, arsenic, and the like; and by means of these it is soon made to run like lead. *Mem. Acad. Scien. Par.* 1736.

One great proof of the sparks being melted and rendered globular by means of the sulphur of the flint is, that sparks may be struck from steel, in the same manner, by glass as by flint, but in less quantity; these, having been received on a paper, were examined by Mr. Reaumur, and were found to be scoriæ, of an irregular figure, having never been melted, and therefore never reduced to the globular shape of the others. In regard to the great change wrought in iron by this operation, or its being, according to the words of Kemp, destroyed, no longer retaining its great character of being attracted by the load-stone, Mr. Reaumur, willing to try the experiment before he reasoned upon it, found this assertion not to be fact, or at least not a general one.

All the several kinds of sparks which he mentions, those produced by the common collision of flint and steel, those by dropping steel-filings through the flames of a lamp, and even those from the filing of the antimoniated iron, all as readily answer to the load-stone as common filings of iron; so that, if this case sometimes happen, and iron be liable thus to be destroyed, it is however no general fact, but a very rare and extraordinary one. *Mem. Acad Par.* 1736.

Everlasting FIRE, a very extraordinary phænomenon, near Baku, in Persia, before which the Geberrs offer their supplications. See GEBERRS.

This object of devotion to the Geberrs lies about ten English miles N. E. by E. from the city of Baku, on dry rocky land. There are several ancient temples built with stone, supposed to be all dedicated to Fire; most of them are arched vaults not above ten to fifteen feet high. Among others, there is a little temple, in which the Indians now worship: near the altar, about three feet high, is a large hollow cane, from the end of which issues a blue flame, in colour and gentleness not unlike a lamp that burns with spirits, but seemingly more pure. These Indians affirm that this flame has continued ever since the flood, and they believe it will last to the end of the world; that, if it was resisted or suppressed in that place, it would rise in some other. Here are generally 40 or 50 of these poor devotees, who come on pilgrimage from their own country, and subsist upon wild celeri, and a kind of Jerusalem artichokes, which are very good food, with other herbs and roots, found a little to the northward. Their business is to make expiation, not for their own sins only, but for those of others; and they continue the longer time, in proportion to the number of persons for whom they have engaged to pray. They mark their foreheads with saffron, and have a great veneration for a red cow. They wear very little cloathing, and those who are of the most distinguished piety put one of their arms upon their heads, or some other part of the body, in a fixed position, and keep it unalterably in that attitude.

A little way from the temple is a low cliff of a rock, in which there is a horizontal gap, two feet from the ground, near six long, and about three broad, out of which issues a constant flame of the colour and nature already described; when the wind blows, it rises sometimes eight feet high, but much lower in still weather: they do not perceive the flame makes any impression on the rock. This also the Indians worship, and say it cannot be resisted, but it will rise in some other place. About twenty yards on the back of this cliff is a well cut in a rock, twelve or fourteen fathom deep, with exceeding good water.

The earth round this place, for above two miles, has this surprising property, that, by taking up two or three inches of the surface, and applying a live coal, the part which is so uncovered, immediately takes fire, almost before the coal touches the earth: the flame makes the soil hot, but does not consume it, nor affect what is near it with any degree of heat. Any quantity of this earth, carried to another place, does not produce this effect. Not long since, eight horses were consumed fumed by this fire, being under a roof where the surface of the ground was turned up, and by some accident took flame.

If a cane or tube, even of paper, be set about two inches in the ground confined and closed with earth below, and the top of it touched with a live coal, and blow up, immediately a flame issues, without hurting the cane or paper, provided the edges be covered with clay; and this method they use for light in their houses, they having only the earth for their floor: three or four of these lighted canes will boil water in a pot, and thus they dress their victuals. The flame may be extinguished in the same manner as that of spirits of wine. The ground is dry and stony, and, the more stony any particular part is, the stronger and clearer is the flame; it smells sulphureous, like napthæ, but not very offensive.

Lime is burnt to great perfection by means of this phænomenon; the flame communicating itself to any distance where the earth is uncovered to receive it. The stones must be laid on one another, and in three days the lime is compleated.

FIRE-*ball*, a composition of meal powder, sulphur, salt-petre, pitch, &c. about the bigness of a hand granade, coated over with flax, and primed with the slow composition of a fuze. This is to be thrown into the enemies works in the night-time, to discover where they are; or to fire houses, galleries, or blinds of the besiegers; but they are then armed with spikes or hooks of iron, that they may not roll off, but stick or hang where they are desired to have any effect.

FIRE-*pots*, are small earthen pots, into which is put a granade filled with fine powder till the granade be covered; and then the pot is covered with a piece of parchment, and two pieces of match laid across and lighted. This pot, being thrown where it is designed to do execution, breaks and fires the powder, and thereby fires the powder in the granade, which ought to have no fuze, that its operation may be the quicker.

FIRE-*ships*, in the navy, vessels charged with artificial Fire-works; which, having the wind of an enemy's ship, grapple her and set her on Fire.

FISHES, in natural history, make one of the distinct classes of animals, the characters of which are, that they have either a naked or scaly body, that they have no feet, but always fins. *Linnæi Syst. Nat.*

FISHES, *aboard a ship*, are pieces of timber used to strengthen the masts and yards, when they begin to fail in stress of weather. They both nail the Fishes on with iron spikes, and also would them, as they call it, that is, wind ropes hard round about them. There is also a tackle called the Fish, which hangs at the end of the davit by the strap of the block, in which is the runner of the fish-hook, by which means the fluke of the anchor is haled up to the ship's bow or chain-waile. Perhaps this tackle was called a Fish, from that which the ancients called a dolphin, which was a pointed and vastly heavy piece of iron, which they used to heave up by a tackle to a good height, and then, when they came near enough to the enemies ship, let it fall at once, to break or pierce a hole through the bottom of the enemies vessel, and sink her.

FISH-*block*, in a ship, is the block which is hung in a notch at the end of the davit, and serves to hale up the fluke of the anchor to the ship's bow.

FISH-*ponds*, are not only a thing of convenience to great families, but may be made a profitable article with the farmer under due management. Watery and boggy lands are often fit for no other use, and these are then a great improvement on them. Ponds, made in dry grounds in the flat bottoms between hills, will also serve not only to supply the cattle with water, but the profit of the Fish that may be bred in them, is greater than many are aware of, and comes without any labour or expence. The head of a pond must be placed at the lowest part of the ground, and the trench of the flood-gate, or sluice, must have a good fall, that it may not be too long in emptying. The best way of making the head, is by driving three or four rows of stakes about six feet long, and at about four feet distance from one another, the whole length of the pond-head; the first row of these is to be driven in four feet deep, that they may be very firm and secure, and, if the bottom be not good but be of a loose sand, some lime is to be added, which will harden into a sort of stone. The earth dug out of the pond is to be placed between these stakes and rammed hard down. Other rows of stakes must be added behind, and over these, and the spaces filled up, till the whole is as high and thick as is necessary. The face of it must be made even and slanting, and there must be a wash left to carry off the superfluous water in floods, &c. *Mortimer's Husbandry.*

FISTULA *in ano*, in surgery, an abscess, running upon, or into the intestinum rectum; though an abscess in this part, when once ruptured, does generally, if neglected, grow callous in its cavity and edges, and become, at last, what is properly called a Fistula.

That the anus is so often exposed to this malady, in any crisis of the constitution, is chiefly ascribed to the depending situation of the part; but what very much conduce to it likewise, are the great quantities of fat surrounding the rectum, and the pressure the hæmorrhoidal vessels are liable to, which, being sustained upon very loose membranes, will be less able to resist any effort, that nature shall exert, to fling off a surcharge; and from one step to another, that is, from inflammation to suppuration, lead on to the distemper we are treating of.

That the fat is the proper subject of abscesses, may be learned from an inflammation of the skin affecting the membrana adiposa, and producing matter there; in which case, a suppuration runs from cell to cell, and, in a few days, lays bare a great quantity of flesh underneath, without affecting the flesh itself: nay, I think it may be doubted, whether, in those abscesses which are esteemed suppurations of the muscles, the inflammation and matter are not absolutely first formed in this membrane, where it is insinuated between the interstices of their fibres.

The piles, which are little tumors formed about the verge of the anus, immediately within the membrana interna of the rectum, do sometimes suppurate, and become the forerunners of a large abscess; also external injuries here, as in every other part of the body, may produce it; but, from whatever cause the abscess arises, the manner of operating upon it will be according to the nature and direction of its cavity.

If the surgeon has the first management of the abscess, and there appears an external inflammation upon one side of the buttock only; after having waited for the proper maturity, let him, with a knife, make an incision the whole length of it; and, in all probability, even though the bladder be affected, the largeness of the wound, and the proper application of dossils lightly pressed in, will prevent the putrefaction of the intestine, and make the cavity fill up like imposthumations of other parts.

If the sinus is continued to the other buttock, almost surrounding the intestine; the whole course of it must be dilated in like manner; since, in such spongy cavities, a generation of flesh cannot be procured but by large openings; whence also, if the skin is very thin, lying loose and flabby over the sinus, it is absolutely necessary to cut it quite away, or the patient will be apt to sink under the discharge, which, in the circumstance here described, is sometimes excessive. By this method, which cannot be too much recommended, it is amazing how happy the event is likely to be; whereas, from neglecting it, and trusting only to a narrow opening, if the discharge does not destroy the patient, at least, the matter by being confined, corrupts the gut, and, insinuating itself about it, forms many other channels, which, running in various directions, often baffle an operator, and have been the cause of a Fistula being so generally esteemed very difficult of cure.

Here I have considered the imposthumation as possessing a great part of the buttock; but it more frequently happens, that the matter points with a small extent of inflammation on the skin, and the direction of the sinus is even with the gut: in this case, having made a puncture, you may, with a probe, learn if it has penetrated into the intestine, by passing your finger up it, and feeling the probe introduced through the wound into its cavity; though, for the most part, it may be known by a discharge of matter from the anus. When this is the state of the Fistula, there is no hesitation to be made, but, immediately putting one blade of the scissars up the gut, and the other up the wound, snip the whole length of it. This process is as adviseable, when the intestine is not perforated, if the sinus is narrow, and runs upon or very near it; for, if the abscess be tented, which is the only way of dressing it, while the external orifice is small, as I have here supposed, it will almost certainly grow callous; so that the surest means of cure will be opening the gut, that proper applications may be laid to the bottom of the wound. However, it should be well attended to, that some sinuses, pretty near the intestine, neither run into nor upon it, in which case they must be opened, according to the course of their penetration. There are abundance of instances, where the intestine is so much ulcerated as to give free issue to the matter of the abscess by the anus; but I believe there are none where there is not, by the thinness and discolouration of the skin, or an induration to be perceived through the skin, some mark of its direction; which, if discovered, may be opened into with a lancet, and then it becomes the same case as if the matter had fairly pointed.

If the sinuses into, and about the gut, are not complicated with an induration, and you can follow their course; the mere opening with scissars, or a knife guided on a director, will sometimes suffice; but it is generally safer to cut the piece of flesh, surrounded by these incisions, quite away, and, when it is callous it is absolutely necessary, or the callosities must be wasted afterwards by escharotic medicines, which is a tedious and cruel method of cure.

When the Fistula is of long standing, and we have a choice of time for opening it, a dose of rhubarb the day before the operation will be very convenient, as it not only will empty the bowels, but also prove an astringent for a while, and prevent the mischief of removing the dressings in order to go to stool.

It sometimes happens that the orifices are so small, as not to admit the entrance of the scissars, in which case, sponge tents must be employed for their dilatation.

In performing these operations on the anus, I do not think, in general, any instrument so handy as the knife and scissars; almost all the others which have been invented to facilitate the work, are not only difficult to manage, but more painful to the patient; however, in those instances where the Fistula is very

very narrow, and opens into the inteftines, juft within the verge of the anus, the fyringotomy may be ufed with advantage: but, where the opening into the gut is high, it cannot be employed without giving great pain. I do not caution againft cutting the whole length of the fphincter, experience having fhewn it may be done with little danger of an incontinence of excrement; and, in fact, the mufcle is fo fhort, that it muft generally be done in dilatations of the inteftine.

The worft fpecies of Fiftula, is, that communicating with the urethra, and fometimes, through the proftate gland, with the bladder itfelf. This generally takes its rife from a former gonorrhœa, and appears externally firft in peritonæo, and afterwards increafing more towards the anus, and even fometimes into the groin, burfts out in various orifices, through the fkin, which foon becomes callous and rotten; and the urine, paffing partly through thefe orifices, will often excite as much pain, and of the fame kind, as a ftone in the bladder.

This fpecies of Fiftula, taking its rife from ftrictures of the urethra, is only manageable by the bougie: for, fo long as the urethra is obftructed, the cure of the Fiftula will be imperfect; but, if the canal is opened by this application, it is amazing what obftinate indurations and foul finufes will in confequence difappear; though there are fome fo callous and rotten, as to demand the knife and fkilful dreffings, notwithftanding the urethra fhould be dilated by the ufe of bougies. *Sharp's Surgery.*

FITCHES, a name given by our farmers to a fort of pulfe they fow in their fields. Many fuppofe it the fame with the tare, but erroneoufly: it is the chich or chich pea of authors. There are two principal kinds of this in ufe among us, the winter and the fummer Fitch. The one is fown before winter, and abides the extremity of it; the other is fown in fpring. They are propagated in the fame manner as peafe, and they make a very good and nourifhing food for cattle, whether given in the ftraw, or threfhed out. They are fometimes fown only to improve the land. In this cafe, they are to be plowed in, juft as they are beginning to bloffom, and in this manner they finely enrich a tough ftiff clay. *Mortimer's Hufbandry.*

FLAKE, in gardening, a name given by the florifts to a fort of carnations, which are of two colours only, and have very large ftripes, all of them going quite through the leaves. *Miller's Gard. Dict.*

FLA'MMULÆ *auri*, in natural hiftory, a name given by Dr. Woodward, and others, to thofe fmall pieces of gold found among the fands of rivers in fome places. They are fometimes found in roundifh pieces, but more ufually in their fhining flakes, whence the name Flammulæ feems to have been given them, as being very bright and gloffy. This fort of gold is pure and malleable, and lofes fcarce any part of its weight in fufion.

The gold duft, as it is called, which is brought from Guinea, is much of this kind; its particles are ufually very fmall, though, fometimes lumps of the fize of a pea or horfe bean are found, and fometimes maffes of an irregular figure of three or four ounces weight; but thefe lofe the name of Flammulæ, when they become fo thick and folid, and fo large, and are called by the merchants rock gold.

All the Flammulæ of gold, found among the fands in the beds of rivers, are doubtlefs parts of a rich ore, lodged in fome neighbouring hills, and wafhed away by the impetuous rains, which carry them down in the currents they form, and afterwards drop them in the places where the waters of the river they mix themfelves with, run more flowly. This appears plainly from thefe particles of gold being always found towards the heads of the rivers; or near the mountainous countries, where the torrents, caufed by fudden rains, difcharge themfelves into them near their entrances into the fea; and alfo by this, that the people always find the gold moft plentifully after great rains. *Woodw. Cat. Foff.*

FLA'TULENCIES, a relaxation of the periftaltic motion of the guts; but this not extending to the whole canal, but only to fome one part, the tranfpiration of the halituous matter being chiefly in this flaccid part, which it diftends in a manner that it could not do by a part that had its natural tone and motions. And the defect in one part is always attended with an excefs of the periftaltic motion in another, in order to the driving off the caufe; hence proceed alternate conftrictions and relaxations, to which, in a great meafure, the pain is owing; and, in cafes of the commotions of the blood about the vena portæ, the fame conftrictions and relaxations always happen. The material caufes of Flatulencies, are thofe fubftances fwallowed in food, which are of a mucous and tenacious confiftence, and, by their obftinately adhering to the bowels, are capable of giving great trouble. Of this kind are the herbs in ufe in food, which are of a thick tough juice; or the leguminous tribe, as peas, beans, and the like; alfo dried fea fifh, and all animal fats, as that of fheep and calves, efpecially if the perfon drink immediately after eating heartily of them. The drinking fæculent liquors will alfo occafion them very violently; as new malt liquors, or the fame, when the veffels are almoft out; the fummer fruits alfo are to be accufed in this fenfe, and, above all things, honey. To all thefe caufes the habit of the patient greatly concurs, and a general coolnefs of the body and drynefs of the bowels are a frequent occafion of them.

Method of cure.—In this, it is firft to be confidered, whether the Flatulencies have their origin in the bowels, or whether they affect them only by confent, as is often the cafe in difeafes of the neighbouring parts in hypochondraic and hyfteric patients, and in perfons afflicted with hæmorrhoidal and nephritic complaints, and in cafes where women have been ill managed in lying-in, or in mifcarriages: in all thefe cafes the original caufe is to be confidered and treated with its proper remedies. But, in cafes of direct and fimple Flatulencies, the following method will be ufually found effectual. The bowels muft be carefully kept gently open, for, in cafes of coftivenefs, Flatulencies will always be increafed. To this purpofe, the common clyfters muft be given at repeated times, and to thefe, by way of increafing the ftimulus, fome of the leffer centaury is to be added, and fome common falt. After thefe the laxative medicines of the gentler kind are to be given, and, in the intermediate days, the digeftive falts to attenuate the vifcous matter in the bowels; to thefe nitre and a little cinnabar may be added, and thefe always have a much better effect than all the hot carminatives ufually given. After thefe, thofe things are to be given which reftore the tone of the part; fuch are the bitter and aromatic extracts, with fpirit of falt of tartar, fpirit of nitre dulcified, and the volatile urinous falts aromatifed. Externally ftomachic plaifters may be applied to the pit of the ftomach, as may alfo the ftomachic balfams, fuch as the oils of nutmeg, carui, fennel, and the like.

The general method of treating Flatulencies, is, by the hot aromatics, but thefe are to be given with great caution; for, when the commotions of the blood about the vena portæ are in fault, thefe things always irritate, rather than do good; but, beyond all things, the too common method of giving a vomit in thefe cafes is to be avoided, for the difcharge of the Flatulencies upwards is inverted by this means, and then ufually follow exquifite pains and tenfions of the parts, difficulty of breathing, and vertiginous complaints in the head, with noifes in the ears, and many other complaints which are continually increafing, till they are a little abated, for the prefent, by an eructation. The happy way of getting rid of thefe anterior flatufes, is by driving the caufe of them downwards, and the reftoring the loft tone of the parts. Continued exercife is alfo of the utmoft fervice. *Juncker's Confp. Med.*

FLAX, (*Dict.*)—There are feveral forts of this plant, which are preferved in fome curious gardens of plants for variety fake; but, as they are of little ufe or beauty, it would be needlefs to mention them in this place.

The linum fativum, or manured Flax, is that which is cultivated for ufe in divers parts of Europe, and is reckoned an excellent commodity: the right tilling and ordering of which is efteemed a good piece of hufbandry.

This fhould be cultivated upon a rich foil, that has not been plowed for feveral years, upon which Flax always makes the beft improvement: but, as it draws greatly from the foil, it fhould not be fown two years together upon the fame ground. The land muft be well plowed, laid flat and even, upon which the feeds fhould be fown about the middle of March, when the weather is mild and warm. During the fpring, you muft carefully weed it; which if neglected (efpecially in a moift feafon) the weeds will overgrow and deftroy the crop. There are fome people who recommend the feeding of fheep with flax, when it is a good height; and fay, they will eat away the weeds and grafs, and do the flax good; and, if they fhould lie in it, and beat it down, or flatten it, it will rife again the next rain: but this muft not be practifed but in a moift feafon, and upon a rich foil; for, if the ground be poor, or the fpring dry, it will not rife again to any confiderable height.

The beft feed is that which comes from the eaft country, and is known by the name of Riga Flax; for, if the Englifh feed be fown three or four times, it is very apt to degenerate. If the feed be good, two bufhels will be enough to fow an acre; but, if it be but middling, there fhould be a greater allowance. Toward the latter end of Auguft the Flax will begin to ripen, when you muft be careful, that it grow not over ripe: therefore you muft pull it up as foon as the heads begin to change brown, and hang downwards, otherwife the feeds will foon fcatter, and be loft: fo that the pluckers muft be nimble, and tie it up in handfuls; fetting them upright till they be perfectly dry, and then houfe them. If the Flax be pulled, when it firft begins to flower, it will be whiter and ftronger than if it ftand till the feed is ripe; but then the feed will be loft.

This is a plant of the greateft ufe, in feveral of the moft effential parts of life: from the feeds an expreffed oil is drawn, which is of great ufe in medicine, painting, &c. from the bark of the ftalks is made linen, and from the rags of linen is made paper; fo that this plant may be efteemed as one of the moft valuable and neceffary, in many of the principal conveniencies of life. *Miller's Gard. Dict.*

This plant has a more oily tafte than the mallow, and is the chief of the emollient tribe. The feeds afford an excellent medicine, fince from them is expreffed an oil, which is anodyne, demulcent, and extremely adapted to all manner of afperities;

perities; it relaxes, and diffolves acridities, whence it is of extraordinary fervice in the moft defperate cholics. The ftiff and rigid limbs, being anointed with this oil, are relaxed and rendered flexible. This oil, when frefh drawn, and taken at the mouth, is very good in a pleurify, and a cough, to help expectoration; and, injected in clyfters, is very proper in the hæmorrhoids, and indurated fæces, whence proceeds the cholic; mixed with fealed and japan earth, it is a great arcanum in the dyfentery. An emulfion of the feeds is of fervice in the pleurify and peripneumony; the oil is a very good remedy againft the ftone: the feeds reduced to a meal, and boiled and prepared in the form of a cataplafm, are applied to tumors and abfceffes, in order to mollify and ripen them. The feed, boiled in water, makes a mild oily decoction, prefcribed to be drank as an anodyne in inflammations of the fmall inteftines, the diarrhœa, the dyfentery, nephritic pains, and retention of urine. The oil, boiled with honey, clears the face and fkin of fpots, and all cutaneous blemifhes. The leaves are emollient, and the fmell of the flowers is not poifonous, as fome authors have written. To clofe all, we fhall obferve, that whereas cotton can never be ufed about wounds, on account of its denticulated parts, which difpofe to inflammations; linen, the manufactured produce of this plant, is, by its extraordinary foftnefs, fmoothnefs, and flexibility, of all other things, the beft adapted to fuch purpofes. *Hift. Plant. afcript. Boerhaave.*

As it is agreed, that the lighteft loams and the thickeft crop afford the fineft Flax, it may be of ufe to let the farmer know how he may fave fuch crops from lodging, as they generally do. The method is a little expenfive; but, if it anfwers, it will quit coft very well. When the Flax is in the ground, divide your field into equal fquares, the fides of which may be four or five feet long; and at each angle thruft a forked ftick fteady in the ground. When your Flax is fome inches high, lay from ftick to ftick a light crofs pole; and this will fupport the Flax, and hinder it from lodging. Some ufe ropes inftead of poles; but they yield too much, and anfwer but imperfectly.

High winds are fo common in this country, that there is reafon to apprehend, that the Dutch method of laying your Flax loofe upon the ground would be attended with confiderable inconveniency. I believe the method I purfue is fafer. I gently tie each handful as clofe as may be to the heads; and then, fpreading out the ends, fet it upright on the ground. Three or four of thefe, together, make one ftook; and into fuch fmall ftooks I divide all the Flax I have. They dry foon, becaufe the wind has free accefs to the ftalks, as the fun has to the heads, and the rain cannot lodge in any quantity upon them.

Rippling comes next. Two men may work at every inftrument, by fixing it on a bench, that one may fit at either end. Let them take fmall handfuls at a time, and draw the Flax through the ripple without violence. Two women to each bench are neceffary to hand the Flax in bundles to the ripplers, to receive it from them again, to fort it according to their feveral degrees of length, ftrength, ripenefs, and finenefs, and to tie it loofely in little fheaves.

After rippling, the feed muft be carried to the grainary, and the Flax laid down to water. If poffible, difpofe of the whole into your ponds together. The fummer, which draws haftily towards an end, is your fitteft feafon, and fhould be hufbanded with care. However, let nothing tempt you to ufe bog holes and running waters. It is better to delay to the next feafon, than difcolour or damage all your Flax.

Cover your Flax, to keep it down, with your flutch or mire at the bottom of your ponds, or, till that be gathered in fufficient quantities, with clay, rufhes, fern, or timber. From four to twelve or thirteen days is the time requifite for watering. After the fourth, examine your Flax daily, and be particularly careful not to let it lie too long. It is a miftake, on the fafer fide, to draw it off the fooneft.

In graffing, the fhorteft grafs fhould be preferred. Dry fandbanks do well. On either the Flax muft be turned every fecond day, and generally lies from a fortnight to three weeks.

To dry your Flax, heat your oven thoroughly; then let it cool, till a man can ftand in it without uneafinefs; fill it over night, and your Flax will be ready for the break next morning. The dirt and ftraws fcutched out of the Flax, in one day, will heat the oven for the next.

When you break your Flax, take fheaf by fheaf out of the oven, as you ufe it: it comes crifp under the engine, works the better and more eafily. It is an error to lay the Flax, as we do, as far as may be from the joint. The nearer it is placed to the center of motion in the break, the more readily it fplits, and the lefs damage it receives.

In fcutching, chufe the broad round fcutch: the fquare and narrow one, in ufe among us, cuts and deftroys the Flax.

By the time the Flax is fcutched, and about the middle of October, it will be time to threfh the feed.

This may be done by driving horfes backwards and forwards on the bows, or by drawing over them a heavy rolling-ftone upon a fmooth hard floor.

Cleaning it requires more nicety. To do it thoroughly, it muft firft go through the winnow, which feparates it from the bows; through the riddle next, to take out ftraws, ftones, and larger dirt; then fucceffively through two different fieves; the firft bored with oval holes, to let through the feed and nothing elfe of greater bulk; the fecond clofer, to retain the feed, and afford a paffage to all fmaller bodies; and laftly through the fcreen or wire-harp, which frees it from all duft.

When the Flax-dreffer has thus cleaned his feed, he fhould return to his Flax, and put it through the fining-mills. The wheel in thefe turns alternately from right to left, and from left to right, twice each way; and, according to the number of thefe double turns, the Flax comes out the finer, the fmoother, and the fofter. Fourfcore fuch turns is the moft that any Flax requires, and probably as much as it will bear.

N. B. For want of thefe fining-mills in Scotland, beating of Flax is directed.

In hackling, women and children fhould be employed from choice. They work with greater gentlenefs than men, and care and tendernefs are the main excellencies in this bufinefs. For the beft Flax, four fets of hackles will be requifite, each of them of a different finenefs: through thefe it may be drawn fucceffively, and every time with proportionable caution. The laft, whofe teeth is like the fineft needles, requires the utmoft fkill, and fhould be trufted with few hands.

FLINTS, in the glafs trade.—The way of preparing Flints for the niceft operations in the glafs trade is this:

Chufe the hardeft Flints, fuch as are black and will refift the file, and will grow white, when calcined in the fire. Cleanfe thefe of the white cruft that adheres to them, and calcine them in a ftrong fire, and throw them while red-hot into cold water; wafh off the afhes that may adhere to them, and powder them in an iron mortar, and fift them through a very fine fieve; pour upon this powder fome weak aqua fortis, or the phlegm of aqua fortis, to diffolve and take up any particles of iron it may have got from the mortar; ftir this mixture feveral times, then let it reft, and in the morning pour off the liquor, and wafh the powder feveral times with hot water, and afterwards dry it for ufe. You will thus have a powder for making the pureft glafs as perfectly fine and faultlefs, as if you had ufed rock cryftal itfelf. *Cramer's Art of affaying Metals.*

The wafhing off the ferrugineous particles with aqua fortis is not neceffary, when the glafs intended to be made is to be tinged with iron afterwards; but, when meant to be a pure white, this is the method to be fure of fucceeding.

FLOS *Afiæ*, in natural hiftory, a name given by Swenkfeld and fome other writers to that falt which is found on the furface of the earth in fome parts of Afia in form of an efflorefcence, and is called the Smyrna foap earth.

FLOWER (*Dict.*)—Tournefort defines it to be a part of a plant very often remarkable for its peculiar colours, for the moft part adhering to the young fruit, to which it feems to afford the firft nourifhment, in order to explicate its moft tender parts. Which definition is ftill more deficient than the fucceeding, by this uncertain mode of expreffion.

Pontedera, profeffor of botany, at Padua, defines it to be a part of a plant unlike the reft in form and nature, always, when the Flower has a tube, adhering or fixed very near to the embryo, to the ufe of which it is fubfervient; but, if the Flower has no tube, not adhering to the embryo. Which definition is not much clearer, being fcarce intelligible to any perfon who has not ftudied botany a confiderable time, as Mr. John Martyn well obferves; and alfo that it is liable to this objection, that it may include fome parts, which no perfon ever called by the name. For a root, or a ftalk, or a leaf, are parts of a plant unlike the reft in form and nature, having no tube, and fo adhering to no embryo's; and thus, by Pontedera's definition, are Flowers.

Monf. Juffieu, the Paris profeffor, feems not to have fucceeded much better in this affair: he fays, that is properly called Flower, which is compofed of chives and a piftillum, and is of ufe in generation. But this is too defective; for that there are many plants in which the piftillum or ftyle is found a confiderable diftance from the chives; many Flowers that have no piftillum, whether that word be taken to fignify the embryo of the fruit, or its appendix; and many which have no chives. But the late Monf. Vaillant feems to be happier, in forming a clearer idea of this part of a plant. We find in a lecture he read in the regal garden at Paris, that the Flowers, ftrictly fpeaking, ought to be reckoned the organs which conftitute the different fexes in plants, feeing they are fometimes found without any covering, and that the coats, or petals, which immediately encompafs them, are defigned only to cover and defend them: but (fays he) as thefe coats are the moft confpicuous and moft beautiful part of the compofition, which is called by the name of Flower; to thefe coats therefore I give the name of Flower, of whatfoever ftructure or colour they be; whether they encompafs the organs of both fexes, together, or contain only one of them, or only fome part depending on one of them; provided always that they be not of the fame figure of the leaves of the plant.

But, in my opinion, Mr. John Martyn has been happier, in his definition of a Flower, than all thofe abovementioned: he defines

defines a Flower to be the organ of generation of both sexes adhering to a common placenta, together with their common coverings; or of either sex separately, with its proper coverings, if it have any.

The parts of a Flower are, 1. The ovary, which is the rudiment of the fruit, and so is properly the female organ of generation. 2. The style, which is a body accompanying the ovary, either arising from the top of it, or standing as an axis in the middle, with the embryo's of the seeds round it.

3. The summits, or apices, which are those bodies that contain the prolific powder, analogous to the male sperm in animals; and generally hang upon slender threads, which are called the chives.

The petals are those tender fine-coloured leaves, which are generally the most conspicuous parts of a Flower.

The empalement, or calyx, is those tender leaves which cover the other parts of a Flower.

Flowers, according to the number of their petals, are called monopetalous, dipetalous, tripetalous, tetrapetalous, &c.

The structure of Flowers is indeed very various: but, according to Dr. Grew, the generality have these three parts in common, viz. the empalement, the foliation, and the attire. *Miller's Gard. Dict.*

FLOS'CULOUS, in botany, a term used by Mr. Tournefort, and others, to express such Flowers of plants as are composed each of a great number of other smaller Flowers placed close to one another, and inclosed in the same common cup; each of these smaller Flowers consists of one petal, which is slender and hollow, and wider than the bottom, and usually divided into many segments, which sometimes are disposed in the form of a star. Each of these Flowers stands upon an embryo, or young fruit, from which there grows a capillament which reaches beyond the Flowers. These embryo's are lodged in the bottom of the cup, which is called by authors the thalamus of the Flower, and finally become seeds winged with down, or sometimes without that, and sometimes are armed with prickles. Of this sort are the flowers of thistles, knapweed, &c. See *Plate* XXII. *fig*. 5. *Tourn. Inst.*

Preservation of FLOWERS. The method of preserving Flowers in their beauty, through the whole year, has been diligently sought after by many people; some have attempted it, by gathering them when dry, and not too much opened, and burying them in dry sand; but this, though it preserves their figure well, yet takes off from the liveliness of their colour. Muntingius gives a method which he says is preferable to all others; this is as follows: gather roses or other Flowers, when they are not yet thoroughly open, in the middle of a dry day; put them into a good earthen vessel glazed within, fill the vessel up to the top with them, and, when full, sprinkle them over with some good French wine with a little salt in it; then set them by in a cellar, tying the mouth of the pot carefully down. After this, they may be taken out at pleasure, and on setting them in the sun, or within the reach of the fire, they will open as if on the tree, and not only the colour, but the smell will be preserved.

Sir Robert Southwell has communicated to the world a method of drying plants, by which all Flowers may be preserved in their natural shape, and many in their proper colours. To this purpose two plates of iron are to be prepared of the size of a large half-sheet of paper, or larger for particular occasions; these plates must be made so thick as not to have any power of bending, and there must be a hole made near every corner for the receiving a screw to fasten them close together.

When these plates are prepared, lay in readiness several sheets of paper, and then gather the plants with their Flowers, when they are quite perfect; let this always be done in the middle of a dry day; and then lay the plant and its Flowers on one of the sheets of paper doubled in half, spreading out all the leaves and petals, as nicely as can be. If the stalk be thick, it must be pared or cut in half, so that it may lie flat; and, if it be woody, it may be peeled and only the bark left; when the plant is thus expanded, lay, round about it, some loose leaves and petals of the Flower, which may serve to compleat any part that may prove deficient; when all is thus prepared, lay several sheets of paper over the plant, and as many under it; then put the whole into the iron plates, laying the papers smoothly on one, and laying the others evenly over them; then screw them close, and put them into an oven after the bread is drawn, and let them lie there two hours; after this make a mixture of equal parts of aqua fortis and common brandy; shake these well together, and, when the Flowers are taken out of the pressure of the plates, rub them lightly over with a camel's hair pencil dipped in this liquor; then lay them upon fresh brown paper, and, covering them with some other sheets, press them between this and other papers with a handkerchief, till the wet of these liquors is wholly dried away. When the plant is thus far prepared, take the quantity of a nutmeg of gum dragon, put this into a pint of fair water cold, and let it stand four and twenty hours; it will in this time be wholly dissolved; then dip a fine hair pencil in this liquor, and with it daub over the back-sides of the leaves, and lay them carefully down on a half-sheet of white paper fairly expanded, and press them with some more papers over these. When the gum water is fixed, let the pressure and papers be removed, and the whole work is finished. The leaves retain their verdure in this case, and the Flowers usually keep their natural colours. Some care must be taken, that the heat of the oven be not too great. When the Flowers are thick and bulky, some art may be used to pare off their backs, and dispose the petals in a due order; and after this, if any of them are wanting, their places may be supplied with some of the supernumerary ones dried on purpose; and, if any of them are only faded, it will be prudent to take them away and lay down others in their stead; the leaves may be also disposed and mended in the same manner. Another way of keeping both Flowers and fruit the whole year, without spoiling, is delivered by the same author in the following manner: take salt-petre, one pound; bole armeniac, two pounds; clean common sand, three pounds; mix all well together; then gather fruit of any kind, that is not full ripe, with the stalk to each; put these in one by one into a wide-mouthed glass, laying them in good order; tie over the top with a sail-cloth, and carry the glass into a dry cellar, and set the whole upon a bed of this prepared matter of four inches thick in a box; fill up the remainder of the box, with the same preparation, and let it be four inches thick over the top of the glass and round all its sides. Flowers are to be preserved in the same sort of glasses in the same manner, and they may be taken up after a whole year as plump and as fair as when buried.

Sexes of FLOWERS.—The learned and ingenious Mr. Watson, in the 47th volume of the Philosophical Transactions, has given us the following curious observations on this subject:

It is in the Flowers of vegetables only, that the parts subservient to generation are produced. Simple Flowers (I use this term in opposition to the compound Flowers of the botanists) are either male, female, or hermaphrodite. By male Flowers, I would be understood to mean those which are possessed only of those organs of generation, analogous to the male parts of animals; and these are what former botanists have denominated stamina and apices, but are named more properly, by Linnæus since, filamentum and anthera. The female Flower is only endowed with parts like those, which perform the office of generation in females; and these are the pistillum and its appurtenances, which by Linnæus, with his accustomed accuracy, are divided into three parts, viz. the germen, stylus, and stigma. The hermaphrodite Flower, which constitutes the great bulk of the vegetable creation, is possessed of all these parts in itself, and is itself thereby capable of propagating its species without any foreign assistance; which, by many incontestable experiments it has been found neither the male nor female Flower simply is able to do.

Much the greater number of plants, as I have just hinted, have hermaphrodite Flowers; but there are some, which have both the male and female Flowers growing from the same root. Such are mays or Indian corn, nettles, box, elm, birch, oak, walnut, beech, hazel, hornbeam, the plane-tree, pine, fir, cypress, cedar, the larch-tree, melons, cucumers, gourds, and several others. In many of these, though the male and female Flowers are at considerable distances, the farina fœcundans, which providence, on account of its being liable to be spoiled by rain, or dissipated by winds, has provided in great abundance, is conveyed to the female by means of the atmosphere. It is this class of vegetables, and the following, the quantity of the produce of which is much more precarious than those plants which have hermaphrodite flowers; as the impregnation of these last may be performed within their own calyx; whereas the former must necessarily commit their farina to the circumambient air. It is for this reason, that, if during the time of the flowering of these plants, the weather is either very wet or stormy, their produce of fruit will be very inconsiderable, from the spoiling or hasty dissipation of the male farina. Thus, independent of frosts, the fruit of the nut and filberd-tree will be most numerous in those years, in which the months of January and February are the least stormy and wet; as at that time their Flowers are produced. For the same reasons, a stormy or wet May destroys the chesnuts; and the same weather in July prodigiously lessens the crop of mays or Indian corn, as its spikes of male Flowers stand lofty, and at a considerable distance from the female. In like manner a judgment may be formed of the rest of these.

Some of the more skilful modern gardeners put in practice, with regard to melons and cucumers, the very method mentioned by Theophrastus two thousand years ago, in regard to the palm-tree. As these plants, early in the season, are in this climate confined to frames and glasses, the air, in which they grow, is more stagnant than the open air, whereby the distribution of the farina fœcundans, so necessary towards the production of the fruit for the propagation of the species, is much hindered; to obviate which, they collect male Flowers, when fully blown, and, presenting them to the female ones, by a stroke of the finger they scatter the farina fœcundans therein, and this prevents the falling of the fruit immaturely. Besides the vegetables before-mentioned, which bear both male and female Flowers upon the same root, there are others, which produce those necessary organs upon different roots. In the number of those are the palm-tree, hops, the willow-tree, misletoe, spinach, hemp, poplar, French and dog's mercury, the yew-tree, juniper, and several others. Among these the valisneria of Linnæus, as to the manner, in which

which its male Flower impregnates the female, is one of the most singular prodigies in nature. The manner of this operation is figured by Micheli, in his Nova Plantarum Genera, and described by Linnæus, in the Hortus Cliffortianus. As that elaborate and expensive work is in very few hands, in such only as owe it to the munificence of Mr. Clifford of Amsterdam, of which number I with pleasure acknowledge myself one, I will here lay before you a short account thereof: The valisneria grows in rivulets, ditches, and ponds, in many parts of Europe. The male plant, which is continually covered with water, has a short stalk, upon the top of which its Flowers are produced. As this top never reaches the surface of the water, the flowers are thrown off from it, and come unopened to the surface of the water; where, as soon as they arrive, by the action of the air, they expand themselves, and swim round the female Flowers, which are blown at the same time.

These last have a long spiral foot-stalk, by which they attain the surface of the water, and, remaining there in Flower a few days, are impregnated by the male Flowers detached from the stalk at the bottom. This operation seems to be thus directed, as the farina fœcundans could not exert its effects in so dense a medium as water; and we find, that even the hermaphrodite Flowers of water-plants, such as those of potamogiton, ranunculus aquaticus, hottonia, and nymphæa, these, I say, never expand themselves, until they reach the surface of the water.

But to return: it was not possible for me, without premising these things, to make evident what I intended, in relation to the falsely denominating the sexes of plants; as it is to this last class that the wrong application has been made by botanical writers. This error seems to have been first introduced so early as by Dioscorides, and has been continued through a great variety of writers even to our own time. It is most certain, that those plants, which produce the seed, ought to be considered as females; but it happens that, in the French and dog's mercury, the seeds are produced in the female plants by pairs; and these are contained in a capsule, which was thought to resemble the scrotum of animals; and from this testiculated appearance they called these plants males, and the others females.

Discorides, when treating of mercurialis, or what we here call French mercury, says, that 'the seed of the female is produced 'in bunches, and is copious; that of the male grows near the 'leaves; that it is small and round, and is dispofed in pairs 'like testicles'. Dodonæus, Lobel, Delechamp, John and Caspar Bauhin, Morrison, Tournefort, and Boerhaave, in their several works, have in this followed Dioscorides, and have denominated the seed-bearing plant of this kind, the male; and the other, the female. Fuchsius and John Bauhin likewise call the cynocrambe or dog's mercury, which bears fruit, the male; and the spiked one with male flowers only, the female. This mistake is observable in hemp, hops, and spinach.

We observe, that the operations of nature are carried on most usually by certain general laws, from which however she sometimes deviates. Thus almost all plants have either hermaphrodite Flowers, or male and female Flowers, growing from the same root, or male and female Flowers from different roots: but there are a few of another class, which from the same root furnish either male and hermaphrodite Flowers, or female and hermaphrodite Flowers. Of this kind are the mulberry-tree, the mura or plantain-tree, white hellebore, pellitory, arrach, the ash-tree, and a few others. But of this class the empetrum or berry-bearing heath is the most extraordinary; as of this are found some plants with male Flowers only, others with both male and female Flowers separately, and still others with hermaphrodite flowers. *Philos. Transf.* Vol. XLVII.

The learned Dr. Alston, king's botanist in Scotland, has endeavoured to overturn the whole doctrine of the sexes of plants, by shewing that the farina fœcundans, is not necessary to the producing of the fertile seeds. We shall add the following instances which he has brought to support his doctrine:

In the spring 1737, I transplanted three sets of common spinage, long before it could be known, whether they were flowering or seed-bearing plants, from a little bed on which they were raised, into a place of the garden, full eighty yards distant, and almost directly south; there being two haw-thorn, and three holly hedges, all pretty thick and tall, between them and their seed bed; and no other spinage in the garden, nor so near them by far: all the three proved fertile plants, and ripened plenty of seeds. I sowed them, they grew, and prospered as well as any spinage seed possibly could do. This, I own, made me, at first, call in question the sexes of plants, which I formerly too implicitly believed.

The same year, a few plants of the common hemp, which I had raised for a specimen from the seed, being accidentally destroyed when very young; and finding afterwards, about the end of June, a pretty strong but late plant of hemp, growing in the inclosure to the east of Holyrood house, commonly called the bowling green, by itself: I caused great care to be taken of it; there not being that year any hemp raised within a mile of it, that I could find. This plant grew luxuriantly; and, though bad weather in the autumn made me pluck it up a little too soon, yet I got about thirty good seeds from it, which the succeeding spring produced as thriving male and female plants as if the mother hemp had stood surrounded with males. And, In the spring 1741, I carried too young seedling plants of the French mercury, long before there was any in flower, from the city physic garden, the only place where it was then to be found in this country, to the king's garden at the abbey, which are more than 700 yards distant from one another, with many high houses, trees, hedges, and part of a hill between them; and planted one of them in one inclosure, where it was shaded from the sun the greatest part of the day; and the other, in another, twenty-five yards distant, exposed to the south and west. Both plants ripened fertile seeds; and the last shed them so plentifully, that it proved a troublesome weed for several years: though none of the species was to be found in that garden, for more than twenty years preceding.

Hence, the dust of the apices of these species of plants cannot, on any account, be called their genitura. And the same may be said of the lupulus, according to Mr. Tournefort's observation; of the bryonia, as noticed by Mr. Miller; also of Mr. Geoffroy's mays.

One year, observing two strong tulips growing together, in an inclosure surrounded with a tall and thick quick-set haw-thorn hedge; I cut down two or three more tulips, which stood at some distance from them so as to leave none within that inclosure, save the two I mentioned: out of these, gently opening the petala, I plucked all the stamina with their apices still intire. The consequences of this too rude castration, were a considerable extravasation of the juices, in the bottom of the flower, and a sudden decay of the ovarium or fruit, which never increased, but turned yellow, shrunk, and withered. In order to discover whether this abortion was owing to the wounds, or to the want of the dust of the apices; I suffered these two tulips to remain in the place where they were: and next season, with the same precaution that no other tulips should flower within the inclosure, I opened the petala, and took out carefully, not the stamina, only, but all the apices; which prevented any sensible bleeding of the parts. This more gentle castration they bore perfectly well; the ovarium suffered nothing, in either of them, but increased, and came to maturity, quite full of seeds. See the *Essays, Physical and Literary, read before a Society in Edinburgh*, Vol. I.

FLOWER-*root worm*, in natural history, a peculiar species of fly-worm, which makes its habitation only in the bulbous roots of Flowers. The roots of the narcissus, at the time they are taken up out of the earth toward the end of autumn, very frequently are found to contain in each a single worm, which eats and destroys them. Sometimes one root is found to contain two of them; but this is but rarely the case. The roots which have them may easily be known, by having each a round hole in some part, at which the destroyer has entered, while it was small, and which probably serves it now in its larger state for the respiration of the freer air. The interior part of these bulbs is always found rotted and destroyed, and the worm is found in these, lying in a brown sort of dirt made by its own liquid excrements, mixed among the fragments of the coats of the root which it has destroyed. *Reaumur's Hist. Insect.*

FLOWERING *of bulbous plants.* — The best method of managing the whole process is this: place the bulbs at first only on the surface of the water; for thus they will strike out their fibres most strongly. When they have stood thus six weeks, pour in the water so high as to cover them intirely, and keep them at this standard till they have done Flowering.

Sometimes the roots will become mouldy in several parts, while they stand above the water; and the cleaning them of it is to no purpose, for it will eat and spread the farther, and frequently eat through two or three of their coats. In this case, they must be immediately covered with water, and the mould will be stopped, and they will become sound, and flower as well as those which never had any such distemperature. If the roots are suffered to remain in water all the year, they will not decay, but will flower again at their proper season, and that as vigorously as those which are taken out and dried. The old fibres of these roots never rot till they are ready to push out new ones. It is found by experience, that the hyacinth, and many other plants, grow to a greater perfection thus in water, than when in the ground. There is a peculiar species of hyacinth, called Keyser's jewel; this never, or however very rarely, produces seed vessels in the common way of Flowering in the ground, but it often will produce some pods when blown in water. Mr. Miller has intimated, in the Philosophical Transactions, that bulbs, set in water, grow weaker, and should be renewed with fresh ones every other year; but it is found that, when they are managed in this manner, and kept under water, at the time of taking them up, they are as large, and some of them larger and stronger than when planted; and, if these be dried in a proper season, they will flower year after year as well as the fresh ones.

Ranunculus and anemone roots have been found to shoot up their stalks very well in this way, but the flowers are usually blasted, which seems to arise from want of free air. Pinks will flower very well in this manner, and auriculas thrive very well, and may with care be brought to flower, but not strongly. Roses, jessamines and honey-suckles, may also be made to flower this way, and will thrive and send out suckers; the best pieces to plant are suckers cut off about three inches under ground, without any fibres.

The

The succulent plants may also be raised this way, for instance an opuntia or Indian fig. If a fragment of a leaf of this plant be cut and laid by to dry for a month, till it is an absolute skin, as soon as it is put in this manner into water, it begins to plump up, and soon sends out fibrous roots, and produces new leaves, at least as quickly as it would do in the ground. *Philos. Transf.* N°. 432.

FLOX, in the colour trade, a very well cleaned wool used to absorb the colours of cochineal, &c. It is prepared in this manner: infuse a pound of the finest sheering of woollen cloth in cold water for one day, then take them up, and press them well together to wash off the unctuosity the wool naturally has. This is the simple Flox, which, when impregnated with a solution of alum, is called alumed Flox; this is done in the following manner: take four ounces of roach alum, and two ounces of crude tartar, both in fine powder; put them into an earthen vessel with three quarts of water, set it over the fire, and, when it begins to boil, then put it into the Flox; let the liquor now boil half an hour over a gentle fire, then take it off, and when all is perfectly cooled, wash the Flox with fair water, letting them stand in it two hours, then press them in the hand and let them dry. *Neri's Art of Glass.*

FLUVIATILES *Cochleæ*, fresh water shell fish, a term used by naturalists to express those kinds of shell fish which never inhabit the sea, but are found in our ponds, rivers, and ditches. These, though greatly less numerous than the species of sea shells, are yet of greater variety and beauty, than is usually supposed.

FLUIDS (*Dict.*) — Under this article in the Dictionary, we have observed that the surface of a Fluid becomes level by its own gravity, when no external force prevents its being so. The demonstration of this is founded upon a supposition, that bodies tend downwards by their gravity in lines parallel to each other; which, though physically true, is not strictly so, their tendency being towards the center of the earth, and consequently in lines which meet in a point: and therefore, if we would be accurate, the Fluid contained in a vessel should be considered, as divided into columns and strata, as represented *plate* XXX. *fig.* 6. in the Dictionary, where A B D is the earth, C its center, E F G H a Fluid contained in a vessel, and divided into columns, which, if continued down to the center of the earth, would there terminate in a point C; and into the concentric strata, *a b*, *c d*, &c. having the center of the earth for the center of their convexity. And then we should find that the particles of the Fluid will not be in æquilibrio with each other, till all the parts of its surface are at equal distances from the center of the earth, forming thereby the surface E F, concentric to that of the earth. For, supposing the Fluid E F G H continued down to C, so as to fill the space E C F; it is evident the columns, into which the Fluid is divided, cannot be of equal lengths, and therefore cannot be of an exact counterpoise to each other, unless the surface E F is a portion of a sphere, whose center is C: but the action of the parts of the Fluid upon each other, at the surface, is the same, whether the lower part G C H be a Fluid, or not. Consequently the surfaces of Fluids are not level or plain, but convex, having the center of the earth for the center of their convexity.

This convexity, by reason of the great distance of the earth's center, approaches so near to a plane, that, in small portions of it, the difference is not sensible, and therefore may be neglected: but at sea it is evident to sense; for, when the mariners put to sea, the shore first disappears, then the lower buildings, afterwards the towers, mountains, &c. in like manner, when they approach a distant ship, the top of its mast and sails appears first, while the ship itself is intercepted from their view, by the convexity of the water between them.

FLY, in natural history. — As weak and contemptible as this creature may appear to us, there is scarce any species of the insect, but what is furnished with five or six advantages that are perpetually serviceable to it in all its necessities. For instance, it has excellent eyes, it has likewise antennæ, or horns, wings, claws, sponges, and a trunk.

Its eyes, as well as those of beetles and dragon flies, are of a peculiar structure: they are two little crescents, or immoveable caps, disposed round the head of the insect, and comprehending a prodigious number of minute eyes, or crystalline humours, ranged like lentils, in lines crossing each other, in the form of lattice work. Under these one may discover a set of fibres, or optic nerves, corresponding in number to the external divisions, or little planes; and curious observers will tell you, they have counted several thousands in each combination. But, whatever their number may be, it is certain that all these planes are a collection of eyes, on which, as on so many mirrors, outward objects are painted. One may see the figure of a lighted taper multiplied almost to infinity, on their surfaces, and shifting its beams into each eye, in proportion to its being varied in its motions by the observer's hand.

The eyes of other creatures are multipled by motion, if I may use that expression; whereas those of a Fly are fixed and immoveable, and can only see what lies directly before them; they are very numerous therefore, and placed on a round surface, some in a high, others in a low situation, to inform the Fly of every thing wherein she can be interested. She has a number of enemies, but, with the aid of these eyes that surround her head, she discovers whatever danger threatens her from above, behind, or on either side, even when she is in full pursuit of a prey directly before her; and the same object is as distinctly perceived by that profusion of eyes, as it by us, who behold it with no more than a couple.

In the microscope, the round edgings, together with the glazed substance and fringe of its wings, appear surprizingly beautiful. There we observe seven or eight articulations, two bending claws, and several minute points, on each of its paws; the double packet of sponges, placed below, at the juncture of its claws, is admirable. Some naturalists suppose, that, when this animal marches over any polished body, on which neither her points nor claws can fasten, she sometimes compresses her sponge, and causes it to evacuate a fluid, which fixes her in such a manner as prevents her falling, without diminishing the facility of her progress. But it is much more probable that sponges correspond with the fleshy balls, which accompany the claws of dogs and cats; and that they enable the Fly to proceed with a softer pace, and contribute to the preservation of its claws, whose pointed extremities would be soon impaired without this prevention. Beside these sponges, her paws are shaded with a growth of hair, which she employs instead of a brush to clean her wings and eyes.

Her trunk is composed of two parts, one of which folds over the other, and both of them are sheathed in her mouth. The extremity of this trunk is sharp like a knife, to enable her to cut what she eats. She likewise forms it into two lips, that she may the better take up proper quantities of food; and, when she sucks up the air it contains, she employs it, as a pump, for drawing up liquors. Several Flies, at the other extremity of their body, are furnished with a piercer, above three twelfths of an inch in length, with which they penetrate wherever they please, and then sheathe it between their scales. This instrument consists of several parts, as particularly one or two saws, finely pointed at the end, and well indented through the whole length; a long case to inclose them; a system of muscles to unsheathe them; and a set of fibres, to bring them back to their socket. Its last piece of furniture is a bag of corroding water, to eat into the cavities that have been first opened by the saws. Those Flies that penetrate the leaves of the oak, are furnished with such a piercer as I have already described.

Those, whose punctures are seen in the bark of rose-trees, have one of a very different structure. It is formed into a long tube, which terminates in a bending point, like a pruning-knife, and is accompanied, through its whole length, with several ranges of teeth. The Fly first traces out, with the sharp part of this instrument, a small furrow on the branch of a rose-tree, after which she places the long indented tube on that furrow, and then, by twining and returning the whole instrument, she opens, on all sides, a number of cells, which appear like ranges of teeth, disposed in pairs, along the extent of a line that separates them.

The same tube likewise enables her to deposit an egg in each cavity, and, when the heat has at last hatched the little worm in the egg, it quits its mansion, to gnaw a leaf of the rose-tree, and gradually increases in growth, like a small caterpillar. The animal, at the end of six weeks, and after it has frequently changed its skin, ceases to eat, and descends to the lower part of the tree, where it spins a covering around its body. The Fly, contained in this worm, endeavours to force itself a passage through the skin of that creature, and accomplishes her purpose by degrees. The skin of the worm cleaves open, and shrinks with the head and intestines, that are now become useless. The fluid in which the Fly swims, and which might possibly contribute to its disengagement from the worm, begins to dry all around the new animal, and is then converted into a kind of bag or shell, which makes the Fly seem in a state of inactivity, and even without any symptoms of life. She either continues but a short space of time in the state of an aurelia, or else passes the whole winter in that situation, according to the degree of heat she then experiences. These few instances will enable us to judge of the instruments with which each species is accommodated, and of the various changes through which they pass.

The common Fly, instead of a piercer qualified for penetrating wood, has only a tube, with which she deposits her eggs, in flesh that has been softened by heat, and likewise in all substances that are succulent or milky, and salted but little; because the sharp particles of salt are more apt to tear the tender organs of her young, than contribute to their preservation. From these eggs proceed a brood of worms, who, afterwards change to aurelia's, and then to Flies; I omit the consequences of their extreme fecundity, and shall only observe, that neither the lion's threat, nor the wolf's teeth, nor all the horns and fangs of wild beasts, in their united rage, are so pernicious to man, as this little piercer, which nature has bestowed on a common Fly, to dig a repository for her eggs. The case is not the same with ichneumon Flies, and several other species; for they are in some measure beneficial to us. The generality of these creatures sustain and shelter themselves in some particular plant, and it is to their sollicitude to lay their eggs there that we owe both the invention and materials of the finest colours, used either in dying or painting, as also the deepest black, common ink, scarlet, and many more.

FLY-*tree*, in natural hiſtory, a name given by the common people of America to a tree, whoſe leaves, they ſay, at a certain time of the year, produce Flies. On examining theſe leaves about the middle of ſummer, the time at which the Flies uſe to be produced, there are found on them a ſort of bags of a tough matter, of about the ſize of a filbert, and of a duſky greeniſh colour; on opening one of theſe bags with a knife, there is uſually found a ſingle full-grown Fly, of the gnat kind, and a number of ſmall worms, which in a day or two more have wings and fly away in the form of their parent. The tree is of the mulberry kind, and its leaves are uſually very largely ſtocked with theſe inſect bags, and the generality of theſe are found to contain the inſects in the worm ſtate; when they become winged, they ſoon make their way out. The bags begin to appear when the leaves are young, and afterwards grow with them; but they never rumple the leaf, or injure its ſhape. They are of the kind of leaf galls, and partake in all reſpects, except ſize, of a ſpecies we have frequent on the large maple, or, as it is called, the ſycamore. *Philoſ. Tranſ.* N°. 431.

The Fly-tree is found in many parts of France, where it grows in great abundance, and is there ſaid to bear fruit, which give origin to vaſt numbers of Flies.

The truth of the matter is this: the tree is a ſpecies of turpentine-tree, and frequently produces or gives origin to certain tubercles, which in the common turpentine-tree are called horns. Theſe are a ſort of long bladders of the length and thickneſs of a finger, which ariſe not from the ſtalks as fruits do, but from the ſurface of the leaves, and are only a kind of an elongation of its outer membranes, occaſioned by the punctures of a number of inſects contained within it, which occaſions a derivation of freſh juices to the part. Theſe inſects are not Flies of the common kind, but are the pucerons ſo well known for feeding on the leaves and tender ſtalks of trees; and ſome few of theſe only are winged, the others being deſtitute of them. The origin of theſe tubercles or bladders is this: the female puceron, as ſoon as produced from the parent, makes a way under the membrane that covers the leaf by means of a hole bored in it with her trunk. The hole ſoon heals up after ſhe is in, and the young ones which ſhe afterwards produces, by their wounding and ſucking the ſides of the lodgement in which they find themſelves placed, occaſion all the ſwelling and growth of the tubercle. *Reaumur's Hiſt. of Inſects.*

FLY, in the ſea language, that part of the mariner's compaſs on which the thirty-two winds are drawn, and to which the needle is faſtened underneath.

FLYING *Fiſh*, a name given by the Engliſh writers to ſeveral ſpecies of fiſh, which by means of their long fins have a method of keeping themſelves out of water for ſome time. The Flying fiſh, moſt properly ſo called, is the exocœtus of the ancient authors, and of Artedi. See *plate* XXII. *fig.* 8. It is called alſo the Adonis, hirundo, and mugil alatus or winged mullet, by others; but they uſe theſe words indeterminately for this and the other kinds.

FOAL, or COLT, the young of the horſe kind. The word colt, ſimply ſpoken, is among the dealers underſtood to mean the male kind; the female, or mare colt, being called a filly.

Colts are uſually foaled in the beginning of ſummer, and it is the cuſtom to let them run with the mare till Michaelmas, when they are to be weaned. This is to be done ſooner or later according as the cold weather comes in. Some are for not having them weaned till the middle of November, and three days before the full of the moon, if it happen near that time. And ſome of the beſt writers on this ſubject are of opinion, that we do not let the Foals ſuck long enough, and that this is the reaſon, why they are ſo very long before they are fit for uſe. Theſe authors are of opinion, that a colt ought always to ſuck the whole winter, and that this would make them fit for ſervice a great deal ſooner than they are at preſent.

When firſt weaned, they muſt be kept in a convenient houſe with a low rack and manger for hay and oats, that they may eat freely and eaſily; and the hay muſt be very ſweet and fine, eſpecially at firſt; a little wheat bran ſhould be mixed with the oats, in order to keep their bodies open, and make them eat and drink freely.

It has been obſerved, that the eating too much oats has rendered colts blind; but the cauſe has been wrongly attributed to the heating quality of the oats. If the oats are bruiſed in a mill before they are given them, though they eat ever ſo much of them, there never happens any miſchief of this kind; but, endeavouring with their teeth to break and chew them, when whole, they are apt to ſtretch and ſwell the veſſels of the head, and occaſion a fulneſs of blood about the eyes, which often terminates in inflammations, and in blindneſs.

The difficulty of chewing oats, and not their heating nature, is therefore the true reaſon of this miſchief; and, if this be obviated by the firſt bruiſing the grain, the colt always grows the better for eating it. His legs do not grow thick, but he becomes broader and better knit, and, as he grows up, will bear fatigue much better than if he had been fed only with bran and hay. Above all things, theſe creatures ſhould be kept from wet and cold, while they are young; for nothing is more tender than a colt, and the miſchiefs he gets at this time are not ſo eaſily got over. Experience ſhews the great advantage of houſing and taking care of colts: for, if the ſame ſtallion covers two mares, both alike in age, beauty, and other particulars, and theſe bring both Foals of the ſame ſex, ſo that there is no room to expect the leaſt difference between them; let one of theſe colts be houſed every winter, and let the other always run abroad, it will be found, as they grow up, that the colt which has been kept abroad, ſhall have large fleſhy ſhoulders, flabby and gouty legs, weak paſterns, and bad hoofs, and ſhall be a dull heavy creature; and that the other which has been houſed and taken care of, ſhall have a fine fore-hand, be well ſhaped, have good legs, and good hoofs, and be of good ſtrength and ſpirit. From this it may be learned, that it is of no conſequence to have a good ſtallion, and a good mare, if the colts are ſpoiled in the breeding up.

FŒNICULUM, *fennel, or finckle*, in natural hiſtory, a genus of plants whoſe characters are:

The root is fibrous; the leaves capillaceous; the petals of the flowers entire, the ſeeds oblong, ſomewhat thick, gibbous, and ſtriated. Our ordinary fennel has pretty large, thick, white roots, which run deep into the earth without much dividing, beſet with ſmall fibres. It has large winged leaves, branched into ſeveral ſegments of long, ſlender, very fine, capillaceous parts, of a dark-green colour, and ſometimes a little reddiſh; the ſtalk grows to be four or five feet high, much divided, and full of whitiſh pith: the flowers grow on the tops of the branches, in flat umbels, of ſmall yellow five-leaved flowers, each of which is ſucceeded by a couple of roundiſh, ſomewhat flat, ſtriated ſeed. The whole plant has a pretty ſtrong but not unpleaſant ſmell. It is generally planted in gardens to be near at hand, but it grows wild in ſeveral places towards the ſea-coaſt; and, at Woolwich and Graveſend, it is frequently met with: it flowers in June. The leaves, root, and ſeed are in uſe; the root being one of the five opening roots, and the ſeed one of the great carminative ſeeds.

Nutrition of the FŒTUS. How the nutrition of the Fœtus is performed, is diſputed among the learned. Mr. Monro is of opinion, that the Fœtus in viviparous animals is nouriſhed by the navel alone. He has given a curious diſſertation on this ſubject in the Medical Eſſays. Where he obſerves, 1. That the Fœtus is capable of receiving its whole nouriſhment by the umbilical vein alone, whereas no Fœtus can ſubſiſt without the umbilical veſſels. 2. That the liquor of the amnios is ill calculated, in its natural ſtate, for the food of a Fœtus, and becomes altogether unfit food in morbid caſes. 3. That it is highly improbable that a creature ſhould furniſh its ſubſtance out of its own body, which muſt be the caſe, if the Fœtus feeds on the liquor of the amnios. 4. That it cannot be inferred, from any reſemblance of the liquor of the ſtomach and amnios, nor from any other appearances, that the liquor of the amnios is ever ſent down into the ſtomach. 5. That no direct proof can be had of the liquor of the amnios being preſſed or ſwallowed down; but, on the contrary, all circumſtances make it probable, that it does not go down. 6. That all the phænomena of a Fœtus can moſt reaſonably be accounted for, without ſuppoſing the liquor of the amnios to be any part of its food; hence, he thinks it reaſonable to exclude the mouth from the office of conveying the aliment of the Fœtuſes of viviparous animals, and to believe that all their nouriſhment is conveyed by the umbilical veſſels. Hippocrates among the ancients was of opinion, that the Fœtus was nouriſhed both by the mouth, and by the umbilical veſſels. He maintains, that the child in the womb with its lips compreſſed together attracts nouriſhment, for which he aſſigns this reaſon, that, unleſs the child had ſucked in utero, it neither could depoſit excrement, nor know how to ſuck, ſo ſoon as it is born. Mr. Gibſon, in the Medical Eſſays of Edinburgh, has lately adopted this opinion, that the Fœtus is nouriſhed by the mouth and by the navel alſo, as moſt probable. Mr. Monro has anſwered him, loc. cit.

St. FOIN. See SAINTFOIN.

FOLDING *of ſheep*, a term uſed by our farmers to expreſs the keeping theſe creatures on their arable lands, within folds made of hurdles, which they remove about, ſo that, when the ſheep have dunged one place, they are ſet upon another. This is a very great advantage to the land; the dung of theſe creatures being a very rich manure. It ought only to be done in ſummer time, and in good weather, for the Folding them in bad weather is apt to give them the rot. Care muſt be taken that they are only driven into theſe folds over night, and let out again in the morning, half an hour after ſun-riſe, into places where there is good food; for, being hungry at this time, they will eat whatever comes next them. Many ſheep are ruined by this practice in moiſt ground, and ſome farmers who think all Folding very bad for ſheep, only ſtick up ſloping ſtakes in ſuch parts of the lands as they would have dunged, and never fold the ſheep at all, but truſt to their coming to theſe ſtakes to rub themſelves for the dunging the ground, as they conſtantly void their dung and urine at that time. *Mortimer's Huſb.*

FOOD *of plants*, that matter, which, being added and united to the firſt ſtamina of plants, cauſes their increaſe.

It is agreed, that all the following materials contribute, in ſome manner, to the increaſe of plants; but it is diſputed which of them is that very increaſe or food.

1. Nitre. 2. Water. 3. Air. 4. Fire. 5. Earth.

Nitre is uſeful to divide and prepare the Food, and may be ſaid to nouriſh vegetables in much the ſame manner as my knife

knife nouriſhes me, by cutting and dividing my meat: but, when nitre is applied to the root of a plant, it will kill it as certainly as a knife miſapplied will kill a man: which proves, that nitre is, in reſpect of nouriſhment, juſt as much the Food of plants, as white arſenic is the Food of rats. And the ſame may be ſaid of ſalts.

Water, from Van-Helmont's experiment, was by ſome great philoſophers thought to be it. But theſe were deceived, in not obſerving that water has always in its intervals a charge of earth, from which no art can free it. This hypotheſis having been fully confuted by Dr. Woodward, no-body has, that I know of, maintained it ſince: and to the doctor's arguments I ſhall add more in the ſequel.

Air, becauſe its ſpring, &c. is as neceſſary to the life of vegetables, as the vehicle of water is; ſome modern virtuoſi have affirmed, from the ſame and worſe arguments, than thoſe of the water-philoſophers, that air is the Food of plants. Mr. Bradley being the chief, if not only author, who has publiſhed this phantaſy, which at preſent ſeems to get ground; it is fit he ſhould be anſwered: and this will be eaſily done, if I can ſhew, that he has anſwered this his own opinion, by ſome or all of his own arguments.

His firſt is that of Helmont, and is thus related in Mr. Bradley's general Treatiſe of Huſbandry and Gardening, Vol. I. 'Who dried two hundred pounds of earth, and planted a willow of five pounds weight in it, which he watered with rain, or diſtilled water; and, to ſecure it from any other earth getting in, he covered it with a perforated tin cover. Five years after, weighing the tree, with all the leaves it had borne in that time, he found it to weigh one hundred ſixty-nine pounds three ounces; but the earth was only diminiſhed about two ounces in its weight.'

On this experiment Mr. Bradley grounds his airy hypotheſis. But let it be but examined fairly, and ſee what may be thence inferred.

The tin cover was to prevent any other earth from getting in. This muſt alſo prevent any earth from getting out, except what entered the roots, and by them paſſed into the tree.

A willow is a very thirſty tree, and muſt have drank in five years time ſeveral tons of water, which muſt neceſſarily carry in its interſtices a great quantity of earth, probably many times more than the tree's weight, which could not get out, but by the roots of the willow.

Therefore the two hundred pounds of earth not being increaſed, proves that ſo much earth as was poured in with the water, did enter the tree.

Whether the earth did enter to nouriſh the tree, or whether only in order to paſs through it (by way of vehicle to the air) and leave the air behind for the augment of the willow, may appear by examining the matter of which the tree did conſiſt. If the matter remaining after the corruption or putrefaction of the tree be earth, will it not be a proof, that the earth remained in it, to nouriſh and augment it? For it could not leave what it did not firſt take, nor be augmented by what paſſed through it. According to Ariſtotle's doctrine, and Mr. Bradley's too, in Vol. I. 'Putrefaction reſolves it again into earth, its firſt principle'.

The weight of the tree, even when green, muſt conſiſt of earth and water. Air could be no part of it, becauſe air, being of no greater ſpecific gravity than the incumbent atmoſphere, could not be of any weight in it; therefore was no part of the one hundred ſixty-nine pounds three ounces.

Nature has directed animals and vegetables to ſeek what is moſt neceſſary to them. At the time when the fœtus has a neceſſity of reſpiration, it is brought forth into the open air, and then the lungs are filled with air. As ſoon as a calf, lamb, &c. is able to ſtand, it applies to the teat for Food, without any teaching. In like manner Mr. Bradley remarks, in his Vol. I. 'That almoſt every ſtem and every root are formed in a bending manner under-ground; and yet all theſe ſtems become ſtraight and upright when they come above-ground, and meet the air; and moſt roots run as directly downwards, and ſhun the air as much as poſſible'.

Can any thing more plainly ſhew the intent of nature, than this his remark does? viz. That the air is moſt neceſſary to the tree above-ground, to purify the ſap by the leaves, as the blood of animals is depurated by their lungs: and that roots ſeek the earth for their Food, and ſhun the air, which would dry up and deſtroy them.

No one truth can poſſibly contradict or interfere with any other truth; but one error may contradict and interfere with another error, viz.

Mr. Bradley, and all authors, I think, are of opinion, that plants of different natures are fed by a different ſort of nouriſhment; from whence they aver, that a crop of wheat takes up all that is peculiar to that grain; then a crop of barley all that is proper to it; next a crop of peaſe, and ſo on, till each has drawn off all thoſe particles which are proper to it; and then no more of theſe grains will grow in that land, till, by fallow, dung, and influences of the heavens, the earth will be again repleniſhed with new nouriſhment, to ſupply the ſame ſorts of corn over again. This, if true (as they all affirm it to be,) would prove, that the air is not the Food of vegetables. For the air, being in itſelf ſo homogeneous as it is, could never afford ſuch different matter as they imagine; neither is it probable, that the air ſhould afford the wheat nouriſhment more one year, than the enſuing year; or that the ſame year it ſhould nouriſh barley in one field, wheat in another, peaſe in a third; but that, if barley were ſown in the third, wheat in the firſt, peaſe in the ſecond, all would fail: therefore this hypotheſis of air for Food interferes with, and contradicts this doctrine of neceſſity of changing ſorts.

I ſuppoſe, by air, they do not mean dry particles of earth, and the effluvia which float in the air: The quantity of theſe is too ſmall to augment vegetables to that bulk they arrive at. By that way of ſpeaking they might more truly affirm this of water, becauſe it muſt be like to carry a greater quantity of earth than air doth, in proportion to the difference of their different ſpecific weight; water, being about 800 times heavier than air, is likewiſe to have 800 times more of that terreſtrial matter in it; and we ſee this is ſufficient to maintain ſome ſort of vegetables, as aquatics; but the air, by its charge of effluvia, &c. is never able to maintain or nouriſh any plant; for, as to the ſedums, aloes, and all others, that are ſuppoſed to grow ſuſpended in the air, it is a mere fallacy; they ſeem to grow, but do not; ſince they conſtantly grow lighter, and though their veſſels may be ſomewhat diſtended by the ferment of their own juices, which they received in the earth, yet, ſuſpended in air, they continually diminiſh in weight (which is the true augment of a plant) until they grow to nothing. So that this inſtance of ſedums, &c. which they pretend to bring for proof of this their hypotheſis, is alone a full confutation of it.

Yet if granted, that air could nouriſh ſome vegetables by the earthy effluvia, &c. which it carried with it, even that would be againſt them, not for them.

They might as well believe, that martins and ſwallows are nouriſhed by the air, becauſe they live on flies and gnats, which they catch therein; this being the ſame Food, which is found in the ſtomach of the chameleon.

If, as they ſay, the earth is of little other uſe to plants, but to keep them fixed and ſteady, there would be little or no difference in the value of rich and poor land, dunged or undunged; for one would ſerve to keep plants fixed and ſteady, very near, if not quite, as well as the other.

If water or air was the Food of plants, I cannot ſee what neceſſity there ſhould be of dung or tillage.

Fire. No plant can live without heat, though different degrees of it be neceſſary to different ſorts of plants. Some are almoſt able to keep company with the ſalamander, and live in the hotteſt expoſures of the hot countries. Others have their abode with fiſhes under water, in cold climates: for the ſun has his influence, though weaker, upon the earth covered with water, at a conſiderable depth; which appears by the effect the viciſſitudes of winter and ſummer have upon ſubterraqueous vegetables.

Though every heat is ſaid to be a different degree of fire, yet we may diſtinguiſh the degrees by their different effects. Heat warms, but fire burns: the firſt helps to cheriſh, the latter deſtroys plants.

Earth. That which nouriſhes and augments a plant, is the true Food of it.

Every plant is earth, and the growth and true increaſe of a plant is the addition of more earth.

Nitre (or other ſalts) prepares the earth, water and air move it, by conveying and fermenting it in the juices; and this motion is called heat.

When this additional earth is aſſimilated to the plant, it becomes an abſolute part of it.

Suppoſe water, air, and heat, could be taken away, would it not remain to be a plant, though a dead one?

But, ſuppoſe the earth of it taken away, what would then become of the plant? Mr. Bradley might look long enough after it, before he found it in the air amongſt his ſpecific or certain qualities.

Beſides, too much nitre (or other ſalts) corrodes a plant; too much water drowns it; too much air dries the roots of it; too much heat (or fire) burns it; but too much earth a plant never can have, unleſs it be therein wholly buried; and, in that caſe, it would be equally miſapplied to the body, as air or nitre would be to the roots.

Too much earth, or too fine, can never poſſibly be given to roots; for they never receive ſo much of it, as to ſurfeit the plant, unleſs it be deprived of leaves, which, as lungs, ſhould purify it. And earth is ſo ſurely the Food of all plants, that with the proper ſhare of the other elements, which each ſpecies of plants requires, I do not find but that any common earth will nouriſh any plant. *Tull's Horſe-hoeing Huſbandry.*

FORCE *of bodies in motion.* It has been a famous diſpute among philoſophers, 'whether the Force of bodies in motion, ſtriking each other, be proportional to the ſimple velocity of the motion, or to the ſquare of the velocity'? The Engliſh and French maintain the former; the Dutch and Germans the latter.

This diſpute firſt commenced between Mr. Huygens and the abbot Catalan, about the Force of oſcillating bodies; it continued ſome time between theſe two gentlemen; at laſt, another ſubject of the ſame kind engaged the ſaid abbot with the famous Leibnitz, who is to be eſteemed the firſt author, that plainly

plainly declared, in expreſs words, 'That the Forces of bodies 'were as their maſſes multiplied by the ſquare of the velocity.' Catalan, and afterwards Mr. Papin, anſwered Leibnitz; he replied again, and ſeveral papers were written on the ſubject. It then became a matter of general enquiry, and the philoſophers of every nation began to conſider which ſide to be of, and whether they ſhould declare for the old or for the new opinion. However, they did here, as they do in religion, go by a whole nation together; the common herd of philoſophers following the dictates of their leaders. Thus Leibnitz, Polenus, S'Graveſande, and Muſchenbroek led the German and Dutch; Papin, Mairan, &c. the French; and Pemberton, Eames, Deſaguliers, Clarke, &c. the Engliſh.

In this controverſy alſo, as in thoſe of religion, the opponents diſputed with very great warmth, wondered at each other's ſlowneſs of apprehenſion, or backwardneſs of belief; and I wiſh I could ſay, that they had always obſerved ſuch an impartial, free, and generous behaviour and ſtile of expreſſion, as the dignity of philoſophy demands. We ſhould then perhaps have found Dr. Deſaguliers better employed than in blaming Dr. Samuel Clarke for uncivil treatment, for rude and impertinent expreſſions, &c. in regard to thoſe who defend the new opinion of the ſquare of the velocity.

As it uſually falls out in other caſes, ſo here, when men find themſelves preſſed with difficulties and abſurdities in their ſchemes and notions, they have recourſe to the ſubtilties of metaphyſical diſtinctions, though ſeldom to any good purpoſe. Thus when it appeared too plainly by all experiments, and even to common ſenſe, that the natural Force of bodies was proportional to the ſimple velocity and maſs of matter conjointly; we were told it was neceſſary to diſtinguiſh the Force of bodies into two kinds, viz. the vis viva or living Force; and the vis mortua, or the dead Force.

By this vis viva, or living Force, we were to apprehend that which reſulted from the viſible action of one body upon another, as that of a falling weight; but the vis mortua or dead Force was to be underſtood of that which was deſtroyed by a contrary agent, as a weight in one ſcale of a balance is kept from deſcending by a counter-poiſe in the other ſcale. But, unluckily for the author of this refinement, both thoſe Forces appear, even by the balance, to be in the ratio of the ſimple velocity into the maſs.

Thus for the living Force, if on the proportional balance you place 4 lb. at the diſtance of ſix inches on one ſide, and 2 lb. at the diſtance of twelve inches on the other ſide, and, if the balance be put into motion, they will each of them have a vis viva, or an active force, becauſe they will keep the beam in motion for ſome time, till, by militating, they murder or kill each other; and then ſurely enough they become vires mortuæ, or dead Forces.

But let us ſee how they exerted their power, while living. One (A) acted againſt the other (B,) with the gravity of every particle in a maſs of 4 lb. and with the velocity in each ſtroke that ſix inches diſtance could give; but, ſince all allow the weight to be as the maſs of matter, and the velocity as the diſtance from the center of motion, therefore all the Force which A exerted was as $4 \times 6 = 24$. In the ſame manner it is ſhewn the whole Force of B acting againſt A was as $2 \times 12 = 24$; that is, in each caſe, the Force was as the velocity into the maſs of matter. And, becauſe they were equal, they deſtroyed each other.

But, had thoſe combatants A and B been armed with Forces proportioned to the ſquares of the velocities, that of A would have been but $4 \times 6 \times 6 = 144$; whilſt B would have had a Force equal to $2 \times 12 \times 12 = 288$; by which he would have demoliſhed A at one ſingle ſtroke, and been the ſurviving conqueror.

Let us now conſider theſe two bodies A and B as dead, and ſee what Forces they exert (verbo detur venia) in that ſtate. In order to this they muſt be hanged upon the arms of the balance, one on each ſide, till they are dead, i. e. motionleſs; but this will not happen till their diſtances from the center of motion become reciprocally proportional to their maſſes of matter; and then it is plain the caſe is the ſame as before; for the dead Force of A will be as $4 \times 6 = 24 = 2 \times 12 =$ dead Force of B. Whereas, if theſe Forces were as the maſſes into the ſquare of the velocities, A of 4 lb. and B of 2 lb. ought to die at the diſtances 6 and 8, 4 inches from the center reſpectively; but, if the experiment be tried there, ſuch ſtrong ſymptoms of life will be found in A, as manifeſt the falſity of this hypotheſis.

Being driven from this ſubterfuge, they ſeek another in a critical diſtinction between Force and preſſure. Preſſure, ſay they, is the power with which bodies act by means of inſtruments; thus a weight in one ſcale acts againſt the weight in another by preſſure; but the power by which bodies act on each other alone, is properly called Force, as when one ſtone ſtrikes another by falling on it, or a hammer ſtrikes an anvil. The former they allow is proportional to the velocity and maſs of matter conjointly; but the latter, they ſay, is as the maſs multiplied by the ſquare of the velocity.

But this Eclairciſſement boots them as little as the former, if they mean a momentary impact or ſtroke, or ſuch whoſe effect is produced in a moment of time. For in ſuch a caſe we ſay,

FOR

the ſtroke is in proportion to the maſs of matter, and alſo to the degree of velocity, and therefore as both conjointly; but we deny there is any other ſource of power from whence a body can derive any Force for producing a momentary effect: nor have any of thoſe gentlemen been able to ſhew there is, though ſome (bewildered in the labyrinth) have attempted it, but in how weak and ridiculous a manner may be ſeen in a piece intitled, De Conſervatione Virium vivarum, &c. And it is worth the reader's while to ſee the jocular confutation of this ludicrous piece by Phileleutherus Londinenſis.

If they ſay, they would not be underſtood of momentaneous effects, but ſuch as are produced in time, then they have no antagoniſts. And, it is plain from their experiments, that this is their meaning, after all. For their experiments which they ſo much inſiſt on, are ſuch as are made by letting bodies fall on ſoft ſubſtances, as clay, butter, &c. or by the action of bodies on yielding ſprings, or ſpringy bodies; in all which caſes, the effect is not produced inſtantaneouſly, but in time; the clay takes time to recede, the ſpring to bend, &c.

If the time be taken into conſideration, then every body muſt know that the effect will be proportional to the intenſity of the cauſe, and the time of its continuance: thus, for example, the effect of gravity on bodies left to themſelves cauſes them to deſcend; their deſcent therefore will be proportionate to the power of gravity upon them, and therefore greater in thoſe which fall freely, than in others which deſcend on inclined planes in a given time, where part of the Force of gravity is deſtroyed by the re-action of the plane. But, ſince the action of gravity is not inſtantaneous, but continual, therefore its effect, i. e. the deſcent of the body, will be greater in proportion to the time of its continuing to act on the body, ſeparately conſidered from its intrinſic Force. But this Force is as the velocity produced by it in a given time; alſo the time is as the velocity, when the Force is given; therefore the effect, viz. the deſcent of the body, is as the ſquare of the velocity.

Or in ſymbols thus: let $E =$ the effect produced by any power $= P$, acting in any ſpace of time $= T$, upon any body $= Q$, moving with any degree of velocity V. Then it is plain, E will be as $Q =$ maſs of matter in the body, when P, T, and V are given; alſo the effect E will be as the intenſity of the power P, when T, Q, and V are given; again, when P, Q, T are given, E muſt be as V; and laſtly, we ſhall have E as T, when P, Q, V are given. Therefore, when neither of theſe are given, $E : Q \times P \times V \times T$; and, in caſe of any different effect, let $e : q \times p \times v \times t$.

Then ſuppoſing the bodies equal, viz. $Q = q$, we have $E : e :: PVT : pvt$. Thus the ſame or two equal bodies, deſcending on two planes unequally inclined, will deſcend through ſpaces, which will be as the different powers of gravity P and p, as the different velocities V and v in any point of time, and as the different times T and t of their deſcent, conjointly.

If not only the bodies Q and q, but alſo the powers P and p which actuate them, be ſuppoſed equal, or $P = p$; then $E : e : TV : tv$. Thus, in equal bodies falling freely by gravity, the effect, or the ſpace which they deſcribe, will be as the time T and t of the falls, the velocities V and v at any point of time in the fall. And becauſe in this caſe the velocity is always proportional to the time, that is, $T : t :: V : v$; if we multiply each ratio by the ſame ratio $V : v$, the analogy will ſtill be the ſame, viz. $TV : tv :: V^2 : v^2$; whence $E : e :: V^2 : v^2$; or the effect of falling bodies, in deſcribing the ſpace, will be as the ſquare of the velocities.

If we ſuppoſe the times given, that is, $T = t$, then (the reſt as before) we have $E : e : V : v$; that is, the Forces or effects of equal bodies, falling in equal times, are proportional to the ſimple velocities.

If $V = v$, or the velocities given; then $E : e :: T : t$. Thus, if two equal bodies, lying on an horizontal plane, receive a ſtroke each from ſprings of equal Force, then will the velocities be equal in every part of the motion, and the effects E and e, in this caſe, being the ſpaces deſcribed, will be as the times of their motion.

Hence we have ſeen every poſſible caſe wherein the Forces of bodies or their effects can be ſuppoſed to vary; and it is plain there is none where the Force is as the ſquare of the velocity but where the time is concerned; or where ſome one of the factors Q, P, V, T, is proportional to the velocity; thus in ſpouting-water, becauſe Q is always as V, therefore, though T be given, E will be as QV, or as V^2; for P alſo in this caſe is given, the power of gravity which gives motion to the particles of the fluid being always conſtant. Nor have they any experiment which ſhews the Force or effects of bodies proportional to the ſquares of the velocities, but where the time in which the effect is produced ought to be conſidered. Thus in their famous experiment of cavities, formed in ſoft clay by falling bodies, it is true, thoſe cavities are the effect of the falling bodies, and proportional to the ſquares of the velocity. But what is this to the purpoſe, unleſs they will ſay, thoſe pits are inſtantaneouſly produced, which I believe none will pretend to do?

It is evident, this cavity muſt be proportional to the quantity of matter put in motion in the clay, by the falling body: but this is proportional to the velocity on two accounts; the firſt is, that every particle which comes in contact with the

ſtriking

ſtriking body, receives a ſtroke proportional to the velocity; therefore alſo the number of particles which each of theſe can move, will be as the Force of the ſtroke, or as the velocity of the falling body. Secondly, among yielding particles, the number which the falling body can apply to in a given time, will be as the velocity; conſequently the whole number of particles which can be moved, both immediately by the body itſelf, and by the motion communicated to the particles, will be as the ſquare of the velocity; and therefore the cavity will be in the ſame ratio alſo.

We hence obſerve, the ſame method of reaſoning may be applied to ſoft and yielding ſubſtances, as has always been uſed in the caſe of unelaſtic fluids; and for this reaſon only, that, in every caſe of yielding particles, the effect of a body in ſtriking them is not deſtroyed momentaneouſly, but in time, which time (cæteris paribus) will be as the velocity; and therefore, E being as T V, and T, in all theſe caſes, being as V, it will be univerſally for all ſoft and yielding ſubſtances E : V^2.

Hence we may obſerve that, as bodies are more or leſs yielding or ſoft, ſo the effect will be more or leſs approaching to the ratio of the ſquare of the velocity. This conſideration is of great uſe in mechanical affairs. Thus a hammer with a double velocity will produce much more than a double effect in driving a nail; the ſame may be ſaid of a rammer driving a pile: hence the reaſon why a ſmall hammer will by its velocity do more execution upon red-hot iron, than the large hammer by its momentum. In ſhort, all theſe things are ſo plain and eaſy to be underſtood, that it is ſurprizing to think how ſuch a diſpute could ſubſiſt ſo long, and occaſion ſo much to be ſaid about it.

The learned Dr. Jurin, in the Philoſophical Tranſactions, number 476, propoſes the following experiment, which he looks upon as ſufficient to put a final end to this controverſy, which has now ſubſiſted above ſixty years.

Upon an horizontal plane, at reſt, but moveable with the leaſt Force, ſuppoſe upon a boat in a ſtagnant water, let there be placed, between two equal bodies, a bent ſpring, by the unbending of which the two bodies may be puſhed contrary ways.

In this caſe it is evident, that the velocities, which the two bodies receive from the ſpring, will be exactly equal, and their moving Forces will alſo be exactly equal; and that the plane they move upon, and alſo the boat upon which it lies, will have no motion given them either way. Let us call the velocity of each body 1, and the moving force alſo 1.

Now, let us ſuppoſe the ſpring to be bent afreſh to the ſame degree as before, and to be again placed between the two bodies lying at reſt; then let the plane, upon which the ſpring and the bodies lie, be carried uniformly forwards, in the direction of the length of the ſpring, with this ſame velocity 1. In this caſe it is manifeſt, that each of the bodies will have the velocity 1, and the moving Force 1, both in the direction of the axis of the ſpring.

During this motion, let the ſpring again unbend, and puſh the two bodies contrary ways, as before, the one forwards, the other backwards: then the ſpring will give to each of theſe bodies the velocity 1, as before, when the plane was at reſt.

By this means the hindmoſt body, or that which is puſhed backwards, will have its velocity 1, which it had before by the motion of the plane, now intirely deſtroyed, and will be abſolutely at reſt.

But the body, which is puſhed forwards, will now have the velocity 2, namely, 1 from the motion of the plane, and 1 from the action of the ſpring.

Thus far every body agrees in what will be the event of this experiment.

But the queſtion is, what will be the moving Force of the foremoſt body, or of that which is puſhed forwards, and which has the velocity 2; viz. 1 from the motion of the plane, and 1 from the action of the ſpring.

By the Leibnitian doctrine, its moving Force muſt be 4: and, if ſo, it muſt have received the moving Force 3 from the action of the ſpring; for it had only the moving Force 1 from the motion of the plane.

Let us examine, whether this be poſſible, or reconcileable to their own doctrine.

Their doctrine is, that equal ſprings, equally bent, will, by unbending themſelves, give equal moving Forces to the bodies they act upon, whatever thoſe bodies are.

We agree to this, not generally indeed; but in the caſe before us, where the bodies are of equal maſſes or weights, we agree to it.

Let us therefore imagine the bent ſpring, which is placed between the two bodies, to be divided tranſverſly into two equal parts. In this caſe it is plain, that the two halves of the ſpring may be conſidered as two intire ſprings, equal, and equally bent, each of which reſts at one end in æquilibrio againſt the other ſpring, and, at the oppoſite end, preſſes againſt the body it is to move.

Conſequently, by the Leibnitian doctrine, to which, in this particular caſe, where the bodies are equal, we alſo agree, the two ſprings will give equal moving Forces to the two bodies.

But the moving Force, received by the hindmoſt body from the hinder ſpring, was undoubtedly the moving Force 1: for, by that Force given it in the direction backwards, the moving Force 1, which it had before from the motion of the plane in the direction forwards, is exactly balanced and deſtroyed, the body remaining, as was obſerved before, in abſolute reſt. Therefore the moving Force, received by the foremoſt body from the foremoſt ſpring, was alſo the moving Force 1. And this, added to the other moving Force 1, which it had before from the motion of the plane, makes the moving Force 2, and not the moving Force 4, as the Leibnitian philoſophers pretend.

Conſequently, that body, which had before the velocity 1, and the moving Force 1, and now has the velocity 2, has alſo the moving Force 2: that is, the moving Forces are proportional to the velocities.

FO'RCING, in the wine trade, a term uſed by the wine-coopers for the fining down wines, and rendering them fit for immediate draught.

The principal inconvenience of the common way of fining down the white wines by iſinglaſs, and the red by whites of eggs, is, the ſlowneſs of the operation; theſe ingredients not performing their office in leſs than a week, or ſometimes a fortnight, according as the weather proves favourable, cloudy, or clear, windy, or calm: this appears to be matter of conſtant obſervation. But the wine merchant frequently requires a method that ſhall, with certainty, make the wines fit for taſting in a few hours. A method of this kind there is, but it is kept in a few hands a valuable ſecret. Perhaps it depends upon a prudent uſe of a tartarized ſpirit of wine and the common Forcing, as occaſion is, along with gypſum, as the principal; all which are to be well ſtirred about in the wine for half an hour before it is ſuffered to reſt. *Shaw's Lect.*

FORCING, among gardeners, is uſed for producing ripe fruits from trees before their natural ſeaſon. The method of doing it is this: a wall ſhould be erected ten feet high; a border muſt be marked out on the ſouth ſide of it, of about four feet wide, and ſome ſtakes muſt be faſtened into the ground all along the edge of the border; theſe ſhould be four inches thick. They are intended to reſt the glaſs lights upon, which are to ſlope backwards to the wall, to ſhelter the fruit, as there ſhall be occaſion; and there muſt be at each end a door to open either way, according as the wind blows. The frame ſhould be made moveable along the wall, that, when a tree has been forced one year, the frame may be removed to another, and ſo on, that the trees may be each of them forced only once in three years, at which rate they will laſt a long time. They muſt be always well grown trees that are choſen for Forcing, for young ones are ſoon deſtroyed, and the fruit that is produced from them, is never ſo well taſted. The fruits moſt proper for this management are the avant, or ſmall white nutmeg, the Albemarle, the early Newington, and the brown nutmeg peaches; Mr. Fairchild's early, and the elrugo and Newington nectarines; the maſculine apricot, and the May-duke and May-cherry. For grapes, the white and black ſweet-water are the propereſt; and, of gooſeberries, the Dutch-white, the Dutch early-green, and the walnut gooſeberry; and the large Dutch-white and large Dutch-red currants.

The dung before it is laid to the wall ſhould be laid together on a heap for five or ſix days, that it may heat uniformly through; and, when thus prepared, it muſt be laid four feet thick at the baſe of the wall, and go ſloping up till it is two feet thick at the top. It muſt be laid at leaſt within three or four inches of the top of the wall, and, when it ſinks, as it will ſink two or three feet, freſh dung muſt be laid; for the firſt heat will do little more, than juſt ſwell the bloſſom buds.

The covering the trees with glaſſes is of great ſervice, but they ſhould be taken off to admit the benefit of gentle ſhowers to the trees, and the doors at the ends ſhould be either left intirely open, or one or both of them opened, and a mat hung before them, at once to let the air circulate and to keep out the froſts.

The dung is never to be applied until toward the end of November, and three changes of it will be ſufficient to ripen the cherries, which will be very fine in February. As to the apricots, grapes, nectarines, peaches, and plums, if the weather be milder, the glaſſes are to be opened to let in ſun-ſhine, or gentle ſhowers. If a row or two of ſcarlet-ſtrawberries be planted at the back of the frame, they will ripen in February, or the beginning of March; the vines will bloſſom in April, and the grapes will be ripe in June.

It ſhould be carefully obſerved not to place early and late ripening fruits together, becauſe the heat, neceſſary to force the late ones, will be of great injury to the early ones, after they have fruited.

The maſculine apricot will be ripe in the beginning of April, and the early nectarines will be ripe about the ſame time, and the forward ſort of plums by the latter end of that month. Gooſeberries will have fruits fit for tarts in January or February, and will ripen in March, and currants will have ripe fruit in April.

The trees need not be planted ſo diſtant at theſe walls as at others, for they do not ſhoot ſo freely as in the open air: nine feet aſunder is ſufficient. They ſhould be pruned about

three

three weeks before the heat is applied. *Miller's Gard. Dict.*

FO'RMICA-*Leo*, the lion pismire, a very remarkable insect, as long as the common palmer, but something thicker; it has a very long head, and the body grows round, as it lengthens towards the tail. The animal is of a dark grey, marked with black spots. Its body is composed of several flat rings, that slide over one another. It has six feet, four of which are inserted in the breast, and two in the neck. Its head is small and flat, and, from the fore part of it, two little horns shoot out: these are smooth and hard, extend two twelfths of an inch in length, and bend like hooks in the extremity. Towards the base of these horns, appear two small eyes, very black and lively, and which are very serviceable to the creature, for he starts from the smallest objects he discovers. Other animals are furnished with wings, or feet at least, to make them expeditious in the pursuit of their prey; but this is only capable of marching backward. He never follows his prey, and would sooner die than advance a step towards it. The prey must come to him, and he is gifted with the secret of making it fall into the ambuscade he has prepared. This is the only method he has for his subsistence, and is all the science he is master of; but however it suffices for his purpose.

He chuses for himself a bed of dry sand, at the foot of a wall, or under some shelter, that the rain may not disconcert his work. He is obliged to make use of sand, and of the driest he can get, because a solid soil, as well as a moist sand, would not prove tractable under his operations. When he intends to hollow the trench where he ensnares his game, he bends the hinder part of his body, which tapers into a point, and then plunges it, like a plough-share, into the sand, which he throws up in his rear, with a backward motion of his body; and thus, by repeating his efforts, and taking several rounds, he at last traces out a circular furrow, whose diameter always equals the depth to which he intends to sink it. Near the edge of the first furrow, he opens a second, and then a third, and several others, which are smaller than the preceding, and sinks himself from time to time, deeper in the sand, which he throws aside with his horns, on the edges of the furrows, and to a much greater distance, always marching backward in a spiral line. The repeated strokes of his head whirl the sand out of the circle, and gradually scoop out a cavity, in which operation he exceeds the best engineers; he describes a perfect circle, and draws out a volute, without the assistance of a pair of compasses. He likewise gives the slope of earth, which he hollows with all possible solidity. In this dexterous and indefatigable manner he compleats his trench, which resembles a cone reversed, or rather the inside of a funnel.

When this creature is newly hatched, he opens a very small furrow, but, when he increases in bulk, he digs one more spacious, the cavity of which may contain two inches or more in diameter, and as many in depth. When the work is compleated, he forms his ambuscade, and conceals himself under the sand, in such a manner, that his horns exactly wind round the point in which the bottom of the funnel terminates. In this situation, he watches for his prey, and woe to the ant, the palmer, or any other insect who is so indiscreet as to play round the edge of this precipice, which descends in a slope, and that too in the sand, to give a downfal to the little animals who are too incautious in their approaches. It is for the female ant that the lion-pismire thus adjusts his kitchen. She is not aided with wings, like the generality of insects, to disengage herself from this cavern; but then she is not the only prey, for other animals are also destroyed by the dexterity of this hunter. When he knows by the fall of some grains of sand, that a prize is near, he shrinks back and moves the sand, which immediately rolls to the bottom with the prey. If this prey has agility enough to be capable of remounting in an instant, and, with this advantage, is likewise assisted with wings; the lion-pismire whirls a quantity of sand into the air, above the height of the flying animal. This is a dreadful shower of stones to such a tender creature as a gnat or an ant. The unfortunate insect, blinded and overwhelmed in this manner, by the tempest that pours down from every quarter, and hurried away by the instability of the sand that rolls from under her feet, falls between the jaws of her enemy, who plunges them into her body, drags her under the sand, and then feasts upon the victim. And, when nothing is left but the carcase drained of all its juices, he is particularly careful to remove it out of sight. The appearance of a dead body would deprive him of future visits, and bring his place of residence under a bad reputation: he therefore extends his horns, and, with a sudden spring, tosses the slain half a foot beyond the trench; and, if this should happen to be disconcerted and filled up, by such an expedition, or if the aperture becomes too large for the depth, and the declivity loses its proper slant, he repairs the whole with all speed; he rounds, he deepens, he clears the cavity, and then watches for a new prey.

An hunter's profession, they say, generally requires patience, and the lion-pismire has as large a share of this quality as he has of craft. He sometimes passes whole weeks and months without motion, and, what is most surprizing, without food itself.

His abstinence, which is very serviceable to him, is so extraordinary, that I have known him live above six months in a box exactly closed up, where he had no other accommodation than sand. I have seen them complete their work as usual, and then change into nymphs like others, whom I have carefully nourished. It is true, those who eat improve both in growth and vigour.

When he has attained a certain age, and would undergo a state of renovation, in order to appear in his last form, he then troubles himself no more with his trench, but begins to work in the sand, where he strikes out a multitude of irregular tracts, and certainly engages in this labour, in order to warm himself into a sweat; after which he plunges into the sand, and the viscous humidity which flows from every part of his body, fixes and unites all the grains he touches. With these sandy particles, and the dried glue that consolidates them, he forms a crust which encompasses his whole body, like a little ball of five or six twelfths of an inch in diameter, in which the animal reserves himself a competent space for motion. He is not satisfied with a bare wall, which would inevitably chill him; but spins out of his own bowels a thread, which, in fineness, infinitely surpasses that of the silk-worm, which we have so much admired. This thread he fastens first to one place, and then extends it to a second, still crossing and interlacing it. By these means he hangs all his apartment with a sattin tinged with the colour of pearls, and perfectly beautiful and delicate. In this work all the propriety and convenience is confined to the inside, for nothing appears without but a little sand, which confounds and incorporates the mansion with the contiguous earth. And now he lies secreted from the pursuit of ill-disposed birds; he rests in oblivion, and lives in perfect tranquillity; whereas he would infallibly be lost, were the outside of his habitation ornamental enough to attract the view of any creature, whose curiosity might prove injurious to him.

In this manner he lives, secluded from the world, six weeks or two months, and sometimes more, and then divests himself of his eyes, his horns, his paws, and skin. His spoils sink to the bottom of the ball, like a heap of rags; all that now remains is a nymph, who hath other eyes and paws, other entrails and wings enfolded with a skin, and laid in a nutrimental liquor that gradually dries around her, in the same manner as is customary with all papilio's, when they divest themselves of their vermicular spoils, to assume the form of aurelias.

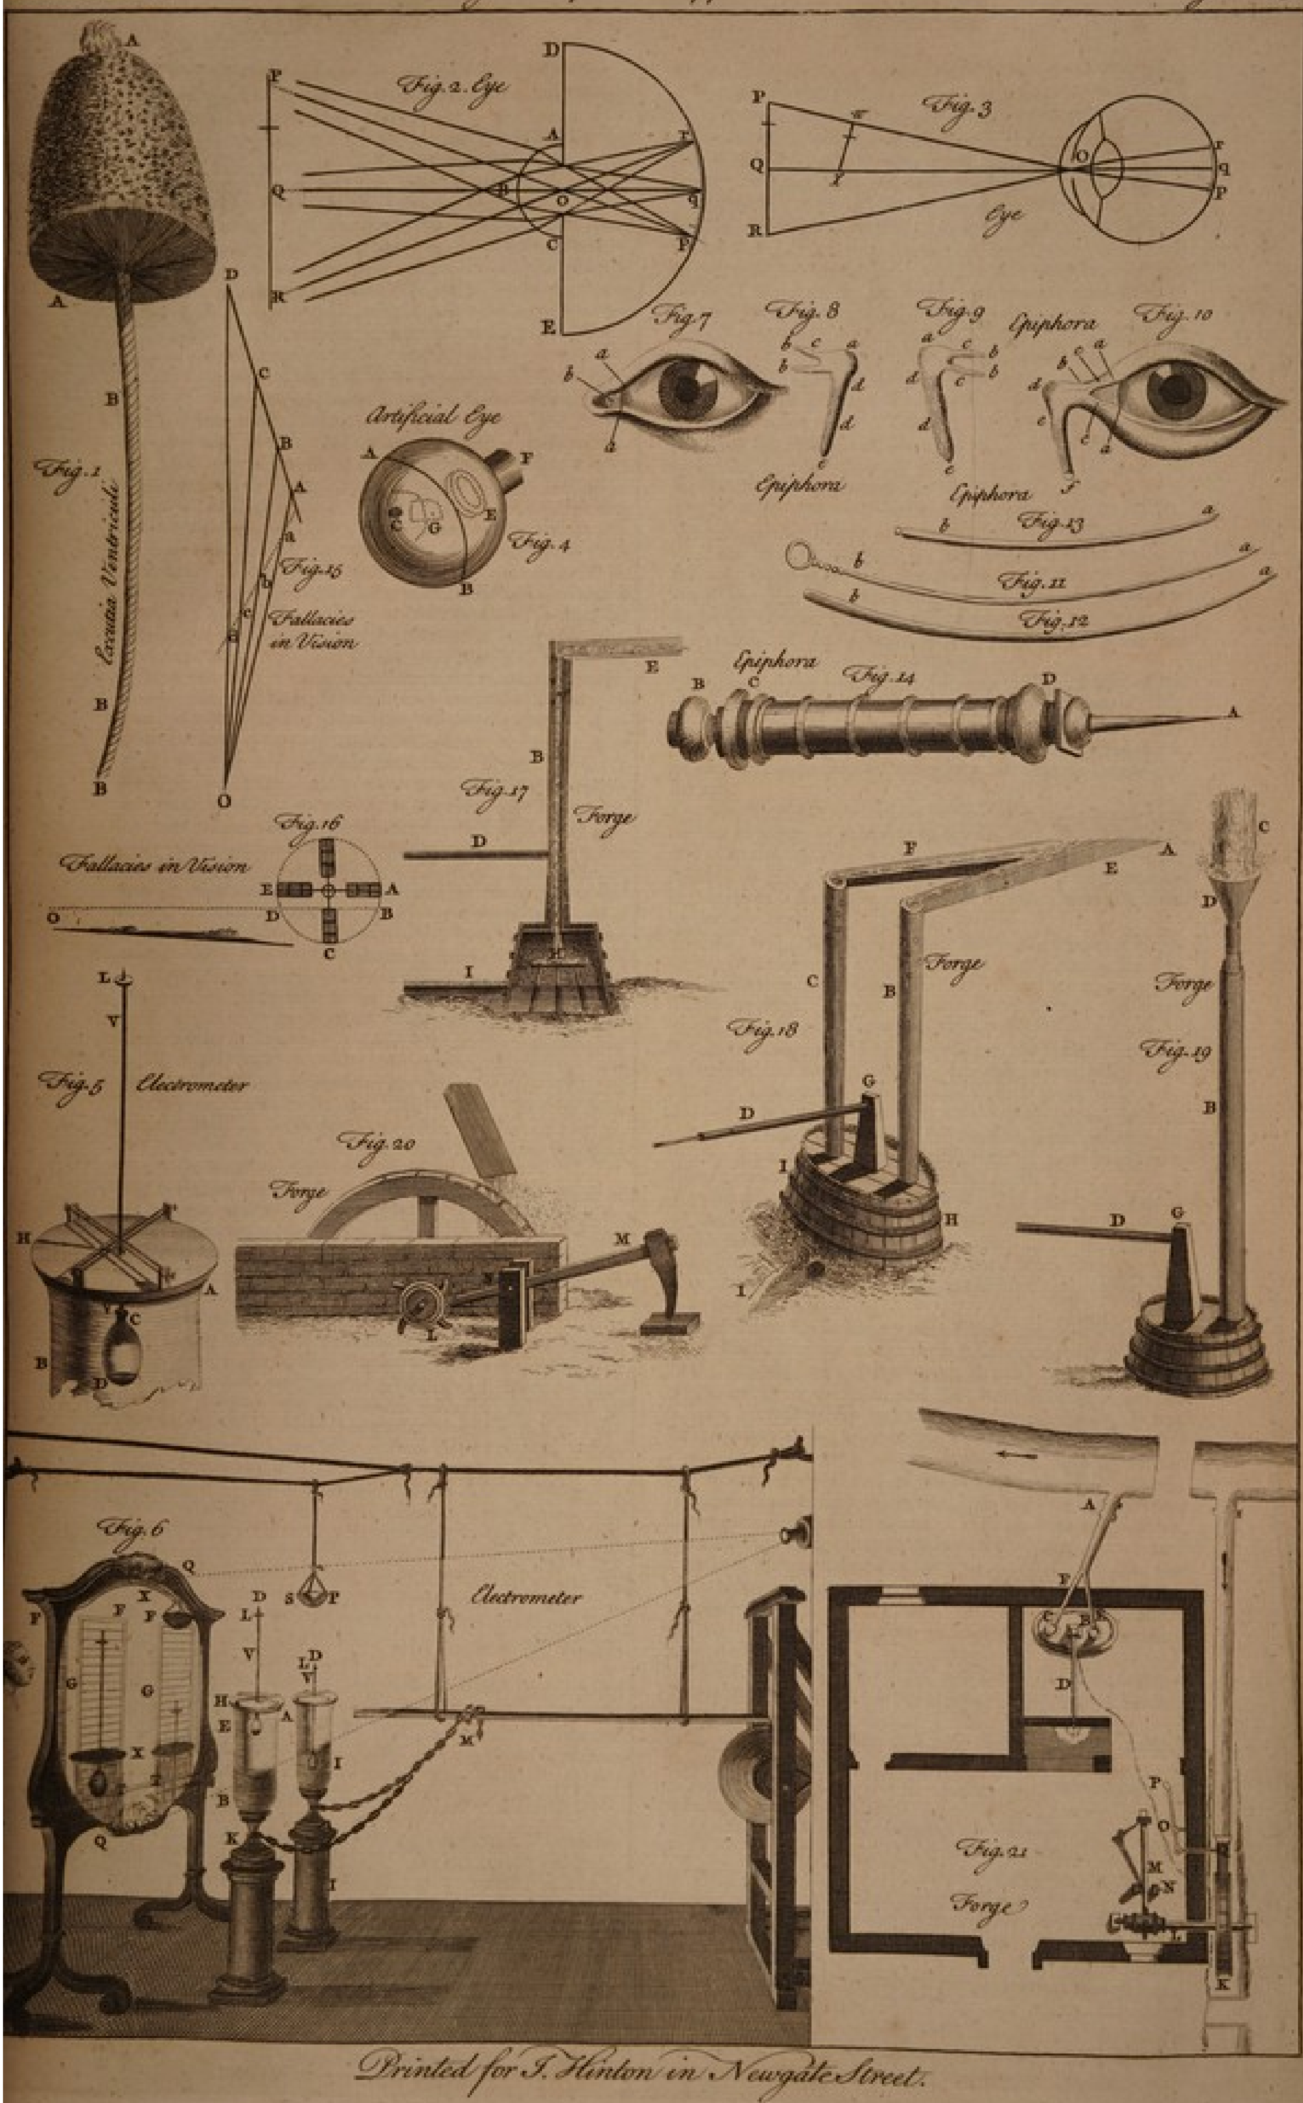
When the limbs of the new animal have acquired their necessary tone and activity, he tears away the tapestry of his apartment, and pierces through the walls; for which purpose, he employs a couple of teeth, like those with which the grasshopper is furnished. And now he makes his efforts, enlarges the opening, thrusts out half his body, and, at last, intirely quits his solitary seat. His long form, that winds like the volute of an Ionic capital, and possesses only three twelfths of an inch in space, begins to unfold and extend itself, and, in an instant, stretches to the length of an inch and three or four twelfths. His four wings, that were contracted in little folds, and whose dimensions did not exceed two twelfths of an inch, in the film that sheathed them begin to be expanded, and, in the space of two minutes, shoot into a greater length than the whole body. In a word, the malignant lion-pismire assumes the form of a large and beautiful dragon-fly, who, after she has for some time continued immoveable and astonished at the glorious prospect of nature, flutters her wings, and enjoys a liberty with which she was unacquainted in the obscurity of her former state; and, as she hath cast off the spoils of her first form, so she is likewise divested of her cumbersome weight, as well as her barbarity and pernicious inclinations. In fine, she appears entirely a new creature, is all gaiety and vigour, graced at the same time, with a noble and majestic air.

Along the edges of standing waters, one may find other animals like this in form, but painted with colours much more radiant and lively, and their original is also very different. The insect that arises from the lion-pismire, lays her eggs in the sand, that her young may be supplied with food, when it forsakes the egg. Sand is no part of its sustenance, but then it facilitates its manner of life. The creature immediately sinks a commodious trench, and in less than an instant becomes completely skilled in hunting and geometry. The other dragon-fly, that flutters along the surface of ponds, plunges the extremity of her body into the water, and there deposits her eggs. The animals that issue from them, inhabit the fluid element for some time, after which they assume a new figure, and live upon earth in form of aurelias.

FORGE, in manual arts, a place where iron is smelted, and formed into different pieces.

The iron ore being taken from the mine, if it be found to be incorporated with a stony substance, it is broke in stamping mills before it is washed and melted: but, if mixed with a coarse sand or earth, it is not stamped, but put immediately into a flat tub ten feet square, and about two feet deep, through which runs a constant stream of water; and the ore kept constantly stirring and pounding in the tub, by which means the earthy particles are carried away by the current, while the metalline particles, by their specific gravity, subside to the bottom.

When the ore is sufficiently purified by stamping and washing, it



Printed for J. Hinton in Newgate Street.

it is taken out and carried to the Forge, where it is melted; and the fire, which muſt be prodigiouſly fierce, is generally blown by means of a fall of water.

The flux-ſtone is preferred by the workmen for this uſe, foraſmuch as it abounds with particles of iron, and therefore increaſes the quantity of metallic matter: it does alſo facilitate the buſineſs of fuſion. The ore conſiſts of metallic, ſandy, and earthy particles; now, the buſineſs is to ſeparate theſe three diſtinct kinds of matter, or elſe to extract the metal from the ſand and the earth. The firſt of theſe offices is performed by lotion in the trough or waſhing-tub, the water carrying off a pretty large quantity of theſe extraneous matters.

The melted metal is nothing but a torrent of liquid fire, which rarefies and keeps in motion the metallic particles, which, upon the extinction of the fire, coaleſce and ſubſide one upon another. The vitrified ſand is alſo a liquid maſs of fire, keeping in a ſtate of agitation the finer grains of ſand, and the ſaline particles, which, after ignition, fix into a conſiſtent body. The calcined earth is a ſubject conſiſting of parts eaſily ſeparable, which, being penetrated by the fire, are reduced to aſhes. The ſand being put into a ſtate of fuſion by the fire, the metallic matter, which is more weighty by nature, diſengages itſelf from it, and ſubſides to the bottom; for theſe two bodies, being of different ſpecific gravities, are eaſily ſeparated by the action of the fire; whereas the earth, which is compoſed of light flaky maſſes, is eaſily entangled in the fuſed metal, the vitrified ſands, and the alkaline or ſpongy ſalts that are mixed with them. The greater the quantity there happens to be of this earth or calcined powder in the metal, the coarſer, more brittle, and imperfect it proves; the leſs of this heterogeneous matter there is in the iron, the more malleable, ductile, and ſolid it is, and approaches nearer to the nature of ſteel, which is only pure unmixed iron. Now, in order to purge and purify the metal as much as poſſible from this powder which infects it, they muſt, at the time of its fuſion, inject into it ſome matter, which may lay hold of as many particles of the calcined earth as poſſible, without imbibing the metal; and this is performed by vitrification. The ſands and ſalts of the flux-ſtone, being ſeparated by the fire, give free liberty to the particles of iron to diſengage themſelves, and at the ſame time abſorb a great part of the earth that was mixed with the ore. For want of flux-ſtone, flints or river ſand may be made uſe of, which, when vitrified, purge the iron from the droſs, in proportion to the quantity of ſcoriæ or calcined earth which they lay hold of. Some maſters of Forges uſe lime, inſtead of flux-ſtone or ſand; but, as this is nothing but calcined earth itſelf, it cannot have any abſorbing power, and ſerves to foul inſtead of purifying the ore. The only reſpect in which lime can be ſerviceable, and ſupply the place of flux-ſtone or ſand, is, by ſerving as a cruſt or covering to reverberate the heat, and to make it act with more force inwardly on the ore which is mixed with the coals.

The ore is no ſooner melted than it runs along the bottom of the furnace, which is made ſloping, to a ſort of flood-gates, which are drawn up for it to pour down in a torrent of liquid fire, into long trenches made in the ſand, or into moulds of different figures, to be caſt for cannons, chimney-backs, bomb-ſhells, granado's, mortar-pieces, pipes for the conveyance of water, caldrons, &c.

After having diffuſed itſelf equally from one end of the trench to the other, it conſolidates into a triangular maſs, which they call a pig of iron, weighing from twelve to eighteen hundred pounds; this they run on wooden rollers to the mouth of the fining furnace, where they gradually melt it, not to a degree of liquefaction, but till it reſolves into a ſoft paſte, which the workmen keep ſtirring with their iron prongs; then they take from it a piece of about ſixty pounds weight, which they beat with a light hammer, till it comes to a conſiſtency; this done, they give it a heating in the fining furnace, and thence carry it on an iron ſledge, and ſubject it to the diſcipline of a monſtrous hammer, weighing upwards of ſix hundred pounds, the noiſe of which may be heard above three miles off. It is made to riſe and fall by the motion of a wheel turned by a running water. They turn the iron under this hammer, till it is beat out into an oblong ſquare.

They tell you that the force of percuſſion inflicted, by this hammer on the iron, is ſo great, that it penetrates the very heart of the maſs, agitates the fineſt particles of the iron, diſſipates the calcined earth with the ſcoriæ and other heterogeneous matter, and makes the whole perfectly malleable, by conſolidating the metallic particles, and uniting them in cloſe contact.

After the maſs of iron has paſſed the operation of the great hammer, it is carried back again to the fining furnace, to be thoroughly purged of its droſs and ſcoriæ; where, while it is perfecting, it facilitates another operation; for it thereby contracts ſo intenſe a heat, as is ſufficient to reſolve the pig iron that is near it. Laſt of all, it is carried to the Forge or nealing furnace to ſoften it, and fit it for the anvil, on which they hammer it into flat triangular pieces for plough-ſhares, into ſquare bars for all ſorts of ſmiths works, or into plates of different dimenſions.

In order to give the reader a better idea of a Forge, we have given a plan, &c. of it, on *Plate* XX. where *fig.* 21. exhibits a plan of the conſtruction of one of theſe Forges, and the ſituation of the bellows with regard to the furnace; this pair of bellows is compoſed of a tub turned upſide down, of an oval figure, repreſented by H I ſeven feet deep, three or four feet over, expreſſed by the figures 18, 19; its extremities are buried five or ſix inches to prevent the intromiſſion of external air; on the bottom of this tub are faſtened two wooden pipes B, C ten or twelve feet high, between which is fixed on the tub a kind of pyramid G made of planks, which has a third tube near its top at D, which carries the wind to the Forge; all theſe tubes are well joined and caulked, ſo as to exclude all air.

A ſmall canal one foot broad, about ſeven or eight inches deep, and which divides itſelf into two branches E F, conducts the water into the pipes B C in greater or leſſer quantities, as you would increaſe or decreaſe the action of the wind; which thoſe that work at the Forge regulate by a little flood-gate placed at the entrance of the canal A, as the pipes B C are perforated towards the top, with ſeveral holes inclining on the inſide, through which the air introduces itſelf, a great deal of which the water carries with it into the tub; which, being compreſſed, ſeeks to dilate itſelf, and, having no other vent but through the pipe D, which grows leſſer towards the end, it comes out with impetuoſity, and blows the fire of the Forge with ſo much ſtrength, that they are ſometimes forced to mitigate the blaſt by opening a little hole made on the pyramid G, not permitting it to act at its full power but when there are large pieces to Forge.

Under each of the pipes B, C in the tub is placed a kind of little ſtool H, *fig.* 17. that the air may ſeparate itſelf more eaſily from the waters, by ſpouting upon them, after which the water goes off by a trench which is always ſtopped with it, that the air may not eſcape through the opening neceſſary to be made in the tub.

Fig. 20. repreſents a wheel by the ſide of a mill, turned by a current of water, as exhibited in *fig.* 21, at K Q. The arbor of this weel L moves the hammer M, the handle of which is faſtened at N; and the motion of the wheel is regulated by the means of a flood-gate at Q which is drawn up or put down by the help of the lever Q P, *fig.* 21.

FO'REST-*trees*. Many are wholly averſe to pruning Foreſt-trees; but, though it is to be done with care, and under proper regulations (ſee LOPPING) yet, it is by no means to be wholly omitted. It may be obſerved in Foreſts and large woods, that, for one tree which thrives well, there are twenty that grow faulty, and all this is owing to the want of pruning or lopping in a proper manner; for this, when wiſely executed, is a renewal of their age, and of their growth too; the want of it being what occaſions trees to run out into ſuckers, and to load themſelves with uſeleſs boughs, which draw away the ſap from the upper part, and make it grow knotty and diſtempered, and uſually covered with moſs.

If a tree grow crooked, the buſineſs of the owner is to cut it off ſloping at the crooked place, and nurſe up ſome young bough that grows upright from that part, and it will make it a ſtraight body. This is not to be done when trees are very large, but the careful owner will not ſuffer them to grow very large without doing it.

The beſt time for pruning young Foreſt-trees is in February; and it ſhould be done where there is occaſion every year, or, at the utmoſt, every ſecond year, ſo that the tree may be able to overgrow the knot, and the place not liable to put out ſuckers, becauſe the ſap has had no great recourſe to it. When it is neceſſary to cut off a bough of any bigneſs, there muſt always be given a chop or two underneath, oppoſite to the part where it is cut above, otherwiſe the weight of the bough, in its fall, is apt to ſtrip off the bark from the remaining ſtump, to the great detriment of the tree. When trees are kept for pollards, they muſt be regularly lopped every two years; for, if the branches are ſuffered to grow longer than that, they are apt to be faulty at the wound when cut off, and to let in water, the conſequence of which will be the decay of the tree, and it can no more bear any great quantity of branches or lop. *Mortimer's Huſbandry.*

FO'RTRESS, in military affairs, a caſtle or fortified town.— The method of fortifying a town, &c. may be ſeen in the following problems.

Prob. 1. The maſter line of a Fortreſs being given, to draw the plan of the rampart.

1. Draw the lines ag (*Plate* VI, *fig.* 29.) perpendicular to each face, flank, and curtin.

2. In each of the lines ag take $ag = 24$ yards.
$ab = 20$ yards.
$ac = 8$ yards.
$ad = 6$ yards.

3. Through the points d, c, b, g, draw lines parallel to the maſter line; that is, to each face, flank, and curtin, interſecting one another.

		yds.
Then the breadth of the rampart is repreſented	by $ag =$	24
of the parapet	by $ad =$	6
of the foot-bank	by $dc =$	2
of the walk of the rampart	by $cb =$	12
And of the ſlope of the rampart	by $bg =$	4

The

The breadths of theſe parts of the rampart are ſometimes different, according to the quality of the earth, or other materials the work is to be built with.

Sometimes the baſtions are made ſolid; that is, the rampart fills up the whole ſpace contained within the faces, flanks, and neck: the plans of ſuch are repreſented by continuing the pair of lines *b g*, forming the inner ſlope of the rampart, againſt the adjacent curtins, till they meet the capital in the breaſt of the baſtion, as at R: but then this pair of lines is to be omitted againſt the flanks and faces of ſuch baſtions.

In plans drawn from a large ſcale, it is uſual to expreſs the outſide ſlope of the rampart by a pair of lines; that is, by drawing a parallel to the maſter line at about five or ſix feet diſtant from it on the outſide.

The maſter line is to be drawn the thickeſt; the inſide of the parapet ſomething finer; and the other lines as fine as they can be drawn.

Before any of the lines are drawn in ink, for it ſhould be remarked that every thing is firſt to be drawn in black lead pencil, let the ramps be put in the inner ſlope of the rampart; the embraſures in the parapets of the flanks; the barbets in the ſaliant angles of the baſtions, *fig.* 16. with their ramps; and the cavaliers, if any are to be, in the ſolid baſtions, *fig.* 23, with their ramps and embraſures.

All theſe ſeveral parts being laid down with black lead pencil, let the lines be neatly drawn with Indian ink, taking care not to draw them beyond their proper terminations; for, wherever ſuperfluous ink lines are ſcraped off, thoſe plans will never look well, when they come to be waſhed with any colour.

When the plan is to be waſhed, that is, coloured, either with tints of Indian ink or other colours, leave the lower line of the inner ſlope of the rampart in lead pencil, which will make it appear ſofter, when the drawing is cleaned off.

In the middle of baſtions, *fig.* 26, it is uſual to build magazines for the ſtores of powder, bombs, and other fireworks, and alſo to contain the proviſion for the troops: for in theſe places they are not only more out of the way of doing damage to the town on an accident of blowing up, but they are alſo nearer at hand to be tranſported to the ſeveral works where they may be wanted.

Prob. 2.—The maſter line of a Fortreſs being given, to draw the plan of the foſs and eſplanade.

1. On the flanked angle B (*fig.* 12.) of each baſtion, with the radius B C equal to the breadth of the foſs, deſcribe an arc C C.

2. Lay a ruler to touch each arc at C, and the angle E of the neareſt ſhoulder of the next baſtion, and in that direction draw the lines C *p*, meeting one another in *p*.

3. From the flanked angle of each baſtion, draw lines B *q* at right angles to C *p*.

4. In each of the lines B *q*, take C *a* = 10 yards,
C *o* = 12 yards,
and C *q* = 60 yards.

5. Through the points *a*, *o*, *q*, draw lines parallel to C *p*, meeting before the middles of the curtins at C and *s*, *fig.* 13, and before the flanked angles of the baſtions in *v*, *x*, *y*.

Then will B C repreſent the breadth of the foſs.
C *q* of the eſplanade.
C *o* of the covered-way.
a o of the foot-bank.
o q of the glacis.

The arcs C C repreſent the roundings of the foſs.

The lines C *p*	the counterſcarp.	
x C	the head	of the glacis.
x y	the ridges	
s t	the vallies	
And *y t*	the foot	

The head of the glacis is to be drawn ſtrong, and all the other lines are to be fine.

When the plan is to be waſhed, if the foot of the glacis be drawn in lead pencil only, the termination of the glacis, or its concourſe with the adjoining lands, will appear more ſoft and neat.

In the colouring of the glacis, it is uſual firſt to lay a very light tint of colour over every plane, and then to ſtrengthen the colour on every ſecond plane, beginning at any ſaliant angle; the ſtrongeſt tint to be next the head of the glacis, and to be waſhed gradually off; ſo that the limits of the lighteſt ſhade ſhall lie in a diagonal line from the foot of the glacis at a ridge, to the head of the valley, as from *y* to *s*.

Give a light touch of the pencil or bruſh, with a middling tint of Indian ink along the inſide of the line, denoting the foot-bank.

Waſh the borders of the ditch near the ſcarp and counterſcarp, ſoftening the edge of the colour with a bruſh wet with fair water: in wet ditches the colour uſed is diſtilled verdigreaſe; but in dry ditches uſe biſter.

The parapet is generally coloured with a middling tint of Indian ink.

By this method of drawing the counterſcarp, all the foſs is ſeen from the flanks, and conſequently is defended by them, and muſt be more advantageous than if the counterſcarp was directed to any other part of the flank, the intercepted part next the ſhoulder being thereby rendered uſeleſs for the defence of the ditch; nevertheleſs, if it was on any account neceſſary, the direction of the wall of the ditch may point within the ſhoulder by the thickneſs of the parapet of the face, and ſtill the foſs would have the whole defence of the flank.

Fortifications in general would be very defective without foſſes; for the wall or rampart need not be raiſed ſo high when there is a ditch, as they muſt be without one, to ſecure the place from ſurprizes by ſcaling, &c. Neither is a low wall ſo much expoſed as a high one is in the modern methods of attack: beſides, a place is not ſo liable to the attempts of a ſurprize with a foſs as it would be without one; for the enemy, if diſcovered, may eaſily retreat while he is on a level with the country, which he would find ſome difficulty in doing from the bottom of a deep foſs bounded by walls or banks nearly upright: add to theſe, that the earth taken out of the ditch ſerves to make the ramparts, parapets, glacis, &c.

It may appear to ſome perſons, that, the broader and deeper a foſs is, the better, as it would throw more difficulties in the way of the beſiegers, when they wanted to paſs it: but it muſt be obſerved that ſome advantages are beſt waved, when, by taking them, greater diſadvantages would enſue. For, beſide the great expence that the digging and removing of ſo much earth would occaſion, the enemy might ſee the foot of the wall at a greater diſtance in a broad ditch; and, in a deep one, the cannon of the flanks could not dip low enough to defend the bottom. And on the whole, if the foſs by its magnitude furniſhed more earth than was wanted, ſome inconvenience might ariſe in the diſpoſing of the overplus.

Thoſe foſſes are beſt which can be filled with water and drained at pleaſure by the help of ſluices or flood-gates; becauſe all the advantages that may be reaped either from a wet or dry foſs, are by theſe means obtained: but, as theſe cannot be had every-where, the ditch muſt be adapted to the ſituation of the place.

In dry foſſes, a row of paliſades is ſometimes planted along the middle, either upright, or ſloping towards the counterſcarp 20 or 30 degrees from the upright.

In ſome dry foſſes, where water can be had, a trench called cuvette *n n*, *fig.* 30, is dug along the middle, of about 15 feet wide and 9 feet deep, for the water to run in.

The breadth of the foſs, although unequal in itſelf, is reckoned from the flanked angles, before which it is always rounded; the depth here may be from 15 to 20 feet, and thence riſe gradually to the middle of the curtin, where the depth is 4 or 5 feet leſs.

To draw a bridge in the plan of a Fortress.— Before the gates draw four lines acroſs the ditch, making three intervals or ſpaces, the middle one being 10 feet broad, and the ſpace, on each ſide, three feet.

Divide the length of the bridge into parts of about 16 feet long each, to expreſs the diſtance between pier and pier, or the bays of building; and againſt each diviſion, on the outſide of the lines, make a ſquare of a foot, to expreſs the ends of the piers ſupporting the bridge.

Allow the bay next the gate for a draw-bridge; and, if the length of the bridge exceeds 40 yards, allow the middle bay for another draw-bridge: theſe are to be diſtinguiſhed by drawing two diagonals acroſs the middle interval of theſe bays; that of the other bays having lines drawn acroſs them at a foot diſtance from one another, and the ſpace on each ſide left white for the footway; which are to be broke off at each draw-bridge. See *fig.* 17, 21.

To conſtruct the orillon and retired flank.— 1. As right angles to the face A S, *fig.* 14, draw from the angle of the ſhoulder the line S *b* equal to 8 or 9 yards, and make *b* the center of the arc, S *a* forming the orillon.

2. From a point *z* in the face of the next baſtion, *fig.* 16, about 15 yards from the point A, draw through *a* a line *z m*; in which, and alſo in the line of defence A *r* produced, take the briſures or breaks *a m* and *r n*, each 10 yards.

3. From *m* and *n*, with the radius *m n*, deſcribe arcs cutting in *d*, which make the center of the arc *m n*, or concave flank.

4. In *d m* produced lay the ſeveral breadths of the parts of the rampart; as the parapet = 6 yards, foot-bank = 2 yards, walk 12 yards, and the ſlope = 4 yards; then from the center *d*, through thoſe points, deſcribe arcs, meeting in the continuation of the correſponding lines from the face of the next baſtion.

The parapet of the orillon is drawn parallel to S *a* at 6 yards diſtance.

The axis or middle line of each embraſure ſhould tend towards a point about the middle of the foſs oppoſite the flanked angle of the next baſtion.

The wall in the upper briſure *a m*, as it cannot be battered, need not be above 2 or 3 feet thick to ſupport the earth behind it.

Through this wall there ſhould be a ſally port coming out at the bottom of the foſs, if a dry one, or a little above the water-line in a wet foſs: the deſcent to this port is by a paſſage under the rampart of the flank; but, in ſtraight flanks, the ſally port is in the curtin next the angle of the flank, the paſſage to it being under the rampart of the curtin.

As the progreſs of the works of the beſiegers generally depends on their having a greater army than is in the town beſieged, and on forming a greater fire on the town than they can return; therefore ſome engineers have endeavoured to hinder the progreſs of the beſiegers batteries, by furniſhing the town with an equivalent, or rather a ſuperior fire; and this has been propoſed to be effected, by making ſecond and third flanks one behind another, gradually more elevated than thoſe before: For as it is found convenient to ſilence the fire of the flanks, before the beſiegers can avail themſelves of the breach they make in the face of the baſtion; therefore batteries to ruin the flanks are made, and play at the ſame times as thoſe for the breaches in the faces. Now, the batteries for the ruin of the flanks can be conveniently made only within about 10 yards of the head of the glacis, and their length not greater than about 40 yards, containing at moſt about 6 or 7 cannon: but if the beſieged can by any artifice preſerve the cannon in the oppoſite flank, and have a greater number there than are in the battery oppoſed, conſequently their fire will be ſuperior, and ruin the battery intended to offend them; and this was expected to be accompliſhed by double, or cazemated flanks. In ſome places two or three tier of cannon were placed one above the other, the upper ones being ſupported by vaulted work, as in the Tower of London; but, ſuch having been found very inconvenient, on account of the great ſmother contained in the vaults, they have been generally conſtructed open.

The cazemated flanks have been condemned by many writers, becauſe they may be rendered uſeleſs by the enemy's bombs; was this objection juſt, it would hold againſt any ſmall work; for, the beſiegers having once got the length to any place, they may be ſuppoſed to render that place alſo uſeleſs to the beſieged; and it would thence follow, that it were beſt not to have any places of defence: but, as the utility of ſuch works have been commended by ſome of the moſt eminent engineers, it was judged proper here to mention how theſe flanks may be conſtructed. For the reſt of the works uſually conſtructed: See OUTWORKS.

FO'UNDERY *of cannon* (*Dict.*)— Braſs cannon, as they are commonly called, are not made of pure braſs. They cannot be made either of pure braſs or pure copper, but it is always found neceſſary to mix with theſe metals ſome coarſer ones, in order to make the whole run cloſer and ſounder: ſuch are lead, and what the founders call pot-metal, which is a compoſition of copper and lead. About twenty pounds of lead is uſually put to an hundred weight of pot-metal, but about ſix pounds is ſufficient for an hundred weight of gun-metal, and is of vaſt ſervice.

The method of caſting iron differs very little from that of braſs. That the iron ore may melt the more eaſily, it was formerly a common practice to mix it with a ſulphureous ſtone, which vitrifies a great part of the groſs earth adhering to the native iron ore; but this practice is now diſcontinued, the cannon caſt of iron ſmelted in that manner being found to be brittle, and incapable of ſtanding proof.

FOUNDERY *of bells.*— Theſe are in moulds of ſand, into which the melted metal is conveyed by a canal from the furnace.

FOU'NTAIN (*Dict.*)— *Plate* XXXVII. *fig.* 7, in the Dictionary, is a perſpective view of a Fountain in a garden.

FRA'GARIA, *ſtrawberry*, in botany, a genus of plants, whoſe characters are:

It hath a perennial fibroſe root: the leaves are veined, growing three upon each footſtalk: the ſtalks trail upon the ground: the cup of the flower conſiſts of one leaf, which is divided into ten equal parts, and expands in form of a ſtar: the flower conſiſts, for the moſt part, of five leaves, which expand in form of a roſe, and have many ſtamina in the middle, round the baſe of the ovary: the fruit is globoſe or oval, and conſiſts of a fleſhy eatable pulp, full of protuberances.

Theſe ſpecies are, 1. The common or wood ſtrawberry. 2. The common ſtrawberry, with white fruit. 3. The hautboy ſtrawberry. 4. The Virginian ſtrawberry, with ſcarlet fruit, commonly called ſcarlet fruit. 5. The large Chili ſtrawberry. 6. The globe-hautboy ſtrawberry. 7. The ſtrawberry with a ſmall greeniſh white fruit.

The firſt and ſecond ſorts of ſtrawberry are found wild in the woods in divers parts of England, from whence the plants are taken, and tranſplanted into gardens, by which the fruit is improved. The beſt ſeaſon for this work is in September, that the plants may be rooted in their new quarters before the froſt begins; which is very apt to looſen the earth ſo much about their roots, that, when the froſt goes off, the plants are apt to be turned out of the ground. They may alſo be tranſplanted in February; but then, if the ſpring ſhould prove dry, they will require a great expence of water to keep them alive.

The ſoil which is moſt proper for theſe plants, is a freſh hazelly loam, not over rich, which would cauſe the plants to ſpread and flouriſh; but they would not be ſo fruitful as upon a moderate ſoil. The ground ſhould be well dug, and cleared from the roots of all noxious weeds; and, after it is levelled even, you muſt mark it out into beds about three feet and an half wide; leaving a path between each bed two feet broad, for the conveniency of walking between them to water and clean them, as alſo to gather the fruit. In theſe beds may be planted four rows of plants, whereby they will be about a foot aſunder row from row; and, in the rows, they ſhould be planted at leaſt eight inches diſtant plant from plant; for, if they are planted nearer, they will in one year's time be ſo thick, that they will not have room to thrive.

Note, The diſtance here deſigned being for the wood ſtrawberry, which is of the leaſt growth, the other large-growing kinds muſt have a greater ſhare of room, according to their different degrees of growth; as for example, the ſcarlet ſtrawberry ſhould be planted a foot ſquare plant from plant; and the hautboy ſixteen or eighteen inches diſtance each way, and the Chili ſtrawberry twenty inches, or two feet.

In the ſpring of the year, when the ſtrawberries begin to flower, if the ſeaſon be dry, you muſt obſerve to water them plentifully, otherwiſe the flowers will fall away without producing any fruit. You muſt alſo carefully clean your beds of ſtrawberries from weeds from time to time, as they ſhall require; for, if they are once ſuffered to overbear the plants, they will decay in large patches, and alſo greatly weaken all thoſe that may continue alive. About Michaelmas, you ſhould clear off all the weeds from the beds, as alſo cut off all the ſtrings or runners from the roots, pulling out all weak plants where they are too cloſe; then dig up the walks between the beds, burying the ſeeds that came off in the bottom, and throw a little fine earth over the beds between the plants; being very careful not to lay it ſo thick as to bury the plants: this will greatly ſtrengthen them, and cauſe their fruit to be larger, and in greater quantities, than they would be, if left undreſſed.

Theſe few rules will be ſufficient, if duly regarded for cultivating theſe plants. I would only farther obſerve, that theſe beds will not continue bearing well more than three years; therefore, in order to have a conſtant ſupply, you ſhould plant a freſh plat of ground a year before you deſtroy the old beds; otherwiſe, your young plantation producing few or no fruit the firſt year, you will be deſtitute a whole ſeaſon.

The wood ſtrawberry is by many people preferred for the firmneſs of its fruit, and delicacy of its flavour: others greatly admire the ſcarlet ſort for its goodneſs; and the hautboy is eſteemed for the largeneſs of its fruit: but the ſort with white fruit is by far the beſt-flavoured of all the kinds, though it is a bad bearer.

The ſcarlet ſtrawberry is a native of America, and was firſt brought into England from Virginia; but this is now become ſo common in the gardens, as to be thought, by many, a native of this country. This is the earlieſt ſort, always coming a fortnight ſooner than either the wood or hautboy ſtrawberries; and is an excellent well-flavoured fruit; ſo is generally eſteemed.

The hautboy is alſo a firm well-flavoured fruit; and the globe hautboy, as it is generally called, is a very good bearer, and a large fruit.

The wood ſtrawberry, both the red and white, will bear in greater plenty, when they are planted in a ſtrong moiſt ſoil, than when they are on a dry light ground; where, if they are not well ſupplied with water in dry ſeaſons, they will produce very little fruit.

The green ſtrawberry is the lateſt of all the ſorts; this produces its fruit in large bunches upon long footſtalks; ſo requires to have ſome ſupport, eſpecially in wet ſeaſons; otherwiſe the fruit will lie upon the ground, and the earth will be waſhed over them. This ſort ſeldom produces much fruit in warm dry land; but upon ſtrong ſtiff ground bears plentifully, and is the richeſt fruit of all the kinds yet known; being very firm, and of a remarkable quickneſs in its flavour. This ſort is by ſome perſons ſtiled the pine-apple ſtrawberry, from an affinity, as they ſuppoſe, between the flavour of this fruit and that of the pine-apple; and ſome others have given it the name of Drayton ſtrawberry, from its having been much cultivated there.

The Chili ſtrawberry was brought firſt into Europe by Monſieur Frezier, engineer to the late French king, and given to Monſieur de Juſſieu, profeſſor of botany to the royal garden at Paris; who hath ſpread it into divers parts of Europe. This plant, Monſieur Frezier ſays, is cultivated in the fields near Chili in great plenty; and that it differs from the European kinds, in having larger, thicker, and more hairy leaves: the fruit is generally as large as a walnut, and ſometimes as big as an hen-egg, of a whitiſh red colour, and ſomewhat leſs delicious in taſte than our wood ſtrawberries. This has produced fruit ſeveral years in the royal garden at Paris, where Monſieur Juſſieu aſſured me it was commonly as large as a ſmall apple. I brought ſome of the plants from Holland, anno 1727, which thrive and increaſe exceedingly; but theſe bear very indifferently, and, the fruit being leſs delicate than the hautboys, few perſons care to propagate this ſort in England. Theſe plants have been placed in the ſun, and cultivated with care; but have never ſucceeded where they have been thus treated. I have obſerved, they have ſucceeded beſt where they have grown under the ſhade of trees, in a loamy ſoil, and little more care taken of them than to keep them clear from weeds, and to diveſt them of their runners every autumn; for they are the old plants only which produce fruit, and thoſe ſeldom, except in very ſtrong land, for in the clays I have ſeen plenty of this fruit. *Miller's Gard. Dict.*

Fragria has the fame virtues as cinquefoil: the decoction of the herb, and the immature fruit, are ftrengthening and aftringent: the fruit is emollient, nutritive, relaxing, cooling, diuretic, aperitive, and corrects acrimony; hence it becomes proper in the higheft burning fevers, and under the greateft degree of an inflammation, when the thirft is extremely urgent. The fruit eaten cures a gonorrhoea. A very good drink in fevers is thus prepared: take of the juice of ftrawberries and lemons, and of fpring water, an equal quantity; of fugar, enough to render it grateful; mix them together. The pulp, applied in a cataplafm, is good for all external inflammations; and I have frequently experienced its virtue in a relaxation of the veffels of the uterus. In tertian and quartan fevers, it does the fervice of the Peruvian bark: it is, alfo, a lithontriptic. Take the ripe berries, and put them in water; then fhake the veffel, and the feeds will fall to the bottom: thefe dried, and taken to the weight of one or two drachms in white wine, in the morning, fafting, are an excellent and ufual remedy with lithotomifts, to prevent the regeneration of the ftone in thofe who have been cut for the fame. The berries gathered in watery and marfhy places, though larger, are of lefs virtue than the mountain ftrawberries, as Gefner obferves. This ufeful plant has one inconvenience, in that it has always toads concealed under it; which, as we are affured by authors, have rendered it mortal to many who have eaten of the fruit; for which reafon, fome will never eat ftrawberries before they are wafhed. In Italy they bruife the pulp in rofe water, and make it into a conferve with juice of citrons, for the purpofes before mentioned. *Hift. Plants, afcribed to Boerhaave.*

FRANCINI's *Engine*, a particular kind of machine, or joint-pump contrived by M. Francini.

This ingenious machine was contrived and put in execution by Mr. Francini, in the year 1668, by Mr. Colbert's orders, in the garden of the king's old library. To judge of it well, you muft know that near the houfe there is a natural fpring, which ufed formerly to difcharge its water in a bafon fituated in the middle of the garden, and that the wafte water ufed to run along a canal into a well, where it was loft. Mr. Francini, taking advantage of the wafte water, and the depth of the well, raifed an artificial jet in the middle of the garden, which produced a fine effect.

The firft and fecond figures of *Plate* XXIII. reprefent the profile and elevation of this machine, compofed of a couple of double endlefs chains made of fmall iron bars joined together by joints or hinges: to thefe are faftened buckets making two joint-pumps of unequal height, which turn upon a rag-wheel FEDG, that has notches where the chains go, to hold them always in the fame direction; and the intervals of the bars of this wheel are equal to the length of one of the links of the chain, that, the great joint-pump turning with the rag-wheel, the other joint-pump may be forced to turn along with it.

The axis of the rag-wheel is fuftained by two pofts P framed into cills on the curb at top of the well, and fo brought up to their height, and kept faft by two crofs pieces Q R, the loweft of which fuftains the ciftern A, which the wafte water of the bafon runs into.

The buckets B of the great joint-pump are made of plates of brafs, making a veffel wider at top than bottom, the better to receive the water from the ciftern A, which runs continually through the trough X; this figure is fo much the more convenient for thefe buckets, that, when one of them is full, the furplus of the water that runs along its furface, runs naturally into the next bucket below, and from that into the third, and fo on, fo that no water can be loft by fpilling over.

The buckets C and S of the leffer joint-pump, *fig.* 2, have the fame figure as the others, with this difference, viz. that they are clofed all round, except at the place S, where they have a little neck towards the bottom, where the bucket is leaft, which neck is upwards when the buckets rife full of water to difcharge it into the upper ciftern M I. To make the thing plainer, we have drawn by themfelves, between *fig.* 1. and *fig.* 2, one bucket of the great joint-pump, and one of the fmall one, which fhews the fituation in which they are, when, being full of water, thofe of the great pump defcend into the well, and thofe of the fmall one rife to empty themfelves into the upper ciftern.

Though the firft figure reprefents only one joint-pump feen fide-wife, it may ferve to fhew the working of each in particular. For example, you may confider the buckets B, as thofe of the great pump, when they go down into the well, and the others H of the fame, when they rife empty. If on the contrary we confider the fmall pump, you may judge of the fituation of its buckets H, when they rife full of water, and of the fituation they have at B, when they come down empty. A wheel with teeth O has been fixed to the axis of the rag-wheel, whofe teeth take a pinion or lantern N, *fig.* 1. and *fig.* 2. that has a fly to keep the uniformity of the motion of the machine, that it may not go by jerks, and not feel the fmall alterations that may be caufed by obftacles met with in the way, *fig.* 1.

As the great joint-pump is fuppofed to go down into the well to a depth fomething greater than the height to which the water is to be raifed above the level of the ground, there will always be a greater number of its buckets that will go down full of water, than there will be of the little pump that will carry up theirs full to the rag-wheel; confequently, the weight of the water that defcends being fuperior to that which rifes, the great pump will neceffarily make the little one turn, whofe buckets will fill themfelves, as they go through the ciftern A, which upon that account muft have a certain depth, that the water may have time to fill them.

As to velocity proper for this machine, it can only be determined by experience, by increafing or diminifhing the number of the buckets of the great pump, to know how much the power muft be fuperior to the weight; which muft alfo depend upon the quantity of water the fpring is able to give.

When the buckets of the great pump are of the fame bignefs as thofe of the fmall one, and the firft chain of buckets is fomething more than double the length of the fecond, fomething lefs water will rife in the upper ciftern than is loft in the well; that is, there will be raifed fomething lefs than half of what the fpring affords. If you would have more than half raifed, but to an height lefs than the fall, you muft then make the contents of the buckets of the fmall pump greater than the buckets of the other, in a reciprocal ratio of the fall of the water to the height to which it is raifed: and on the contrary, when you would raife the water to a greater height than the fall, you muft make the buckets of the fmall pump lefs than thofe of the great one, again in the reciprocal ratio of the defcent and the rife of the water; then there will rife lefs than what is loft in the well, in the reciprocal ratio of the fame terms.

You fee that in the cafe where Francini made ufe of this machine, after the water had been raifed into the upper ciftern M I, it came down by a conduit-pipe, and went and played a jet in the bafon of the garden, whence it came back into the ciftern A, and united again with that of the fpring, to help to play the two joint-pumps, fo that, by means of this circulation, a fpring, affording but little water, raifed without interruption fo great a quantity of water, that one might borrow a part for other ufes.

The chief difficulty here is to have a well deeper than the fall, in a foil where the water can be loft; unlefs you can find a lower place to conduct the water to from the bottom of the well.

FREE-*ftone.*—The qualities of the feveral kinds of Free-ftone in common ufe in the feveral parts of Europe are very different. They all agree in this general property indeed, that they are fofter while in the quarry, than when they have been fome time expofed to the air: but even this general property differs greatly in degree. They have a fort of grey Free-ftone in ufe at Paris, of which we do not feem yet to have met with any quarries in England, though probably enough there are fuch, which has this property in fo eminent a degree, that the expence of working it is in a great meafure faved.

This ftone lies every-where on the fouth fide of the river Seine, and is of a coarfe and large grit. It is fo foft, when newly taken out of the ftrata, that they cut it very conveniently with a fort of broad axe, and fafhion as many ftones for building in this manner in an hour, as an equal number of our people do in a day or two. Though this ftone is as foft as dry clay, when firft taken up, it is found to harden fo confiderably in the air, that it becomes more than equal to our ordinary Free-ftone.

Our Portland ftone of the fineft kind, which is white, and of a clofe grit, is very fit for hewing or carving; but it will neither refift water nor fire, which is a very fingular circumftance in fo denfe a ftone; while the Free-ftone of Kent, which is lefs beautiful to the eye, and is of a greyifh colour, and confiderably clofe, though of a larger grain, refifts the air and water very well.

The Free-ftone of Derbyfhire, on the other hand, is fo brittle as to be unfit for any fine working, and fo coarfe and open in its texture that it lets water through; yet it bears the fire extremely well, and is fit for ovens, hearths, &c. *Phil. Tranf.* Numb. 93.

FREEZING *of wines*, a method propofed by Dr. Shaw, for depriving wines of their aqueous parts, by the means of cold. In the Freezing of wines and the like liquors, the aqueous parts freeze firft, and are by this means feparated from the truly vinous; an obfervation which may be made of great ufe, in the wine trade. The experiment may be made by art, at any time: take a quart of common red port, put into a Florence wine flafk, and bury it in a mixture of one part of common falt, and two parts fnow or beaten ice, the confequence will be, that the aqueous part of the wine foon turns to ice, and the rich thick remainder of the true vinous parts may be poured off by inclination. Natural cold, however, in Freezing wines, performs this experiment much better. By this means, wines, vinegars, and malt liquors may be all reduced to a fourth part of their quantity for exportation, without any confiderable lofs of their effential parts, little more than the mere water freezing, and the effential part of the wine remaining thus admirably cured, and capable of keeping feveral years. It is eafy to fee, that a great ufe may be made of this in the wine trade, as large quantities of the pooreft wines might thus be converted into rich ones, and the quinteffence of the richer

richer wines might be procured for the amending the poor ones; and vast advantages might be reaped from this in wine countries.

Wines and vinegars concentrated by Freezing, though they keep unaltered for several years, yet are liable to some accidents, in process of time.

Thus wines, on being concentrated, seem to acquire a more austere taste than they had originally; and this is not wonderful, as the condensation brings the saline and rough matter into a third or a fourth part of the compass that it originally lay in; so that this is properly no addition or increase of the rough taste, but probably, on the contrary, some mitigation of it, in regard to the closeness to which this rough matter is brought, which of itself ought rather to multiply the effect in a greater proportion.

The change may be conceived owing to this, that all wines are observed to grow mild and soft by lying long; which effect is greatly promoted in them by a successive separation of their tartar, and a gentle evaporation of some part of their water occasioning that necessity which is frequently found in the summer months of filling up the casks: but in our concentrated wine, though the same tartar be successively separated, yet there is found no concurrent slow evaporation, for the concentrated wine grows soft and mellow in a well stopped glass, where no diminution of the quantity is perceived; the effect in this case proceeds principally from a closer and more intimate combination of the spirituous with the grosser and more terrestrial part. *Stahl de Concentrat.*

Beside this, there seems another remarkable change incident to the concentrated wine, not only in the taste, but more abundantly in the smell. For, if an austere and rough wine, and of the usual smell of such wines, be put up in bottles, its taste, after two or three years, not only becomes more mellow and smooth, but its smell, at this time, perfectly resembles sack or canary. This is a high degree of melioration, and will give a poor austere German wine, for such were those on which Stahl made the experiments, the flavour of so rich a wine as canary, and that so perfectly, that very good judges may not find out the difference by their smell, though the taste is abundantly different. Whatever advantage the dealer in wines may foresee from the success of these experiments, there is this farther inducement to his bringing them into practice in the large way, that every thing will answer better, and not worse, than the experiments in the smaller quantities. All these experiments have been made with little portions, which are very well known not to keep so well as larger; and it is evident both from reason and experience that great bulks of liquor are much less subject to changes and alterations from the external effects of air and heat, which are the two great incentives to fermentative motions; and that, if such small parcels suffered no change for the worse, much less need it be apprehended that any larger would. *Shaw's Comm. Essay on concentrating Wines.*

FREEZING *rains.*—Our own annals give us many accounts of the damage done to our trees by rains Freezing, as they fall, and consequently forming cakes of ice about all the branches, which by degrees increase to a weight that the branch is unable to support. In the year 1672, there fell such a rain as this at Bristol, and over all the country thereabouts. Most of the orchards, exposed to the north-east, were destroyed by it, and, had it continued longer, and been attended with gusts of wind, scarce any thing could have stood before it. A piece of an ash-tree of just three quarters of a pound weight was weighed, with its coat of ice upon it occasioned by this rain; the ice weighed sixteen pounds, besides what was melted off by the person's hands who brought it. The stalks of grass were surrounded with coats of ice, some of which were five inches round by measure. All the time that the orchards and hedges were thus breaking under the loads of ice, the waters were all free, and not so much as a puddle frozen over. The roads were rendered impassable by the parts of trees every-where fallen across them, and the noise of the icy boughs rattling against one another, as shook by the wind, was very terrible. Where this rain fell upon the snow, it immediately became ice as on the trees.

It is remarkable that men who were out on the road, complained of the most excessive colds, and were in agonies on coming into a warm room; though all the while, in some places, there only fell a kind of sleet, which was wet under the feet, and gave no appearance of frost upon the ground.

This sort of temper in the air preceded also the Freezing rains, in the very places where they happened. Though this severe weather happened in December, as soon as it was over, which was in a few days, there was a sudden change, into not only a mild, but a hot season. People complained of excessive sweating, both by night and day, and the trees and hedge-bushes put forth their buds for leaves and blossoms, as if it had been April; some of the apple-trees flowered before Christmas, and had the young fruit before New-year's day. *Phil. Transf.* Numb. 90.

FREIGHT (*Dict.*)—The laws of England relating to Freight are as follows.

1. Respect is always had herein to the ship itself, or a certain part of it. Again, merchants freight either by the month, the voyage, or the ton; for to freight a ship, or take certain tonnage to Freight, are different things, as are also to be a cap-merchant, or an under freighter.

2. There was of old another way of freighting, the merchant agreeing with the master, for a sum, to convey his goods insured against all peril, being responsible for any loss; but it is now out of use.

3. Freight is governed generally by the written agreement called a charter-party, executed between the owners or master and merchants, or else by parole.

The master or owners generally covenant to provide a pilot, and all necessaries for the voyage, and for lading and delivering. If there be agreement and earnest, but no writing, the merchant breaking off loseth his earnest, but the owners or master double the earnest.

But, by the common law of England, the party oppressed may bring his action, and recover all damages on the agreement. If a time be appointed by charter-party, and either the ship be not ready to take in, or the merchant to put on board, the parties are at liberty, with remedy by action for the detriment. If part be on board, and some misfortune prevent the merchant's sending the whole in time, the master may contract with another, and have Freight as damage for the time they were on board longer than limited. And, though it be not prudent for every merchant or master to break the contract, though the agreement as to lading be not according to promise (seldom or ever done, if part be aboard) yet it is the highest justice, that ships and masters be unfettered and free: as, by the bare lading of a cask or bale, they may lose the passage or season of the year.

So on the other hand, if the vessel is not ready, the merchant may ship the remainder of his goods on board another, and recover damages against the first master, or owners. This is grounded on the like reason.

Therefore, by the law marine, chance, or other notorious necessity, will excuse the master, but he loses his Freight till he breaks ground.

But, if the merchant be in fault, he must answer the damage, or be liable to maintain the crew ten days; but, if after that, the full Freight; if damage afterwards, it is the merchant's risque. But, by the common law, while the goods are on board, the master must see them forth-coming.

4. Charter-parties have always, by the common law, had a genuine construction as near as may be, not according to the literal sense of traders, yet must be regularly pleaded.

5. If goods are fully laded, and the ship hath broke ground, the merchant afterwards declines the adventure, and will unlade again; by the law marine the Freight is due. And if the ship on her voyage become unable without the master's fault, or he be arrested by some prince or state in her voyage, he may either mend his ship or freight another. But, if the merchant will not agree to it, the Freight becomes due for what the ship has earned, otherwise the master is liable for all damages that shall happen. If therefore the ship to which the goods were passed perished, the master shall answer; but, if both perish, he is discharged. But if there be extreme necessity, as the ship a sinking, and an empty ship pass by, or at hand, he may translate the goods; and, if that ship perish, he is excused: but it must appear the ship seemed probable and sufficient.

6. If a set time be agreed on, between the merchant and master, to begin and end the voyage, it may be altered by the supercargo without special commission.

If a master shall fail on his voyage after the time agreed on for his departure, if damage happens afterwards, he shall make it good. Yet, if a charter-party is made, that the plaintiff shall sail from London to Lisbon with the first opportunity, &c. in consideration of which the merchant covenanted for so much Freight; the ship departs not with the first wind, yet afterwards breaks ground, and arrives at her port, the Freight here is due; for nothing can debar the ship of it but the not departure, which only is in law traversable, being material to avoid payment of Freight.

7. If the ship be freighted from one port to another, thence to a third, &c. and so home to the port whence she first sailed (commonly called a trading voyage) it is all but one and the same voyage, if in conformity to the charter-party.

8. If a ship freighted by the ton be full laden according to the charter-party, the Freight is payable for the whole, otherwise for the amount of the tons only.

9. If the ship, by any fault of the freighter, as lading aboard prohibited goods, be detained, he shall answer the Freight contracted.

If a ship be freighted out and in, no Freight is due till the voyage be performed: if, therefore, the ship perish coming home, the whole Freight is lost.

10. A master freighting his ship, and afterwards secretly taking in other goods, loses his Freight; and, if any of the freighter's goods should, for the ship's safety, be cast overboard, the rest shall not be subject to average, but the master must make it good; but, if the goods are shipped unknown to him, it is otherwise, and they are subject to what Freight the master thinks fit. The ship putting into any other port than she is freighted to, the master shall answer damage to the merchant;

merchant; but, if forced in by ftorm, enemy, or pirates, he then muft fail to the port conditioned at his own cofts.

Generally, the touching at feveral ports by agreement imports not a diverfity, but a voyage entire.

11. If paffengers having goods die on fhip-board, the mafter is to inventory their concerns, which if none claim within a year, he becomes proprietor defeafible: but the bedding and furniture becomes the mafter's and his mates, and the cloathing muft be brought to the maft-head, and there appraifed and diftributed amongft the crew, as a reward for their feeing the body put into the fea.

If the captain die leaving money on board, the mate becomes captain, and if he improves the money; he fhall, on allowance for his care, account both for intereft and profits.

12. The fhip's lading, in conftruction of law, is tacitly obliged for the Freight, it being, in point of payment, preferred before any other debts to which the goods laden are liable, though fuch were precedent to the Freight, for the goods remain as it were bailed for the fame: nor can they be attached in the mafter's hands, though it is vulgarly conceived otherwife. Ships deferve wages, like a labourer; and, therefore in the eye of the law, actions touching them, are generally conftrued favourably, for the fhip and owners: and, therefore, if four part-owners of five account with freighters, and receive their proportions, yet the fifth may fue fingly both by common and marine law.

FRITILLA'RIA, *fritillary, or chequered tulip*, in botany, a genus of flowers whofe characters are:

The flower confifts of fix leaves, and is of the bell-fhaped lily-flowers, pendulous, naked, and, for the moft part, chequered; the ftyle of the flower becomes an oblong fruit, which is divided into three cells, and filled with flat feeds, lying in a double row: the root confifts of two flefhy knobs, which are, for the moft part, femiglobular, betwixt which arifes the flower ftalk.

Thefe plants are propagated either by feeds, or off-fets from the old roots: by the firft of which methods new flowers will be obtained, as alfo a larger ftock of roots in three years, than can be obtained in twenty or thirty years in the latter method: I fhall therefore only treat of their propagation by feeds.

Having provided yourfelf with fome good feed, faved from the faireft flowers, you muft procure fome fhallow pans or boxes, which muft have fome holes in their bottoms to let out the moifture: thefe you fhould fill with light frefh earth, laying a few potfherds over the holes, to prevent the earth from ftopping them: then having laid the earth very level in the boxes, &c. you muft fow their feeds thereon pretty thick, covering it with fine fifted earth a quarter of an inch thick. The time for fowing the feeds is about the beginning of Auguft; for, if it be kept much longer out of the ground, it will not grow: then place the boxes or pans where they may have the morning fun until 11 o'clock, obferving, if the feafon proves dry, to water them gently, as alfo to pull up all weeds, as foon as they appear; for, if they are fuffered to remain until they have taken deep root into the earth, they would draw feeds out of the ground, whenever they are pulled up. Towards the latter end of September you fhould remove the boxes, &c. into a warmer fituation, placing them under an hedge or wall expofed to the fouth; in which place they may remain until the middle of March; by which time the plants will be come up an inch high: you muft therefore remove the boxes, as the weather increafes hot, into a more fhady fituation; for, while the plants are young, they are liable to fuffer by being too much expofed to the fun: and, in this fhady fituation, they may remain during the heat of the fummer, obferving to keep them clear from the weeds, and to refrefh them now and then with a little moifture; but be careful not to give them much water after their leaves are decayed, which would rot the roots. About the beginning of Auguft, if the roots are very thick in the boxes, you fhould prepare a bed of good light frefh earth, which muft be levelled very even, upon which you fhould fpread the earth in the boxes in which the fmall roots are contained, equally covering it about one fourth of an inch thick with the fame frefh earth: this bed fhould be fituated in a warm pofition, but not too clofe to hedges, walls, or pales, which would caufe their leaves to be long and flender, and make the roots weaker than if placed in a more open expofure.

In this bed they may remain until they flower, which is generally the third year from fowing; at which time you fhould put down a mark to the roots of all fuch as produce fair flowers, that, at the time of taking them out of the ground (which ought to be foon after their green leaves are decayed) they may be felected into a bed amongft your old roots of this flower, which for their beauty, are preferved in the beft gardens; but the other lefs valuable flowers may be planted in the borders of the parterre garden for their variety, where, being intermixed with other flowers of different feafons, they will make a good appearance. *Miller's Gard. Dict.*

FRITT, or FRIT, in glafs-making, the calcined matter to be run into glafs. To make this for cryftal glafs, take of the fineft tarfo, powdered fine and fifted, two hundred pounds; of the falt of polverine, an hundred and thirty pounds; mix them well together, and put them into the calcar, or calcining furnace, which muft be thoroughly heated firft, otherwife the operation will be very difficult; a moderate fire is to be kept up for an hour, and the matter continually ftirred together with a rake, and then the firft muft be made very violent, and kept up for five hours. After this, take it out and cover it from duft, it will be white as fnow. It muft be kept in this ftate, three or four months, and is then ready to make the fineft cryftal glafs. *Neri's Art of Glafs.*

FROTH *Spit*, or *cuckow fpit*, a name given to a fort of white Froth or fpume very common in the fpring, and firft months of the fummer, on the leaves of certain plants, particularly on thofe of the common white field lychnis, or catch-fly, thence called by fome fpattling poppy. All writers on vegetables have taken notice of this Froth, though few have underftood the caufe or origin of it, till of late. Many imagined it an exhalation of the earth, fome have efteemed it, as its name expreffes, the faliva of the cuckow, others the extravafated juices of the plant, and fome a hardened dew. But all thefe are erroneous opinions, and the true account of it is that it owes its origin to a fmall infect.

There are very frequently to be feen in the fummer months a fort of fmall leaping animals, called by fome the flea grafhoppers, becaufe they are very fmall, and leap like a flea; thefe little creatures have each a pointed probofcis, by means of which they fuck the juice of the plants, they are found upon. Thefe animals lay their eggs in autumn, from which in the fpring following the young ones are hatched; and thefe are at firft tenderly fheltered from injuries by a delicate and thin membrane, which makes a fort of nymph, having the lineaments of all the parts of the animal, which is to iffue from it. When it is firft hatched from the egg, it is a fmall white point on the leaf, not larger than the point of a needle; a few days after, it is greenifh, its colour changing with the juices of the plant on which it feeds: in this ftate it not unaptly refembles that fmall fpecies of frog, called the tree-frog, which is common on the branches of trees in many places; it moves about very fwiftly in this ftate, though ftill covered with its membrane; but, till it gets rid of that, it can neither leap nor fly.

The manner in which the little creature forms this Froth upon the plant is this: it applies its anus clofe to the leaf, and difcharges upon it a fmall drop of a white vifcous fluid, which, containing fome air in it, is foon elevated into a fmall bubble; before this is well formed, it depofits fuch another drop, and fo on, till it is every way overwhelmed with a quantity of thefe bubbles, which form the white Froth which we fee. It adds to this upon occafion, but never moves from under it, till it has got rid of its enveloping membrane, or arrived from the nymph ftate to that of the perfect animals. It throws out thefe globules of vifcous humor, by a fort of dilatation, and contraction of its belly; and, as they fucceed one another, it difpofes them every way round it with its feet. A proof, that, while thefe animals are in this imperfect ftate, and covered with Froth, they yet feed on the juices of the plant, is, that, if one of them be placed on a leaf of mint, or any other fuch plant, the leaf on which they live will never grow beyond the fize it was of, when the animal was placed upon it, while the oppofite leaf will acquire its full dimenfions. When the animal has quitted its nymph ftate, it make no more Froth, but leaves that under which it had lived, and takes its courfe freely about the plant.

FRUCTIFICA'TION. The organs of Fructification in plants are the pointal, generally contained in the middle of flowers; and the threads, which furround it, furnifhed at their extremities with little heads; these the botanifts term, the firft the piftillum, the fecond the ftamina, and the third, or heads of the ftamina, the antheræ, or apices.

The apices contain the farina fœcundans, a fine fubtile matter analogous to the femen mafculinum in animals; the ftamina ferve only for their fupport, and to convey nutrition to them; and the piftillum is the part deftined to receive this farina, and convey it to the feeds.

It is upon thefe principles that the excellent Linnæus has founded his fyftem of the vegetable world, and formed his claffes. This author's work has been received by the learned world in all nations with the refpect it merits; but has been too generally cenfured among the flighter proficients in botanical refearches, as abftrufe, difficult, and unintelligible. The viewing thefe things in a new light, and the neceffity of making new words to convey new ideas, has indeed given this great attempt fomething of the face of an abftrufe piece; but, premifing a few general hints, it may not be difficult to vindicate the author from the heavy charges which have been laid againft him, and give the Englifh reader a clear and perfect view of his work.

From the ftructure and ufe of the piftillum, ftamina, and apices, it is eafy to conceive that the former muft be accounted the female, and the two latter the male parts of flowers. This is the great bafis of his fyftem. To exprefs the different combinations of thefe in the different claffes of plants, by formal defcriptions of each, had been tedious, and an overburden to the memory: to avoid this, he has excellently contrived the comprifing that defcription, or general character, in one word. It is eafy to conceive there could be no words already in ufe, that could exprefs what had never before been thought of; he has therefore been neceffitated to invent new ones for this purpofe. He has ventured therefore to form twenty-four fuch, for his claffes, classes, which are of that number, and has taken them from that language which all the learned have ever used on the same occasion, the Greek; and this with the least ostentation or shew of learning imaginable: in short, to understand all these, there is no need of knowing more Greek than that ἀνὴρ signifies a man, or any thing male; and γυνὴ, a woman, or female; that δύναμις, is power or efficacy; ἀδελφὸς, a brother; and thence ἀδελφαὶ, brotherhoods or communities; that σὺν is together; γένεσις, generation or origin; and οἶκος, a house, or habitation; that πολὺς, signifies many; γάμος, marriage; and κρυπτὸς, hidden or concealed; and that the numbers one, two, three, four, five, six, seven, eight, nine, ten, twelve, and twenty, or their derivations, once, twice, &c. are expressed by the Greek words μόνος, δὶς, τρὶς, τέτρα, πέντε, ἓξ, ἑπτὰ, ὀκτὼ, ἐννέα, δέκα, δώδεκα, εἴκοσι: there needs, I say, no more knowledge of Greek than this, to understand perfectly the meaning of all the terms this author, to avoid tedious descriptions, has used as the characters of his classes. To begin with certainty and regularity,

He first divides the whole vegetable world into such species as have their flowers visible and obvious to the eyes, and such as have them invisible, or at the utmost scarce discernable.

Those which have them visible he then divides again into such as have the stamina, apices, and pistillum, that is, the male and female part, of Fructification, in the same flower:

These he, for that reason, calls hermaphrodite flowers.

And such as have the male and female parts of Fructification, that is, the apices and pistillum, either in different flowers upon the same stalk, or upon different plants of the same species: these he calls the distinct male and female flowers.

Those which have the different organs of Fructification lodged in the same flower, he again divides into such as have the stamina in no part growing together, or cohering to one another: and such as have them either growing together or cohering together mutually in some part, either with one another, or with the pistillum.

Those which have them in no part cohering either with the pistillum, or with one another, he again subdivides into such as observe no exact or accurate proportion of length one among another, and such as have ever two of the stamina shorter than the rest.

From these general divisions he descends to his particular classes, of which he establishes twenty-four.

The first thirteen are of the plants which have hermaphrodite flowers, with the organs of Fructification disjunct, no where cohering with one another, and observing no exact proportion in length.

The first is of the monandria: the word is derived from the Greek μόνος and ἀνὴρ one male part, and signifies a flower which has only one such. This class accordingly comprehends those plants with an hermaphrodite flower, and in it only one single stamen: of this class are the blite, turmeric, &c.

The second is of the diandria; the word, derived from the same ἀνὴρ and δὶς, twice, and signifying a flower that has two male parts, comprehends all those plants which have hermaphrodite flowers with two stamina on each: of this class are the jasmine, phillerea, olive, rosemary, butterwort, &c.

The third is of the triandria; the word, derived from the same ἀνὴρ and τρὶς, thrice, signifies a flower that has three male parts in it, and comprehends those plants which have hermaphrodite flowers with three stamina in each: of this class are the valerian, saffron, many of the grasses, &c.

The fourth is of the tetrandria; the word, derived from the same ἀνὴρ and τέτρα, four times, signifies a flower that has four male parts, and accordingly comprehends those plants which have hermaphrodite flowers with four stamina in each; of this class are the teasel, madder, plantain, &c.

The fifth is of the pentandria; the word, derived from the same ἀνὴρ and πέντε, five, signifies a flower with five male parts, and accordingly comprehends those plants which have hermaphrodite flowers with five stamina in each; of this class are the primrose, willow-herb, bind-weed, &c.

The sixth is of the hexandria; the word, derived from the same ἀνὴρ and ἓξ, six, signifies a flower that has six male parts, and accordingly comprehends those plants which have hermaphrodite flowers with six stamina in each; these stamina, the author observes, are either all equal in length, or alternately one shorter than another: of this class are garlic, hyacinths, meadow saffron, &c.

The seventh is of the heptandria; the word, derived from the same ἀνὴρ and ἑπτὰ, seven, signifies a flower which has seven male parts, and comprehends those plants which have hermaphrodite flowers with seven stamina in each: of this class are the horse chesnut and trientalis.

The eighth is of the octandria; the word, derived from the same ἀνὴρ and ὀκτὼ, eight, signifies a flower with eight male parts, and comprehends those plants which have hermaphrodite flowers with eight stamina in each: of this class are the maple, rue, heath, &c.

The ninth class is of the enneandria; the word, derived from the same ἀνὴρ and ἐννέα, nine, signifies a flower that has nine male parts, and comprehends those plants which have hermaphrodite flowers with nine stamina in each: of this class are the bay, rhubarb, &c.

The tenth class is of the decandria; the word, derived from the same ἀνὴρ and δέκα, ten, signifies a flower which has ten male parts, and comprehends all those plants which have hermaphrodite flowers with ten stamina in each: of this class are the judas tree, bastard dittany, caltrop, &c.

The eleventh is of the dodecandria; the word, derived from the same ἀνὴρ and δώδεκα, twelve, signifies a flower which has twelve male parts in it, and comprehends those plants which have hermaprodite flowers with twelve stamina in each: of this class are the asarabacca, agrimony, &c.

The twelfth is of the icosandria; the word, derived from the same ἀνὴρ and εἴκοσι, twenty, signifies strictly a flower with twenty male parts in it; the author however does not understand it in that strict sense, but, using it as we frequently do words expressing large quantities, as indefinite and in an indeterminite sense, defines it to mean only a larger number of stamina than are expressed under any other of the distinctions; and comprehends under it, in this class, all those plants which have hermaphrodite flowers and more than twelve stamina in each; those stamina also growing to the inner side of the cup of the flower, not to the receptacle of the future seeds: of this class are the torch thistle, the myrtle, storax, the almond, &c.

The thirteenth is of the polyandria; the word, derived from the same ἀνὴρ and πολὺς, many, signifies, in an exact sense, no other than what he makes the icosandria, the title of the last class, express: these are, perhaps, the only two words in which his expression is deficient, the names he has given the classes not at all importing their particular difference from one another: this, however, he has very accurately done in the character which follows them; and comprehends under this class those plants which have hermaphrodite flowers with more than twelve stamina in each, but which grow in this to the receptacle of the future seed, not as in the other class to the inner side of the cup of the flower; of this class are the water lily, poppy, celandine, &c.

These are the classes this accurate distinguisher has established among the hermaphrodite flowers, whose stamina have no regular proportion of length, in regard to one another. To these he next subjoins two classes of such of them as have two of their stamina shorter than the rest.

The first of these (the fourteenth class of the general order) is of the didynamia: the word, derived from the before-mentioned δὶς and δύναμις, power or efficacy, signifies with him such flowers as have two of their male parts of more efficacy than the rest; and, in this class, he accordingly comprehends all those plants which have hermaphrodite flowers, two of whose stamina are longer, and of greater efficacy in the great work of fecundating the seeds, than the rest: of this class are the thyme, lavender, basil, &c.

The second of these (the fifteenth class of the general order) is of the tetradynamia; the word, derived from the before-mentioned τέτρα and δύναμις, signifies a flower with four of its male parts of more efficacy than the rest; and in this class he comprehends the plants with the hermaphrodite flowers, four of the stamina of which are longer than the rest: of this class are the scurvy-grass, radish, mustard, &c.

From these he proceeds to those hermap .rodite flowers whose stamina cohere, either mutually among one another, in different manners, or with the pistillum of the flower: these coalitions of the stamina he calls brotherhoods or communities; and according to the different state of these, and their conjunctions with the pistillum, he establishes five classes of them.

The first of these (the sixteenth in the general order) is of the monadelphia; the word, derived from the before-mentioned μόνος, single, and ἀδελφαὶ, brotherhoods, or communities, signifies, with him, a flower whose stamina, by the filaments running in one among another, are all formed into one body; and under this class he comprehends those plants with hermaphrodite flowers, whose stamina, or male parts, are all bound together in one body: of this class are the crane's bill, mallow, &c.

The second of these (the seventeenth class in the general order) is of the diadelphia; the word, derived from the before-mentioned δὶς and ἀδελφαὶ, signifies, with him, a flower whose stamina are, by the conjunction of their filaments, formed into two bodies; and under this class he comprehends those plants with hermaphrodite flowers, the stamina of which are so clustered together into two bodies: of this are the fumitory, milkwort, broom, &c.

The third of these (the eighteenth in the general order) is of the polyadelphia; the word, derived from the before-mentioned πολὺς and ἀδελφαὶ, signifies with him a flower whose male parts are clustered into three or more separate bodies; and in this he comprehends these plants with hermaphrodite flowers, whose stamina, by the conjunction of their filaments, are formed into three or more clusters: of this class are the orange, St. John's wort, &c.

The fourth of these classes (the nineteenth in the general order) is of the syngenesia: the word, derived from σὺν, together, and γένεσις, generation, origin, or formation, signifies, with him, such flowers as have their male parts naturally formed into a single regular congeries; and accordingly he comprehends under this class such plants as have hermaphrodite flowers, the stamina of which, by the junction of their apices, are formed into a single,

regular,

regular, cylindric body: of this class are the lettuce, succory, hawkweed, &c.

The fifth of these classes (the twentieth in the general order) is of the gynandria: the word, derived from γυνη, a woman, or female, and ανηρ, male, signifies, with this author, a conjunction of the male and female parts of a flower at their origin; and he accordingly comprehends under this class those plants which have hermaphrodite flowers, the stamina or male parts of which grow to the pistillum, or female parts of the flower, and not to the receptacle of the seeds: of this class are the barrenwort, passion-flower, birthwort, &c.

Next after these he ranges those plants which have flowers not hermaphrodite, but regularly and distinctly male and female, as the sexes in animals are disposed; and after these such plants as have flowers irregularly of one, or the other, or sometimes of both sexes.

Of these he establishes only three classes.

The first of these (the twenty-first class of the general order) is of the monœcia: the word, derived from the before-mentioned μονος, and οικος, a habitation, signifies, with this author, such plants as have their distinct flowers on the same individual; and he comprehends accordingly under it those plants which have the male and female flowers distinct in themselves, but placed on the same plant, or the different stalks from the same root: of this class are the alder, mulberry, amaranth, arrowhead, &c.

The second of these (the twenty-second class in the general order) is of the diœcia: the word, derived from the same, οικος and δις, signifies, with him, plants which have their male and female flowers, not on the same individual; and accordingly comprehends under it such plants as have distinct male and female flowers, and different plants of the same species, either of which, the male and female plants, as they are hence called, might have arisen from the same seed: of this class are the willow, misletoe, hemp, and spinach, &c.

The third of these (the twenty-third in the general method) is of the polygamia: the word, derived from πολυς many, and γαμος, marriage, signifies, with this author, plants which have a diversity of combinations and many ways of Fructification, in the same species; and accordingly he comprehends under this class those plants which have, in the same species, some flowers male, others female, each distinct and perfect in its kind, and others mixed or hermaphrodite, with the male and female organs of Fructification both in each: of this class are pellitory, of the wall, orrache, the ash, &c.

After all these he places those plants whose flowers are either absolutely invisible, or scarce discernable by the eye: of these he makes only one, his twenty-fourth and last class, the cryptogamia: the word, derived from κρυπτος, hidden, or concealed, and the before-mentioned γαμος, or marriage, signifies a set of plants, in which the Fructification is concealed: and under this last class he comprehends those plants which either flower, as is generally supposed, within the fruit, or have the organs of their Fructification so mingled as to escape our observation: of this class are the ferns, mosses, liverworts, and mushrooms.

These are the classes into which this author has regularly and certainly reduced the whole vegetable world; the characters of which are so expressive, and the parts they are founded upon so fixed and invariable in their nature and office, that there seems no reason hereafter to perplex the world with any new system.

As the classes are here taken from the number, site, and disposition of the male parts of the flower; so the orders which make their subdistinctions are, by this author, deduced from the differences of the female parts or pistillum; and as that is single, double, triple, and so on, they are on the same principles named monogynia, digynia, trigynia, &c.

It were to be wished indeed that the characters of the different genera of these classes were as perfect and accurate as the classes themselves: this, however, was more than the work of one man; the author has fixed the general distinction, and led the way; and it is easy now for a much less genius to follow him.

FRUIT (*Dict.*)—The Fruit of some plants are produced singly, as are their flowers; and sometimes they are produced in clusters, as in most fruit-trees, which are also fleshy; but in many plants they are dry.

The word Fruit is also used to signify an assemblage of seeds in a plant; as in a pea, bean, ranunculus, &c. and, in its general signification, for all kinds of grain, whether naked, or inclosed in a cover, capsula, or pod, whether bony, fleshy, skinny, membraneous, or the like.

Fruit is the product or result of the flower, or that for whose production, nutrition, &c. the flower is intended.

The structure and parts of different Fruits are different in some things; but, in all the species, the essential parts of the fruit appear to be only continuations or expansions of those which are seen in the other parts of the tree.

Dr. Beale suggests some very good reasons for a direct communication between the remotest parts of the tree and the Fruit; so that the same fibres or stamina, which constitute the root, trunk, and boughs, are extended into the very Fruit.

Thus, if you cut open an apple transversely, you will find it to consist chiefly of four parts: viz. 1. a skin or cortex; which is only a production of the skin or outer bark of the tree. 2. A parenchyma or pulp, which is an expansion and intumescence of the ble or inner bark of the tree. 3. The fibres or ramifications of the woody part of the tree. 4. The core, which is the produce of the pith or medulla of the plant, indurated or strengthened by twigs of the wood and fibres inosculated therewith. This serves to furnish a cell or lodge for the kernels, filtrates the juice of the parenchyma, and convers it, thus prepared, to the kernel.

Of the fibres authors generally reckon fifteen branches; of which, ten penetrate the parenchyma, and incline to the basis of the flower; the other five ascend, more particularly from the pedicle or stalk, and meet with the former at the base of the flower; to which branches the capsulæ or coats of the kernels are fastened.

These branches, being first extended through the parenchyma to the flower, furnish the necessary matter for the vegetation of it: but, as the Fruit increases, it intercepts the aliment; and thus the flower is starved, and falls off.

In a pear, there are five parts to be distinguished, viz. the skin, parenchyma, ramification, stone, and acetarium.

The three first parts are common to the apple. The stone, observed chiefly in choke pears, or baking pears, is a congeries of strong corpuscles, that are dispersed throughout the whole parenchyma, but in the greatest plenty, and closest together, about the center, or acetarium: it is formed of the stony or calculous part of the nutritious juice.

The acetarium is a substance of a tart acid taste, of a globular figure, inclosed in an assemblage of several of the stony parts before-mentioned.

In a plum, cherry, &c. there are four parts, viz. a coat, parenchyma, ramification, and nucleus or stone. The stone consists of two very different parts: the external or harder part, called the stone or shell, is a concretion of the stony or calculous parts of the nutritious juice, like the stone in pears, within it. The inner, called the kernel, is soft, tender, and light, being derived from the pith or medulla of the tree by seminal branches, which penetrate the base of the stone.

The nut, or acorn, consists of a shell, cortex, and medulla; the shell consists of a coat and parenchyma, derived from the bark and wood of a tree.

The cortex consists of an inner and outer part; the first is a duplicature of the inner tunic of the shell: the second is a mossy substance, derived from the same source as the parenchyma of the shell. But authors are not agreed, whether the medulla or pulp of the kernel does arise from the pith of the tree, or the cortical part thereof.

Berries, as grapes, &c. contain, besides three general parts, viz. coat, parenchyma, and ramification, grains of a stony nature, to do the office of seeds.

Fruits, in general, are serviceable in guarding, preserving, and feeding the inclosed seed; in filtrating the coarser, more earthy, and strong parts of the nutritious juice of the plant, and retaining it to themselves; sending none but the most pure, elaborated, and spirituous parts to the seed, for the support and growth of the tender delicate embryo, or plantule, which is therein contained.

FRUIT-*trees*. There is, in the Philosophical Transactions, a method of making Fruits and flowers grow in winter instead of summer, without the common way of doing it by heat. This method is, to take up the trees with their roots in the spring season, just as they begin to shoot out their buds; let them be placed upright in a cellar, and stand there till the end of September following; then fit vessels to them, and place the roots in them, covering them in a proper manner with earth, and bring them up into a common stove; water them at times with a solution, of the bigness of a walnut, of crude sal armoniac, in a quart of rain water, and they will make their natural progress, as in summer; and, in the months of February or March following, the Fruit will be full ripe, and as well tasted as if it had grown on them in the common way, and ripened at its natural season. *Philos. Transf.* N°. 282.

The superfluous shoots from these trees must be pruned off at such times of the year, when the trees are full of juice, and furnished for a farther supply; and, by this means, there will be no marks of the wounds, they will close up so perfectly.

The manner of producing pyramidal trees by ingrafting is not only applicable to Fruit-trees, but has been tried on oaks, limes, and roses, with the same success.

Laurembergius tells us of a peculiar way of managing Fruit-trees for ready services and beauty, by means of which they will bear fruit the first year. The method is this: draw a branch of a Fruit-tree through a pot of earth, and prick it full of holes with a knife, so far as it is to stand in the pot; let it be well watered for the first seven or eight days, to make it shoot out a great quantity of roots: in the March following cut off the branch from the tree, and let it depend wholly on itself for nourishment; break the pot away, and place the clump of earth with the young tree in it in the place where it is intended to stand. The author assures us, it will partake so much of the nature of the stock, as to bear Fruit the first year. *Phil. Transf.* N°. 3.

FULIGO, *soot*.—The learned Boerhaave has given us the following analysis of soot.

Take of the blackest and driest soot, gathered in the chimney of of an oven, where nothing but bread is baked, and nothing burnt but vegetables, and gathered on a very dry day; with this fill a large glass retort almost to the neck; apply a large glass receiver, after the neck of the retort has been thoroughly cleansed, on the inside; and lute the juncture with the common linseed paste; raise a fire of an hundred and fifty degrees, and keep it up equably: a large quantity of transparent water will thus come over, with considerable violence; so that, if the fire was immediately made strong at first, the receiver would easily crack. Continue in this manner, so long as any clear water comes over, which it will long do, although the soot was dry. Then taking away this first water, and pouring it into a glass, apply the receiver again, and raise the fire a little above two hundred degrees; a white, milky, fat water, will now come over in quantity, and with considerable violence; proceed with a slowly increased fire, so long as this continues; keep it apart; apply the receiver again, and raise the fire briskly; a yellow, volatile, copious salt will come over, and stick all round the sides of the receiver; continue the fire thus brisk, so long as any salt arises; then with the strongest heat, that sand will give, and with a heat of suppression, there arises a thick black oil. Let all cool, and there will be found, in the neck of the retort, a salt which could rise no higher, even by so violent a fire; but, in the bottom of the retort, there remains a black feculent matter; the upper surface whereof is covered with a very thick, whitish, saline crust, which, both in colour, figure, concretion, and striæ, resembles the common sal ammoniac. If the milky water be rectified, it affords a very penetrating volatile spirit, and some sharp volatile salt.

Remarks.

Here we are taught what the agitation of an open fire can move, change, expel, and drive through the air by burning; first, in the form of smoke; then, of flame; lastly, of exhalation, and how high it may carry them. For a chimney is a kind of still-head, converging in an open top; and sometimes rises to the height of above thirty feet, and carries soot up to the top; and, after this, discharges a black smoke, at its upper orifice, and disperses it through the air, where it seems gradually to vanish. It may deserve to be considered, what an immense quantity of such matter is, by the force of fire, thrown up from the surface of the whole habitable globe, in the places where fire is constantly used: whence we may learn, that combustible vegetables, thin smoke, flame, and soot, and the black clouds dispersed in the air, consist of one and the same matter agitated by fire. This matter consists of several parts; as, 1. a fœtid, oily, bitter, unpleasant, nauseous spirit, residing in the water, that first comes over, and is afterwards constantly dispersed through all the other parts: this spirit seems to be the oily and more subtile part of the vegetable, acted on by the force of fire. 2. Water, which is here contained in great plenty, residing in this spirit, in the first limpid, and in the second milky liquor, as also in the saline spirit, the volatile salt, and, in some measure, in the oil itself. This water can scarce be rendered pure by any art, being always foul with the unalterable bitterness, and the inseparable disagreeable odour of the spirit. 3. A sharp, volatile, alcaline, oily salt, which first comes over, rises into the receiver, and sticks to the sides thereof; for this salt is truly alcaline, as appears by its state, smell, fiery virtue, the violent effervescence it makes with acids, and by concreting therewith into a compound salt; and hence a volatile alcali continually impregnates the atmosphere, in great plenty, by conflagration. 4. A sharp, alcaline, fat spirit, consisting of the salt just now mentioned, dissolved in water, and so resembling spirit in fluidity, pungency, subtility, and volatility. 5. A fœtid, black, bitter, nauseous, inflammable, thick, and almost caustic oil, mixed with an oily salt. 6. A true sal ammoniac, sticking in the lower part of the neck of the retort, and raised to the surface of the black earth below. For, if this salt be carefully collected and separated from the alcaline kind, that first comes over, it proves a genuine sal ammoniac. It is of a whitish colour somewhat transparent, makes no effervescence with acids, and, if mixed with fixed alkalies, presently affords a true volatile alcaline salt, as sal ammoniac does; whence the true origin of this salt is derived from soot. 7. A black fixed earth, which, being afterwards calcined in an open fire, and burnt from its oil, which tenaciously adheres thereto, leaves a white earthy calx behind.

This is the analysis of soot; by considering of which, we may learn what parts of vegetables are volatile, and fly off by an open fire, and what are fixed and remain behind, and what fire throws off from vegetables into the air. Hence we see, that even earth, which appears so fixed in the most violent fire, after being separated from the other principles, yet, when mixed with the rest, is, either by the force of flame, or fire, thrown to the distance of forty feet through the air, in the form of a thin cloud; but there would be no end, if we should minutely pursue the physical uses of this process. Pills composed of dry soot, and gilded, are recommended for the cure of cold distempers, and this often with success. The volatile salt of soot is used with the same success as that of animals. Hartman recommends the salt which rises last, for giving relief in cancers; and, certainly, sal ammoniac, prudently employed, is of service against the putrefaction of running cancers. But the soot, produced by oak wood alone, the common Dutch tufts, or pit coal, appears different upon chymical analysis; and that again would be very different, which should be collected from the chimney of a public kitchen, which is continually filled with the fumes, not only of the fuel, but likewise of all kinds of boiled, roasted, and fried meats. And thus much may help us to form a judgment of soot. *Boerhaave's Chymistry.*

FU'LLING (*Dict.*) — *Method of* FULLING *cloths and woollen stuffs with soap.*

Let a coloured cloth of about forty-five ells be laid, in the usual manner, in the trough of a Fulling-mill, without first soaking it in water, as commonly practised in most places.— To full this trough of cloth, fifteen pounds of soap are required, one half of which is to be melted in two pails of river or spring-water, made as hot as the hand can bear. Let this solution be poured, by little and little, upon the cloth, in proportion as it is laid in the trough: thus it is to be fulled for at least two hours; after which, let it be taken out and stretched. — This done, let the cloth be immediately returned into the same trough, without fresh soap, and there fulled two hours more. Then take it out, wring it well, and express all the grease and filth.—After the second Fulling, dissolve the remainder of the soap, as the former part, and throw it at four several times on the cloth, not forgetting to take it out every two hours to undo the plaits and wrinkles it got in the trough. —When it is sufficiently fulled, and brought to the requisite quality and thickness, it is scoured out for good in hot water, keeping it in the trough till it be thoroughly clean. — White cloths Fulling more easily than coloured ones, a third part of the soap may be spared.

Fulling of caps, stockings, &c. is performed either with the hands or feet, or a kind of wooden machine, either armed with wooden teeth, or those of horses or bullocks.—The ingredients generally used on this occasion are urine, green soap, white soap, and fuller's-earth. — But a water softened with chalk is far preferable.

FUMA'RIA, *fumitory*, in botany, a genus of plants whose characters are:

The leaves are divided as in umbelliferous plants; the calyx is small, and bifoliated, in some lying under the spur of the flower, and in others wanting. The flower, if curiously examined, in many plants, appears tetrapetalous, the lower petal running out in the shape of a keel from the end of the pedicle: the upper, being bent in the figure of a spur, rises upwards, in the form of an erect galea; to this latter petal grow the calyx and pedicle: the third and fourth petals are lateral, and, by their opposition, form the representation of a very sharp-pointed vagina, concealed between the two former petals.

The ovary, at the extremity of the pedicle, is short and contracted, and furnished with a long tube, with a globous or discous head: the whole length of it seems carefully covered up, and concealed within the vagina before described. To the tube, for its whole length, grow two stamina, so closely, that, in conjunction with it, they are included in one very small, thin, pellucid, vagina, in such a manner, that nothing appears outwardly but the apex of the tube of the ovary, and the two testes. The ovary, when ripe, becomes an unicapsular pod, full of round seed.

If the ripe flower be cautiously opened, as soon as the two interior petals are disclosed, the testes discharge the seed by a sudden explosion.

This plant gives the blue paper much such a red colour as aloes; so that, probably, it contains very near the same principles, such as a salt like that which is natural in the earth, but in which the sal ammoniac predominates over the nitre and marine salt: besides, the salt of the fumitory is joined with a great deal of sulphur and earth, and dissolved in a considerable quantity of phlegm.

By the chymical analysis, fumitory yields a great deal of concreted, volatile, fixed, lixivial salt, and very thick oil.

All these principles render this plant laxative, diuretic, good to cleanse the blood, and remove obstructions of the parts. It passes for a specific in all diseases of the skin, in hypochondraic melancholy, in a cachexy, and dropsy: they give the juice of fumitory from two ounces to six; the infusion in whey, from six ounces to ten or twelve; the simple syrup, to two or three ounces, in ptisans; the compound syrup, to one or two ounces, if you would have the patient purged. The water, also, of fumitory is detersive, and good to dry up ulcers of the mouth. Anointment is made of the juice of this plant, mixed with equal quantities of the juice of elecampain, thickened over the fire with some hog's lard. Fumitory is used in the electuary de Psyllis, in that which they call sennatum, in the confection hamech, and in the compound syrup of succory. *Martyn's Tournefort.*

FU'NDS, a term adopted by the monied men, and those who speak of the public revenue of nations, to signify the several taxes that have been laid upon merchandizes, either by way of duties of custom or excise or in any other shape, to supply the exigencies of the state, and to pay the interest for what sums of money it may have occasion to borrow. Thus we say, such a duty, or such a tax, is a good Fund to answer such a purpose. The term is also applied to the stocks of great trading and monied corporations.

The Funds, or taxes if you please, of this kingdom are, to ſpeak in the language of parliament, either temporary or perpetual. Temporary ones are ſuch which are impoſed for a certain number of years, or annually, as the land and the malt-taxes; the perpetual Funds are ſuch whereon monies have been borrowed for the public ſervice, and which are appropriated for the ſecure and certain payment of the intereſt of ſuch monies, till the diſcharge of the principal ſo borrowed.

FU'NGUS (*Dict.*) — Certain tumors of the joints, generally called white ſwellings, are alſo called Fungi, by ſome authors, particularly Heiſter, who gives the following directions relative to them:

Excreſcences of the joints very nearly reſemble œdematous tumors, are attended with danger, and therefore require a peculiar examination; nothing but an ignorance of the nature and origin of them, that is, whether they proceed from the blood or ſerum, from a corrupted matter, flatus, or any other cauſe, could have tempted ſo many authors to paſs them over in ſilence, or treat of them ſo ſuperficially. A Fungus in the joints is a tumor in the articulations of the limbs, without heat or pain, ſo ſoft, that it eaſily yields to the preſſure of the fingers; but, upon the removal thereof, expands itſelf immediately, like a muſhroom, without retaining any marks. Though no joints either of the arms or legs are exempt from this diſorder, the knees, from the quantity of glands and latent fat between the ligaments and tendons, are moſt ſubject to it. There are ſeveral kinds of theſe Fungi; ſome are ſmall, others large; ſome ſoft, others hard; according as the humours, producing it by their ſtagnation and inſpiſſation, are either thin or glutinous. In ſome the noxious fluids are without ſide the articulation; theſe are properly termed Fungi: in others they ſtagnate within the very joint, as the ſerum in the ſcrotum, when there is an hydrocele, which I have both ſeen and cured: this laſt may juſtly be called a dropſy of the joint; and, by its diſtention of the intire joint, may be diſtinguiſhed from the Fungus, as that occupies rather one ſide. Theſe two diſeaſes, then, may be eaſily diſtinguiſhed from what has been ſaid.

A Fungus undoubtedly ariſes from an inſpiſſation of the viſcid, glutinous ſerum about the ligaments of the joints, which, being collected after a fall, or violent blow, immediately raiſes a tumor externally, or in the very joint, and, by debilitating the ligaments, deſtroys the natural mobility of the part. When the nerves, arteries, or veins, are affected by theſe ſwellings, the uſual conſequence is, that the ſubjected parts are deprived of their nutriment, and the joint, being preternaturally inlarged, is by degrees inſenſibly conſumed.

We have already obſerved, that, in excreſcences of the joints, the ligaments are too much extended and relaxed, and, conſequently, the natural ſtrength of the affected limb is more or leſs weakened, in proportion to the violence of the injury received: now, ſince it is very difficult to remedy this diſorder, and theſe tumors cannot eaſily be reſolved or ſuppurated, every one muſt acknowledge, that the ſurgeon lies under great difficulties, who attempts this cure; for, beſide the difficulty of bringing them to ſuppurate, there is danger in the ſuppuration, as it is often attended with a caries, or incurable fiſtula, which induce a neceſſity of amputation. Recent, ſmall, and ſoft, Fungi are often remedied by reſolvent and corroborating medicines, though they are generally irritated by emollients; whereas great and inveterate ones reſiſt all the power of medicine, and depend intirely on the knife for relief, and this does not always prove ſucceſsful: for, though by inciſion you may extract the noxious humours, the ſwelling often returns, after the wound is healed.

But the proper method for the cure ſeems to be this: rub the part affected ſeveral times in a day with warm cloths; then foment it with the beſt tartariſed ſpirit of wine, or linen dipped in the ſame; continue this, till the natural form and vigour of the limb are reſtored. Purmannus's fomentation is likewiſe a very noble remedy: take of the pickle of herrings, two pints; of the ſtrongeſt vinegar, one pint; leaves of ſage, two handfuls; Roman vitriol, an ounce and an half; and alum, ſix ounces; boil theſe together for half an hour; then apply them. When the tumor begins to be diſperſed, and the former vigour of the limb a little recovered, the reſolution is greatly promoted by fomenting with tartariſed ſpirit of wine, or fœtid oil of tartar, ſeveral times in a day; then, to keep out the cold, which is very injurious, bind it up firmly with compreſſes and bandages. Laſtly, I cannot but recommend fomentation above all others: which I have uſed myſelf, with great ſucceſs: take of litharge, half a pound; Armenian bole, an ounce; maſtic and myrrh, each half an ounce; wine vinegar, a pint: boil theſe together for a quarter of an hour. You muſt uſe this decoction warm, and every morning and evening dip compreſſes, or thick linen cloths, into it, and foment the part; obſerving to order, internally, proper purging, attenuating, and ſudorific medicines.

If none of the medicines recommended anſwer the purpoſe, Wurtzen and Purman place their ſole confidence in an inciſion into the tumefied joint, towards the lower and moſt commodious part, but with the utmoſt circumſpection, leſt any of the ligaments or tendons ſhould be injured; for, by the help of this, if the ſtagnating ſerum is collected in one cavity only, it will immediately diſcharge itſelf; if it is diſperſed into ſeveral, it will gradually flow out in a few days. This may be promoted, by applying tents dipped in ſome digeſtive, and ſprinkled with alum. But, before the inciſion, you ſhould preſs the tumor hard with your fingers, and retain it with a bandage placed above it, to prevent its giving way; for this will not only expoſe the part more commodiouſly to your ſight, but, after inciſion, promote the efflux of the ſerum, and make it burſt out, as the blood does after veneſection, or the water after an inciſion of the hydrocele. When you have done this, if any ſwelling ſtill remains, lay on a dyachilum or oxycroceum-plaiſter, or Wurtzen's red one, which, in this caſe, he ſtrongly recommends; with limewater, or ſpirit of wine, which will reſolve the remainder. Thus, when the member is reſtored to its priſtine form, the wound is healed by vulnerary balſams; carefully avoiding the uſe of fat oily medicines, as very prejudicial to the ligaments and tendons. But, if the ſerum be found too tenacious and glutinous to diſcharge itſelf voluntarily, apply ſome attenuating injection at every dreſſing. A decoction of agrimony, alchimilla, and birthwort, mixed with honey of roſes, or of celandine, is the beſt. Theſe injections will generally reſolve the tumors ſurpriſingly.

Though inciſion is the more ready way of cure, ſome prefer cauſtics; and, when the eſchar is ſeparated, they turn out the collected humors, proceeding afterwards as directed above. During this proceſs, I would adviſe anointing the affected joints with a nervous unguent, or ſome aromatic ſpirit, till it has recovered its natural ſtrength.

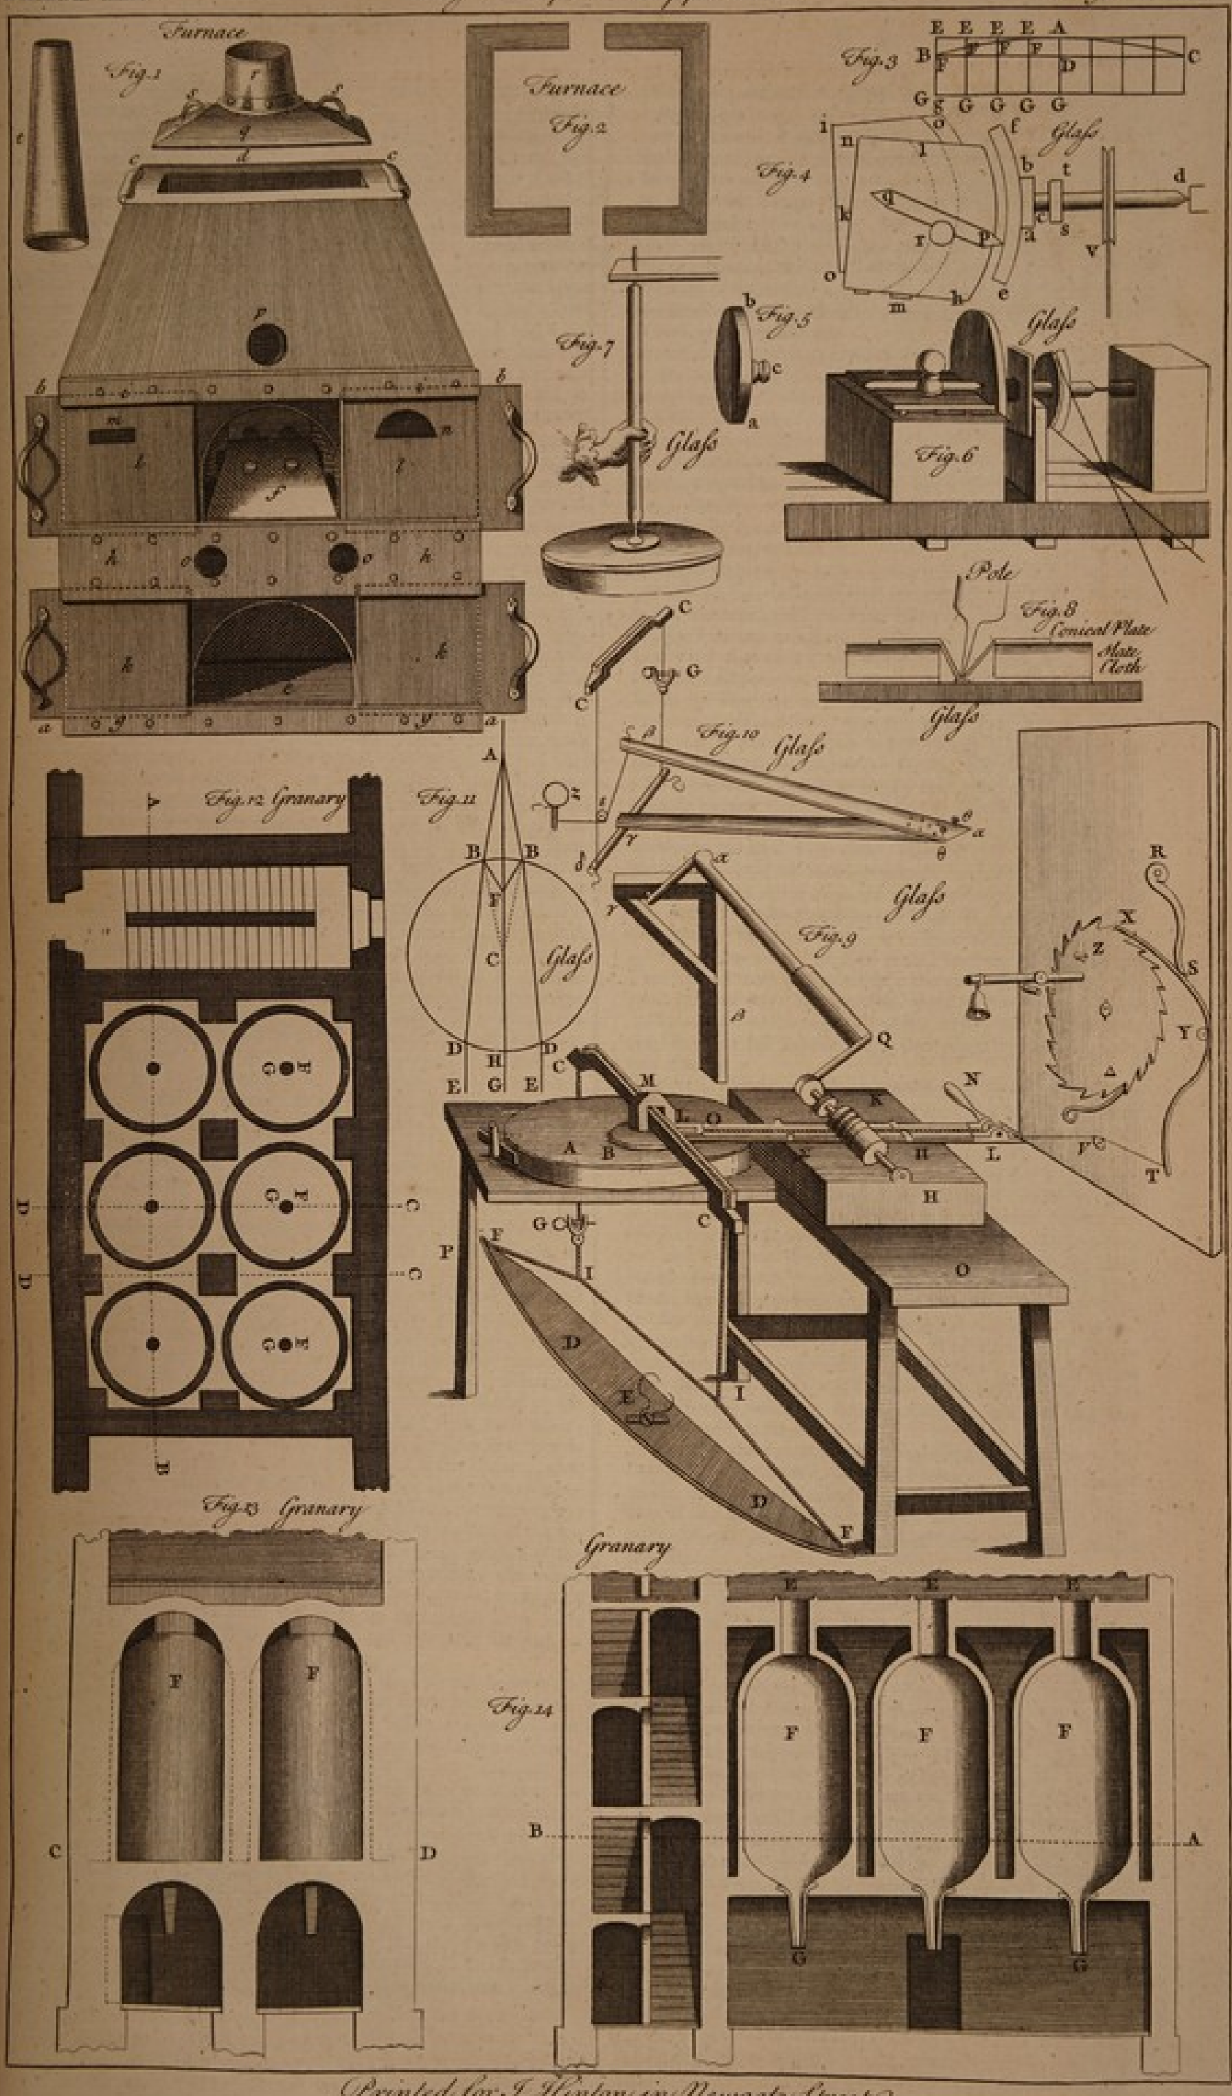
As it is very common for the inſpiſſated ſerum, after the formation of the cicatrix, to collect again; in order to prevent this, you muſt obſerve, not only to preſcribe internal reſolvent, purging, and ſudorific medicines, but likewiſe to keep the wound open with tents for ſome time, and cleanſe it daily with a vulnerary injection of a decoction of birthwort, agrimony, alchimilla, or the like, mixed with honey of roſes, or of celandine; for in Purman's opinion this method is the moſt expeditious, inſomuch that the ſinus of the wound is not only cleanſed, but filled up alſo with new fleſh, ſometimes in ſix days. It will, however, not be improper to inject ſome lime water into the wound, and to apply the ſame, or a digeſtive plaiſter, externally, always binding up the knee carefully, to prevent a collection of the ſerum. This will prevent a return of the Fungi, as Wurtzen, who had been very converſant in theſe cures, teſtifies.

Every excreſcence of the joints is not formed, ſo as to admit of an inciſion ſafely; for, when it is inveterate, hard, or very large, or the patient is weak, you muſt forbear it, as rather more prejudicial than ſerviceable, becauſe it is frequently attended with new diſorders, as a caries, fiſtula, and gangrene, by which the man is deſtroyed, who might otherwiſe have arrived at a good old age. *Heiſter's Chirurg.*

Fungus, in minerology, a name given by Dr. Liſter to a blackiſh bituminous ſubſtance, found in ſome of the mines of Derbyſhire. It adheres to the ſides of the fiſſures of rocks, and lies in ſeams of the ſtrata. It is of a blackiſh colour and fatty ſubſtance, which never dries in the air, but always remains as moiſt, as when taken out of the mine. Some maſſes of it are ſoft and like a jelly, others are hard and firm, and in theſe there are ſeveral lumps of bitumen in many parts. This is inflammable like reſin. It is light, but breaks finer, and ſhines like good aloes when freſh broken, but that it is a little darker-coloured, and has ſome tinge of purple in it. In ſome pieces the purple is wanting, and there is a green in the place of it. On being diſtilled, it yields firſt a limpid and inſipid, then a whitiſh water of a ſharp taſte, and finally a yellow and clear oil, much reſembling oil of amber; but the proceſs affords no volatile ſalt in the neck of the receiver, in which it differs from amber when treated in the ſame manner. *Phil. Tranſ.* N°. VI. See AMBER, in the Dictionary.

FU'RNACE (*Dict.*)—*Docimaſtical* Furnace, a Furnace uſed in aſſaying metals, ſometimes called the aſſay-oven.

It is made in the following manner. 1. Make with iron plates an hollow quadrangular priſm, eleven inches broad, and nine inches high, *a a*, *b b* (*plate* XXI. *fig.* 1.) ending at top in a hollow quadrangular pyramid *b b*, *c c*, ſeven inches high, terminating in an aperture at top ſeven inches ſquare. But this priſm muſt be cloſed at bottom with ſuch another iron plate, which ſerves as a baſis or bottom to it *a a*. 2. Near the bottom make a door *e*, three inches high, and five inches broad, that leads to the aſh-hole. 3. Above this door, and at the height of ſix inches from the baſis, make another door *f*, of the figure of a ſegment of a circle, four inches broad at its baſis, and three inches and a half high in the middle. 4. Then faſten three iron plates on the fore-part of this Furnace: let the firſt of them *g g*, eleven inches long, and half an inch high, be clapped, its lower edge, againſt the bottom of the Furnace, with three or four rivets, in ſuch a manner, that there may be, between the upper edge of the ſaid plate and the ſide of the Furnace, a groove ſo wide, as that the ſliders of the lower door *k k* may be put into it, and freely move backwards and forwards therein; theſe muſt be made of a thicker iron plate. The ſecond iron plate *b b*, eleven inches long, three inches high, and perfectly parallel to the foregoing plate, muſt be clapped in the ſpace between the two doors, in ſuch manner, that both the upper and the lower edge of it may form a hollow groove with the ſide of the Furnace. One of theſe grooves, which



Printed for J. Hinton in Newgate Street.

which looks downwards, serves to receive the upper edges of the sliders, that shut the lower door. The other that looks upwards, is to receive the inferior edges of the sliders of the small door above. The third plate *i i*, which is like the first, must be riveted close above the upper door, in such manner, that it may form a groove looking downwards, and contiguous to the upper edge of the upper door. 5. In order to shut both doors, you must adapt to each of them two sliders made of iron plates, that may move within the above-mentioned grooves, *k k*, *l l*. But the two sliders, belonging to the upper door, must have each a hole near the top; that is, one a small hole one fifth part of an inch broad, and one inch and a half long *m*; and the other a semi-circular aperture, one inch high and two inches broad *n*. Let besides each slider have a handle, that they may be laid hold of, when they are to be moved. 6. Moreover, let five round holes, one inch broad, be bored in the Furnace: two of which must be made in the fore-part of the Furnace *o o*, two others in the back-part, all at the height of five inches from the bottom, but three inches and a half distant from each side of the Furnace; and, finally, a fifth hole *p*, at the height of one inch above the upper edge of the upper door *f*. 7. In short, let the inside of the Furnace be armed with iron-hooks, jetting out half an inch, and about three inches distant from each other, to fasten the lute with which the Furnace is to be covered over within. 8. Let then an iron, moveable, hollow, quadrangular pyramid *q*, three inches high, be adapted to the upper aperture *d* of the Furnace at the basis seven inches broad, ending upwards in a hollow tube *r* three inches in diameter, two inches high, almost cylindrical, tho' somewhat convergent at top. This prominent tube serves to support a funnel or flue, which is almost cylindrical, hollow, made of iron plates, and two feet high *t*, and which, when a very strong fire is required, is put perpendicularly upon the shorter tube, in such manner, that it enters close into it one inch and a half, or two inches deep, and may again be taken off at pleasure, when there is no need of so strong a fire. But this pyramidal cover *q* must besides have two handles *s s* adapted to it, that it may be laid hold of, and thus be taken away or put on again. And, that this, being put on the aperture *d* of the Furnace, may not be easily thrown down, let an iron plate be riveted to the right and left upper edge of the Furnace *c c*, and be turned down towards the inside, so as to make a furrow open before and behind, into which the lateral edges of the cover may enter and be fastened, and at pleasure be moved backwards and forwards, whenever it must be put on, or removed. 9. Let a square ledge, made of a thick iron plate *fig.* 2. be fastened at top of the upper edge of the lower door *e*; this is designed to support the grate and the lute. But it must be made of two pieces, that it may be easily introduced into the cavity of the Furnace. Thus you will have an assay Furnace, which must afterwards be covered over inwardly on the inside with lute: this you are to do as follows:

That the fire may be the better confined, and the iron not be destroyed by growing red-hot, the whole inside of the Furnace must be covered over with the lute, one finger, or one finger and a half thick. The lute, fit for this, is made with Windsor loam, or with French clay, moistened with three or four times as much of ox-blood diluted with water. But, before you cover the insides of your Furnace with this lute, you must first put within the Furnace small iron-bars, equal in length to the diameter of the oven, quadrangular, prismatical, half an inch thick, having their extremities supported by the ledge, and three fourths of an inch distant from each other; and you must fasten them so, that their flat sides may be oblique with regard to the transverse section of the Furnace, and, that the two opposite angles may look one upwards and the other downwards, the bars must not be laid flat, but edge-ways; by which situation, you hinder the ashes of the fuel of the fire from being detained too long, between the interstices of the said iron-bars, and from making an obstruction, that would oppose the free draught of the air. The Furnace, being then covered over with lute, and dried up by a gentle heat, is at last fit for docimastical operations, and especially for such as must be performed in the assay-oven.

If then an operation is to be made in the Furnace hitherto described, you must let through the four lower holes above described, of the Furnace *o o*, placed before and behind, and directly opposite to each other, two iron bars one inch thick, and long enough, that their extremities on every side may jut out of the holes a small matter. These serve to support the muffle, and its bottom. You then introduce the muffle thro' the upper aperture of the Furnace, and place them upon the above described iron bars, in such manner that the open forefide of it be contiguous to the inward border of the upper door *f*. The fuel of the fire is introduced through the top of the Furnace; the cover of which, on this account, must be moveable, and not very heavy as *q*. The best fuel for the fire is charcoal made of the hardest wood, especially of beech, broken into small pieces of the bigness of an inch, wherewith the muffle must be covered over some inches high. We then reject larger bits of coals, because they cannot fall through the narrow interstices, between the sides of the muffle and those of the Furnace, and cannot of course sufficiently surround the circumference of the muffle: whence it happens, that there are on every side places void of fuel, and the fire is either not strong enough, or unequal. But, if, on the contrary, you use coals too small, then a great part fall immediately through the interstices of the grate into the ash-hole; and the tenderest particles of them turn too soon into ashes; and, by increasing the heap of ashes, obstruct the free draught of the air, which is here greatly requisite.

A perfect management of the fire is most commonly necessary, in the performing of operations in this Furnace: therefore, the reader must give attention to what follows. If the door of the ash-hole *e* is quite open, and the sliders of the upper door *f* drawn towards each other, so as to touch one another in the middle of the door; and, if besides the cover *q*, and the funnel *t*, adapted to its tube *r*, is upon the top *d* of the Furnace, the fire will then be in the highest degree possible: though, in the mean time, it is hardly ever necessary to put the funnel on, except in a very cold season. But if, after having disposed the Furnace in the manner just described, you put red burning coals into the open upper door *f* of it, the fire is still more increased thereby: however, this artifice is never, or very seldom, necessary. When you shut the upper door, with only that slider, that has a narrow oblong hole in it *m*, then the heat becomes a little less: but it diminishes still more, when you shut the door with the other slider, that has in it the semi-circular hole *n*, which is larger than that of the first slider: nay, the heat again is less, when you take away the funnel put at top of the cover: finally, the door of the ash-hole being either in part or totally shut, the heat is still diminished, because the draught of air, so necessary to excite the fire, is thereby hindered. But if, besides all these, you likewise open the upper door quite; then the cold air rushing into the muffle, cools the bodies put under it, that are to be changed to a degree never required in any operation, and such as will entirely hinder the boiling of lead. If, during the operation, the fire begins to decay, or to grow unequal, it is a sign, that there are places void of coals, between the sides of the Furnace and those of the muffle: therefore, in this case, you must stir your coals on every side, with an iron rod, which is to be introduced through the upper hole *p* of the Furnace, that they may fall together, and thus act in a proper manner, and equally.

However, you are to observe, concerning the regimen of the fire just described, that, though the apparatus is made with all the exactness mentioned, the effect does not always answer it: the cause of which difference has most commonly its origin in the various dispositions of the air. For as every fire is more excited by coals, in proportion as the air more condensed, and more quickly agitated, strikes them more violently (which the effect of bellows plainly shews) it thence appears, that in warm and wet weathers, when the atmosphere is light, the fire must be less efficacious in Furnaces; that likewise, when several Furnaces, situated near each other, are burning at the same time, the fire is in part suffocated; because the ambient air is thereby rendered more rare and lighter. The same effect is produced by the sun, especially in summer-time, when it shines upon the place where the Furnace is situated. The atmosphere, on the contrary, being heavier in cold dry weather, excites a very great fire.

The heat of the fire acts the stronger upon the bodies to be changed, as the muffle put in the Furnace is less; as the said muffle has more and larger segments cut out of it; as the sides of this muffle are thinner; in short, as there are more vessels placed in the hinder part of the muffle; and on the contrary.

In this case, when many of the conditions requisite for the exciting of fire are wanting, then indeed the artificer, with all his skill, will hardly be able to excite the fire to a sufficient degree, in order to perform operations well, in common assay-ovens, even though he uses bellows, and puts coals into the upper door of the Furnace. For this reason, I have put the grate almost three inches below the muffle, lest the air, rushing through the ash-hole, should cool the bottom of the muffle, which happens in common assay-ovens; and again, that the smaller coals, almost already consumed, and the ashes, may more easily fall through the interstices of the grate, and the larger coals still fit to keep up the fire, be retained. Finally, I have added the funnel *t*, that, the blowing of the fire being, by means of it, increased as much as possible, this might at last be carried to the requisite degree: for the fire may always be diminished, but not always increased at pleasure, without the assistance of a proper apparatus.

FU'SILE *Marble*, a very common but very improper term used for the green or greenish grey marble full of small sea shells, of which the slender pillars of our Gothic buildings are made.

G.

G.

GAD-*Bee*, in natural hiftory, the common name for a winged infect, called alfo the dun-fly, or ox-fly; a creature very troublefome to cows, horfes, &c.

This creature, examined by the microfcope, has feveral peculiarities worthy of obfervation. It has, like the gnat, a long probofcis, with a fharp dart, or two darts, fheathed within it; the ufe of thefe darts is to penetrate the flefh of animals, for the fucking their blood; whereas the probofcis can only ferve to fuck the dews from flowers, &c.

The eggs of this fly are laid in the waters, and there produce a very remarkable fort of maggot. It is a brown one, of a long flatted figure, with a pencil of fine downy hairs at its tail, which is fpread into a circular form on the furface of the water, while its head is funk down in fearch of food. When the creature would defcend toward the bottom, thefe hairs are made to approach one another in an oval form, and in this ftate they inclofe a bubble of air, by means of which it is able to rife again; and, if this bubble by any accident efcapes, the creature immediately fqueezes another out of its own body to fupply its place. The fnout of this maggot has three divifions, whence are thruft out three little pointed bodies, like ferpents tongues. Thefe maggots are very common on the furface of ditch water, and the motion of their inteftines is very fingular and obfervable. *Baker on the Microfcope.*

GADD'ING, among miners, the digging the ore out of the veins with an inftrument called a gad; which is a fmall punch of iron with a long handle of wood. One of the miners holds the gad in his hand, directing the point to the proper place, while the others drive it into the vein with a large fledge or hammer.

GA'DWALL, in zoology, the name of a fpecies of duck that frequents frefh waters, and is called, in fome parts of England, the gray. It is called anas ftrepera by authors. It is of the fize of the widgeon, or fomething larger; its body is of a longifh fhape, and its rump black; its back is brown, but the edges of the feathers are edged with white; the front of the head, and upper part of the throat, are white, fpotted with fmall brown fpecks; the head is of a bluifh black, the throat of a greyifh white, and towards the breaft fomewhat reddifh; the upper part of the breaft and the fhoulders are beautifully variegated with brown, white, and black; the breaft is white, and belly brownifh, with fmall tranfverfe ftreaks of black; the beak is blackifh and yellow, and the legs are whitifh. The female is different from the male in many refpects, particularly it wants the blacknefs of the rump; but both the male and female are diftinguifhed at fight from the other fpecies, by having marks of three different colours one above another on their wings; thefe are white, black, and a reddifh brown. *Ray's Ornithol.*

GALE, in botany, the name of a genus of plants, whofe characters are:

The leaves are alternate; the male flowers are produced on pedicles from the alæ of the leaves, and difpofed on a ftalk, in the form of a long fpike; thefe flowers are naked, and adorned with fix ftamina, which appear like branches from them. The ovary is feated in another place of the fame plant, on a much fhorter pedicle, being lodged within a tetraphyllous caducous calyx, and furrounded with other male flowers; it is of a globofe figure, here and there irregular, and containing one feed.

It delights in heaths and uncultivated foils, as well as in watery and marfhy places; and is found in great plenty in the ifle of Ely, among the marfhes, in a boggy foil, and in many fuch places in the north of England, and near the town of Wareham, in Dorfetfhire. The flowers appear in May and June, and the feed is ripe in July and Auguft.

Its extraordinary bitternefs demonftrates it to be of a drying and difcuffive quality; but we are told, that it is principally ferviceable in killing and expelling worms, whether it be taken inwardly, or outwardly applied. The leaves and branches are ufed in fummer, to adorn the windows and chimneys of chambers and parlours, for the fake of the extraordinary fweet fmell diffufed by the flowers and buds; the fame, laid in chefts among cloaths, not only render them fweet-fcented, but keep away moths. Simon Pauli tells us, that the Polanders ufed to deftroy the lice in their fwine by this plant; which being ftrewed in the hog-fties, all the lice die in the fpace of a few hours, and the nits never come to be animated. And ferpents are never known to fettle, or have their nefts, in thofe marfhes where Gale grows, or ever to approach, much lefs to creep over them. Some boil the flowers, inftead of hops, in their beer; which, for that reafon, affects the head, and foon induces ebriety. In Bergen, and other places of Norway, they commonly prepare an ointment of Gale pulverized and May butter, which is found to be very efficacious in the moft ftubborn itch. *Raii Hift. Plant.*

GALE'NA, a name given by mineralifts to a fpecies of poor lead ore. It was alfo the original name given by Andromachus to the theriaca, from its effect in bringing on a pleafing calm over the blood and fpirits on taking it.

GALENA *inanis*, in minerology, a name given by authors to a glittering fubftance, very much refembling fome of the plated ores of lead, but really containing none of that metal. It is more ufually called mock-lead and blende.

GA'LEOPSIS, *hedge-nettle*, in botany, a genus of plants, whofe characters are:

The calyx is quinquefid and funnel-fhaped; the upper lip, or galea, is entirely hollow; the lower lip, or beard, trifid; the middle fegment being the greateft.

The Galeopfis fmells of bitumen, or fœtid oil: it has an herby tafte, a little faltifh, aftringent, and does not ftain the blue paper; which makes us conjecture, that its falt participates very much of the natural falt of the earth, which in this plant is involved in a great deal of fulphur, and terreftrial parts.

It is vulnerary, and very fweetening: an oil made of it by infufion is excellent for burns, and for wounds of the tendinous parts. In the country, they ufe fucceffively the infufion of its leaves and flowers, for a nephritice cholic, fcrophulous tumors, and the pleurify. An extract may be prepared of it to ferve during the winter. *Martyn's Tournefort.*

It has the reputation of difcuffing hard tumors, cancers, pani, and parotides; and is recommended againft putrefactions, gangrenes, and fpreading ulcers. Boerhaave efteems it excellent in hyfteric fits.

GA'LEUS *glaucus*, the blue fhark, a very fierce and voracious fifh of prey. It is of a fine deep blue colour on the back, and of a bright filver white on the belly. The fkin is fmoother than that of the white fhark, and the nofe long-pointed, and fomewhat flatted. The noftrils are long, and placed tranfverfly to the length of the nofe. The fockets of the eyes are of an elliptic figure, but the eyes themfelves are exactly round, and have a membrane, which, at times, the fifh draws over them, and there are no cavities behind the eyes. The teeth are not fo numerous as in the white fhark, there being only two rows of them; but thefe are very large and triangular, exactly of the fhape of the gloffopetræ. The tail is bifid, and one portion of it much larger than the other. It is very voracious of human flefh, and will follow clofe under the fhore, if there is depth enough, and a man is walking there. It is fometimes found on the Englifh fhores, and has been caught on the Cornwal coaft. *Wilaughby's Hift. Pifc.*

GALLI'NA *Guinea*, the Guinea hen, in zoology, the name of a fpecies of gallinaceous fowl, of the fize of the common hen, but with a longer neck. Its body is floped like that of a partridge, and its colour is all over a dark grey, very beautifully fpotted with fmall white fpecks; there is a black ring round the neck; its head is reddifh, and has on its top a hard horny protuberance, of a brown colour; it is blue under the eyes, and has a red flefhy appendage hanging down from thence. They naturally herd together in large numbers, and breed up their young in common; the females taking care of the broods of others, as well as of their own. They breed very well with us. *Ray's Ornithology.*

GA'LLING.— Good horfes are often fubject to gall upon their backs, and the utmoft care ought to be taken to prevent or cure it. The beft method of prevention is, to take a hind's fkin, well furnifhed with hair, and fit it neatly beneath the pannel of the faddle, fo that the hairy fide may be next the horfe; this does not harden by fweat, but keeps the horfe from Galling. This is alfo a method that fhould never be omitted with horfes that are newly cured of fuch a hurt, as it will prevent their falling into it again. In long journeys, and in horfes that are fubject to gall, it is always proper to take off the faddle, as foon as the horfe is brought in, and examine whether the back be at all preffed, or pinched in any part: it will be well

well to re-examine it after an hour or two, to fee what effect the ftanding has had; for often the part hurt will not fhew it at firft, but will fwell very violently afterwards. In this cafe, where the fkin is not fretted, but a fwelling comes on, a bag of coarfe cloth fhould be filled with warm dung, and tied upon the fwelling, which will not only prevent it from growing worfe, but will take it often quite down; or the fwelling may be well rubbed with good brandy, laying on a paper foaked in it. If the fkin be broken, a mixture of red wine and fallad oil is a good remedy.

GA'LLIUM, *cheefe-rennet*, in botany, a genus of plants whofe characters are: it refembles the mollugo in every thing, only its leaves are even fofter than thofe of that herb.

This plant, from a long flender fpreading root, fends forth many fquare weak ftalks, a foot or two high, befet at the joints with flender narrow leaves, about an inch long, fet in a circle; the ftalks of a dark green colour. On the tops of the ftalks, as well as on the fmaller branches, which come out of the fides, grow thick fpikes of fmall, yellow, monopetalous flowers, divided into four fegments, of a pleafant fmell; each of which is fucceeded by two fmall globular black feeds: it grows on banks, and dry barren places, flowering in June and July. The whole herb is ufed.

The plant is drying and incraffating, good in ftopping all kinds of fluxes and hæmorrhages, and for the cure of wounds: fome commend the decoction of it for the gout; and a bath made of it is refrefhing to wafh the feet of perfons tired with over walking. In the northern countries they ufe this herb for the making their cheefes, inftead of rennet, whence it is called cheefe rennet; the flowers containing an acidity, which may be got by diftillation. This is a plant but feldom ufed in the fhops.

This plant is vulnerary and deterfive; it is ufed in Catalonia for the epilepfy. The fyrup made with the juice of its flowers is very aperitive and emmenagogic. Tabernæmontanus fays, that the decoction of it is excellent for the dry fcab of young children, provided you bathe them often with it. *Martyn's Tournefort.*

GALLS (*Dict.*)— The Galls caufed by different infects have a very different internal ftructure; fome of them have only one large cavity within, in which a number of the animals live in community; others have feveral fmall cavities with communications between each; and others have different numbers of little cellules, each feparate, and having no communication with the others: there are fometimes a hundred of thefe cellules in one Gall, fometimes only two or three; and finally, there are others, in which there is only one cavity inhabited by one infect. The creatures of thefe two laft kinds live in perfect folitude during the worm ftate, and can have no knowledge of any other living creature befides themfelves, till they have paffed through the intermediate ftate of chryfalis, and become winged animals, like thofe to which they owed their origin, and are ready to lay eggs themfelves. The general divifion of Galls into thefe claffes admits of a vaft number of fubdiftinctions under each, from the different figure and confiftence of the feveral fpecies. Some of them are fo hard, that they equal, or exceed, the hardnefs of the wood of the tree they grow upon; and, when cut, appear compofed of fibres, much more denfely and clofely arranged: others are foft and fpongy, and refemble fome of the tender fruits in appearance. The firft kind are ufually called Gall-nuts, and the latter apple Galls, or berry Galls. The common Galls, ufed in dying, are of the firft kind, and what are called oak-apples, and oak-grapes, are of the latter. The oak produces feveral of this laft fpecies of Galls, fome of which are oblong, and others round, refembling grapes, goofeberries, and other fruits; thefe are alfo ufually beautifully coloured, fome being of a bright red, others of a bright yellow. Thefe Galls of the oak are of the auftere tafte of the juices of that tree; but thofe of other plants are often well tafted. There is a fpecies of fage, well known by the name of apple-fage, the leaves of which afford a lodging to the worm of a peculiar fpecies of fly, and this Gall grows to a very confiderable fize, fo as to have obtained the name of an apple from its refemblance to this fruit; thefe are eaten by the people of the eaftern nations, and are commonly fold in the markets of Conftantinople, and other places. A plant very common with us, the ground-ivy, has the fame property: its leaves are often loaded with Galls on their under fide, which are very green and juicy, and of no difagreeable tafte. Mr. Reaumur gives us an account of their being one year fo plentiful in the neighbourhood of Paris, that the poor people eat them both raw and boiled as food. *Reaumur's Hift. Inf.*

Box GALLS, in natural hiftory, the name given by authors to a very fingular kind of Galls, of a conic figure, with a conic top, or cover refembling a wooden box, and inclofing a white worm, in the manner of the other vegetable lodgements of the fame kind; this fort of Gall is found only on the leaves of the lime-tree. It is common to obferve the leaves of this tree, in the month of July, to be pierced through with feveral round holes of about a tenth of an inch in diameter, and as exactly circular, as if a round piece of the leaf had been taken out in each place by an inftrument. Mr. Reaumur, to whom the world owes the difcovery of this fingular fpecies of Gall, was led to the obferving it by meeting with leaves thus pierced, and then examining others, till he found fome which had on them the box Galls, which give origin to thefe holes.

Bramble GALLS, a fpecies of Galls found on the branches of the common wild bramble. Thefe are often no other than tumefactions of the ftalk, for the fpace of an inch, or thereabout, which fometimes form only fo many thick cylindric pieces; at other times they are of the fhape of an olive, and fometimes they affect only one fide of the branch: in all cafes, however, the tumid part, or Gall, is much harder than the other parts of the branch, which are in their natural ftate. Thefe Galls are very common in June and July, and in the other fummer months, and, when cut, either longitudinally or tranfverfly, they are found to be inhabited by a great number of worms of an oblong figure, and yellow colour; thefe live in the interftices, which they make between the woody fibres, and thefe interftices they alfo make themfelves, by eating away the fubftance of the wood; for, if the Galls are opened when old, they are found to have a large cavity filled with the fragments of the woody fibres, which the worms have eat to pieces; and there are ufually twenty or thirty worms in every Gall.

GALL-*infects*, in natural hiftory, the name of a clafs of infects, fo called, from their refemblance to fmall Galls, or vegetable protuberances of a like kind upon trees. They are indeed fo like thefe fubftances, as to have been by many miftaken for them, and thought not of the animal, but of the vegetable kingdom. Thefe infects pafs a very great part of their lives, even many months together, faftened againft the leaves or ftalks of plants, without any appearance of life or motion; and this is the time in which they acquire their ftated growth. They are in this ftate as immoveable as the branch they are fixed on, and feem to make a part of it. Their exterior form is remarkably plain and fimple, and, the more the creature increafes in growth, the lefs appearance of life it fhews; and, even when it has acquired its maturity, and is in a condition to depofit its eggs, for the propagation of its fpecies, it then appears leaft of all of an animal form, and more, than in any other ftate, refembles a Gall, or fuch vegetable protuberance. Not only the vulgar and incurious have been deceived by this appearance, but the accurate Count Marfigli, among others, after very attentively examining the Gall-infects of one fpecies, remained feemingly convinced that they were real vegetable excrefcences.

The Gall-infects are ufually found on the ftalks and branches of trees, fhrubs, and perennial plants. There are fo far from being particular trees or plants allotted for their production, that very few are without them, and even the fame fpecies are found on very different fpecies of vegetables. The figures and colours of thefe animals enable us to diftinguifh feveral diftinct kinds of them; they are all very fmall, even at their full growth, and fome of them, in their perfect ftate, refemble little round balls, faftened to the branches of trees, &c. by a very fmall part of their furface. Of thefe round ones, fome fpecies never arrive at a fize beyond that of a pepper-corn; others acquire that of a large pea; other fpecies of them are of the figure of a fphere, part of which has been cut off, and thefe are fixed on the trees by the part feemingly cut; others are of the figure of elongated fpheres, the greater axis of which is raifed above the branch; others are fomewhat flatted, and more pointed at one end than at the other; others are of the figure of a kidney, and thefe are fixed by the part where the cavity is; others refemble, in figure, the half of an oblong fpheroide, and thefe alone furnifh a large number; thefe are divided, as it were, along their larger axis, and have fome fort of refemblance to a boat turned upfide down.

GA'LLOWS *of a plough*, a name given by our common farmers to a part of the common plough, from its refembling a gallows made for the execution of malefactors, in its form; being compofed of three pieces of timber, one placed tranfverfely over the heads of the other two. The Gallows are a part of the plough-head; they are fixed into the box of the plough, or that part through which the axis of the wheels paffes. They make an angle with the box inclining upwards. The upper, or tranfverfe fpecies, is notched in feveral places, and ferves to fuftain the wilds, a pair of irons, to which a ring and hooks are faftened, and to thefe the chains of the harnefs, by which the whole plough is drawn along.

In fome other parts of England they call this whole part of the plough the three pieces, being iron inftead of timber, by the name of the wilds; and the Gallows of the plough is then the tranfverfe piece at the top of the crow-ftaves. *Tull's Hufbandry.*

GA'LLY-*worm*, in zoology, an infect known by moft writers under the name of iulus. It is a land infect, with a long body, compofed of a great number of rings, and furnifhed with a great number of feet. It is found very frequently in gardens, and, when touched, has the power of rolling itfelf up into a ball. *Ray's Hift. Inf.*

GAME-*cock*.— The beft feafon for the breeding the Game-cock is, from the beginning of February to the middle or latter end of March; the neft for the hen is to be made of fweet and clean ftraw, and fhould be placed in fome warm corner, out of the way of difturbance from other fowls; for this fort of inter-

interruption provokes this quarrelsome bird in such a manner, as to endanger the eggs. That she may never have occasion to leave the nest, and cool her eggs, it will be proper to lay all sorts of food, that she is likely to approve of, before her; and to put clean water every day, not only for her to drink, but to wash and trim herself in; some ashes, sand, and gravel should also be sifted on about the nest. The chickens are hatched in about three weeks, and the nest is to be carefully watched about this time, for there are always some of the chickens hatched before the others; these should be taken away, as soon as out of the shell, and laid before the fire, or in some warm place in wool, and, as soon as the rest are hatched, these should be given back to the hen: they are not to be suffered to go abroad for the first fortnight, and the room they are kept in must be boarded, all other floors being too cold and too moist. At about a month old the chickens may be turned out into a walk of some fresh grass, that they may feed at liberty, and eat worms and other insects; but there must be no puddle of water in the place, for they are apt to get into such, and it occasions them a number of diseases. As soon as the comb and wattles appear on the cocks, they must be cut away, and the sore place anointed with fresh butter till it is well. The chickens may all be suffered to run together till they begin to peck one another, then the cocks are to be separated; each must have his particular walk, and, the more free from disturbance this is, the better. The place of feeding them must either be a boarded floor, or a very soft and dry piece of ground. If the place be hard, as a stony pavement, or a plaistered floor, the taking up their food will injure and blunt their beaks, so that they will never be able to hold fast afterwards. Any white corn is good for the Game-cock in his walks, and so is a white bread toast steeped in ale; at times, this may be given him steeped in urine, which will serve to scour and cool him very well. There never should be more than three hens allowed to one cock in his walk, for, if there are more, he will consume his strength in the treading; and, though his courage may not fail, yet he will never have the ability to go through a battle. Care is to be taken also of his roosting-place, that the perch be not too small in the gripe, and be so placed, that he may sit on it without straddling; if the perch be crooked, it is also very disadvantageous, for it will accustom the cock to such an uneven disposition of his feet, that he will be no good striker in the battle. The best method of contriving the roosting-place is, to have a row of short perches, about eight inches long, and the lowest ten inches from the ground, that he may ascend with more ease, and, when he is come to the roosting-perch, be constrained to sit with his legs close together. A cock, bred in this manner, may be fought young, but the best method is, not to hazard a battle till he is somewhat more than two years old.

GA'NET, in zoology, the name used in Cornwal, and some other parts of England, for a large species of larus, or scalpel, called by authors cataractes. It is one of the largest birds of the larus kind, being larger than the common duck. Its beak is stronger, shorter, and more crooked than that of any other bird of this kind; it is web-footed, but has the strongest and sharpest claws of all the birds of that kind: its back is of a dusky, brownish, ferrugineous grey, like that of the buzzard; its belly and breast are paler, but of the same dye, and its long wing feathers are black; its tail also is all black. It is a very bold and voracious bird; it follows the shoals of pilchards and other fish, and picks up vast numbers of them. It is very common in the western coasts of England. *Ray's Ornithology.*

GA'NGRENE (*Dict.*)— The following medicines are, by Heister, recommended for the several intentions of a cure in a Gangrene.

A fomentation which digests, stimulates, and resists putrefaction.

Take of quick-lime-water, one pint; of camphorated spirit of wine, three ounces; and of the spirit of sal ammoniac, half an ounce; mix all together.

Let this preparation be frequently applied warm, with proper compresses: the same intention is also excellently answered by a pint of quick-lime-water, mixed with an ounce of mercurius dulcis. Heister tells us, that, in the hospital of Amsterdam, the surgeons, with great success, use the following fomentation against a Gangrene:

Take, of the spirit of wine, three ounces; of the powders of aloes and myrrh, each half an ounce; and of Egyptian ointment, three ounces: mix all together.

Or spirit of wine, gently boiled with aloes, myrrh, and saffron; or camphorated spirit of wine, mixed with Venice treacle; or the spiritus theriacalis, or the spiritus matricalis, mixed with about a sixth part of elixir proprietatis; or, what Garengeot so much extols, warm wine, mixed with simple or camphorated spirit of wine, either by itself, or quickened with sal ammoniac; which he recommends as a highly efficacious medicine for reviving the gangrenous parts.

Or take of leaves of scordium, southernwood, and recent rue, each two handfuls; of chamomile flowers, one handful: boil in a sufficient quantity of common water, strain off the liquor, and, to every two pints of it, add, of the spiritus vini theriacalis, four ounces; of Venice soap, two ounces; and of sal gemmæ, half an ounce.

These fomentations are to be applied frequently every day, with linen or woollen cloths; applying over them, in order to preserve the heat, folded cloths and heated bricks.

A penetrating, resolvent, and digestive cataplasm, for restoring the circulation of the blood in the affected part, may be prepared in the following manner:

Take of the herbs scordium, mallows, wormwood, and feverfew, each two handfuls; of mint and southernwood, each one handful.

Boil these in a sufficient quantity of oxycrate, in a close vessel, to the consistence of a cataplasm; to which add, of sal ammoniac, half an ounce; of the meal of linseed, two ounces; of the oil of rue, or chamomile, by infusion, an ounce and an half: and, before the cataplasm is applied, let it always be sprinkled with camphorated spirit of wine, or the spiritus vini theriacalis, in order to render it more efficacious: or, instead of this, the following cataplasm, recommended by Koenerdingius, may be used:

Take of the crums of wheaten bread, one pound; of the powders of wormwood, scordium, and rue, each one handful; of wine, a quantity sufficient to reduce them to the consistence of a cataplasm: after gentle boiling, add four ounces of the spirit of wine, and apply warm.

A fomentation for stopping the spreading of a Gangrene may be prepared in the following manner:

Take of the decoction of barley, or scordium, one pint; of the vinegar of rue, six ounces; of the spiritus vini theriacalis, four ounces; of sea-salt, one or two ounces: to be applied warm with compresses.

A cataplasm for softening the gangrenous crust, and promoting its separation, may be prepared in the following manner:

Take of the flowers of scordium, two handfuls: and of the leaves of mallows, henbane, and marshmallows, each one handful; and of the flowers of lavender, half a handful: boil in vinegar, or oxycrate, to the consistence of a cataplasm: to which add, of the meal of linseed, three ounces; of the oil of linseed, one ounce; and of sal ammoniac, two ounces.

If, in any stage of the disorder, the use of corrosives should be indicated, the celebrated Belloste orders the following preparation, as the most efficacious of all others:

Take of the spirit of nitre, or of aqua-fortis, two parts; and of quick-silver, one part: mix over a gentle heat, till the mercury is dissolved.

With this corrosive liquor, the mortified part is to be anointed, or a little lint, or a linen cloth soaked in it, is to be applied to the corrupted part; for, by this means, the mortified parts will soon be divided from such as are sound and alive. *Heister's Chirurgery.*

GA'RBOARD-*strake*, in a ship, is the first seam next to the keel.

GARBOARD-*plank*, in a ship, the first plank fastened on the keel.

GA'RDEN (*Dict.*)— In a garden, the principal things to be considered, are, 1. The situation; 2. The soil, aspect, or exposure; 3. Water; 4. Prospect.

1. Situation: this ought to be such a one as is wholesome, in a place that is neither too high nor too low; for, if a garden be too high, it will be exposed to the winds, which are very prejudicial to trees; if it be too low, the dampness, and the vermin, and venomous creatures, that breed in ponds, add much to their insalubrity.

A situation on a rising ground, or on the side of an hill, is the most happy; especially if the ground be not too steep; if the slope be easy, and in a manner imperceptible; if a good deal of level may be had near the house; and if it abounds with springs of water; for, being sheltered from the fury of the winds, and the violent heat of the sun, a temperate air will be there enjoyed; and the water that descends from the top of the hills, either from springs or rain, will not only supply fountains, canals, and cascades, for ornament; but, when it has performed its office, will water the adjacent valleys, and render them fertile and wholesome, if it be not suffered to stagnate in them.

Indeed, if the declivity of the hill be too steep, and if the water be too abundant, a garden on the side of it may often suffer, by having the trees torn up by the torrents and floods; and the earth above tumbling down, the walls may be demolished, and the walks spoiled.

It cannot, however, be denied, that the situation on a plain, or flat, has several advantages that the higher situation has not: floods and rains make no spoil; there is a continued prospect of champaigns, intersected by rivers, ponds, and brooks, meadows, and hills, covered with buildings or woods; and the level surface is less tiresome to walk on, and less chargeable, than that on the side of an hill; the terrace walks are not necessary: but the greatest disadvantage of flat gardens is, the want of an extensive prospect, which rising grounds afford.

2. The second thing to be considered in chusing a plat for a garden, is a good earth or soil.

It is scarce possible to make a fine garden in a bad soil: there are

are indeed ways to meliorate ground, but they are very expensive; and sometimes, when the expence has been bestowed of laying good earth three feet deep over the whole surface, a whole Garden has been ruined, notwithstanding the exposure has been southerly and healthful, when the roots of the tree have come to reach the natural bottom.

To judge of the quality of the soil, observe whether there be any heath, thistles, or such-like weeds, growing spontaneously in it; for they are certain signs, that the ground is poor. Likewise, if there be large trees growing thereabouts, observe whether they grow crooked, ill-shaped, and grubby, of a faded green, and full of moss, or infested with vermin; if so, the place is to be rejected: but, on the contrary, if it be covered with good grass fit for pasture, then you may be encouraged to try the depth of the soil.

To know this, dig holes in several places, six feet wide, and four feet deep: if you find three feet of good earth, it will do well; but less than two will not be sufficient.

The quality of good ground is, neither to be stony, nor too hard to work; neither too dry, nor too moist; nor too sandy and light; nor too strong and clayey, which is the worst of all for Gardens.

3. The third requisite is water. The want of this is one of the greatest inconveniencies that can attend a Garden, and will bring a certain mortality upon whatever is planted in it; especially in the greater droughts that often happen in an hot and dry situation, in summer; besides the usefulness of it in fine Gardens, for making jets d'eau, canals, cascades, &c. which are the greatest ornaments of a Garden.

4. The fourth thing required in a good situation is, the view and prospect of a fine country; and, though this is not so absolutely necessary as water, yet it is one of the most agreeable beauties of a fine Garden; besides, if a Garden be planted in a low place, that is buried, as I may say, and has no kind of prospect, it will be not only disagreeable, but unwholesome, by being too much shaded and obscured; as the trees will rather retain insalubrious damps, than communicate the refreshing air, that is so purifying to vegetable nature.

In short, a Garden necessarily requires, besides the care of the gardener, the sun, a good soil, a full, or, at least, an open prospect, and water; the last, above all, and it would be egregious folly to plant a Garden where any of these are wanting.

In a fine Garden, the first thing that should present itself to the sight, should be an open lawn of grass, which, in size, should be proportionable to the Garden: in a large Garden, it should not be less than six or eight acres; but, in middling or small Gardens, the width of it should be considerably more than the front of the house; and, if the depth be one half more than the width, it will have a better effect. The figure of this lawn need not be regular; and if, on the sides, there are trees planted irregularly, by way of open grove, some of which may be planted forwarder upon the lawn than others; whereby the regularity of the lawn will be broken; it will render it more like nature; the beauties of which should always be studied in the laying out and planting of Gardens; for, the nearer these Gardens approach to nature, the longer they will please: for what is a Garden but a natural spot of ground, dressed, and properly ornamented? There are those who have erred in copying of what they call nature, as much as those who have drawn a whole Garden into straight lines, great alleys, stars, &c. by bringing the roughest and most deformed part of nature into their compositions of Gardens: as, for instance, where the ground has been naturally level, they have, at great expence, made hollows and raised molehills; so that the turf has been rendered not only more unpleasant to walk upon, but much worse to keep: and, after all the pains that have been taken to ape nature, the whole is as easy discovered to be the work of art, as the stiffest slopes, and the most finished parterres.

The great art of laying out of Gardens is, to adapt the several parts to the natural position of the ground, so as to have as little earth to remove as possible: for this is often one of the greatest expences in making of Gardens; and it may with truth be affirmed, that, wherever this has been practised, nine times in ten, it has proved for the worse: so that, if instead of levelling hills, to form large terraces, stiff slopes, and even parterres, as has been too often practised; or the sinking of hollows, and raising of hills, as hath by others been done; the surface of the ground had only been smoothed, and well turfed, it would have had a much better effect, and been more generally approved than the greatest number of these Gardens, which have been made with an infinite expence both of time and money.

The next thing to be observed is, to contrive a dry walk, which should lead quite round the whole garden: for, as Gardens are designed to promote the exercise of walking, the greater the extent of this dry walk, the better it will answer the intent; since in bad weather, or in dewy mornings and evenings, when the fields are unpleasant, or unsafe to walk over, these dry walks in Gardens become useful and pleasant: and such walks, if laid either with gravel or sand, may lead through the different plantations, gently winding about in an easy natural way; which will be more agreeable than those long straight walks, which are too frequently seen in Gardens.

Another thing absolutely necessary is, where the boundaries of the Garden are fenced with walls or pales, they should be hid by plantations of flowering shrubs, intermixed with laurels, and some other ever-greens, which will have a good effect; and at the same time conceal the fences, which are disagreeable, when left naked and exposed to the sight.

In situations where there is a good supply of water, the designer has room for adding one of the greatest beauties to the Garden, especially if it will admit of a constant stream: for, in such places, if the water is properly conducted through the Garden, it will afford infinite pleasure: for, although these streams may not be sufficient to supply a large surface, yet, if these narrow rivulets are judiciously led about the Garden, they will have a better effect than many of the large stagnating ponds or canals, so frequently made in large Gardens: for where these pieces of water are large, if the boundaries can be seen from one point of view, they cannot be esteemed by persons of judgment; and frequently these standing waters are brought so near the house, as to render the air damp and unhealthy; and many times they are so situated, as to occasion this inconvenience, and, at the same time, are not seen to any advantage from the house.

Where wildernesses are intended, these should not be cut into stars and other ridiculous figures; nor formed into mazes or labyrinths, which in a great design is trifling: but the walks should be noble, and shaded with tall trees; and the spaces of the quarters planted with flowering shrubs and ever-greens; whereby they will be rendered pleasant at all seasons of the year: and, if there are hardy sorts of flowers, which will thrive with little care, scattered about near the sides of the walls, they will have a very good effect, in making a variety of natural beauties almost through the year.

The situation of these wildernesses should not be too near the house, lest they should occasion damps; therefore it is much better to contrive some open groves, through which there may be a communication, under shade, from the house to these wildernesses; which are much the best when they are planted at the farthest part of the Gardens, provided they do not obstruct the view of fine objects.

Fountains are also very ornamental to a Garden, if they are magnificently built, and where a constant supply of water can be obtained: but, if they are meanly erected, or have not water to keep them constantly running, they should never be introduced into Gardens; for nothing can be more ridiculous than to see a dry fountain, which, perhaps, at a great expence, may have water forced up, to supply it for an hour or two, and no more; and this, perhaps, not in dry seasons, when there is a general scarcity of water.

When trees have been long growing in a Garden, nothing can be more disagreeable than to have them destroyed, to alter the Garden according to the fashion of the time; because it requires much time to bring up trees to such height as to afford shade and shelter: and, as time is precious, so, where the disposition of the Garden is altered, there should be great attention given to the preservation of all the good trees, wherever they can be either useful or ornamental.

There is another essential part of Gardening, which cannot be too much considered by persons who design Gardens; which is that of adapting the several sorts of trees and shrubs to the situation and soil of the garden; as also to allow the trees a proper share of room: but, however necessary this will appear, yet very few persons have made this their study: insomuch that, when one views many modern gardens, and sees the great number of trees and shrubs, which are crouded into them, one would be induced to believe, that private interest has had a greater influence, than any other motive, with the designers. Indeed this fault may often be ascribed to the master, who perhaps is too much in haste for shade and shelter; so will have three or four times the number of trees and shrubs planted, as should have been; or that can remain long without injury, where the plantations succeed: and to this over haste are owing the miserable plantations of large trees, so often seen in gardens and parks; where trees of all sorts, and of any age, are taken out of woods, hedge-rows, &c. and removed at a great expence to stand and decay annually, till they become so many dead sticks, than which nothing can be a more disagreeable sight to the owner, who, after an expectation for several years, attended with an expence of watering, digging, and cleaning, finds himself under a necessity either of replanting, or giving up the thoughts of having any. Numbers of persons have indeed amused themselves with the hopes of success, by seeing these new planted trees put out branches for a year or two which they generally do; but in three or four years after, instead of making a progress, they decay at the top, and continue so to do gradually, until they quite perish; which perhaps may not happen in eight or ten years, especially if no severe winter, or very dry summer, intervenes: either of which generally proves fatal to these plantations; so that persons may be led on with hopes, for so many years, in the best part of their lives, when there is a certainty of their falling, or at least of their never increasing in size. *Miller's Gard. Dict.*

GA'RNET, aboard a ship, is a tackle having a pendant coming from the head of the main-mast, with a block strongly fixed

fixed to the main-ſtay juſt over the hatch-way, in which block is reeved the runner, which hath an hook at one end, in which are hitched the ſlings; and at the other end is a double block, in which the fall of the runner is received; ſo that by its means any goods, or caſks, that are not over heavy, may be haled and hoiſed into, or out of the ſhip; when this Garnet is not uſed, it is faſtened along by the ſtay at the bottom of it.

GARNET *colour*. To give this colour to glaſs, the workmen take the following method: they take equal quantities of cryſtal and rochetta frit, and to every hundred weight of this mixture they add a pound of mangancſe, and an ounce of prepared zaffer; theſe are to be powdered ſeparately, then mixed and added by degrees to the frit while in the furnace: great care is to taken to mix the manganeſe and zaffer very perfectly, and, when the matter has ſtood twenty-four hours in fuſion, it may be worked. *Neri's Art of Glaſs*.

GARNET *paſte*. The making the counterfeit Garnet in paſte is done in three different proportions of the ingredients, which are theſe:

Take prepared cryſtal two ounces, common red lead ſix ounces, manganeſe ſixteen grains, zaffer three grains; mix all well together, and put them into a crucible, cover it with a lute, and ſet it in a potter's kiln for twenty-four hours.

Or take cryſtal two ounces, minium five ounces and a half, manganeſe fifteen grains, zaffer four grains; mix them well together, and leave room for their ſwelling in the pot; bake them twenty-four hours in a potter's kiln.

The laſt method is this: take cryſtal prepared two ounces, minium five ounces, mix them, and add manganeſe fifty-two grains, zaffer ſix grains; mix them well together, and let all be baked, in a pot well luted, in a potter's kiln for twenty-four hours.

The firſt of theſe makes a very handſome Garnet of the common tinge; the ſecond a deep one with ſomething of a violet tinge, as many of the natural Garnets have; but the third makes infinitely the fineſt and brighteſt. *Neri's Art of Glaſs*.

GAVO'TTA, or GAVOTTE, in the Italian muſic, is a kind of dance, the air whereof has two ſtrains, briſk and lively, and in common time; each of its ſtrains are played twice over; the firſt has uſually four or eight bars, and the ſecond contains eight, twelve, or more. The time begins with a minim, or two crotchets, or notes of equal value, and the hand riſing; and ends with the fall of the hand upon the dominant, or mediant of the mode; never upon the final, unleſs it be a rondeau. And the laſt begins with the riſe of the hand, and ends with the fall upon the final of the mode. *Breſſ. Dict. Muſ.*

Tempo di GAVOTTA, in the Italian muſic, is when only the time or movement of a Gavotta is imitated, without any regard had to the meaſure or number of bars, or ſtrains. We often find parts of ſonnatas, which have this phraſe to regulate their motion. *Breſſ. Muſ. Dict.*

GAZE'LLA, in natural hiſtory; ſee ANTILOPE.

GE'BERRS, the name of a ſect in Perſia, who worſhip the everlaſting fire, near Baku. See *Everlaſting* FIRE.

Zoroaſter, the founder of this religion, appeared about the year of the world 2860. This great philoſopher was ſtruck with the demonſtrations of that ſelf exiſtent being, who is the author of all good. Being at a loſs how to account for the introduction of evil into the world, he imagined there were two principles; one the cauſe of all good, which he repreſented by light; and the other the cauſe of all evil, which he figured to himſelf by darkneſs. He conſidered light as the moſt perfect ſymbol of true wiſdom and intellectual endowment, and darkneſs the repreſentative of things hurtful and deſtructive. From hence he was called to inculcate an abhorrence of all images, and to teach his followers to worſhip God only, under the form of fire; conſidering the brightneſs, activity, purity, and incorruptibility of that element, as bearing the moſt perfect reſemblance to the nature of the good Deity. For the ſame reaſon the Perſians ſhewed a particular veneration to the ſun, which was founded on their belief, that it is the nobleſt creature in the whole world, and that the throne of the Almighty is ſeated in it. This good principle which they acknowledge to be the omnipotent creator and preſerver of all things, they called Yezad, and alſo Ormuzd, which ſignify ſupreme. The evil principle they ſtiled Ahariman, i. e. the devil. Some have aſſerted that the antient Perſians held a co-eternity of theſe two principles; but others, who ſeem better acquainted with the true tenets of this religion, agree that Ormuzd, according to the Perſian mythology, firſt ſubſiſted alone; that by him both light and darkneſs were created; and that Ahariman was created, or rather aroſe from darkneſs. In the compoſition of this world good and evil being thus mixed together, they believed they would continue to the end of all things, when each ſhould be ſeparated and reduced to its own ſphere.

The antient Perſians erected no temples, but offered their ſacrifices in the open air, and generally on the top of a hill; for they eſteemed it injurious to the majeſty of the God of heaven, to ſhut up in walls him to whom all things are open, whom the world cannot contain, who fills immenſity by his preſence, and to whom the whole earth, with regard to man, ſhould be eſteemed as an houſe or temple.

Between the beginning of the reign of Cyrus the Great and the end of that of Darius the ſon of Hyſtaſpis, being about 600 years after the firſt Zoroaſter, another philoſopher of the ſame name aroſe. He undertook to reform ſome articles in the antient religion: he taught that there is one ſupreme, independent, and ſelf-exiſtent being. That under him there are two angels, the one of light, who is the author of all good, and the other of darkneſs who is the author of all evil. That theſe two by a mixture of light and darkneſs made all things which are. That they are in a perpetual ſtruggle with each other; where the angel of light prevails, there good reigns; and, where the angel of darkneſs, there evil predominates. That this ſtruggle ſhall laſt till the end of the world, when there will be a day of judgment, in which all ſhall receive a juſt retribution according to their works: after which the angel of darkneſs and his followers ſhall be caſt into a world of their own, where they ſhall ſuffer for their evil deeds in darkneſs, which to all eternity ſhall be ſeparated from the light. But thoſe who cheriſhed and cultivated their ſpiritual nature, and obeyed the angel of light, ſhall go with him into a world, where, amidſt everlaſting brightneſs and triumphant glory, they ſhall receive the rewards due to their good deeds. This laſt Zoroaſter, contrary to his great predeceſſor, cauſed temples to be built, in which the ſacred fires were ordered to be conſtantly preſerved.

Theſe opinions, with a few alterations, are ſtill maintained by ſome of the poſterity of the ancient Indians and Perſians, who are called Geberrs or gaurs, and are very zealous in preſerving the religion of their anceſtors, particularly in regard to their veneration for the element of fire.

GENE'RICAL *Name*, in natural hiſtory, the word uſed to ſignify all the ſpecies of natural bodies, which agree in certain eſſential and peculiar characters, and therefore all of the ſame family or kind; ſo that the word, under the Generical name, equally expreſſes every one of them, and ſome other words expreſſive of the peculiar qualities or figures of each are added, in order to denote them ſingly, and make up what is called the ſpecific name.

Thus the word roſa, or roſe, is the Generical name of the whole ſeries of flowers of that kind, which are diſtinguiſhed by the ſpecific names of the red roſe, the white roſe, the apple roſe, &c. The ignorance of former ages in the true principles of natural hiſtory has occaſioned the bodies, which are the objects of it, to be arranged into very unnatural ſeries under the name of genera; and theſe have been called by names as improper, as the characters they were diſtinguiſhed by. Linnæus has done a great deal in the exploding the bad Generical names in botany, and Artedi has applied his rules about the formation of theſe names, with very little difference, to the ſubjects of ichthyology.

Many of the Generical names of fiſhes, till the time of this author, were ſo barbarous and obſcure, that it was not eaſy to trace them to their original, or to find whether they were truly Teutonic, Engliſh, Dutch, Swediſh, French, Italian, Spaniſh, Portugueſe, Latin or Indian. The ignorance of the writers on theſe ſubjects, or their too ſcrupulous adherence to the cuſtoms of their predeceſſors, ſeem to have been principally the cauſes of this, and often an entire negligence. Artedi's rules for Generical names for fiſhes are theſe: whatever fiſhes there are which agree in the ſame Generical characters, and are properly of the ſame genus; theſe ought all to be called by the ſame Generical name, their differences being only expreſſed by ſpecific ones. This appears ſo plain, ſo juſt, and ſo neceſſary a rule, that it is almoſt a ſhame to lay it down; yet the writers on fiſhes, till the time of this author, had very ſeldom kept up to it: but, in many different parts of their works, fiſhes of the ſame genus were found deſcribed under different Generical names, and in the other parts, on the contrary. The greateſt confuſion imaginable was brought on by the deſcribing fiſhes of really and truly diſtinct genera under the ſame Generical name. Thus the alburnus, the barbus, bubulca, brama, capito, caraſſius, carpa, erythrophthalmus, fundulus, gobius, griſlagine, leuſiſcus, mugil, naſus, orfus, phoxinus, pigus, rutilus, ſqualus, tinca, and varius, are all uſed as ſo many diſtinct Generical names; yet they are all the names of the different ſpecies of only one genus, the cyprini. In the ſame manner, the agonus, alauſa, celerinus, and chalcis, the encraſicholus, harengus, lycoſtomus, pilchardus, ſardanus, ſprattus, ſparlingus, thriſſa, &c. are a parcel of barbarous names uſed as diſtinct Generical terms; yet the fiſhes they are applied to, are all ſpecies of the ſame genus, viz. the clypeæ. Numerous other inſtances of this kind might be brought.

On the other hand, fiſhes of the moſt different genera have been confounded under the ſame Generical name: thus we have two fiſhes deſcribed under the ſame name tinca, as if of the ſame genus, but diſtinguiſhed by the ſpecific additions of their places of abode; the one called tinca lacuſtris, and the other tinca marina. The firſt of them is truly a ſpecies of cyprinus, and the other a ſpecies of as different a genus as can be well conceived.

Another

Printed for J. Hinton in Newgate Street.

Another barbarism and impropriety, in the Generical names of fishes among the old authors, is the using the same words to express them, which are also the names of other animals, quadrupeds, birds, and reptiles. These are subject to great objections; because, when they are used, it is not easy to see, in some cases, whether the author is speaking of a bird, a beast, or a fish. It is therefore one of the general rules of Artedi, that all these names are to be abolished, as also all those which are common to fishes, and to plants, minerals, and to the tools of husbandry, or other services. *Artedi, Ichthyology.*

GENE'VA. There never was so great a quantity of the liquor vulgarly called by this name made as at present; but it is wholly different from what the liquor so called was at first. The best Geneva we now have, is made from an ordinary spirit, distilled a second time with an addition of some juniper berries; but the original liquor of this kind was prepared in a very different manner. It was a custom, in the distilling of spirits from wort, or other fermented liquors, to add, in the working, some aromatic ingredient; such as ginger, cortex Winteranus, or grains of paradise, to take off the bad flavour, and to give a pungent taste to the spirit. Among other things used with this intent, some tried the juniper berries, and, finding that they gave not only an agreeable flavour, but very valuable virtues also to the spirit, they brought it to a general custom, and the liquor sold under this name. The method of adding the berries was to the malt in the grinding: a proper proportion was allowed, and the whole was reduced to meal together, and worked in the common way. The spirit thus obtained was flavoured ab origine with the berries, and exceeded all that could be made by any other method. Our common distillers leave out the juniper berries intirely from the liquor they now make and sell under that name. Our rascally chemists have let them into the secret, that the oil of juniper berries, and that of turpentine, are very much alike in flavour, though not in price; and the common method of making what is called Geneva in London, is with common malt spirit and a proper quantity of oil of turpentine distilled together. *Shaw's Essay on Distill.*

GERA'NIUM, *Crane's-bill*, in botany, a genus of plants whose characters are:

The leaves are, for the most part, conjugated, the calyx pentaphylloidal, and expanded in form of a star. The flower here, in Europe, is pentapetalous, and rosaceous; but in Africa sometimes tetrapetalous, and in a manner galeated and labiated, and furnished with ten stamina, which closely surround the base of the ovary. The fruit is pentangious, or quinquevascular, beaked, containing, at the base, five capsules, including each a tailed seed, and producing a long slender tube; which five tubes, uniting close, representing with the ovary, the head of a stork, or crane. See *plate* XXII. *fig.* 9.

This plant has an emollient virtue like the acetosa: as it is esculent, its tuberous roots are eaten in Africa, as we eat turneps. An infusion, or decoction, of the herb, or its juice, are effectual in resolving the coagulated blood in wounds; it has something of astringency, and is recommended by the antients for the cure of foul ulcers; they used it also in ulcers of the pudenda. A bath prepared of the decoction of this herb has a good effect in fevers; and a decoction of the seeds is in use for the healing of wounds, and as a demulcent of asperities in the body; it is highly comforting and refreshing to the breasts labouring under a cancer, being reckoned among those plants which preserve from corruption: the leaves boiled in wine discuss an inflammation, and are commended for an erysipelas. The juice of the root cures diseases in the ears, and is good in a fomentation for pains of the joints; for which purpose it is used by some surgeons, as also for fissures in the breasts, and discussion of the milk.

Boerhaave mentions several other species of the African Geranium; all which, he says, are possessed of an emollient quality.

GERMA'NDER *Galls*, in natural history, a term used by those who have treated on the subject of galls, to express a peculiar vitiated state of a part of this plant. The stalks and leaves of other plants, and the bark and branches of trees, are the parts which furnish these sorts of excrescences, and, being vitiated by the biting and sucking of some insects, swell out in the parts where so injured into a protuberance; but in this plant it is the flower that becomes then vitiated, and forms what is properly enough called a flower-gall. Mr. Bernard Jussieu was the first who observed this fact. He observed, that many of the flowers of this plant never opened like the rest, and yet grew much larger, and that these always contained an insect. Other galls owe their origin to the worms of several kinds of flies, or to the little pucerons; but this is produced by an insect not known before to have any such power. A small and very beautiful kind of bug of a grey colour, with spots of white and brown, deposits its eggs in the calyx, or cups of this flower.

These soon hatch into so many small worms, which, feeding on the juices of the bud of the flower, eat their way into its cavity; when lodged there, they remain perfectly at ease, and, continuing to feed on the petal, the flower grows like all other parts of vegetables, injured in the same manner, to a much larger size than it otherwise would have done, but never opens into a flower.

While all the rest of the flowers are open, those thus injured, which are usually several on each plant, form so many red tubercles, which, being opened, are always found to contain either the worm of the bug, or its chrysalis, or, at the utmost, the remains of that state from which the creature has escaped in its perfect state. *Reaumur, Hist. Insect.*

GE'RVES'S *Engine*, a curious engine for raising water to supply a gentleman's seat, &c.

If there be a spring affording but a small quantity of water, and having but a small fall, suppose 10 feet, it is possible by the loss of some of the water to raise the rest to supply a gentleman's seat, or any place where it is wanted; but in a less quantity, by a little, than what runs waste, if the place to which the water is to be raised is higher than the fall of the spring is low. For example, the fall of one hogshead 10 feet will raise very near a hogshead 10 feet: one hogshead, falling 10 feet, will raise very near ¼ of a hogshead 40 feet. This has been thought of by Schottus a great many years ago, and he gave a draught of it; but I do not find that it was ever put in execution (at least to any good purpose) till the late George Gerves, carpenter, erected an engine for this purpose, for Sir John Chester, Bart. at his seat at Chichester, in Buckinghamshire. This engine has not been out of order since it was first set up, about 15 years ago.

Explanation of *Plate* XXIII. *fig.* 3. representing Gerves's engine.

A. Is a small spring of water, running four gallons per minute, conveyed 72 yards into B.

B. A cistern holding about 12 gallons, with a fall from B to C.

C. A cistern 10 feet below B, where the waste is conveyed off along D.

D. A drain, or sewer.

E. A plan of the building by a scale of 8 feet in an inch.

F G. A section of the house built over the well or cistern, drawn by a scale of 4 feet in an inch; with

H I K. Three floors, for the conveniency of fixing and ordering the engine; on the uppermost is

L M N. A frame of timber, on which the moving part is supported (part broken off in the figure, to shew the work;) across this frame lies O,

O. An horizontal axis, three feet and an half long, moving on two gudgeons in brasses. Upon this axis are framed three wheels.

(1) P. A wheel 2 feet diameter shrouded, whose sole is 5 inches broad, and shod with iron.

(2) Q. The largest wheel 6 feet diameter, lying close by the other, 1 inch and an half broad on the sole, and shrouded; this is spiraled 2 inches, both in sole and shrouds.

(3) R. A wheel 3 feet 10 inches diameter, fixed on the sides of the spokes of the wheel Q. and shrouded; this is spiraled ¼ of an inch.

P. Upon the wheel P, is fixed a chain, made flat and very flexible, which, after it has wrapped once round, is made double to stride on each side the single part, to prevent its fretting and galling, and to keep exactly the perpendicular.

S S. To this chain is hung S S, a long rod of iron, at the bottom of which the greater bucket *d* is fixed.

Q. Upon the wheel Q, is fixed a smaller chain made flat as the other; and, when this wheel has made one revolution from left to right, the spiral sole takes up as much of the chain, as is between T and T 2. The lower part of the chain from T 2 to T 3 has cross bars, which fall upon the edge of the shroud in notches plated with iron; which, by the help of the spiral, not only prevent this part of the chain from riding upon the other, but help to equiponderate the increase of weight of the other chain S S.

R. Upon the wheel R, is fastened a rope, one end of which goes about V.

V. A wheel of 2 feet diameter, to which that end is fixed; and on the same axis is fixed W.

W. Another wheel one foot diameter, to which is fastened a rope, which goes over a pulley to a sliding weight in a box at X.

X. Being the stilyard end of Y *a a.*

Y *a a.* A quadrant wheel moving on the axis Y; the rope falling upon pullies, running betwixt iron plates, upon the circumference.

Z. Is a lead weight, fixed to counter-balance the weight of the chains, keeping exactly an æquilibrium in every position they move in.

O. Upon one end of the axis O, is a strong iron wheel, giving motion to a fly *b* which regulates the motion of the engine.

T T. Upon one end of the chain T T, is a copper bucket *c*; whose capacity is about 5 gallons, having a valve in the bottom on the left hand, and a waste pipe near the top on the right: upon the lower end of the rod S S, is hung *d.*

d. A copper bucket containing about 15 gallons; in the bottom of this is a valve opened by a trigger falling upon a stud at the bottom of the well.

i i. Are

ii. Are iron-rods, for the guiding of the buckets, whose ears have brass rolls in them, and inclose three sides of each rod, which is square.

The operation.

When the lesser bucket descends, it falls upon a trigger at 4, which is jointed to a treddle at 5, expressed with pointed lines, moving on an axis at 6, which by a rod at 7 opens a valve in the bottom of the cistern B; whence the water, by a brass cock and branch-pipe, is conveyed underneath into both buckets, *c* and *d*.

When the lesser bucket has received about four gallons and an half, it runs out at the pipe or spout into a leaden trough, which conveys the water underneath the cistern into the great bucket, till it overpoises the lesser; which descending, and raising the lesser bucket, the valve shuts, and the water that is left in the trough and branch-pipe runs into the greater bucket *d*, accelerating the motion, which falling 10 feet, the lesser bucket rises 30 feet; which taking up the trough *f*, and its trigger striking upon a stud at *e*, its valve is opened, and its water runs out into a small cistern at *f*, and down a pipe *g g*, and so is conveyed to the place designed: at the same time a stud opens the valve of the greater bucket, the water running along D the drain or sewer.

When both buckets are empty, the lesser overpoises the greater, and descends down to the cistern, bringing up the greater, where they fill as before.

To regulate the weight of the chains in every position, as they act in winding on and off the wheels P and Q, the spiraling of the wheels helps in some measure; but the quadrant wheel and stilyard X, with the weight Z, compleat the equilibrium, by acting with the greatest force in the horizontal position, when the chain T is all down, and acts with its whole weight upon the wheel Q. Then, as that chain is drawn up, its acting weight being thereby diminished, the stilyard X is moving down towards its perpendicular, where the weight Z ceases to influence the motion of the wheel R; at which time the sliding weight runs down to keep the rope tight.

At the first moving down of the lesser bucket, the weight X slides up to a shoulder, before any motion is given to the stilyard; but, whilst the chain T evolves from its wheel Q, its acting weight increasing; and, at the same time, the chain S wrapping itself upon the wheel P, its acting weight decreasing. The stilyard, by rising higher, brings the line of direction of the weight Z farther from the center of the quadrant, and so lays a greater force or obstruction to retard the wheel R, and continually keeps a counter-balance.

The fly *b* regulates the motion of the engine to an equal velocity; and, by its running forwards, after the buckets are quite up or down, holds them steady till they begin to fill or empty, and prevents their recoiling back.

This engine, at a slow motion, carries up one bucket full in five minutes; but, if the spring run double the quantity, it would go up twice in the same time; and an engine, in this kind, may be made to raise one hogshead per minute, or more, if required; the waste water not being the hundredth part of what is spent by a water-wheel, to raise an equal quantity of water to the same height.

GI'BBOUS, *crooked or hump-backed*. Gibbosity is a preternatural incurvation of the spina dorsi, either backward, or on one side. Infants are more subject to this disorder than adults, and it oftener proceeds from external, than from internal causes. A fall, blow, or the like violence, frequently thus distorts the tender bones of infants. When it proceeds from an internal cause, it is generally from a relaxation of the ligaments that sustain the spine, or a caries of its vertebræ; though the spine may be inflected forward, and the back thrown out, by a too strong and repeated action of the abdominal muscles; and this, if not timely redressed, usually grows up and fixes as the bones harden, till in adults it is totally irretrievable: but when the disorder is recent, and the person young, there are some hopes of a cure. The common method is by a machine of pasteboard, wood, or steel, which is made to press principally upon the Gibbous part, and this by long wearing may set all right. The surgeons have however a different instrument which they call a cross, much more efficacious, though not quite so convenient in the wearing; by the use of this, the parts are always prevented from growing any worse, and are often cured. During the application of these assistances, the parts should be at times rubbed with Hungary water, spirit of lavender, and the like, and defended with a strengthening plaister of oxycroceum, opodeldoc, or the like. *Heister's Surgery.*

GIBBOUS *fish*, *gibbosus piscis*, in zoology, a name given by Mr. Ray to the fish called by the Dutch kromrugh. It is a smooth fish without scales; its belly is white, its fins and tail black. It grows to a considerable size, sometimes to four feet. It is caught all over the East-Indies, near the sea-shores, and is very firm, and much esteemed at table. It has its name from the remarkable rising of its back, which is like that of a perch, but much higher. *Ray's Ichthyolog. Append.*

GI'LDING *on China ware*. The gold is very much valued on China ware, and would be much more so, were it not that it is very liable to lose its lustre, and to rub off. The Chinese at present have a method of preventing both these accidents in a great measure, by means of a sort of polishing, which they give it, after it is laid on. They prepare for this purpose a fine piece of agate, which they polish on one surface in as perfect a manner as possible. With this, they rub over the gold as it lies on the porcelain several times, when it first comes from the baking.

This gives the gold a lustre which it would not otherwise have, and fixes it down to the ware in such a manner, that it cannot easily be got off. The principal mischief that gold thus laid on is subject to, is, the tarnishing, or growing dull; this is remedied by the same sort of means. They wet the vessel upon which they would revive the lustre of the gold, in common clean water, and, while it is wet, they rub it with the same polished agate, adding a little fair water at times to keep it moist. If the gold has not been laid on well at first, this may possibly raise it or take it off in some places; but if it was originally put on with the help of this stone, as all the gold on porcelain now is, the rubbing it with it a second time never gives it any scratches, but recovers its pristine lustre and beauty. It must be observed, that the rubbing with this stone must be all done one way, both in the first laying on the gold, and in the brightening it up afterwards. This may serve as a method for us, as well as the Chinese, not only to recover the beauty of our tarnished gilt China ware, but also to lay gold upon some of our home manufactures of this kind. *Obser. sur les Coutumes de l'Asie.*

GILLS *of fishes*, the parts which serve to their taking and throwing out again proper quantities of water, impregnated with its due and natural portion of air. The branchiæ, or Gills of fish, therefore, are the organs which correspond to the lungs in quadrupeds and birds, as also of frogs, serpents, and lizards, creatures too much confounded with fish by the old authors; all fishes therefore have these branchiæ, except the cetaceous and the petromyzum. The Gills in all fish are eight in number, four being placed on each side the throat. The lowest Gill is always much smaller than either of the others; the other three on each side are gradually larger to the top one, which is in all fish the largest. Every one of these Gills is composed of a bony substance formed into a semicircle, in most kinds, or bent into the shape of a bow; in the convex side of which there is formed a sort of plume, or the resemblance of a leaf.

Each leaf, to use that word, is composed of a double row of bony lamellæ, formed like so many sickles; and each of these lamellæ is fixed to the convex part of the bow, by means of the membrane with which that bow is covered. These lamellæ have one part convex, and the other concave. The convex side is covered with numerous hairs in all parts, and these are longest near the base, and shortest toward the apex. They are less hairy on the concave side; the hairs there being shorter, and continued only to the middle of the lamellæ, not running all the way along it. These hairs are all the way connected to the Gill by a very tender membraneous substance, which covers the lamellæ; but they are each single at the base. *Artedi, Ichthyolog.*

GLASS.— Under this article in the Dictionary we have given the method of blowing and casting large plates glass as performed in England; we shall here describe a famous manufacture of that kind at St. Gobin in France.

The building at St. Gobin in France, where the Glasses are run, is called the hall, which may be eleven fathoms long, and about ten and a half broad in the clear. The furnace is in the center, and is three fathoms long, and two and a half wide. It is built of very good brick.

There are two doors three feet high on each of the sides, of two fathoms and a half; and a door three feet and a half high on the longer side. The two former serve to throw wood continually into the furnace, and the last to get the pots and pans in and out; by means of a crane fixed before it for that purpose.

This furnace is upon solid foundations, and paved with square tiles of a well-baked earth, of the same quality with that of the pots into which the matter is put to be melted. It is arched within to the height of ten feet. The tube for the venting of the smoke is in the center.

On one of the sides of the length of the furnace and at the height of three feet and a half, there is the great arched aperture, ten feet wide and three feet high, and shaped like the mouth of an oven. Through this aperture they put in the solder and sand to be melted in the pots, and through it they take out the melted matter, which is carried into the pan, when they are ready to run it.

Round the furnace are the walls of the hall well built with free-stone: there are in these walls, within, apertures like the mouth of a common oven. The hearth of these apertures, which are about four fathoms and a half deep, is two feet and a half from the ground-floor. These small furnaces are called carquaisses, and serve to neal the Glasses after they have been run. These furnaces make so many small buildings round the hall, and much lower than the under part of the roof that covers it. There are without a like number of apertures of the same shape right over-against those that are within the hall, which makes a parallel arch, three feet high. There are by the sides of these apertures small arched niches, with pipes to give vent

to

to the smoke. They light the fire in them to heat the carquaisses. A large gallery terminates these small buildings, and helps the outward service of the carquaisses.

The manufacture is composed of many of these halls, and of a multitude of large rooms, the upper part of which serves to lodge the workmen. It has fine buildings to lodge the masters, a very pretty chapel and wide yards, many of which are full of stacks of wood of several kinds. The compass of the furnace is very large, and inclosed with good strong walls. The whole is situated at the top of a small hill, close to the village of St. Gobin, near la Fere and Chauny, two towns of Picardy. The forest of St. Gobin, which is of considerable extent, gave birth to the establishment of this manufacture. There are fine springs in the forest, that supply, on the declivities of the hill, all the water necessary for the work. Stone is very good and very common there: and now and then they draw some out of the inclosure of the manufacture.

The matter of which the Glasses are made, is a composition of solder, and of a very white sand, which is fetched from the neighbourhood of Creil, eleven leagues distant from Paris. There are above 200 people employed round tables in the halls, about cleaning and picking the solder and sand, to take out all heterogeneous bodies out of them. After this, the whole is washed several times, and dried so as to be pulverised in a mill, consisting of many pestles, which are moved by horses that turn round blindfold. This done, the sand is sifted through silk sieves, and then carried to be dried in narrow places, contrived in the corners of the furnace, four feet and a half from the ground-floor, whence it is put into the pots, to be melted.

The largest Glasses are run: the middle-sized and small ones are blown.

The abovesaid furnace is not sufficiently heated before it has consumed 50 cords of wood, which is 100 cart-loads. After that, it melts the solder and sand. It keeps the same degree of heat by means of a continual supply of wood: which is done by two men in their shirts, who are relieved every six hours. The furnace is never extinguished but at six months end, in order to be rebuilt. During this time, they rebuild that which was extinguished before the furnace actually made use of was employed, and they make the necessary repairs in both the hall and the carquaisses.

The furnace contains several pots formed like crucibles, three feet high, and about as much in diameter, of a well-baked earth of a whitish colour, inclining to that of tripoly. These pots may hold the quantity of a hogshead of wine, and are very costly. Few of them will hold out the full six months of the furnaces being hot. It happens sometimes that the pots break, when full of matter, which is a considerable loss to the manufacture.

These pots being in the oven, the solder and sand are put into them by the men that run the Glasses, who have in their hands an iron shovel in the form of a scoop to take water out of a boat, and which is full either of sand or solder: they pass one after another before the master workman, who puts a small quantity on each shovel-ful to facilitate the melting of it, by repeating the same mixture till the pots are quite full. The solder and sand remain in the pots for six and thirty hours together, after which the matter is fit to be run.

All hands are now ready for the running of the Glasses. They begin by emptying with a large iron-ladle the matter out of one of the pots into a pan, which is put into the furnace for that purpose. This pan is of the same earth as that of the pots, and may be six and thirty inches long, eighteen inches wide, and as many deep. There are some thirty inches long, with the same depth and width as the rest. There are in the length of these pans notches three inches wide, to stop them on the sides of the sledge, which is all iron, and very low: the tail of this sledge forms a square kind of pincers, which, when shut into the pan, takes off the notches. The two sides of these pincers, stretched out in form of an X, make the shaft of the sledge. The motion of these pincers is made upon the axle-tree of the sledge, where there is a large iron peg that crosses it, and is stopped with a pin. They fix the pan upon the sledge, with an iron chain on the side of the shaft.

Several workmen carry the sledge over-against one of the heated carquaisses, where the Glass is to be run upon a table of cast iron, which is horizontal and level with the hearth of that carquaisse. This table is ten feet long, and five feet wide, and stands solid upon a timber-support.

They put, in a parallel direction upon this table, a couple of flat iron bars or rulers, of the thickness intended in the glass, and which serve also to fix the width of it by their distance from each other. They put on the right side of the table an engine in form of a crane, which is fastened to the wall at top, and ends at bottom in a pivot, to make it turn, as occasion requires. This machine is full three fathoms high, its cross-piece a fathom in length, and its upright beam eight or ten inches thick. This engine is moveable, and they carry it to all the carquaisses. It serves to lift the tub above the table, by means of a couple of iron bars nine feet long, and forged so as to clip the whole tub, that it may be easily inclined, and the matter run out of it upon the table. There are four iron chains to support the pincers, which unite at a big rope that runs through a couple of pulleys in the cross-beam of the crane. The whole is lifted up or lowered with a cric, which is a kind of dented machine that wheel-wrights and coach-makers use to lift up the wheel from the ground, to make it turn freely on its axle-tree, when any thing is to be mended in it, and to support the coach on the side: it has several iron teeth which move up and down with a turning handle.

There is, at the foot of the table, a roller of cast iron five feet long, and a foot in diameter, resting up on a couple of timber tressels. This roller being laid upon the rulers or bars on the table, that raise above the said table the pan full of matter, led by two men, who holding the two sides of the bars, they grasp it like pincers, cause the pan to swing in the manner of a sweep, and pour down the matter before the roller, which is held by a couple of workmen. These people make it roll swiftly, and in a parallel situation over the matter towards the carquaisse, and roll it back the same way to bring it to its place again. They have the upper half of their body and their face wrapped up in a thick cloth, to preserve themselves from the dartings of the fire.

There are on the three other sides of the table small wooden troughs full of water, to receive the overplus of the matter just run. The men that run the Glasses are twenty in number at least; and act so perfectly in concert, that the work is done quickly, and without confusion, every one having his peculiar province.

The running of the Glasses is performed in presence of the head of the Glass-house, attended by the overseer and the secretary. When the Glass is run, these gentlemen examine it, whether there are any bubbles in it: these are small places shining like stars, when the Glass is hot. If any be perceived, the Glass is cut directly in that place: if it be at the third or fourth of the Glass, the parts cut off serve to make small Glasses: when they are but sheards, they are thrown among the waste.

When the Glass has cooled and been declared good, or free from bubbles, by the approbation of the inspectors; they push it off the table into the carquaisse level to it. This is done with an iron raker as wide as the table, that has a handle two fathoms long.

On the other side of the carquaisse, without, there are workmen who pull the Glass to them with iron hooks, and range it in the carquaisse, which holds six large Glasses. When it is full, they stop up its apertures with the doors which are of baked earth, and every chink of them with cement, that the Glasses may be smothered and better heated. They remain in that condition for a fortnight, and then are drawn out with all imaginable caution, to be put in boxes, and sent by water to Paris, where they are polished.

It may be observed that the oven full, or the quantity of matter commonly prepared, supplies the running of eighteen Glasses, which is performed in eighteen hours, being an hour for each Glass. The workmen work but six hours, and are relieved by others, who perform the same operations, transporting both the crane and the table near another carquaisse.

The manufacture would make vast profits, if the eighteen Glasses did all succeed, and were all of their intended measure. But there are sometimes runnings in which not one of the Glasses will be able to preserve the finest size, which is an hundred inches in length and fifty in width. However, I have seen many of them succeed with these dimensions.

When the last Glass is run, they scour the pots before they put into the furnace the matter of another running, which is to begin six and thirty hours after the foregoing: so that they put the matter into the furnace and begin to run it every fifty-four hours. The men who run the Glass have nothing to do, whilst the matter is melting, except those who are appointed to watch the fire.

Let us now see the particulars of the blowing of Glasses. The hall of the blown Glasses is smaller than that of the running: it is made in the same manner, with this difference, that there are no carquaisses round it. But there is over-against the furnace a large covered gallery twelve feet wide, in the middle of a building which is above twelve fathoms long: there are all along, and both to the right and left of this gallery, carquaisses, the hearth of which is raised four inches above the ground-floor: they are fifteen feet deep, and their arches three feet high, like those of the run Glasses. The furnace here, as well as in the running, is not heated above six months together; so that there is a second hall to perform the blowing, whilst they are making all proper repairs in that at rest. The pots are of the same earth as those of the run glasses. They are scoured, and the matter put in the furnace in the same manner. The matter is melting the same space of time, to be fit for the blowing of the Glasses, which are all of them less than forty or fifty inches.

The workman who blows the Glasses, when the matter is melted, takes an iron rod six feet long and two inches in diameter, bored hollow quite through, sharpened at the end, which is put in the mouth, and widened at the other, that the matter may adhere to it. He dips this rod into one of the pots through the mouth of the furnace, and by that means

takes

takes up a ſmall ball of matter four inches in diameter; which ſticks to that end of the rod by conſtantly turning it. Then he takes it out and blows a little into the cane, that the air may ſwell this ball of matter. Next to this he carries his rod over a large round bucket full of water, and reſting upon a three-footed ſupport, at the height of four feet; then with his hand he takes water and ſprinkles the end of the rod to which the ball of matter ſticks, ſtill turning the rod, that, by this cooling, the matter may coaleſce, and make but one body with the rod, ſo as that it may ſuſtain a greater weight.

This operation being over, he again dips the rod into the ſame pot, to take a greater quantity of matter, ſtill turning the cane as before: he takes it out, and cools it in the above-mentioned manner.

He, for the third and laſt time, take in the ſame pot a quantity of matter ſufficient to make his glaſs. He takes the rod out of the pot, loaded with matter, and being of the ſhape of a large pear, which may be ten inches in diameter, and a foot long; he goes to the bucket and cools it at the tail: this cooling is performed more quickly than the other two, not to loſe the opportunity of the heat of this maſs of matter. He at the ſame time blows into his rod, and, with the aſſiſtance of one of the labourers, gives his rod a balancing motion, that cauſes the matter to lengthen; which, by being thus blown and lengthened ſeveral times over, aſſumes the form of a cylinder ending like a ball at bottom, and in a point at top, which ſticks to the rod only by means of the ſeveral coolings already mentioned.

When the workman has blown ſufficiently, and lengthened his matter ſo as to make it become of an even thickneſs, he deſires his aſſiſtant to mount upon a ſtool three feet and a half high, on which there are two ſmall upright pieces of timber with a croſs beam of the ſame, to ſupport the weight of the Glaſs and rod, which are kept ſomewhat obliquely by the aſſiſtant, that the maſter may, with a puncheon ſet in a wooden handle, and with a mallet, make a hole into the maſs. This hole is drilled at the center of the ball that terminates the cylinder: it is an inch in diameter at moſt.

When the Glaſs is pierced, if there be any defects in it, they are perceived after this operation: if it have too many, they break it directly, and throw the matter among the waſte: if there be none or very few about the extremities, the workman goes and lays his rod horizontally on a little iron treſſel placed on the ſupport of the aperture of the furnace. He expoſes the Glaſs to the heat of it for about half a quarter of an hour, and then takes it away. In the mean time the aſſiſtant mounts the foot-ſtool again in the former ſituation, whilſt the maſter, with a pair of long and broad ſheers extremely ſharp at the end, widens the Glaſs by inſinuating the ſheers into the hole already made with the puncheon, and by thruſting them more and more into it, as it grows wider. Whilſt the aſſiſtant turns the maſs of Glaſs, the maſter goes on with opening of it, till the opening is ſo large at laſt as to make a perfect cylinder at bottom.

Next to this the workman lays his Glaſs upon the treſſel at the mouth of the furnace to heat it: then he takes it and gives it to his aſſiſtant on the foot-ſtool, and with large ſheers cuts the maſs of matter up to half its height. If there be any defects in the Glaſs, it muſt be cut in that place, as this ſection makes the extremities of it.

There is at the mouth of the furnace an iron tool called pointil, which is now heating, that it may unite and coaleſce with the Glaſs juſt cut, and do the office which the rod did before it was ſeparated from the Glaſs. This pointil is a piece of iron ſix feet long, and much of the form of a rod: there is at the end of it a ſmall iron bar a foot long, laid equally upon the long one, and making with it a T. This little bar is full of the matter of the Glaſs about four inches thick.

This red-hot pointil is preſented to the diameter of the Glaſs, which coaleſces directly with the matter round the pointil, ſo as to be able to ſupport the Glaſs for the following operations. This done, they ſeparate the rod from the Glaſs, by ſtriking a few blows with a chiſſel upon the end of the ſaid rod which has been cooled; ſo that the Glaſs breaks directly, and makes this ſeparation, the rod being unloaded of the Glaſs now carried by the pointil.

This done, they preſent to the furnace the pointil with the Glaſs, laying it on the treſſel to heat; and redden the end of that Glaſs, that the workman may open it with his ſheers, as he has already opened one end of it to complete the cylinder, the aſſiſtant holding it on his foot-ſtool as before.

They then again, and for the laſt time, put the pointil on the treſſel, that the Glaſs may grow red-hot, and the workman cuts it quite open with his ſheers right over-againſt the foregoing cut. This he does as before, taking care that the two cuts make but one and the ſame line.

In the mean time, the man who looks after the carquaiſſes, comes to receive the Glaſs upon an iron ſhovel two feet and a half long without the handle, and two feet wide, with a ſmall border of an inch and a half to the right and left, and towards the handle of the ſhovel. They lay the Glaſs upon it, flattening it a little with a ſmall ſtick a foot and a half long; ſo that the cut of the Glaſs is turned upwards. They ſeparate the Glaſs from the pointil, by ſtriking a few gentle blows between the two with a chiſſel. This done, they carry the Glaſs on the ſhovel to the mouth of the hot carquaiſſe, where the Glaſſes are to be nealed. They take away the ſhovel: the Glaſs grows red-hot gradually, by the vaſt heat which is at the mouth of the carquaiſſe: the workman belonging to it takes an iron tool ſix feet long, and widened at the end in form of a club at cards, four inches long and two inches wide on each ſide, very flat, and not half an inch thick. With this tool he gradually lifts up the cut part of the Glaſs to unfold it out of its form of a flattened cylinder, and render it ſmooth by turning it down upon the hearth of the carquaiſſe. The ſaid club, being inſinuated within the cylinder, performs this operation, by being puſhed hard againſt all the parts of the Glaſs.

This done, and the Glaſs being quite ſmooth, the workman puſhes it to the bottom of the carquaiſſe with a ſmall iron-raker. He ranges it with a little iron hook. When the carquaiſſe is full, they ſtop and cement it as they do the carquaiſſes of the run Glaſſes; and the Glaſſes remain there alſo for a fortnight to be nealed. When this time is over, they take them out to poliſh them.

A workman can make but one Glaſs in an hour, and he works but ſix together, after which he reſts ſix hours, to begin the ſame operation a-new: being never at reſt, but when the matter is melting in the pots.

Glass *for teleſcopes*. The following curious method of grinding and poliſhing Glaſs for teleſcopes, is that practiſed by the ingenious Mr. Molyneaux and Mr. Huygens.

Of making and poliſhing the tools. — It is eaſier to make an object Glaſs of equal convexities than of any other figure, becauſe the ſame tools will ſerve for forming both its ſurfaces. And a Glaſs of this figure will make as perfect an image in its focus as any other, becauſe the aberrations of the rays cauſed by the ſphericalneſs of the figures of the ſurfaces, whatever be the proportion of their ſemidiameters, are inconſiderable in long teleſcopes, in compariſon to the aberrations cauſed by the different refrangibility of the rays; and theſe latter aberrations are the ſame, whether the ſemidiameters of the ſurfaces be equal or unequal, ſuppoſing the aperture and focal diſtance to be the ſame. If it be propoſed then to make a Glaſs of equal convexities, that ſhall have a given focal diſtance, the radius of the ſpherical ſurface will be found by taking it in proportion to the given focal diſtance as twelve to eleven, putting the ſine of incidence to the ſine of refraction out of air into Glaſs, as ſeventeen to eleven, as Sir Iſaac Newton has accurately determined it.

The focal diſtance of the Glaſs being found, and becauſe its figure cannot be formed exactly true to the very edges, the breadth of the Glaſs may be taken about half an inch more than the diameter of its aperture, or even three quarters or a whole inch more, if its focal diſtance be between fifty and 200 feet.

Mr. Huygens directs in general to make the breadth of the concave tool, or plate, or diſh, or form, in which an object Glaſs muſt be ground, almoſt three times the breadth of the Glaſs. Though, in another place, he ſpeaks of grinding a glaſs whoſe focal diſtance was 200 feet, and breadth eight inches three quarters, in a plate only fifteen inches broad. But, for eye Glaſſes and others of leſſer ſpheres, the tool muſt be broader in proportion to the breadth of theſe Glaſſes, to afford room enough for the motion of the hand in poliſhing. Mr. Huygens made his tools of copper or caſt braſs; which, for fear they ſhould change their figure by bending, can hardly be caſt too thick; nevertheleſs, he found by experience that a tool fourteen inches broad, and half an inch thick, was ſtrong enough for forming Glaſſes to a ſphere of thirty-ſix feet diameter, when the tool was ſtrongly cemented upon a cylindrical ſtone an inch thick, with hard cement made of pitch and aſhes.

In order to make moulds for caſting ſuch tools as are pretty much concave, he directs that wooden patterns ſhould be turned in a lathe, a little thicker and broader than the tools themſelves. But, for tools that belong to ſpheres above twenty or thirty feet diameter, he ſays it is ſufficient to make uſe of flat boards turned circular to the breadth and thickneſs required. When the plates are caſt, they muſt be turned in a lathe, exactly to the concavity required. And for this purpoſe it is requiſite to make a couple of braſs gages in the manner following:

Take a wooden pole a little longer than the radius of the ſpherical ſurface of the Glaſs to be formed, and through the ends of it ſtrike two ſmall ſteel points, at a diſtance from each other, equal to the radius of the ſphere intended; and by one of the points hang up the pole againſt a wall, ſo that this upper point may have a circular motion in a hole or ſocket made of braſs or iron fixed firmly to the wall. Then take two equal plates of braſs or copper, well hammered and ſmoothed, whoſe length is ſomewhat more than the breadth of the tool of caſt braſs, and whoſe thickneſs may be about a tenth or twelfth of an inch, and whoſe breadth may be two or three inches. Then, having faſtened theſe plates flat againſt the wall in an horizontal poſition, with the moveable point in the pole, ſtrike a true arch upon each of them. Then file away the braſs on one ſide exactly

5

exactly to the arch struck, so as to make one of the brass edges convex and the other concave; and, to make the arches correspond more exactly, fix one of the plates flat upon a table, and grind the other against it with emery. These are the gages to be made use of in turning the brass tools exactly to the sphere required.

But, if the radius of the sphere be very great, the gages must be made in this manner: I imagine the line A E (*plate* XXI. *fig.* 3.) drawn upon the brass plate to be the tangent of the required arch A F B, whose radius, for example, is thirty-six feet, and diameter seventy-two. From A set off the parts A E, E E, &c. severally equal to an inch, and let them be continued a little beyond half the breadth of the tool required. Then, as seventy-two feet, or 864 inches, are to one inch, so let one inch be to a fourth number; this will be the number of decimal parts of an inch in the first line E F, reckoning from A. Multiply this fourth number successively by the numbers 4, 9, 16, 25, &c. the squares of 2, 3, 4, 5, &c. and the several products will be the number of parts contained in the 2d, 3d, 4th, 5th, E F respectively. But, because these numbers of parts are too small to be taken from a scale by a pair of compasses, subtract them severally from one inch, represented by the lines E G, and the remainders, being taken from a scale of an inch divided into decimal parts, and transferred by the compasses from G to F, will determine the points F, F, of the arch required. And, the same being done on the other side of the line A D, the brass plate must be filed away exactly to the points of this arch, and polished as before.

To apply the brass tool to a turning lathe, in order to turn the concave surface of it exactly spherical, let figure 4 represent a view of some part of the lathe taken from a point directly over it; and here let (*fig.* 4, 5, 6,) represent a strong flat disk of brass, half an inch thick at least, having a strong iron screw-pin fixed firmly in the center of it, and standing out exactly perpendicular to one side of it; by which it may be screwed into the end *c*, of the mandrel or axis of the lathe represented by *c d*. This disk is represented separately in figure 5, and must be well soldered to the back side of the tool *e f*, which therefore in the middle of it must be made plane, and exactly parallel to the circumference of its opposite surface, to the intent that the circumference may be carried round the axis of the lathe in a plane perpendicular to it. The mandrel or axis *c d* turns upon a point *d* in the puppet-head of the lathe, and in an iron collar represented by *s t*, as usual.

Let *g h i k* represent a board nailed fast upon the other puppet-head; and let the concave gage *g h* be laid upon this board, with its concave arch parallel to the concavity of the tool *e f*, and be screwed down to the board with flat-headed screws sunk into the brass. Let *l m n o* represent such another board lying upon the former, with the convex gage *l m* screwed to the underside of it, so that by moving this upper board the arch of the convex gage may be brought to touch the concave one and slide against it. The turning tool *p q* is laid upon this moveable board, and is held fast to it by a broad-headed screw at *r*, to be turned or unturned by the hand upon occasion. To know whether the concave gage be exactly parallel to the concavity of the tool *e k* screwed fast to the mandrel, direct the point *p* of the turning tool *p q* to touch any point of the tool *e f* near its circumference; then, having fixed the turning tool *p q* by the screw *r*, turn the brass tool *e f* half round, and move the upper board till the point *p* of the turning tool be brought over-against the same mark upon the tool *e f*; and, if it just touches it as before when the gages coincide, all is right. If not, the position of the head of the lathe may be altered a little by striking it with a mallet. But the best way is to make this examination of the situation of the concave gage, when only one end of it is fixed to the head of the lathe by a single tack or screw, about which it may easily be moved into its true position. And, while the tool or plate *e f* is turning, the same examination of its parallelism to the gage must be frequently repeated; otherwise its surface will take a false figure. It is convenient that the upper board *l m n o* should project over both the gages; and, to keep its surfaces parallel to that of the under board, two round-headed nails, or a plate of brass, as the gages, must be fixed to its under surface, towards the opposite side *n o*. Care must be taken to drill the holes in the gages, through which they are screwed to the boards, not too near the polished arches, for fear of altering their figure, by the yielding of the brass. The tool and all the parts of the lathe must be fixed very firm; because any trembling motion will cause the graving tool *p q* to indent the brass. After the tool is well turned, it must be separated from the back *a b*, by melting the solder with live coals laid upon it.

It is easy to understand, that, by transposing the gages, a convex tool may be turned in the same manner.

Mr. Huygens would have his plates or tools first formed in a turning lathe, and then ground together with emery; that is to say, the concave and convex tool of the same sphere together. But the tools of very large spheres he would have ground at first quite plane by a stone-cutter; and then ground hollow, with a round, flat stone and emery, to the desired gage. And he prescribes to use for this grinding first a stone half as broad as the tool, and after that another stone very nearly as broad as the tool; and, in this way of forming the tools, it is convenient to tie a little frame of thick paper, or rather of thin paste-board, about an inch high round about the tool to keep in the emery; and, in grinding, the whole must be made extreamly firm and stable. And, when the tool is to be polished, it must still remain upon the stone pedestal; otherwise it will be in danger of bending a little in the operation.

For polishing these tools thus ground, Mr. Huygens takes some soap, and daubs the concave tool therewith; then he takes the last mentioned round stone, somewhat less than the tool (or the convex tool itself) and heats it, and then he pours upon it some hot melted cement (made of pitch and fine powdered and sifted ashes as much as he can mix with it) and then he turns over the stone and cement upon the concave tool, into which also he had poured a good quantity of the same cement, having first laid three little pieces of brass of equal thickness on the circumference thereof, in order to press and keep this crust of cement of an exact equal thickness in all its parts; and thus he lets them cool together: then, taking the stone from the tool and turning it up, he sifts, upon the cement that sticks to it, a crust of very fine emery, and with a flat iron spatula about one third of an inch thick, gently warmed, he presses lightly the emery, to stick to and incrustate upon the cement; then he again gently warms the whole stone (or convex tool) cement and emery, and he again replaces it upon the concave tool, and leaves it again to cool; so that he has by this means a crust of emery exactly of the figure of his tool; with this he polishes the tool dry, without the addition of any wet, pressing it down hard on the surface of the tool. And, to press it the harder, he places upon it a long pole, a little bent to make it spring; whose upper end is fixed to the cieling of the room, or else is pressed downward by a strong iron spring; and he says it will be necessary to have two persons to rub the stone upon the tool. And here it is to be noted, that great care must be taken, in this and all cases where this way of grinding by a pole is made use of, to fix the point of pressure exactly and truly in the middle, as shall be more particularly explained hereafter, when the Glass comes to be ground in this tool.

For the method of making the cement, see CEMENT.

To bring the concave tool still to greater perfection, and still to preserve its true form, take equal pieces, about an inch square, of blue hone, such as engravers polish their copper withal, and place as many of them, laying the grain some one way, and some another, as you can, upon the surface of the tool to be polished; sticking and steadying the same, as close as you can to one another, with soap or common white starch; then fill up all the interstices between the said pieces of hone with clean dry sand, to about two thirds of the thickness of the said hones; then, having a border of paper or paste-board put round the tool as before, shake the tool gently, that the sand may every-where equally subside, and blow it to an equal depth with a pair of bellows. Then take some hard cement extreamly hot, and pour it all over the hones, and having cleaned the stone (or the convex tool) which before was incrustated with pitch and emery, place this stone (or convex tool) warmed on the top of this cement, and let all cool together. Then, rubbing the tool with this polisher made with hones, by applying your pole to the top of the stone as before, you shall know when the tool is brought to perfection, if, wiping off the dirt and filths you fine, by looking obliquely upon it against the light, that it shines equally bright and strong in all parts. If you would use this polisher again, it must be kept in a cool cellar, leaving the hones uppermost; otherwise in warm weather they will change their situation in the cement, even with their own weight.

And here is to be observed that this method of grinding these tools by an incrustation of emery on hard cement, formed to a convexity by the very tool itself, and also the method of polishing the same by the blue hones fixed in hard cement, may probably as well be used and applied to the grinding and polishing of a reflecting metal for a telescope. But in that case I believe it is best not to use a springing pole, but one that shall turn upon a point above, being nearly equal in length to the radius of the sphere intended.

Of chusing GLASS.—The best sort of Glass has generally a yellowish, reddish, or a greenish colour, when we look through it against the sky-light, or lay it upon a sheet of white paper. That which is perfectly white, though it transmits the most light, is generally fuller of veins, and is often subject to grow moist in the air, which in time destroys its polish. In these parts there is no better Glass to be had, than pieces of broken looking Glasses. But after some time I found pretty good Glass at a Glass-house; and made use of the same matter with which they make drinking-Glasses, which I found was always the best after the matter had rested for two or three days, when the workmen kept holydays. I ordered pieces of Glass to be made for my own use in the same manner as they make looking Glasses, that is, by cutting off the top and bottom of the round globe they blow up, and by slitting the side of it, and then by flatting it upon the hearth of the furnace. These pieces, which were about half an inch or three quarters thick, I ordered to be ground to an equal thickness by a stone-cutter, in the machine they polish marble with.

To discover the veins in Glass one should look very obliquely against a small light in a room, otherwise dark. Thus one may examine the pieces of a polished looking-Glass. But, because they are seldom thick enough for object Glasses, it is necessary to take some pieces of the same sort of Glass before it is polished, and to get it round to an equal thickness, and polished a little by the common Glass-grinders, in order to judge what pieces are fit for use. Sometimes little veins will appear like fine hairs or threads, which scarce do any harm. I have several very good Glasses of this sort. Sometimes their imperfections cannot be discovered by the former way of trial, and yet, after the Glass is well formed and polished, they will appear by reflection in this manner: in a dark room, place the Glass upright upon a table, turning that surface from you which is suspected to be faulty; then holding a lighted candle in your hand, so that the middle of the broad light reflected from the first surface may fall upon your eye, recede from the Glass till the rays reflected from the back surface shall just begin to invert the candle; then the whole Glass will appear all over bright, and then you will discover its defects, and the imperfections of the polish. When the glass is a portion of a large sphere, we use a small perspective, three or four inches long, to magnify the defects.

Of preparing the GLASSES *before they can be ground and polished.*—The pieces of Glass above-mentioned, which we directed to be planed to an equal thickness and polished a little by a Glass-grinder, should be much broader than the intended object Glass, and there may be room enough for chusing the best part of them. For planing and smoothing those large pieces of Glass, I ordered the workmen to make use of plates of cast iron, such as are sold at the ironmongers shops, after they had been ground and planed in a stone-cutter's engine. Upon the plate of Glass, with a diamond-pointed compass, strike a circle representing the circumference of the object Glass; and also another concentric circle, with a radius about a tenth or twelfth part of an inch bigger. And also two other such circles, on the other side of the Glass directly opposite to the former: which may be done by means of a circular Glass to be described by and by. The larger parts of the Glass may be separated from the outward circle by a red-hot iron, or by a strong broad vice, opened exactly to the thickness of the Glass. The remaining inequalities may be taken off by a grind-stone, beginning with the largest first, and taking care they do not splinter. Then, having warmed the Glass, cement a wooden handle to it, and in a common deep tool for eye Glasses, making use of white clear sand and water, grind the circumference of the Glass exactly true to the innermost circle on each side of it. Then having made a great many small cavities with a punch upon one side of a round copper-plate, and having fixed the other side of it upon the middle of the round Glass, by cement made with two parts of rosin or hard pitch, and one part of wax, place the steel-point of the springing pole, being fourteen or fifteen feet long, into that cavity of the copper-plate, which lies nearest to the thickest part of the Glass. Then work the Glass by the pole with sand and water, upon a flat plate of cast iron, of a round figure, the plate having been planed with sand and water by a stone-cutter. Then having examined the thickness of the Glass in several places, by a hand-vice, which is better than a pair of callippers, by repeating the same operation it will be reduced to an equal thickness in all its parts.

Towards the end of this operation it is convenient to make use of sifted emery, because the sand will scratch too deep; and then it will also be necessary to place the steel point of the pole exactly over the center of the under surface of the Glass; otherwise that surface will take a cylindrical or sort of a convex figure instead of a plane one, even though it was exactly plane before you began to grind it. The reason of which is well worth observing. And, when convex Glasses are to be polished, it is also absolutely necessary to place the point of pressure exactly over the center of the under surface of the Glass. Therefore, to bring one of the little cavities in the copper-plate exactly over that center, we make use of a circular Glass formed from a broken looking-Glass, the quicksilver being rubbed off; having described upon it, with a diamond-pointed compass, eight or ten concentric circles at the distance of about a quarter of an inch from each other, so that the large circles may be somewhat bigger than the circumference of the Glass to be polished. Lay this circular Glass upon the surface of the Glass to be polished, and move it to and fro, till you perceive the circumference of the Glass to be polished is exactly parallel to the nearest circle upon the circular Glass; then, having inverted both the Glasses, lay the circular Glass upon a table, and, having laid a small live coal upon the copper-plate to make it moveable upon the cement, place one point of a pair of compasses in one of the little cavities, and move the copper till a circumference described with the other point coincides exactly with any one circle upon a circular Glass, and the business is done. With starch it is convenient to paste three slender shreds of fine linen, directly towards the center of the circular Glass, that the other Glasses may not slide too easily upon it, and that they may not scratch one another.

The cavities punched in the copper-plate, and also the point of the pole, should be triangular, to hinder the rotation of the Glass; which is still more necessary in perfecting the polish of the Glass. And here it must be observed again whether the circumference of the Glass remains exactly circular on both sides of it, which must be tried with a pair of compasses; and, if it be not, it must be corrected again by grinding it exactly circular in a common tool for making eye Glasses; which will contribute very much to its taking an exact spherical surface, when it comes to be ground in its proper tool. For, if any part of the circumference be protuberant, it will hinder the adjoining parts of the surface from wearing so much as they should do; and, by consequence, will spoil the spherical figure of the surface.

Of grinding the GLASSES.—The Glass being planed and rounded as above, take away the plate with several cavities, and with some of the same cement fixed on a smaller round piece of brass or rather steel, truly flat and turned about the bigness of a farthing, but thicker, having first made in the center thereof, with a triangular steel punch, a hole about the bigness of a goose quill, and about the depth of one twelfth of an inch; and, at the very bottom of this triangular hole, a little small round hole must be punched somewhat deeper with a very fine small steel punch. A small steel point, of about an inch long, must be truly shaped and fitted to this triangular hole, and, at the very apex, to the small, round, deeper impression. Nevertheless, it must not be fitted so exactly to the same, but that it may have some liberty to move a little to and fro; the apex always continuing to touch and press upon the surface of the round hole below. This steel triangular point must be fixed to the end of a pole (*plate* XXI. *fig.* 7.) to the other end of which another round iron point must be fixed, of about five or six inches long, to play freely up and down in a round hole in a piece of brass let into a board, fixed against the ceiling for that purpose, perpendicularly over the bench, and over the center of the tool, which must be strongly and truly fixed horizontally thereon.

Now, here is to be noted that Mr. Huygens prescribes to fix his brass-plate to the Glass by the means of a cement, and takes no notice of any other method whatever; though a very small experience in these affairs will convince any body that it is hardly possible, in this or any other case, to bring the cement to a fluidity sufficient to fix two plane surfaces exactly parallel one to the other, without heating the Glass and the brass also to a great degree, and so as to endanger the figure of the Glass considerably.

To avoid this in fixing Glasses to brass or wood, or the like, some have done it with plaister of Paris: Mr. Scarlet does it by cementing another intermediate Glass to the brass (or wood) and then fixing the Glass, to be ground, to the outward surface of the cemented Glass with common glew. Without all this trouble I have done it only with common icthyocolla or fish glew, which will run very fluid, and will fix the Glass and the brass itself strongly together; and, round the edges of the brass, I stick on some common soft red-wax, such as is used for the privy seal, to keep the wet from getting to the glew.

For grinding Glasses truly plane, upon a plane tool, by this method, Mr. Huygens prescribes this pole to be about fifteen feet long; but, in grinding upon a concave plate, the pole had best be made equal to the radius of the sphere of the tool; though I believe it would not be material, if made considerably shorter, according as the height of the room will allow.

It is necessary to have lying by one an ordinary piece of coarse Glass, ground in the same tool, called a bruiser; whereby, when any new emery is necessary to be laid on the tool in grinding your Glass, the said emery is to be constantly first run over and smoothed, for fear any little coarse grains should remain and scratch the Glass to be ground.

Having these things prepared together with some pots of emery of various fineness, take of your roughest sort a small half pugil, wetting the same, and daubing it pretty equally on the tool; then lay on your Glass and fix up your pole, and continue to grind for a quarter of an hour, not pressing upon the pole, but barely carrying the Glass round thereby; then take the like quantity of some finer emery, and work another quarter of an hour therewith; then take the like quantity of emery still finer, and work for the same time; last of all, take a less quantity of some of the very finest you have, which will be sufficient for a Glass of five inches diameter, and work therewith for an hour and half, taking away, by little and little, some of the emery with a wet sponge. Do not keep it too wet nor too dry, but about the consistence of pap; for much depends on this. If it is too dry, your emery will clog, and stick, and incorporate, so as for the most part to cut little or not at all, unless here and there where its body chances to be broke, and there it will scratch and cut your Glass irregularly; and, if it is too wet, and too much diluted, it will form the irregular separation of its parts cut in some places more than others, just as in the other case.

But Mr. Huygens tells us this method of using various sorts of fresh emery is not good, finding by experience that the surfaces of large Glasses are often scratched. And, therefore, he says it is best to take a large quantity of the first or second sort of emery, and so work with the same from the first to the last; taking away, by little and little, every half hour, or quarter of an hour, more and more of the emery with a wet sponge; by which means he could bring the Glass extremely smooth and fine, so as to see pretty distinctly a candle or the sash-windows well

well defined through it; which is a mark when it is ground enough to be ready to receive a polish. But, if the Glass has not acquired this degree of transparency, it is certain, says Mr. Huygens, that too much emery remains; and therefore it must still be diminished, and the operation continued. He found it best to make use of common well-water in this grinding; and he took care to move the Glass in circles, taking in an inch beyond the center of the tool, and somewhat beyond the outside of the tool; and he found in a Glass of two-hundred feet whose diameter was eight inches three-fourths, which he ground in a tool of fifteen inches diameter, that the figure of the tool in grinding would alter considerably, unless he carried the Glass round an inch beyond the center of the tool one way, and three inches one-fourth beyond the skirts of it another way; but, if he carried it no more than a straw's breadth beyond the skirts of the tool, and accordingly farther beyond the center, the Glass would always grind falsly, too much being taken off on the outsides, so that he could never after bring the outsides of the Glass to a true and fine polish.

When you first begin to grind, and the emery begins to be smooth, the Glass will stick a little to the tool and run stiff; then fresh emery is to be added. When it afterwards comes to be polished, it will, if large, require a considerable strength to move it, but this inconvenience will happen less in grinding by the pole than in grinding by hand. For the warmth of the hand makes the substance of the Glass swell, and not only increases the sticking of the Glass, but in some measure may also spoil the figure of it, and also of the tool. When it is ground with the pole, it never sticks very strongly, unless when you take the Glass off from the tool, and keep it from it for some time, and then apply it to the tool again; and this in large Glasses; for, by this means, says Mr. Huygens, the Glass gets from the air a greater warmth than it had on the tool; and, being again applied to the tool, its lower surface is suddenly contracted by the coldness of the tool, and so sticks to it. Wherefore, saith he, you must, in that case, wait till the Glass and the tool come to be of one temper. The like effect is observeable in grinding large Glasses when there is a fire in the room. Perhaps, the cause of those effects may be more truly deduced from the attractive qualities of warm Glass. But, whatever is the cause, we may from hence perceive the great nicety of grinding large Glasses, and the necessity there is of grinding them slowly, and with the greatest caution, in the most minute circumstances.

The method hitherto described of grinding with emery is what is recommended by Mr. Huygens. Le Pere Cherubin prescribes another material, and it is the grit of a hard grindstone well beaten into a fine powder and sifted pretty fine. And here in England the same thing was used to be performed by Mr. Cox with common clean fine white sand, taking away, by little and little, the said grit and sand, as it ground finer and finer. Nay, Mr. Cox was used to continue his grinding till the matter of the sand came to be so fine, and so little of it to remain in the tool, that he could, and frequently did use to polish off his Glasses therein, without the use of any other material whatsoever; and I myself have been present, while Mr. Scarlet ground and polished, or dried off, a Glass of sixteen feet in this manner. They call this way drying off on sand, because, as the matter grows finer and finer, they wet it less and less, till for the last quarter of an hour (the whole work lasting near two hours) they only wet it by breathing upon it, and, at the very last, not at all.

It seems this method is now quite disused; perhaps the violent labour requisite at the last may be the reason of it. A better reason may be the great improbability of grinding or polishing true by this method, by the uncertain and unequal force of the hand; and, if this be the true reason of its disuse, I cannot well see but that this method of grinding and polishing out and out in the same tool, and with the same material, viz. white sand, might be perhaps again restored, and greatly improved by adding, to the old way, Mr. Huygens's method of grinding and polishing with a pole and spring to press down the pole, or some analogous contrivance. And, in relation to grinding by all or any of the methods above described, this one general remark must be made, that the artist must allow time and patience to bring his Glass by grinding to the smoothest and finest surface, that he possibly can, before he attempts to polish. For this, and this only, makes his Glass polish truly smooth, well and easily; and, the smoother you bring it in grinding, the less labour you will have in polishing; in which consists not only the greatest difficulty but the greatest danger too of spoiling all you have done before.

Of giving GLASSES *the last and finest polish.*—Having removed the little brass plate from the Glass (See *fig.* 8.) take, says Mr. Huygens, a very thick slate, or rather a block of blue or grey stone; let it be half an inch thick, and let it be ground true and round at the stone-cutter's; its diameter being somewhat smaller than the diameter of your Glass, leaving a hole, quite through, in the center, of about an inch diameter. Then make some cement two parts rosin, or hard pitch, and one part wax; and, taking a piece of thick kersey cloth, truly and equally wrought, cut this cloth round, and leave a like hole, one inch diameter, in the middle. Then warming the stone, and also warming the Glass, and spreading thinly and equally upon them some of this cement, lay on the cloth, and thereupon lay on also the Glass, having left in the middle a space the breadth of a shilling uncemented and blacked with a candle. Then provide an hollow conical plate of iron or steel (shaped like an high-crowned hat) having the basis of the cone one inch diameter, and having round the basis a flat border about two inches one half diameter, and having the depth or altitude of the cone exactly of the thickness of the slate, cloth, and cement, to which the Glass is fixed. The vertex of this cone must go down through the slate and cloth, so that, being cemented on the slate, the said vertex may approach to the Glass within a hair's breadth, and lie perpendicularly over the center of the lower surface of the Glass: and this must be adjusted by the circular Glass described above. Within the vertex of this hollow cone, the lower point of the pole is to be applied in polishing; but it may be first proper to be observed, that, perhaps, fish-glew and a brass plate, in lieu, and of the dimensions of the above-said slate, may perhaps be better. Mr. Huygens observes also, that the angle of the cone should be eighty or ninety degrees, and that the hollow vertex of it should be solid enough to receive a small impression from a round steel punch, to put the point of the pole into, which might otherwise have too much liberty and slip from the vertex. The design of the black spot, in the middle of the Glass, is to discover, by the light of a candle, obliquely reflected from your Glass, after it has been polished some time, whether it be perfectly clear, and free from the appearance of any bluish colour like that of ashes.

Before the work of polishing is begun, it is proper to stretch an even well wrought piece of linen over the tool, dusting thereupon some very fine tripoly. Then, taking the Glass in your hand, run it round forty or fifty times thereupon; and this will chiefly take off the roughness of the Glass about the border of it, which otherwise might too much wear away the lower parts of the tool, in which the Glass is chiefly to obtain its last polish. If I understand Mr. Huygens right, this cloth is then to be removed, and the Glass to be begun to be polished upon the very naked tool itself. But, first, there is to be prepared some very fine tripoly, and also some blue vitriol, otherwise called cyprion, English and Hungarian vitriol finely powdered; mix four parts of tripoly with one of vitriol: six or eight grains of this mixture (which is about the quantity of two large pease) is sufficient for a Glass five inches broad. This compound powder must be wetted with about eight or ten drops of clear vinegar in the middle of the tool; and it must be mixed and softened thoroughly with a very fine small mullet. Then with a coarse painting brush take great care to spread it thinly and equally upon the tool, or at least upon a much larger space in the middle of it, than the Glass shall run ever in the polishing. This coat must be laid on very thin (but not too thin neither) otherwise it will waste away too much in the polishing, and the tool will be apt to be furrowed thereby, and to have its figure impaired; insomuch that sometimes a new daubing thereof must be laid on, which it is not easy to do so equably as at first. This daubing must be perfectly dried by holding over it a hot clean frying-pan, or a thin pan of iron, with lighted charcoal therein for that purpose; then leave all till the tool is perfectly cold. Then having some other very fine tripoly very well washed and ground with a mullet, and afterwards dried and finely powdered; take some of the same, and strow it thinly and equably on the tool so prepared: then take your coarse Glass which lay by you, and smooth all the said tripoly, very equably and finely: then, take your Glass to be polished, and wipe it thoroughly clean from all cement, grease, or other filth which may stick to it, with a clean cloth dipped in water, a little tinged with tripoly and vitriol; then taking your Glass in your hand, apply it on the tool, and move it gently twice or thrice, in a straight line backwards and forwards; then take it off, and observe whether the marks of the tripoly, sticking to the Glass, seem to be equably spread over the whole surface thereof; if not, it is a sign that either the tool or the Glass is too warm; then you must wait a little, and try again, till you find the Glass take the tripoly every-where alike. Then you may begin boldly to polish, and there will be no great danger of spoiling of the figure of the Glass; which in the other case would infallibly happen. If the tool be warmer than the Glass, it will touch the Glass harder in the middle than towards its circumference; because the upper surface of the tool, being swelled by heat, will become too flat. On the contrary, if the Glass be warmer than the tool, it will bear harder towards its circumference than at the center; because the inferior surface of the Glass is contracted by the coldness of the plate more than the superior.

Mr. Huygens says, that, if the work of polishing were to be performed by strength of hand only, it would be a work of very great labour, and even could not be performed in Glass of five or six feet focal distance: and he seems to think it absolutely necessary that an extraordinary great force or pressure should be applied upon the Glass. For this purpose, he has therefore contrived and described two methods for sufficiently increasing the pressure; for the explanation of which, recourse must be had to the book itself and his figures; it may suffice here to

say

say that they chiefly consist in applying the force of a strong spring to press down the center of the Glass upon the polisher. This operation of polishing, as it is one of the most difficult and nice points of the whole, hath been very variously attempted and described by various authors. Sir Isaac Newton, Pere Cherubin, Mr. Huygens, and the common Glass-grinders have taken different methods in this matter. Sir Isaac is the only person who seems not to insist on the necessity of a very violent and strong pressure. In the English octavo edition of his Optics, page 95, he hath these words: 'An object Glass of fourteen feet, made by an artificer at London, I once mended considerably, by grinding it on pitch with putty, and leaning very easily on it in the grinding, lest the putty should scratch it. Whether this may not do well enough for polishing these reflecting Glasses, I have not yet tried. But he that shall try either this or any other way of polishing which he may think better, may do well to make his Glasses ready for polishing, by grinding them without that violence, wherewith our London workmen press their Glasses in grinding. For by such violent pressure Glasses are apt to bend a little in the grinding, and such bending will certainly spoil their figure.'

As to his own method of polishing Glass, I do not know that he any where expressly describes it; but his method of polishing reflecting metals he doth, and it was thus in his own words, page 92. 'The polish I used was in this manner: I had two round copper-plates, each six inches in diameter, the one convex, the other concave, ground very true to one another. On the convex, I ground the object-metal or concave, which was to be polished, till it had taken the figure of the convex and was ready for a polish. Then I pitched over the convex, very thinly, by dropping melted pitch upon it, and warming it to keep the pitch soft, whilst I ground it with the concave copper wetted to make it spread evenly all over the convex. Thus, by working it well, I made it as thin as a groat, and, after the convex was cold, I ground it again, to give it as true a figure as I could. Then I took putty which I had made very fine by washing it from all its grosser particles, and, laying a little of this upon the pitch, I ground it upon the pitch with the concave copper, till it had done making a noise, and then upon the pitch I ground the object-metal with a brisk motion for about two or three minutes of time, leaning hard upon it. Then I put fresh putty upon the pitch and ground it again, till it had done making a noise, and afterwards ground the object-metal upon it as before. And this work I repeated till the metal was polished, grinding it the last time with all my strength for a good while together, and frequently breathing upon the pitch to keep it moist, without laying on any more fresh putty. The object-metal was two inches broad, and about one third part of an inch thick to keep it from bending. I had two of these metals, and, when I had polished them both, I tried which was best, and, ground the other again, to see if I could make it better than that which I kept. And thus, by many trials, I learned the way of polishing, till I made those two reflecting perspectives I spake of above. For this art of polishing will be better learned by repeated practice than by my description. Before I ground the object-metal on the pitch, I always ground the putty on it with the concave copper till it had done making a noise, because, if the particles of the putty were not by this means made to stick fast in the pitch, they would, by rolling up and down, grate and fret the object-metal, and fill it full of little holes'. It seems not improbable but that the Glass may also be polished with proper care by the same method.

The method of polishing, described by Pere Cherubin, seems to be chiefly thus: he polishes with tripoly or putty, or first with tripoly, and afterwards with putty. But what he seems most to approve of is putty alone. He polishes in the same tool he grinds in, and he very verbosely describes various ways of doing it. He prescribes to stretch, very tight, a very fine thin leather, or fine English fustian, or fine holland, or any fine linen, or fine silk taffety, or sattin, all of an equable thickness as near as may be, upon the tool; then he daubs thinly on this surface, thus stretched, a streak of putty, sufficiently wetted to the consistence of thick syrup, about as broad as the Glass or a little more, passing through the center of the tool directly from him; then smoothing the putty by running his bruiser, and pressing it backwards and forwards to him and from him, he at length lays on the Glass cemented to its handle; and giving it always the same motion, strongly pressing to him, and from him along the streak of putty, and by such pressure forcing the surface of the silk, already somewhat stretched, close to the surface of the tool, to which the figure of the Glass was exactly adapted, he says that he could by that means obtain an excellent fine polish on any of the above-mentioned substances. Before the stroke he turned the Glass a little on its axis, and its handle was on this occasion considerably heavier than usual in grinding, which he commends as very useful in this business; and, if new putty was wanting, he made no difficulty of laying it on, as often as necessary; always carefully smoothing it thereon with the bruiser, before the Glass was applied.

This method I am of opinion might be improved by moving the Glass not by hand but by the pole, and spring, somewhat after the method of Mr. Huygens, especially if the pole were contrived not to move loose in a round brass hole above, but on a strong point pressed down by some spring; the length of the pole being equal to the radius of the tool, and the point where the spring presses the upper end of the pole, being truly perpendicular over the center of the tool, and exactly in the center of its sphere.

Another method which the same author prescribes for polishing in the tool is thus: he takes a sheet of very fine paper, and, examining it very carefully by looking upon it and through it, he takes off with a fine penknife all the little lumps, hard parts, roughnesses and inequalities that he can find; then he soaks it in clean water, then he takes it and dries it between two clean linen cloths, though not so much as to make it quite dry, but to leave it dampish; then with some very thin starch or paste he daubs equally all over the surface of his tool as thin as possible, but some every-where; then he lays on his paper very gently and slowly, letting it touch and stick first at one side, and by degrees more and more towards the middle, and by degrees to cover the whole; and he does this slowly to let all the air get out; then with the palm of his hand he presses the center and every-where round about it towards the circumference to make the paper stick every-where; and this he does three or four times, while it is drying, to get out all the air; he lets it dry of itself, then he revises it again with his knife as before; then he hath a very coarse bruiser of glass whose circumference is sharply ground round and at right angles to its surface, which he had coarsely ground before in the same tool; with this and a very heavy handle he smooths and polishes and rubs off all the remaining inequalities of the paper, and, when this is done, he lays on a streak of tripoly and polishes as in his other method.

At C C (*Plate* XXI. *fig.* 9.) is represented a square beam of wood a little longer than the diameter of the tool, and about 1 , inch thick; the two extremities of it at C and C are bent downwards, and then are again directed parallel to the whole length, and serve for handles for the workman to lay hold upon. In the middle of this beam there is fixed an iron spike, so long that, when the lower surfaces of the handles C, C, are placed upon a plane, the point of the spike shall just touch the plane. This point presses upon the apex of the hollow cone, which descends through the hole in the slate, which by the interposition of a cloth was cemented to the glass B lying upon the tool A. To increase this pressure a sort of bow D E D is shaped out of a deal board, half an inch thick and 5 feet long, being 7 inches broad in the middle, and tapered narrower towards its extremities, so as to end almost in a sharp point. The middle of the bow is fixed to the floor by an iron staple at E driven cross it, and is bent into an arch by a rope F I I F; to which two other ropes are tied at I and I; the interval I I being equal to the length of the beam C C. One of these ropes I C C G goes over the back of the beam C C, passing through a hole in each handle at C and C, and then is lapped round a cylindrical peg at G, that passes through two wooden chaps, to the bottom of which the other rope is tied that comes from the other I. So that by turning the peg G, to lap the rope about it, the bow D D may be bent as much as you please. The tool A is placed upon a strong square board fixed to the table O on one side, and supported on the other side by the post P. Then the workman sits down, and, taking hold of the handles C C, he draws the glass to him and from him over the tool A, with a moderate motion. And after every 20 or 24 strokes he turns the Glass a little about its axis. This way of polishing took up two or three hours, and was very laborious as well as tedious, because the glass, being so much pressed downwards, was moved very slowly.

Instead of the bow D D (*fig.* 10.) afterwards I invented another spring, by sloping the flat ends of a couple of deal boards $\alpha\beta$, $\alpha\gamma$, and by nailing the flat slopes together very firmly, that the boards might make an acute angle $\beta\alpha\gamma$. One of these boards so joined was laid upon the floor under the polishing table, the end $\beta\gamma$ being under the middle of the tool A, so that they lay quite out of the way of the workman, who before was a little incommoded by the ends of the bow.

D D. The boards at the end α were 8 or 10 inches broad, and from thence went tapering almost to point at β and γ. The board $\alpha\gamma$, lying upon the floor, the end β of the upper board was pulled downwards by a rope $\beta\iota\zeta$ that passed under a pulley ι, fixed to the floor, and then was lapped round a strong peg ζ that turned stiff in a hole in the floor. Under the end γ the middle of a strong stick $\delta\gamma\delta$ was fixed at right angles to the board $\alpha\gamma$, and cords were tied to each end of this stick at δ, δ, which went over the polishing beam C, C, as in the former machine. This stick was lifted up but very little from the floor at the time of polishing; and by consequence the ropes, δ C, δ C, were long enough to give liberty of motion to the polishing beam C C. Two iron pins θ, θ, passing through the ends of the boards α, were skrewed into the floor; but the heads of the pins stood up above the boards, to give them liberty to rise up, when the rope $\beta\iota\zeta$ was stretched.

To facilitate the labour of moving the glass backwards and forwards in the tool, I made this addition to the former machine. At M (*fig.* 9.) is represented a strong hand made of wood or iron, having a square cavity cut through the bottom of of it, for the polishing beam C C to pass through, not tight, but with some liberty. To one side of this hand M a long board L L is annexed, some way or other, by means of an iron bolt. The breadth of the lower surface of this board L L is equal to the breadth of the hand M, being 2 inches and a half; its thickness is half an inch, and its length is equal to three semidiameters of the tool. The board L L must be drawn lengthways backward and forward over a block H fixed firmly to a table O; the thickness of the block being such that the boar L L may lie an inch higher than the surface of the tool A. The wooden hooks at Π and the pins at Σ keep the motion of the board in the same direction, by hindering it from slipping either sideways or upwards. Over this board, at right angles to it, and over the middle of the block H, there lies a wooden roller, having a strong iron axis which turns in the holes of two iron plates fixed to the ends of the block. The thickness of the roller is about an inch and a half. Through two holes bored through this roller and made wider at one end of them, two strong cords are made to pass with knots at one end of them, to be drawn into the wider parts of the holes, that they may neither slip through nor stand out from the roller. Then each cord is lapped round the cylinder several times, and one end of each is pegged firmly into the board L L at the end towards M, and the other ends of them are lapped round a peg at N; which, being turned round will stretch the cords as much as you please. At one end of the axis of this roller there is a handle Q, which being turned round, backwards and forwards alternately, the board L L, with the glass annexed to it, is moved to and fro, so far, that about a third part of its diameter shoots both ways over the margin of the tool. The spike in the middle of the beam C C presses the Glass a little obliquely, because the hand M holds the beam C C, not tight but somewhat loosely, to the end that the Glass may pass over the tool without trembling. Nevertheless this inclination of the spike must be but very small, and may easily be increased or diminished several ways. Two pins or stops must be fixed to the under surface of the board L L, to determine the length of the stroke. The tool A, or rather the stone to which it is cemented, is squeezed fast between the block H and a strong stop on the opposite side of the stone, by the interposition of a wedge. The workman sits upon a round stool, and, when one hand is tired with turning the roller, he applies the other; and therefore is not tried so soon as with the other machine, which required both hands, and also a reciprocating motion of his whole body. Some time after, I caused a longer handle Q *a* to be made that turned at both ends, for the convenience of using both hands at once.

After every 20 or 24 strokes it is necessary to give the glass a small turn about its axis; which is easily done by laying hold of the slate fixed to it, with one hand, while the other hand goes on with the polishing motion. The tool must also be moved a little after every 25 or 50 strokes, by drawing it half a straw's breadth towards that part of it which the Glass has left, and by drawing it back again after as many more strokes. At the beginning of the work the tripoly will be gathered into little lumps in some places of the tool, but will be dispersed again, in a little time; and then the area of the tool will become perfectly smooth.

If the tripoly does not appear to stick equally to the glass in all parts, and to be diffused over it in slender straight streaks, the frying-pan, with coals in it, must be held over the tool again; till you perceive the area or coat of tripoly is not quite so cold as the other parts of the tool. Then let tripoly be rubbed upon the tool again, and let the Glass be pressed over it with your hand, to try whether it sticks equally to the Glass in every place. When it does, you may proceed to the work of polishing. But, after I began to make use of vitriol instead of verdigrease, all that I have said about warming the tool may be omitted. Because these coats always touch the Glass as they should do, and stick better than before. Also let the tool be rubbed with tripoly over the coat without warming the tool, that the coat may be preserved more entire, and that the Glass may touch it better; which must always be repeated after 200 or 400 strokes in polishing. The Glass should also be taken from the tool after 200 strokes, by withdrawing the bolt L which connects the hand M to the board L L, and by removing the beam C C. Then rub your finger upon the glass, or a clean rag or a bit of leather, to examine how much it is polished.

To save the trouble of counting the strokes, there is a wooden wheel Δ X, 7 or 8 inches broad, placed flat against a board, fixed to the side of a wall. It turns easily about an axis, and has 24 teeth, like those of a saw, which are pushed round by a bended wire T Y X, in this manner: the wire turns about a center Y, and while one end of it is pulled by the string T V, tied to the end of the board L L, the opposite end Y X pushes back a long string R S fixed to the board at R; which by pressing upon the wire at S causes the part Y X to bend a little, and so the point X, in returning to the wheel (the string being relaxed) falls a little lower, into the next tooth, and pushes it forward into the position represented in the figure. There is a springing catch at Δ which stays the wheel after every stroke at X. Lastly, there is a pin fixed in the circumference of the wheel at Z, which, by pressing the tail of a hammer and letting it go again, causes a bell to sound after every revolution of the wheel, and gives notice that the Glass must be turned a little about its center. It is easy to understand that another piece of wheel-work, having three or four indexes, whose revolutions are in decimal progression, may be fixed to the block H and impelled by the strokes of the board L L; by which means, without any trouble of counting, one may be informed how many strokes go to polish a Glass.

A glass 5 or 6 inches broad requires about 3000 strokes upon each surface, to bring it to perfection: and you must carefully examine the middle of the Glass opposite to the blacking, whether any place appears darkish or of an ash-colour, or whether any small spots appear by an oblique reflection of the light of a candle or of a small beam of light let into a dark room. For the other parts of the Glass will appear perfectly fine much sooner than the middle.

After the glass has been sufficiently polished, let the stone, the cloth, and the cement be warmed over a pan of charcoal, till the cement grows so soft that the Glass may be separated from it by a side motion. Then whatever cement remains upon the Glass must be wiped off with a hot cloth dipped in oil or tallow, and last of all with cleaner cloths. Then if it does not appear perfectly polished (for we are often deceived in this point) the work must be repeated again, by glewing the Glass to the slate as before; then it must be wiped very clean and be made a little rough, as we said before. We may also lay a new fund or coat upon the tool, if the old one be spoiled, provided no other Glass has been polished in the tool in the mean time. The old fund may be washed off from the tool with a little vinegar. Lastly, take care always to chuse the thickest and the clearest pieces of Glass, to avoid a great many difficulties that arise from the unequal pressure in polishing. *Smith's Optics.*

GLASS-*chalcedony.* A mixture of several ingredients, with the common matter of Glass, will make it represent the semi-opake gems, the jaspers, agates, chalcedonies, &c.

The way of making these seems to be the same thing with the method of making marbled paper, by several colours dissolved in several liquors, which are such as will not readily mix with one another, when put into water, before they are cast upon the paper which is to be coloured. There are several ways of making these variously coloured Glasses, but the best is this: dissolve four ounces of fine leaf silver in a Glass vessel in strong aqua fortis, stop up the vessel, and set it aside.

In another vessel dissolve four ounces of quick-silver in a pound of aqua fortis, and set this aside.

In another Glass vessel dissolve in a pound of aqua fortis three ounces of fine silver, calcined in this manner: amalgamate the silver with mercury, mix the amalgama with twice its weight of common salt well purified; put the mixture in an open fire in a crucible, that the mercury may fly off, and the silver be left in the form of powder. Mix this powder with an equal quantity of common salt well purified, and calcine this for six hours in a strong fire; when cold, wash off the salt by repeated boilings in common water, and then put the silver into the aqua fortis. Set this solution also aside.

In another vessel dissolve in a pound of aqua fortis three ounces of sal armoniac, pour off the solution, and dissolve it in a quarter of an ounce of gold. Set this also aside.

In another vessel dissolve three ounces of sal armoniac in a pound of aqua fortis, then put into the solution cinnabar, crocus martis, ultramarine, and ferretto of Spain, of each half an ounce. Set this also aside.

In another vessel dissolve in a pound of aqua fortis three ounces of sal armoniac, then put into it crocus martis made with vinegar, calcined tin, zaffer, and cinnabar, of each half an ounce; let each of these be powdered very fine, and put gently into the aqua fortis. Set this also aside.

In another vessel dissolve three ounces of sal armoniac in a pound of aqua fortis, and add to it brass calcined with brimstone, brass thrice calcined, manganese, and scales of iron which fall from the smith's anvil, of each half an ounce; let each be well powdered, and put gently into the vessel. Then set this also aside.

In another vessel dissolve two ounces of sal armoniac in a pound of aqua fortis, and put to it verdigrease an ounce, red lead, crude antimony, and the caput mortuum of vitriol, of each half an ounce; put these well powdered leisurely into the vessel, and set this also aside.

In another vessel dissolve two ounces of sal armoniac in a pound of aqua fortis, and add orpiment, white arsenic, painter's lake, of each half an ounce: keep these nine vessels in a moderate heat for fifteen days, shaking them well at times. After this pour all the matters from these vessels into one large vessel, well luted at its bottom; let this stand six days, shaking it at times, and then set it in a very gentle heat, and evaporate all the liquor, and there will remain a powder of a purplish green.

When this is to be wrought, put into a pot very clear metal, made of broken crystalline and white glass, that has been used; for with the virgin frit, or such as has never been wrought,

wrought, the chalcedony can never be made, as the colours do not stick to it, but are consumed by the frit. To every pot of twenty pounds of this metal put two or three ounces of this powder at three several times; incorporate the powder well with the Glass, and let it remain an hour between each time of putting in the powder. After all is in, let it stand twenty-four hours; then let the Glass be well mixed, and take an essay of it, which will be found of a yellowish blue; return this many times into the furnace; when it begins to grow cold, it will shew many waves of different colours very beautifully. Then take tartar eight ounces, soot of the chimney two ounces, crocus martis made with brimstone half an ounce; let these be well powdered and mixed, and put them, by degrees, into the Glass at six times, waiting a little while between each putting in; when the whole is put in, let the glass boil and settle for twenty-four hours, then make a little Glass body of it, which put in the furnace many times, and see if the Glass be enough, and whether it have on the outside veins of blue, green, red, yellow, and other colours, and have, besides these veins, waves like those of the chalcedonies, jaspers, and oriental agates, and if the body kept within looks as red as fire.

When it is found to answer thus, it is perfect, and may be worked into toys and vessels, which will always be beautifully variegated; these must be well annealed, which adds much to the beauty of their veins. Masses of this may be polished at the lapidary's wheel as natural stones, and appear very beautiful. If in the working the matter grow transparent, the work must be stopped, and more tartar, soot, and crocus martis, must be put to it, which will give it again the necessary body and opacity, without which it does not shew the colours well. *Neri's Art of Glass.*

GLASS *of lead*, a Glass made with the addition of a large quantity of lead, of great use in the art of making counterfeit gems. The method of making is this: put a large quantity of lead into a potter's kiln, and keep it in a state of fusion with a moderate fire till it is calcined to a grey loose powder; then spread it in the kiln, and give it a greater heat, continually stirring it, to keep it from running into lumps; continue this several hours, till the powder becomes of a fair yellow, then take it out and sift it fine; this is called calcined lead.

Take of this calcined lead fifteen pounds, and crystalline, or other frit, twelve pounds; mix these as well as possible together, put them into a pot, and set them in the furnace for ten hours; then cast the whole, which will be now perfectly melted, into water; separate the loose lead from it, and return the metal, into the pot, and, after standing in fusion twelve hours more, it will be fit to work. It is very tender and brittle, and must be worked with great care, taking it slowly out of the pot, and continually wetting the marble it is wrought upon.

Glass of lead is capable of all the colours of the gems in very great perfection. The methods of giving are these: for green, take polverine frit, twenty pounds; lead calcined, sixteen pounds; sift both the powders very fine, then melt them into a Glass, separating the unmixed lead, by plunging the mass in water; after this return it into the pot, and add brass thrice calcined, six ounces; and one penny-weight of crocus martis made with vinegar; put this in at six different times, always carefully mixing it together; let it finally settle an hour, then mix it together and take a proof of it; when the colour is right, let it stand eight hours, and then work it. If instead of the calcined brass, the same quantity of caput mortuum of the vitriolum veneris be used, the green is yet much finer.

For topaz colour, take crystal frit, fifteen pounds; calcined lead, twelve pounds; mix them well together by sifting the powders through a fine sieve, then set them in a furnace not too hot, and separate the superfluous unmixed lead, by casting the whole into water; repeat this twice, then add half gold yellow Glass, and let them incorporate and purify, and they will be of the true and exact colour of the oriental topazes.

For sea-green, take crystal frit, sixteen pounds; calcined lead, ten pounds; mix and sift them together, and set them in a pot in a furnace, and in twelve hours the whole will be melted; then cast it into water, and separate it from the loose lead; put them into the furnace again for eight hours, then separate the loose lead by washing a second time, and return it to the pot for eight hours more. *Neri's Art of Glass.*

GLASS-*balls*, a term used to express circular or otherwise shaped hollow vessels of Glass, coloured within, so as to imitate the semipellucid gems. The method of doing it is this: make a strong solution of ichthyocolla or isinglass in common water by boiling; pour a quantity of this while warm into the hollow of a white Glass vessel, shake it thoroughly about, that all the sides may be wetted, and then pour off the rest of the moisture. Immediately after this, throw in red-lead; shake it and turn it about, throw it into many places with a tube, and the moisture will make it stick and run in waves and pretty figures. Then throw in some of the painter's blue smalt, and make it run in waves in the ball as the red-lead; then do the same with verdigrease, next with orpiment, then with red-lake, all well ground; always casting in the colours in different places, and turning the Glass, that the moisture within may run them into the waves. Then take fine plaister of Paris, and put a quantity of it into the ball, shake it also nimbly about; this will every-where stick firmly to the Glass, and give it a strong inner coat, keeping all the colours on very fairly and strongly. These are set on frames of carved wood, and much esteemed as ornaments in many places. *Neri's Art of Glass.*

GLASS *globules for telescopes.*— Mr. Butterfield tells us, he had tried several ways of making Glass globules of the bigness of great pins heads, and less, as in the flame of a candle, made of tallow or wax; but, that the best sort of flame for making them clear and without specks was, that of a lamp, made with rectified spirits of wine. Where, instead of a cotton wick, he made use of fine silver wire doubled up and down like a skein of thread. Then, having prepared some fine Glass, beaten to powder and washed very clean, he took a little of it upon the sharp point of a silver needle wetted with spittle, and held it in the flame, turning it about till it melted and became quite round, but no longer, for fear of burning it. The art lies in giving the globule an exact roundness, which can only be learned by experience. When a great many globules are thus formed, he rubs them clean with a soft leather. Then having several small pieces of thin brass-plates, twice as long as they are broad, he doubles them up into the form of a square, and punches a fine hole through the middle of them: and having rubbed off the bur about the holes with a whetstone, and blacked the insides of the plates with the smoke of a candle, he places a globule between the two holes, and tacks the plates together with two or three rivets. Then he tries how they magnify small objects, and keeps the best of them for use.

Dr. Hook used to take a very clear piece of Glass, and to draw it out into long threads in a lamp; then he held these threads in the flame, till they ran into round globules, hanging to the end of the threads. Then having fixed the globules with sealing-wax to the end of a stick, so that the threads stood upwards, he ground off the ends of the threads upon a whetstone, and polished them upon a smooth metal plate with a little putty.

Mr. Stephen Gray tells us, that, for want of a spirit lamp, he laid a small particle of Glass, about the bigness of the intended globule, upon the end of a piece of charcoal; and, by the help of a blast-pipe, with the flame of a candle he soon melted it into a globule. By this means he made them indifferently clear, and the smallest very round; but the larger, by resting upon the coal, were a little flatted, and received a roughness on that side. Therefore he was wont to grind and polish them upon a brass plate, till he reduced them to hemispheres. But he found that the small globules, besides that they magnified more, shewed objects more distinct than the hemispheres.

These experiments led him to another which is very curious. Having observed, says he, some irregular particles within the Glass globules, and finding they appeared distinct and prodigiously magnified, when held close to my eye; I concluded that if I conveyed a small globule of water close to my eye, in which there were any opacous or less transparent particles than the water, I might see them distinctly. I therefore took on a pin a small portion of water which I knew to have in it some minute animals, and laid it on the end of a small piece of brass wire, that then lay by me, about one tenth of an inch in diameter, till there was formed somewhat more than an hemisphere of water. Then, keeping the wire erect, I applied it to my eye, and standing at a proper distance from the light, I saw them and some irregular particles as I had predicted, but most enormously magnified. For, whereas they were scarce discernable by my Glass microscope, they appeared within the globule not much different in form, nor less in magnitude than ordinary pease. They cannot well be seen by day-light, unless the room be darkened, after the manner of the famous dioptrical experiment, but most distinctly by candle-light. They may also be seen very well by the full-moon light.

Mr. Gray explains the reason of this appearance as follows: Let the circle D B B D (*Plate* XXI. *fig.* 11.) represent a sphere of water, A, an object placed in its focus, sending forth a cone of rays, two of which are A B, A B; which, coming into the water at B and B, will be refracted from their direct course, and become B D, B D; and, at D D, they will, at their passing into air, again be refracted into D E, D E; and so run parallel to one another, and to the axis of the sphere A F C G. Now, it is a known principle in optics, that the angle of reflexion is equal to the angle of incidence: wherefore let the rays B D, B D, be imagined to have come from some point F of an object placed within the sphere of water, by being reflected from the interior surface of the sphere at B B. But C B D is the angle of reflexion, to which making C B F equal, the point F will be the place, from whence, if an object sends forth a cone of rays, two of them as F B, F B, will be reflected into the lines B D, B D; and then, coming to the other side of the globule at D D, they will be refracted into D E, D E, as before: and, consequently, will be fit for distinct vision, whether the object be placed in F within, or in A without the sphere, if its interior surface be considered as a concave speculum.

GLASS *porcelain*, the name given by many to a modern invention of imitating the China ware with Glass. The method given

given by Mr. Reaumur, who was the firſt that carried the attempt to any degree of perfection, is delivered by that gentleman in the Memoirs of the Academy of Sciences of Paris, to this effect.

The mixing of Glaſs reduced to powder, with other leſs eaſily vitrifiable ſubſtances for the forming a paſte to be afterwards made into a ſort of porcelain, has been a contrivance long practiſed, but it is very troubleſome, and the reſult ſubject to many faults; but this new ware is made of Glaſs alone, and that with much leſs trouble, and without the reducing it to powder. By this art, veſſels of Glaſs are changed into veſſels of a ſort of porcelain, without altering their form, and the meaneſt Glaſs ſerves as well as the beſt for that purpoſe; our common coarſe green quart bottles, or the great bell Glaſſes with which gardeners cover their melons, &c. being by this means changeable into a beautiful white ſort of porcelain ware; and this is to be done in ſo eaſy a manner, and with ſo ſmall an expence, that it requires no more trouble or charge, than that of baking a common veſſel of our coarſe earthen ware, and, for this reaſon, the veſſels of this ſort of ware may be afforded extremely cheap.

It is very certain, that all porcelain ware is a ſubſtance in the ſtate of a ſemivitrification; and, in order to bring Glaſs, which is a wholly vitrified ſubſtance, into the condition of porcelain, there requires no more than to reduce it to a leſs perfectly vitrified ſtate.

The queſtion which would naturally be ſtarted on this occaſion, is, whether it be poſſible to reduce Glaſs into a leſs vitrified ſtate, it having already undergone what is eſteemed the laſt change by fire? But when we conſider that the Glaſs of antimony, the vitrifications of many of the metals, as the Glaſs of lead, and the counterfeit gems coloured by the metals, are more or leſs eaſily reduced again by chemiſtry to metals, &c. the reducing ſand, flints, &c. after they are vitrified, at leaſt a little way back toward their native or priſtine ſtate, may appear not wholly impracticable; and the attempts which Mr. Reaumur made on this occaſion, were what gave him the firſt hints of the Glaſs porcelain.

The method of making it is this: the Glaſs veſſels to be converted into porcelain, are to be put into a large earthen veſſel, ſuch as the common fine earthen diſhes are baked in, or into ſufficiently large crucibles; the veſſels are to be filled with a mixture of fine white ſand, and of fine gypſum or plaiſter-ſtone burnt into what is called plaiſter of Paris; and all the interſtices are to be filled up with the ſame powder, ſo that the Glaſs veſſels may no where touch either one another, or the ſide of the veſſel they are baked in. The veſſel is to be then covered down and luted, and the fire does the reſt of the work; for this is only to be put into a common potter's furnace, and, when it has ſtood there the uſual time of the baking the other veſſels, it is to be taken out, and the whole contents will be found no longer Glaſs, but converted into a white opake ſubſtance, which is a very elegant porcelain, and has almoſt the properties of that of China. *Mem. Acad. Scien. Par.* 1739.

GLASS *pots*, the veſſels in the Glaſs trade uſed for melting the Glaſs. Thoſe for the white Glaſs works are made of a tobacco-pipe clay, brought from the iſle of Wight, which is firſt well waſhed, then calcined, and afterwards ground to a fine powder in a mill; which, being mixed with water, is then trod with the bare feet, till it is of a proper conſiſtence, to mould with the hands into the proper ſhape of the veſſels. When theſe are thus made, they are afterwards annealed over the furnace. Thoſe for the green Glaſs work are made of the none-ſuch, and another ſort of clay from Staffordſhire; they make theſe ſo large as to hold three or four hundred weight of metal. And, beſides theſe, they have a ſmall ſort called piling pots, which they ſet upon the larger, and which contain a finer and more nice metal fit for the niceſt works. *Neri's Art of Glaſs.*

GLA'ZING, in pottery, a compoſition applied to veſſels of earth, &c. to render them more beautiful, and prevent fluids from penetrating them.

Black GLAZING, is made of lead-aſhes, eighteen meaſures; iron-filings, three; copper-aſhes, three; and zaffer, two meaſures. This, when melted, will make a brown black; and, if you want it blacker, add more zaffer to it.

Blue GLAZING is thus prepared: take lead-aſhes, one pound; clear ſand or pebble, two pounds; ſalt, two pounds; white calcined tartar, one pound; Venice, or other glaſs, ſixteen pounds; and zaffer, half a pound; mix them well together, and melt them for ſeveral times, quenching them always in cold water. If you would have it fine and good, it will be proper to put the mixture into a glaſs furnace for a day or two.

Brown GLAZING, is made of common glaſs and manganeſe, or brown ſtone, of each one part; and lead of glaſs twelve parts.

Fleſh colour GLAZING, is made of twelve parts of lead-aſhes, and one of white glaſs.

Gold-coloured GLAZING. To make gold-coloured Glazing, take of litharge three parts; of ſand or calcined flint, one part; pound and mix theſe very well together, then run them into a yellow glaſs with a ſtrong fire. Pound this glaſs and grind it into a ſubtile powder, which moiſten with a well ſaturated ſolution of ſilver, and make it into a paſte; which put into a crucible, and cover it with a cover. Give at firſt a gentle degree of fire, then increaſe it, and continue it till you have a glaſs, which will be green. Pound this glaſs again, and grind it to a fine powder; moiſten this powder with ſome beer, ſo that, by means of a hair pencil, you may apply it upon the veſſels, or any piece of earthen ware. The veſſels that are painted or covered over with this Glazing, muſt be firſt well heated, then put under a muffle, and, as ſoon as the glaſs runs, you muſt ſmoak them, and take out the veſſels. Mr. Heinſius of Peterſburgh, who ſent this receipt to the Royal Society, uſes the words afflare debes fumum, which is rendered ſmoak them, in the Tranſactions. *Phil. Tranſ.* N°. 466.

Green GLAZING may be prepared of eight parts of litharge, eight parts of Venice glaſs, four parts of braſs duſt; or of ten parts of litharge, twelve of flint or pebble, and one of æs uſtum, or copper aſhes.

Iron-colour GLAZING is prepared of fifteen parts of lead aſhes, fourteen of white ſand, five of copper aſhes, one of manganeſe, one of zaffer, and one of iron filings.

Liver-coloured GLAZING is prepared of twelve parts of litharge, eight of ſalt, ſix of pebble or flint, and one of manganeſe.

Purple-brown GLAZING conſiſts of lead aſhes, fifteen parts; clear ſand, eighteen parts; manganeſe, one part; white glaſs, fifteen meaſures; and one meaſure of zaffer.

Red GLAZING is made of antimony, two pounds; litharge, three; and ruſt of iron calcined, one; grind them to a fine powder.

Sea-green GLAZING is made of five pounds of lead aſhes, one pound of tin aſhes, three pounds of flint, three quarters of a pound of ſalt, half a pound of tartar, and half a pound of copper duſt.

White GLAZING. A fine white Glazing for earthen ware is thus prepared: take two pounds of lead, and one of tin; calcine them to aſhes: of this take two parts, calcined flint or pebble, one part; and ſalt, one part; mix them well together, and melt them into a cake for uſe.

The white Glazing for common ware is made of forty pounds of clear ſand, ſeventy-five pounds of litharge or lead aſhes, 26 pounds of pot-aſhes, and ten pounds of ſalt: theſe are three times melted into a cake, quenching it each time in clear cold water. Or it may be made of fifty pounds of clean ſand, ſeventy of lead aſhes, thirty of wood aſhes, and twelve of ſalt.

Yellow GLAZING is prepared of red-lead, three pints; antimony and tin, of each two pounds. Theſe muſt be melted into a cake, then ground fine; and this operation repeated ſeveral times. Or it may be made of fifteen parts of lead ore, three parts of litharge of ſilver, and fifteen parts of ſand.

Citron-yellow GLAZING is made of ſix parts of red-lead, ſeven parts of fine red brick-duſt, and two parts of antimony. *Vid. Smith's Laboratory.*

GLAU'CIUM, *yellow horned poppy*, in botany, a genus of plants whoſe characters are:

The end of the pedicle is expanded into an orbicular placentula, terminated by a hollow ſpherical ſubſtance, to which it grows. The calyx conſiſts of two leaves, and is caducous: the flower is tetrapetalous, expanding in form of a roſe or poppy, and furniſhed with very numerous ſtamina, which, for the moſt part, fall off, after the opening of the flower. The ovary ariſes from the bottom of the placentula, with a hairy bifid apex; and ripens into a long, ſmooth, bivalve pod, the valves adhering to the intermediate partition, in ſuch a manner as to leave the whole capacity unicapſular, and full of roundiſh ſeeds.

Dioſcorides ſays, this plant is diuretic; and Galen looks upon it to be vulnerary and deterſive; but he conſiders not, that it muſt be uſed only to eat away the proud fleſh of ulcers. Nevertheleſs, in Portugal, they give the infuſion of half a handful of it, in white wine, to thoſe who are ſubject to the ſtone. In Provence, they uſe the ſame leaves, bruiſed, for ulcers; and, above all, for the wounds of horſes. *Martyn's Tournefort.*

GLAUX, in botany, the name of a plant, alſo called the milkwort of Dioſcorides.

It grows in hilly and chalky fields, and the herb is in uſe; which, boiled in barley water, is effectual, as Dioſcorides ſays, for renewing milk in women's breaſts, where it is loſt.

There is a diſpute among the botaniſts, about the Glaux of Dioſcorides. Anguillarius, Parkinſon, and Alpinus, will have it to be the lotus; Geſner, the onobrychis; Turner, the Glaux vulgaris (liquorice vetch) Dodonæus, Cordus, and C. Bauhine, a ſpecies of a certain ſmall marine plant; Lobel, Gerard, and Cluſius, the plant deſcribed by Dioſcorides, as follows: 'The Glaux has leaves like thoſe of the cytiſus or lentil, green on the upper ſide, and whitiſh underneath. The root ſends forth five or ſix ſlender ſtalks, a ſpan high; the flowers are of a purple colour, and reſemble thoſe of the leucoium (ſtock gilliflower) only ſmaller. *Dale.*

GLOBULA'RIA, *French daiſy*, in botany, a genus of plants whoſe characters are:

The floſcules are unilabiated, multifid, connected each to its proper calyculus, and collected very many together into one globoſe flowery head, ſurrounded with one common calyx.

 The

The calyculus, or little flower cup, of the flosçule becomes a capsule, which contains the seed, and is affixed to the common placenta.

It is to be found in the gardens of the curious, and flowers in summer. The plant is a vulnerary. *Dale.*

GLOW-*worm*, *cantharis*, in zoology, a class of insects, the antennæ of which are cetaceous, the exterior wings flexile, the thorax somewhat flatted, and the sides of the abdomen plicated and papillose.

The common Glow-worm is frequently met with under our hedges, and, if carefully taken up, may be kept alive many days on fresh turfs of grass; all which time it will continue to shine in the dark.

The light of this little insect is so strong, that it will shew itself through several substances, in which the creature may be put up; a thin pill-box easily shews it through, and even though lined with paper, the light is not impeded in its passage by both. The creature is sluggish, and appears dead in the day-time; and its light is not distinguishable, even if carried into a darkened room, unless the creature be turned upon its back, and disturbed, so as to be put in motion; and then it is but very faint: after sun-set the light begins to return, and with it the life and motion of the animal. The motion and light of this creature seem, in some measure, to depend upon one another: it never shines but when it is in some sort of motion; and, when it shines most, the body is extended to one third more than its length in the day-time. In the time of brightest shining, it will sometimes, of a sudden, turn its body about, and the light will not be larger than the head of a pin; and, on being touched, she will then immediately extend herself, and the light will become as large and as bright as ever. *Phil. Transf.* N°. 71.

Flying GLOW-*worm*, *cicindela volans*. In the warmer months of the year, this creature is sometimes caught in our houses flying to the flame of a candle; and, when examined in the dark, it is found luminous at these times, though perhaps less, or not at all so, at others; which may be a reason of its not being known, though caught in the fields; and to this it may be owing, that many who have described it, have thought it not a native of England.

Without wings it is frequently enough found in form of the common Glow-worm, and then always shines.

The male and female, in this winged state, both shine in hot weather, and their light is so vivid as to be easily seen, even while there is a candle in the room; the vibrations of it are irregular, and its colour greenish. The luminous parts are two small specks under the tail at the end, and the light continues in these some time after the tail is cut off, but then gradually goes out.

The parts of insects continue alive in some degree, for a considerable time after they are cut off; and probably the light in the tail of this animal continues just as long as that sort of life remains in it. *Moffett.*

The use of this light seems to be to direct the animal in its course, and in the taking of its prey, and to this purpose it is admirably placed. The tail is easily bent under the belly, and then throws the light full upon any object about, or under the head of the animal; and the eyes are placed, not on the upper part, but on the under-side of the head; so that they have all the advantages of it, while the light in this part is not offensive to the eyes, as it naturally would have been, if carried before the head. The creature can upon occasion cover this light so as not to be known, or pursued by it, by its enemies. *Thomas Barthol. de Luce Anim.*

GNATS, in natural history.—All the Gnats have a long cylindric body composed of eight rings; their corslet is short, but large in proportion to the size of the fly, and to this are fixed the legs, the wings, and the balancers; four stigmata are also found here, as is the case in other flies. The two first of these are placed near the head, and have been mistaken for ears.

When the Gnat is in a state of rest, it holds one wing somewhat crossed over the other, in such a manner, as that they cover the body. It has a multitude of little oblong scales on its wings, and not only there, but on its corslet and body; and they are so thick laid on the body, that one cannot touch it without rubbing them off, and leaving the part naked. Besides these, they have also very long and extremely fine hairs, and some of the species have ranges of these on each side of the body appearing like fringes. The antennæ of the Gnats are extremely worth observation, and differ much from one another. Some of them are elegantly feathered; these belong to the males of certain species, for the antennæ of the females are not so beautiful.

These feathered antennæ of the male Gnats, examined by the microscope, shew, at every junction of two of the rings, a small cluster of hairs in form of a pencil on each side; the hairs of which they are composed separate, and spread toward their extremities; these clusters of them grow shorter, as they approach the upper part of the antennæ; and, towards the extremity of each, there is a vacant space where they are wholly wanting; this part, however, is covered with single short hairs.

The antennæ both of the males and females of some species have also thin stalks covered with single hairs, and at certain distances; or at every articulation these have four hairs longer than the rest, and easily distinguishable by the naked eye.

The Gnats have no small or glossy eyes, as most other flies have, but, in recompence for the want of these, they have reticular eyes, so large as to surround, and, in a manner, cover the whole head. Those of many species are extremely beautiful, of a fine changeable green in some lights, and of a bright red in others.

Many of the species of Gnats have before their heads two small oblong cylindric bodies, something resembling the antennæ of the short-bodied flies; these we may not improperly call the beards of the Gnats, for immediately below them is placed the trunk, and they seem to have some analogy with the beards of the butterfly class, which are placed in the same manner. *Reaumur's Hist. Inf.* For the trunk and wings of the Gnat, see the articles TRUNK and WINGS.

GNAT-*worm*, in natural history, a small water insect, produced of the egg of a Gnat, and which is, after its several changes, transformed into a Gnat again.

GOAT, *capra*, in zoology, a genus of animals, the characters of which, according to Mr. Ray, are these: that it is covered with hairs, not with wool; that its horns are less crooked than those of the sheep, and that it has a beard hanging down from its chin, and is of a strong smell.

It is very singular, that this genus of animals are all able to run and climb about the rugged parts of mountains without falling, though their feet seem by no means contrived by nature for any such purposes.

Goats may be of great advantage to the farmers in some parts of the kingdom, as they will live in rocky barren countries, where nothing else can get a support for life. They will climb the steepest rocks, and there browse upon briars, heath, and shrubs of various kinds, which other creatures will not taste of. They will feed on grass in pastures, but, as they love browsing on trees much better, great care must be taken to keep them from valuable plantations.

The greatest advantage of these creatures is their milk, which they yield in large quantities; and which is accounted the best milk of all animals. They mix this and cows milk together in many parts of the kingdom, and a very valuable kind of cheese is made of it. Beside this, the kids or young Goats are very fine food, and the best kinds bring forth these two or three at a time, and that twice a year.

Goats hair also is of value; it may be sheared as the wool from the sheep, and is excellent for making ropes that are to be used in the water, as they will last a great while longer than those made the common way. A sort of stuff is also made of it in some places. The best kind of Goats for keeping to advantage should be chosen in this manner: the male should have a large body, his hair should be long, and his legs straight and stiff; the neck should be plain and short, the head small and slender, the horns large, the eyes prominent, and the beard long. The female should have a large udder, with large teats, and no horns, or very small ones. They should be kept in flocks, that they may not straggle; and they should have good shelter both in summer and in winter, the heat and cold being both prejudicial to them. They should be coupled in December. They should have no litter in winter, but only a paved floor kept clean. The kids are to be brought up for the table in the same manner as our lambs are. They are recommended to lie among horses, their smell, as is supposed, preventing many distempers in those cattle. *Mortimer's Husbandry.*

GOAT-*sucker*, in zoology, a name by which the caprimulgus is called in some parts of England, but its more usual name with us is the churn owl. It is a very beautiful bird, seeming rather to approach to the cuckow than the owl kind, and has had its common Latin name, and this English one, from an opinion, there seems to be no foundation for, of its sucking the Goats dugs in the night-time. *Ray's Ornithology.*

GOATS-*rue*, has many tall, hollow, striated branches, a yard or more in height, with long pinnated leaves growing alternately on the joints, consisting of six or eight pair of long oval pinnæ, smooth, and not indented about the edges, which are subject to be folded together. The flowers grow in long spikes, hanging downwards in the shape of pease blossoms, but less; of a pale, whitish, blue colour: the seed grows in long erect pods: the root is thick, spreading on the earth, and abiding long: it grows in several parts of Italy, by river-sides; but, with us, only in gardens; and flowers in June and July.

Goats-rue is accounted cordial, sudorific, and alexipharmic, and good against pestilential distempers, expelling the venom through the pores of the skin; and is of use in all kinds of fevers, the small-pox and measles; it likewise kills worms, and cures the bites of all kinds of venomous creatures. *Miller's Bot. Off.*

GOLD (*Dict.*)—It is the received opinion, that, whatever has been done to this metal, the common way of purifying it by the copel restores it easily to itself again; but this is not always so certain, or so easy, as is generally imagined. Mr. Homberg put into the copel an ounce of gold, which he had used in several chemical experiments, in order to restore it to its original state; but, after four times copelling it, he found, that,

that, whatever quantity of lead he used, ſtill the metal, though of the right and beautiful colour, was brittle, and not at all in the ductile ſtate of pure gold. Finding therefore that lead would not anſwer his purpoſe, he incorporated the gold with four times its quantity of ſilver, and, having performed the operation of the depart in the common manner, he fuſed it with borax; but after all this the Gold was as brittle as before, though ſtill of the ſame beautiful colour. He then melted it again without any addition, but ſtill it remained in the ſame brittle ſtate. His next trial was by antimony, not doubting but that the particles, whatever they were, that ſtood the operation of the depart, and of lead, would be abſorbed by this powerful ſemi-metal, and the Gold left in its natural malleable ſtate: he melted it twice to this purpoſe, with eight ounces of antimony; but, after ſeparating the antimony, and then melting the Gold ſeveral times with ſalt-petre, and many times without any mixture, it was found of the moſt perfect and beautiful colour imaginable; but ſtill brittle, and not in the leaſt malleable. Surprized to ſee all the common methods fail, he melted it again with ſix ounces of antimony, and afterwards melted this regulus with three times its own weight of lead, and ſet the whole in a copel in a proper degree of fire, to evaporate both the antimony and the lead. But, when the fire was out, he was ſurpriſed to ſee the Gold covered with a browniſh ſubſtance, reſembling a muſhroom, which fell to powder on being touched by the fingers. The Gold itſelf was become of a grey colour, and was full of wrinkles on the upper ſurface, from whence this fungous matter had been thrown out; but on the under ſurface, where it ſtuck to the copel, it was ſtill of a fine and beautiful Gold colour. He then melted ſeveral times the Gold and the fungous ſubſtance together, and every time there appeared the ſame ſort of fungous cruſt at the top. At laſt he gathered this fungous ſubſtance carefully off from the Gold, and then, melting the metal by itſelf, there was no more any fungous matter thrown out upon it, but only a thin layer of a powder of the ſame nature and colour with the former. Three times it was melted, and at every time threw off a quantity of this powder; and, after this, being fuſed with borax, it at length became perfect malleable Gold.

He then fuſed together the fungous matter, and all the quantities of powder which he had ſaved; there appeared a new fungus on the matter, and that for ſeveral times melting; but at laſt this diſappeared, and there was found a ſmall lump of pure Gold in the copel. It is not eaſy to gueſs at the cauſe of this obſtinate brittleneſs of the Gold, becauſe it had paſſed ſeveral experiments, and been mixed with ſeveral ſalts and ſeveral metals, particularly at laſt with iron and with emery. The emery ſeemed moſt to be ſuſpected as the cauſe, but this brittleneſs cannot be given to Gold by emery alone, and muſt have been owing to the mixed effect of ſome of the ſalts and emery together; as, by means of the ſalts, the particles of emery are thrown farther, and more intimately mixed with thoſe of the Gold, than they could otherwiſe be. We have been told of the degradation of Gold. This Gold would have been declared degraded, and robbed of one of its greateſt qualities, its malleability, had it fallen into any hands but thoſe of ſo great a chemiſt; and it is much to be doubted, whether Mr. Homberg would not have been able to reduce the degraded Gold of any other chemiſt, and reſtore it to its natural ſtate and purity, though the common methods of operating on it ſhould all have failed, as they did in this caſe. *Mem. Acad. Par.* 1693.

It is generally underſtood, that ſilver is the peculiar wealth of Peru; and the Spaniards have alſo Gold mines there.— There are alſo two waſhing-places for Gold in the ſouth part of Peru, near the frontiers of Chili. About the year 1709 there were two ſurpriſing large lumps of virgin Gold found in one of theſe places, one of which weighed 32 pounds complete, and was purchaſed by the Count de Monteloa, then viceroy of Peru, and preſented to the king of Spain: the other was ſhaped ſomewhat like an ox's heart; it weighed 22 pounds and a half, and was bought by the corrigidor of Arica.

To find theſe lavadores or waſhing-places, they dig in the corners of a little brook, where, by certain tokens, they judge the grains of Gold to lie. To aſſiſt in carrying away the mud, they let a freſh ſtream into it, and keep turning it up, that the current may ſend it along.— When they are come to the golden ſand, they turn off the ſtream another way, and dig with their mattocks; and this earth they carry on mules to certain baſons, joined together by ſmall channels: into theſe they let a ſmart ſtream of water, to looſen the earth, and carry all the groſs part away. The Indians ſtanding in the baſons, and throwing out all the ſtones; the Gold at bottom is ſtill mixed with a black ſand, and hardly to be ſeen, till it be farther ſeparated.

In theſe waſhing-places are found Gold grains, as big as bird-ſhot; and in one, belonging to the prieſts near Valparaiſo, ſome are found from two or three ounces to a pound and an half weight.— This way of getting Gold is much better than from the mines; here is no need of iron crows, mills, or quickſilver; ſo that both the trouble and expence are much leſs.

The moſt conſiderable port in Chili is that of Valparaiſo, which is eſteemed one of the beſt harbours in the ſouth-ſeas. It lies upon a river, fifteen leagues below St. Jago, the capital of Chili. To this port, all the riches of the Gold mines behind it, and on every ſide, are brought; particularly from thoſe of Tiltil, which are immenſely rich, and lie between this port and the city of St. Jago.

The Gold here is found in a very hard ſtone, ſome of which ſparkles, and betrays the incloſed treaſure to the eye; but moſt of it has not the leaſt ſign of Gold, but appears to be an hard harſh kind of ſtone, of very different colours, ſome white, ſome red, and ſome black. This ore, broken to pieces, is ground in a mill, by the help of water, into a groſs powder; with which quickſilver is afterwards mixed: to this paſte they let in a ſharp ſtream of water, which having reduced it to a kind of mud, the earthy particles are carried off by the current, and the Gold and quickſilver precipitated, by their own weight, to the bottom.— When this mud has ſettled a little, into a ſort of paſte, they put it into a linen bag, and ſtrain it very hard, by which operation the mercury is driven out, or, at leaſt, the greateſt part of it, and the remainder they evaporate by the help of fire; ſo that they have all the Gold together in a little wedge, like a pine-apple; whence it derives its name of pinna.— In order to clear the Gold from the ſilver it is firſt impregnated with, the lump muſt be run, and then the exact weight is known, and the true fineneſs; it is not done otherwiſe there.—The weightineſs of the Gold, and the facility of its amalgamation with mercury, makes the droſs eaſily ſeparate from it: this is an advantage the Gold-miners have over thoſe of ſilver; they every day know what they get, which is not the caſe of the ſilver-miners.

According to the nature of the mines, and the richneſs of the veins, every caxon, or 50 quintals, or 100 hundred weight, yields four, five, or ſix ounces.—When it yields but two, the miner does not make good his expence, which frequently happens; but he has ſometimes good amends made him, when he meets with rich veins; for the Gold mines are, of all mines, thoſe which produce metals the moſt unequally.— They follow a vein, which grows wider, then narrower, and ſometimes ſeems to be loſt in a ſmall ſpace of ground. This ſport of nature makes the miners live in hopes of finding what they call the purſe, being the ends of veins, ſo rich, that they have ſometimes made a man wealthy at once: and this inequality ſometimes ruins them; which is the reaſon that it is more rare to ſee a Gold-miner rich than a ſilver-miner, or of any other metal, though there be leſs expence in extracting it from the mineral. For this reaſon, alſo, the miners have peculiar privileges; for they cannot be ſued to execution on civil accounts, and Gold pays only one-twentieth part to the king, which is called covo, from the name of the perſon to whom the king made the grant; becauſe they uſed before to pay the one-fifth, as they do of ſilver.

On the deſcent of this mountain there runs, during the winter, or, rather, during the rainy ſeaſon, a pretty briſk ſtream of water, which, paſſing through the Gold ore, waſhes away abundance of that rich metal, as it ripens and breaks from its bed: and, therefore, for about four months in the year, this is accounted one of the richeſt lavadero's in Chili, ſince there are found pellets of pure Gold of an ounce weight.

At Palma, which is but four leagues from Valparaiſo, there is another rich lavadero; and, every-where throughout the country, the fall of a brook or rivulet is attended, more or leſs, with theſe golden ſhowers, the richeſt whereof fall into the laps of the Jeſuits, who farm, or purchaſe, abundance of mines and lavadero's, which are wrought, for their benefit, by their ſervants.

Yet it is agreed, that a great part of the inhabitants do not ſeem to abound in wealth; which, however, may be very well accounted for, if we conſider that ſuch as deal in cattle, corn, and other the product of the country, acquire but moderate fortunes; and ſuch as are concerned in mines are frequently ruined, by launching into too great expence about them. But, after all, ſuch as are eaſy in their circumſtances, and, in conſequence of that eaſe, retire to St. Jago, live in ſuch a manner as ſufficiently demonſtrates the riches of Chili, ſince all their utenſils, even thoſe that are moſt common, are of pure Gold; and it is believed that the wealth of this city alone cannot fall ſhort of 20,000,000 l.— Add to this, that the Gold mines are continually increaſing; and it is only for want of hands that they are not wrought to infinitely more advantage, thoſe already diſcovered, and neglected, being ſufficient to employ 40,000 men. It may be likewiſe obſerved, that the frauds, practiſed for deceiving the king, daily increaſe; and, as they meaſure the riches of the Spaniſh Weſt-Indies by the ſtandard of the king's revenue, this muſt neceſſarily make them appear poorer than they really are.

As the policy of the Spaniards has hitherto conſiſted chiefly in endeavouring, by all ways and means poſſible, to reſtrain the vaſt riches of theſe extenſive dominions from paſſing into other hands; ſo the knowledge that other nations have of the mighty wealth of theſe countries, on the one hand, and of the great demand for European manufactures among their inhabitants, on the other, has excited almoſt every nation in Europe to practiſe all methods poſſible, in order to gain a ſhare in them; and this with ſo good effect, that it is very doubtful whether any conſiderable part of the riches of the Weſt-Indies centers among the inhabitants of Old-Spain.

But the ſyſtem of Spain is now upon the change; and they ſeem determined to reap all the benefit in their power by the commerce of the Spaniſh Weſt-Indies, as well as by that in Europe.

The Gold trade of Brazil, belonging to the king of Portugal, being carried on in much the ſame manner as that of Spain, it is needleſs to ſay any more at preſent, than to obſerve, that, in order to judge of the true value of Gold belonging to the king of Spain, which there paſſes through the hands of the preſident and commiſſioners, it is all ſold upon condition to be aſſayed, and not judged of merely by the touch, as is done in ſeveral parts of the Eaſt-Indies. For Gold is ſo precious a metal, that any very ſmall difference, in the aſſay of ſilver or copper in every piece, will run up to a conſiderable ſum; and, therefore, the laws have ſettled the value of Gold and ſilver, not by the touch, but by trial of aſſay, and this ſo exactly and demonſtrably, that what a very ſmall ſcale decides, is afterwards made out and proved by arithmetic. And, becauſe not only money was to be made of this metal, but jewels, chains, utenſils, and other things, therefore the law appointed, that there ſhould be a head marker and toucher, to overlook and approve of the reſt of them, that, being expert at touching Gold and trying ſilver, they might judge of the fineneſs of the Gold-ſmith's work. And whereas, in order to make an aſſay, ſomewhat is to be taken of the ingot of Gold or ſilver that is to be aſſayed, which cannot be done with jewels, chains, or rings, without ſpoiling the faſhion; therefore the only and univerſal method has always been to touch the Gold, and mark the plate, relying only upon the exactneſs of the eye at certain times of the day, and on a ſtone, upon which the true fineneſs does not ſometimes appear ſuperficially, either becauſe the Gold is ill-coloured, or not ſo perfectly refined.

As for ſilver, they rely altogether upon the colour that appears after it is tried; both which methods are no better than conjectures or ſurmiſes, in compariſon of the certainty of the aſſays. For which reaſon, in criminal cauſes, againſt ſuch as do not work Gold or ſilver according to the ſtandard, no caſe has been decided by the head aſſayer, or judges to whom it belongs, without making experiment by aſſay; and, had the touch been ſecure, it would certainly have been relied on in ſome caſes; whereas, on the contrary, ſeveral perſons have been cleared by the aſſay, who have been ſuſpected for cheats by the touch. It follows, therefore, that merchants ought to be perſuaded it is much ſafer for them to diſpoſe of their Gold by aſſay, than by touch; for otherwiſe there might be a vaſt trouble ſaved in aſſaying all the king's Gold over again, as is done at Seville, though it has all been actually aſſayed in the Indies. This has been the practice of all times, in Spain, ever ſince Gold was brought from the Indies, and touching was never yet admitted of.

The purifying of GOLD *by cementation*, is to be performed in this manner: chuſe ſome tiles or bricks not vitrified by an exceſſive fire, nor too much tempered with ſand; the oldeſt alſo are the beſt; clean them well from lime and all other filthineſs, pound them in an iron mortar, and then ſift them through a coarſe ſieve; take four parts of this powder, and one part of colcothar not waſhed, and the ſame quantity of common ſalt; mix theſe thoroughly together, grind them in a mortar, and wet them with a little water or urine, ſo that they may cohere when preſſed between the hands. Then take a clean earthen veſſel of a proper ſize, it muſt be quite ſound, ſufficiently thick, and not glazed; ſtrew the bottom of this with the moiſtened powder, or cement, and diſtribute it evenly all over with a finger, and preſs it down very gently, ſo that the thickneſs of the cement may be half an inch all about; put upon this the Gold in ſmall pieces, and in thin plates, made perfectly clean by heating them red-hot in the fire; cover the ſurface of the cement with theſe pieces, then lay ſuch another bed of cement over theſe, and over that another of Gold, and ſo on alternately, till the veſſel is full within the breadth of a finger; let this laſt ſpace be filled with cement; lute well a tile upon the veſſel, and keep it moderately red-hot in a furnace for ſixteen or twenty hours, then open the pots and waſh the purified Gold. *Cramer's Art of Aſſaying.*

GOLD *colour*.—The manner of giving this colour to glaſs is this: take cryſtal frit two parts, and rochetta frit one part, both made with tarſo, not ſand; mix theſe well, and to every hundred weight of this add of tartar in lumps, but well powdered afterwards, and of manganeſe prepared, each one pound; mix theſe well together and put them into the frit; when this is done, put all into the furnace, and let it ſtand three or four days in a common fire not too violent, and at the end of this time work it. It will be thus very beautiful, but, if all cryſtal frit be uſed, it will be yet much finer. It may be made deeper or paler, by adding to, or diminiſhing the quantity of the ingredients, in proportion to that of the frit. *Neri's Art of Glaſs.*

GOLD *on China ware*.—The Gold on this ware is never laid on alone, but managed in the following manner: they grind it in water to a fine powder, and leave it to dry in the ſhade: They then mix with every ten grains of Gold one grain of ceruſs, and, incorporating the whole with gum water, they lay it on in the manner of other colours.

There have been many methods of imitating the colour and appearance of Gold in the baſer metals, but none of them come up to that of Mr. Homberg, which is performed in this manner: make an amalgame of one part pure copper and three parts quickſilver, boil this in river water for two hours, then diſtil off the quickſilver, and cohobate it once; take out the copper, and fuſe it, and it will be found of a beautiful Gold colour, and more ductile than common copper under the hammer, and is extremely fitted for watch work, gilding, and the finer machines and utenſils. *Shaw's Lectures.*

GOLD-*finch*. This bird is particularly fond of the buds of the gooſeberry-tree. They often come in whole droves at once into gardens, and will clear away the buds from the trees in a few days; they are eaſily ſhot, but the trees are uſually injured by this, ſo that it is better to lime the twigs. *Mortimer's Huſbandry.*

GOLD-*fiſh*, in zoology, a name by which ſome authors have called the alauſa or ſhad, from the yellow colour it frequently has on the covering of the gills. See a farther account of it under the article SHAD.

GOLD-*ſize*. The method of making Gold-ſize, or burniſhed gilding, or wood, is this: take a pound and a half of pipe clay, half an ounce of red chalk, a quarter of an ounce of black lead, forty drops of ſweet oil, and three drachms of pure tallow; grind the clay, chalk, and black lead, all ſeparately, very fine in water; then mix them together, and add the oil and tallow, and grind all to a due conſiſtence. This is the ſize now in uſe, and is accounted the better, the older it is.

GOLD *ſmith*, or, as ſome chuſe to expreſs it, ſilver-ſmith, the artiſt, who makes veſſels, utenſils, and ornaments in Gold or ſilver. The Gold-ſmith's work is either performed in the mould, or beat out with the hammer, or other engine. All works that have raiſed figures are caſt in moulds, and afterwards poliſhed and finiſhed; plates or diſhes of ſilver or Gold are beat out from thin flat plates, and tankards and other veſſels of that kind are formed of plates ſoldered together, and their mouldings are beat, not caſt. The buſineſs of the Gold-ſmith formerly required much more labour than it does at preſent, for they were obliged to hammer the metal from the ingot to the thinneſs they wanted: but there are now invented flatting mills, which reduce metal to the thinneſs that is required at a very ſmall expence. The Gold-ſmith is to make his own moulds, and for that reaſon ought to be a good deſigner, and have a taſte in ſculpture: he ought alſo to know enough of metallurgy to be able to aſſay mixed metals, and to mix the allay.

The Gold-ſmith in London employs ſeveral hands under him for the various articles of his trade. In this great city there are always hands that excel in every particular branch of the trade, and there is commonly employment for every one in his particular branch. The jeweller, the ſnuff-box and toy maker, the ſilver turner, the gilder, the burniſher, the chaſer, the refiner, and the Gold-beater, are all employed by and under the Gold-ſmith.

GO'LDEN *rod*, *virga aurea*, in botany, a very beautiful ſpecies of plants cultivated in our gardens, where they are very great and laſting ornaments, beginning to flower in May, and one kind or other of them continuing flowering till October.

They are all eaſily propagated by parting their roots in the ſpring, before they begin to ſhoot; they will grow in any ſoil, or ſituation; but they ſucceed beſt in a light freſh earth and an open expoſure, and ſhould be planted in the middle of large flower-beds: they are perennial plants, dying down to the ground, as ſoon as they have ripened their ſeeds, but riſing again the following ſpring. Theſe ſeeds ſown will very freely grow, and often produce varieties in the flower. *Miller's Gard. Dict.*

GOOSE, *anſer*, in the Linnæan ſyſtem of zoology, the term uſed to denote one of the orders of the feathered kingdom, the general character of which is that the mouth is dentated or toothed, and jagged or ſerrated.

Soland GOOSE, the Engliſh name of a large water fowl, called by authors anſer Baſanus.

It is of the ſize of the common Gooſe, and its wings are very long and capable of extending to a very remarkable breadth; its beak is long and ſtrait, and of a duſky grey, and a little hooked at the end. It has alſo, near the hooked part, two ſmall appendages like teeth. It is naked behind the eyes. Its mouth opens to a great width, and it ſeems to have no noſtrils; but, in the place of them, has a long furrow running nearly the whole length of the bill; it has alſo a row of ſerratures or indentings all along, provided by nature for its holding fiſh more firmly. Its feet are black, and all the four toes are connected by the ſame membrane. It is all over of a clear white, when full grown, except that the larger wing feathers have blackneſs, and the head with age is apt to become yellow. Its ſkin adheres but looſely to its fleſh, and the young are mottled with grey and brown. It flies well, but, if it fall on the ground, does not eaſily raiſe itſelf. They are a bird of paſſage, and build in the iſland of Baſs in Scotland, in vast numbers. Each female lays only one egg. The young Geese are esteemed a great delicacy, and sell at a great price. *Ray's Ornithology.*

GOO'SEBERRY-*bush.*—The Goosberry-bush is propagated either by suckers or cuttings, but the latter way is preferable, as the roots are less subject to shoot out suckers afterwards.

The best season for planting the cuttings is in February, just before the buds begin to open; observing always to take the handsomest shoots, and to pick them from such branches as produce the greatest quantity of fruit. The cuttings should be about eight inches long, and should be planted in a bed of light earth exposed to the morning sun; they must be planted about three inches deep, and watered to help their taking root. The shoots should all be rubbed off from these plants, as they put out, except those at the top, that there may be a regular stem. In the September following, they should be removed to a bed of fine light earth, and planted at two feet distance. They should remain here two years, and the cross branches at times be cut off, as also the lower ones, so as to keep a clean stem about a foot above the ground. They will then be fit to plant out where they are to stand; which should be in a light sandy loam. They should be kept from the shade of other trees; and, to have the fruit in its utmost perfection, should be set in an exposed place in rows of eight feet asunder, and each of the shrubs, six feet from the others in the rows. The best time for transplanting them is in October, after the leaves are fallen. *Miller's Gard. Dict.*

GOOSEBERRY-*galls*, in natural history, the name given by authors to a species of protuberances of the gall kind, found very frequently on the oak. They are of a roundish figure, and sometimes adhere to the tree by a short pedicle, but more frequently by a part of their spheric surface. They are usually found on the under side of the leaves of the oak, but sometimes on the pedicles of the leaves.

They are most frequent in spring, but they are found at all times when the leaves are upon the trees. These galls are greenish at first, and afterwards become yellowish, and finally red; in which last state they very much resemble the small red Goose-berry. They are very soft to the touch, and, when opened, are found to contain a juicy substance, with a cavity in the middle, in which there is lodged a single insect. This, according to the time in which the gall is opened, is found in the form of a white worm, or else of a white chrysalis, or finally of a small short-bodied four-winged fly of a black colour. For the creature does not leave the gall to go through any of its changes, put passes all its states in it. The gall, in all these cases, is found whole and unhurt; but, if one is opened in which there is a hole perceived, this is sure to be found empty, that being the passage by which the fly has made its way out. *Reaum. Hist. Inf.*

GOOSEBERRY-*worm*, in natural history, the name of an insect, found very frequently on the Gooseberry bushes, and usually supposed to be a caterpillar, but differing essentially from that genus of animals, and being one of those which the French call fauches chenilles. It has a round head, and has twenty-two legs, and finally becomes not a butter-fly, but a common four-winged fly. This worm is at first of a greenish colour, with some yellow variegations, and several black tubercles; but on the last change of its skin it becomes whitish or cream-coloured, and loses its tubercles. *Reaum. Hist. Inf.*

GRA'FTING (*Dict.*)—Mr. Du Hamel of the Academy of Sciences of Paris has observed that, in Grafting of trees, there always is found at the insertion of the graft a change in the directions of the fibres, and a sort of twisting or turning about of the vessels, which greatly imitates that in the formation of certain of the glands in animal bodies; and he very judiciously infers from thence, that, a sort of new viscus being formed by this means, the fruit may very naturally be so far influenced by it as to be meliorated on the new branch; but that no such sudden and essential changes can be effected by this means, as too many of the writers in agriculture pretend.

This author observes, however, that this anatomical observation alone would not have convinced him of the falsity of too many of these relations, had not experiment joined to confirm it; he tried many grafts on different trees, and, for fear of error, repeated every experiment of consequence several times; but all served only to convince him of the truth of what he at first suspected. He grafted in the common way the peach upon the almond, the plum upon the apricot, the pear upon the apple, the quince, and the white thorn; one species of plum on other very different species, and upon the peach, the apricot, and the almond; all these succeeded alike, the species of the fruit was never altered, and, in those which would not come to fruit, the leaves, the wood, and the flowers, all were the same with those of the tree from which the graft was taken.

Authors in agriculture have mentioned also a very different sort of Grafting, that is, the setting grafts of one tree on stocks of a different genus of trees; such as the Grafting the pear upon the oak, the elm, the maple, or the plum; the mulberry upon the elm, the quince, and the fig; the cherry upon the laurel; the peach upon the hazel; the vine upon the cherry-tree, and upon the hazel; and the like unnatural conjunctions. Mr. Du Hamel tried all these separately and carefully, and the event proved very plainly, that those who had mentioned them had never tried them; and a natural conclusion from this was, that there must be a natural alliance between the graft and the stock which receives it, otherwise it will never grow at all, or else very soon perish. *Memoirs Acad. Par.* 1727.

Tools necessary for GRAFTING. In order to Grafting, a person must be provided with the following tools: 1. A neat and small hand-saw to cut off the heads of large stocks. 2. A strong knife with a thick back to make clefts in the stocks. 3. A sharp penknife to cut the grafts. 4. A Grafting chissel and a small mallet. 5. Brass strings, or else woollen yarn, to fasten on the grafts with; and, finally, a quantity of clay, which should be prepared a month before it is used, and kept turned and worked about every day like mortar. The best mixture for this matter is: a quantity of strong fat and viscous loom must be got, and into this must be well beat and mixed some stone-horse dung and some chopped straw cut very short and small; finally, a quantity of common salt must be thrown in; this must be mixed up and beat together into a paste with water, but it must not be exposed to the frosts. This is equally proper to be employed for all the different sorts of Grafting. *Miller's Gard. Dict.*

GRAIN *of iron.* Even iron has its grain as well as wood, and that not the same in all iron, though all iron is very evidently the same species of body. The common cast iron has a Grain very different from that which has been hammered, or wrought; the granules, which compose the mass, being in this last state forced as it were into combinations with one another, by the repeated blows of the hammer; the tempering of iron into steel also alters its grain, partly by means of the salts and sulphurs, which are by that operation introduced into it, and partly by the stopping the effect of the fiery particles received into it at a certain time.

But besides these differences, the common wrought iron has, in its several pieces, or sometimes in the several parts of the same piece, different grains. First a laminated ore, secondly a granulated one, and thirdly a fibrose one. These, however, are not so different in reality, as they appear to be; for the laminæ, as they become smaller, become granules; and arrangements of these granules, in long lines, make the fibres of the thready kind. The artificers, however, know, by these marks of the Grain, what iron is fittest for tempering into steel, and they find the laminated pieces to be the worst of all, and the granulated ones the best. *Mem. Acad. Scien. Par.*

GRAIN *weight.* The Grain weight in use among jewellers is one fourth of a carat; and the carat is about the one hundred and fiftieth part of an ounce troy, according to Mr. Jeffries, in his treatise on Diamonds and Pearls.

Hence, the jeweller's Grain is to the troy Grain, inversely, as 600 is to 480, that is, directly as 4 to 5.

GRA'MEN, *grass*; see the article GRASS.

GRA'MPUS, in ichthyology, an English name given to one of the cetaceous fishes, properly of the genus of the delphinus, or dolphin, according to the new Artedian system, and distinguished from the others of that genus by the name of the dolphin, with the snout bending upwards, and with broad serrated teeth. This is the orca of almost all the antient as well as modern writers, and is called the loper and north caper by the people of Scotland. Sibbald gives it the name of the balæna, but he distinguishes it from the common whale by its smaller size, and having teeth in both the jaws. Paulus Jovius calls it also capidolius. These are all the names it is known by; and that of porpoise is sometimes ignorantly given to it, but properly belongs to another species of the same genus, the phocæna.

GRANADI'LLA, *passion-flower*, a beautiful flower, greatly propagated, in our gardens, by laying down their branches, which in one year's time will take good root, and may then be removed to the places where they are designed to remain; the best season for transplanting these plants is towards the latter end of October, or the end of March, or the beginning of April, just before they begin to shoot; for, if they are removed earlier, and it should prove dry frosty weather, with cold north-east winds (as it often happens in March) these plants will scarcely endure it, which is the occasion of the death of so many of them, as is often observed upon transplantation; but those which are removed early in the autumn, rarely fail.

The plants should be planted against a wall, or other building, which should face the south-east or south-west; or else intermixed amongst flowering shrubs in quarters; where, if they are regularly trained up to poles, they will flower extremely well, and have a very good effect in diversifying such plantations. The best season for pruning of these plants is in the spring, after the cold weather is past; for, if they are pruned very early, and it should happen to be frosty weather afterwards, it would endanger most of the young branches: therefore it is much the better way to let the whole plant remain untouched (suffering the rude part to hang down before the stem and branches) during the winter season, which will be of service in protecting them from the severity of the cold; and, if at Michaelmas you lay a little dung, or other mulch,

about a foot thick, upon the surface of the ground near the stems, it will effectually guard their roots from frost; which method should be constantly practised with such as are planted in open quarters. The manner of pruning is nothing more than to cut off all the small weak shoots, and shorten the strong ones to about three feet in length: or, if the building is high, against which they are planted, they may be left much longer, though you should be careful not to leave them too long; for, as they are vigorous growing plants, they will soon get above the building, and become troublesome.
Those that are planted in quarters, and trained to stakes, must be cut shorter, in order to have the flowers nearer the ground: these, when their season for flowering is past, should have a little mulch laid about their roots; and then their stakes may be taken away, suffering their branches to lie upon the ground, which will also be of service to protect the plants from the injuries of the winter; and in the beginning of April they may be trimmed, and staked up again: and, when the plants begin to shoot, they should constantly be kept trained up to the stakes, whereby they will not only appear handsome, but the place will be clearer to work in, as also to pass through.

The fruit-bearing kind may also be propagated, by sowing of the seeds in the spring of the year, in pots filled with light rich earth, which should be plunged into a moderate hot bed, to facilitate the growth of the seeds; and, when the plants are come up, you must harden them by degrees to bear the open air: in these pots they should remain till the succeeding spring, observing to shelter them in winter under a frame; or else place the pots into the earth under a warm wall, to prevent their roots from freezing through the pots; and the beginning of April you may shake them out of the pots, and divide the plants from each other, planting them in the places where they are designed to remain; or, if you have not the ground ready, they may be put each into a separate pot; so that they may at any time be turned out into the ground, without disturbing their roots; for they are difficult plants to remove, when old.

These plants may also be planted to cover arbours or seats in warm-situated places, where they will flower extremely well, and answer the purposes of those arbours, as well as any other plants which are at present made use of. *Miller's Gard. Dict.*

GRANA'DO (*Dict.*)—Granadoes of different kinds are represented, *plate* XXXV. *fig.* 17, in the Dictionary.

GRA'NARY, a building for preserving corn, &c.

Experimental philosophy has proved that the air is the great source of corruption; keep out that, and all is kept out; and the most corruptible substances, such as meal, butter, milk, and the like, have been preserved fresh four months in the exhausted receiver of an air-pump.

They have, near Grand Cairo, a magazine or Granary, defended with good walls, and called Joseph's Granaries. It is not probable that they are quite so old as the days of that patriarch, but they abundantly prove the utility of such storehouses, by the vast quantities of grain annually preserved in them.

Many parts of Africa abound with Granaries of this kind.

They are so many deep pits made in the solid rock; the descent into them is but just large enough for a man to go down into them by, but they grow larger, as soon as the person is in, and are usually square, from thirty to forty feet in diameter. In these the great men of the country preserve their corn; they first strew over the floor with straw, then they lay on the corn; still, as the heap rises, placing a thin bed of straw between the corn and the sides, as they did at the bottom. In this manner they proceed till the whole cavity is filled: when this is done, they cover the mouth of the entrance with a sort of hurdle of green boughs of trees, interwoven one with another. This they cover with about two feet thickness of sand, and over this raise a ridge of earth, well beat together, in order to throw off the rain both ways, that none may settle on the place and soak into the magazine.

The corn thus stored up always keeps three, four, or more years very good; and, not unfrequently, the proprietor being taken off by the severity of the eastern governments, under which they live, the magazine is forgotten, and, some accident discovering it many years afterwards, the corn is almost always found perfectly good in it. All the care they take, in regard to the corn, is to expose it two or three days to the sun's heat, to dry it thoroughly, before they carry it into the magazine.

In the dutchy of Lithuania and in the Ukraine, the people always preserve their corn in the same manner in wells or pits made in dry places; but in these countries great care is to be taken in the opening these store-rooms; for, if people descend into them, before they have had sufficient communication with the fresh air, they are often killed by the damps; this, however, is easily guarded against. By these, and numerous other instances of the practice of other countries, it appears evident, that the advantage of these subterranean Granaries over all others is very great.

Though these are to be recommended before all others, yet the common Granaries may, with proper care, be rendered greatly more useful than they are at present. The grand caution necessary to this purpose is to guard against the two great humidity, which there always is in places, where there is a great number of doors and windows. A too free access of the external air is also to be carefully guarded against; for this brings in with it the eggs of a vast number of different insects, which prey upon and destroy the corn. A third caution is, when the corn is the produce of the country, where it is preserved, not to fill the place with the crop of one place only, but to mix the harvests of two as different provinces as may be, the one dry, the other moist, or otherwise differing as much as may be; thus, the contrary qualities of the one will prevent the destruction of the other. These are the three great rules to prevent the corrupting of corn; but, when the mischief is once begun, it will prove very difficult to stop it: all the care that can be employed, should therefore be taken in regard to these.

The two great cautions to be observed in the erecting of Granaries are to make them sufficiently strong, and to expose them to the most drying winds. The ordering of the corn in many parts of England is thus: to separate it from dust and other impurities after it is thrashed, they toss it with shovels from one end to the other of a long and large room; the lighter substances fall down in the middle of the room, and the corn only is carried from side to side, or end to end of it. After this, they screen the corn, and, then bringing it into the Granaries, it is spread about half a foot thick, and turned from time to time about twice in a week; once a week they also repeat the screening it. This sort of management they continue about two months, and after that they lay it a foot thick for two months more, and in this time they turn it once a week, or twice, if the season be damp, and now and then screen it again. After about five or six months, they raise it to five or six feet thickness in the heaps, and then they turn it once or twice in a month, and screen it now and then. When it has lain two years, or more, they turn it once in two months, and screen it once a quarter, and, how long soever it is kept, the oftener the turning and screening is repeated, the better the grain will be found to keep.

It is proper to leave an area of a yard wide on every side the heap of corn, and other empty spaces, into which they turn and toss the corn, as often as they find occasion. In Kent they make two square holes at each end of the floor, and one round in the middle, by means of which they throw the corn out of the upper into the lower rooms, and so up again, to turn and air it the better. Their screens are made with two partitions, to separate the dust from the corn which falls into a bag; and, when sufficiently full, this is thrown away, the pure and good corn remaining behind.

Corn has by these means been kept in our Granaries thirty years; and it is observed, that, the longer it is kept, the more flower it yields in proportion to the corn, and the purer and whiter the bread is, the superfluous humidity only evaporating in the keeping. At Zurich, in Swisserland, they keep corn eighty years or longer, by the same sorts of methods.

The public Granaries at Dantzick are seven, eight, or nine stories high, having a funnel in the midst of every floor to let down the corn from one to another. They are built so securely, that, though every way surrounded with water, the corn contracts no damp, and the vessels have the convenience of coming up to the walls for their lading. The Russians preserve their corn in subterranean Granaries of the figure of a sugar-loaf, wide below, and narrow at top: the sides are well plaistered, and the top covered with stones. They are very careful to have the corn well dried before it is laid into these storehouses, and often dry it by means of ovens; the summer dry weather being too short to effect it sufficiently. *Philosophical Transactions*, N°. 26.

There are nine Granaries built in a large subterraneous cavern, near the town of Ardres, a little strong place near Calais, designed to hold corn for the garrison in case of a siege; these are commonly called the poires D'Ardres; from their model, I have drawn the plan and profiles on *plate* XXI. *fig.* 12, 13, 14. They may be made bigger or less than these exhibited here, as occasion may require, or the convenience of the place affords opportunity. I have only given the draught of six, which will will be sufficient to shew their disposition: dig thirty feet deep in the ground, and build a first vault to have the cavern G, G, represented in the 14th figure, and at the same time raise the poires or stone cylinders F F, whose top terminating into a half sphere abuts on a second vault level with the ground floor; every poire must stand by itself, because the air circulating round freely will keep the corn drier; these might be built in other places, as between two floors, instead of subterraneous caverns, but they would not be so safe, in any other situation, from cannon.

Each poire has two apertures E and G, one on the top to take in the corn, the other at bottom to let it out; the first ought to be eighteen inches square, and is shut with a trap-door; the other which terminates in a pipe is shut by a clap-door which turns upon a hinge, and is fastened by a padlock.

All who know these poires agree nothing can be better contrived; I am of opinion they might be of excellent use to preserve ferve gunpowder, as they would contain larger quantities than the magazines made ufe of at prefent for that purpofe with equal fafety.

GRAPES.—Thofe kind of Grapes which are thin-fkinned, grow fooner ripe than others, and will thrive in a temperate climate where the others will not. If it happens that Grapes are ftruck with hail at the time that they are large and near ripening, they never become ripe at all, but harden and fo remain. *Portzius de Vin Rhen.*

We have in the Philofophical Tranfactions a remarkable account of the change of colour in Grapes of the fame tree. A mufcadine Grape tree was raifed from a cutting of a parent vine of this kind, whofe fruit was white; it was planted againft an eaftern wall, where it had the benefit of the fun, from its rifing, to half an hour after twelve. The foil a ftiff clay, but rendered fitter for the growth of this fort of tree, by a mixture of rubbifh of an old wall.

At about five years ftanding it was fo pruned, as to make it fhoot two principal branches, one to the right, the other to the left-hand; from hence it fhot twenty-two inches on each fide before it came to a joint. That on the right was a very luxuriant branch, as thick as the body of the tree; the other about half that bignefs. The leaves on the right-hand were alfo of twice the bignefs of thofe on the left, and indeed larger than the leaves of the parent tree; but what is moft fingular is, that the luxuriant branch produced annually fine black Grapes in large bunches, and the left hand branch white ones. But the white were often in the greateft quantity, though the black grew on the much ftronger branch. It is obfervable, that, in all thofe vines which bear black and blue Grapes, the leaves die red; but in this tree, whofe origin was from a white Grape, the leaves on that branch which bore black Grapes died white as well as thofe on the other. The fucceeding year, the number of the branches on the right-hand fhoot were greatly increafed in number, and the fucceeding year all bore fine deep-black Grapes in very large numbers. *Philofophical Tranfactions*, N°. 366.

GRASS, *gramen*.—There are a great variety of this tribe, which are divided into feveral genera by fome of the modern botanifts; but I fhall not inlarge fo far on this article, as to enumerate all the differences which they have made; but fhall beg leave to infert fome of the forts which are commonly found wild in England, or that have been introduced into the fields or gardens from abroad.

The beft feafon for fowing Grafs feed is the latter end of Auguft, and the beginning of September, that the Grafs may be well rooted before the froft fet in, which is apt to turn the plants out of the ground, when they are not well rooted. This feed fhould be fown in moift weather, or when there is a profpect of fhowers, which will foon bring the Grafs up; for, the earth being at that feafon warm, the moifture will caufe the feed to vegetate in a few days: but, where this cannot be performed in autumn, the feeds may be fown in the fpring; towards the middle of March will be a good time, if the feafon proves favourable.

The land on which Grafs feed is intended to be fown, fhould be well plowed, and cleared from the roots of noxious weeds, fuch as couch Grafs, fern, rufhes, heath, gorfe, broom, reftharrow, &c. which, if left in the ground, will foon get the better of the Grafs, and over-run the land. Therefore, in fuch places where either of thefe weeds abound, it will be a good method to plow up the furface in April, and let it lie fome time to dry; then lay it in fmall heaps, and burn it. The afhes fo produced, when fpread on the land, will be a good manure for it. The method of burning the land is particularly ufeful; (fee the article BURNING *of land*;) efpecially, if it is a cold ftiff foil; but where couch Grafs, fern, or reft-harrow, is in plenty, whofe roots run far under ground, the land muft be plowed two or three times pretty deep in dry weather, and the roots carefully harrowed off each plowing; which is the moft fure method to deftroy them. Where the land is very low, and of a ftiff clayey nature, which holds water in winter, it will be of fingular fervice to make fome underground drains to carry off the wet; which, if detained too long on the ground, will render the Grafs four. The method of making thefe drains is prefcribed under the article LAND, which fee.

Before the feed is fown, the furface of the ground fhould be made level and fine, otherwife the feed will be buried unequal. The quantity of Grafs-feed for an acre of land is ufually three bufhels, if the feed is clean, otherwife there muft be a much greater quantity allowed: when the feed is fown, it muft be gently harrowed in, and the ground rolled with a wooden roller; which will make the furface even, and prevent the feeds being blown in patches. When the Grafs comes up, if there fhould be any bare fpots, where the feed has not grown, they may be fown again, and the ground rolled, which will fix the feeds; and the firft kindly fhowers will bring up the Grafs, and make it very thick.

Some people mix clover and rye Grafs together, allowing ten pounds of clover, and one bufhel of rye Grafs, to an acre: but this is only to be done where the land is defigned to remain but three or four years in pafture, becaufe neither of thefe kinds are of long duration; fo that, where the land is defigned to be laid down for many years, it will be proper to fow with the Grafs-feed fome white trefoil, or Dutch clover; which is an abiding plant, and fpreads clofe on the furface of the ground, fending forth roots at every joint; and makes the clofeft fward of any, and is the fweeteft feed for cattle: fo that, whenever land is laid down to pafture, there fhould always be fix or eight pounds of this feed fown upon each acre.

The following fpring, if there fhould be any thiftles, ragwort, or fuch other troublefome weeds, come up among the Grafs, they fhould carefully be cut up with a fpaddle before they grow large; and this fhould be repeated two or three times in the fummer, which will effectually deftroy them; for, if thefe plants are fuffered to ripen their feeds, they will be blown all over the ground, their feeds having down adhering to them, which affifts their tranfportation; fo that they are often carried by the wind to a great diftance, and thereby become very troublefome weeds to the Grafs. For want of this care, how many paftures may be feen almoft over-run with thefe weeds, efpecially the ragwort; when a fmall expence, if applied in time, would have intirely extirpated them! for a man may go over feveral acres of land in one day with a fpaddle, and cut up the weeds juft below the furface of the ground, turning their roots upwards; which, if done in dry weather, they will foon decay; but this muft always be performed before the plants come to have their feeds formed; becaufe, after that, many forts will live long enough to nourifh their feeds after they are cut, fo as to ripen them: and there will be a fupply of weeds for fome years after, which cannot be extirpated without a much greater expence.

The proper management of pafture land is the leaft underftood of any part of agriculture: the farmers never have attended to this, being more inclined to the plough; though the profit attending that has not of late years been fo great, as to encourage them in that part of hufbandry: but thefe people never think of laying down land for pafture, to continue longer than three years; at the end of which time they plow it up again, to fow it with grain.

Their ufual method is to fow rye Grafs and trefoil with barley, when they intend to lay down the ground; or fometimes fow only clover with the barley; nor is it poffible to convince thefe people of their error in fowing corn with this Grafs; which they affirm to be ufeful, in fhading the Grafs; not confidering how much the corn draws away the nourifhment from the Grafs: but it is in vain to write to thefe people, who are not to be convinced, either by argument or experiment; fo much are they led by cuftom, as not to be led or driven out of their own methods; but, as their practice of hufbandry has greatly leffened the circumftances of the farmers, fo that the lands are daily falling into the hands of the owners, therefore, this part of hufbandry fhould by them be principally attended to, as it may be carried on with a much lefs expence: for pafture land requires but few hands to manage; whereas the fowing of corn is attended with great expence, and the profit is very precarious: but, when this is attended with fuccefs, and the grain at a moderate price, if the whole labour is to be paid for, there will be little coming to the owner for rent, when the balance is fairly ftated; but in this moft gentlemen deceive themfelves, and often fuppofe they gain by farming, when, perhaps, the whole rent of the land is loft: therefore, to avoid the trouble which attends this fort of hufbandry, it will be the beft method to turn as much of their land into pafture, as they can; which, by grazing and feeding of fheep, will be attended with little expence, and a fure profit. *Miller's Gard. Dict.*

GRA'SSHOPPERS.—Thefe animals are of the locuft kind, and fometimes come in fwarms to particular places, in the fame manner as that devouring creature does. They appeared fome years ago in Languedoc, and fome other places, in very formidable fwarms, and eat up all the harveft of feveral years. They took their flight like birds, and were about an inch long, and of a grey colour, in fhape only like the common Grafshoppers. They were found in many places covering the whole furface of the earth four or five inches deep, and ufed to lie quiet till towards noon; but, when the fun then fhone warmly upon them, they ufed to arife and take wing, and, fettling on the corn fields, they would in a few hours eat up the whole produce, ears, leaves, and even the more tender parts of the ftalks. When they had deftroyed one field in this manner, they ufed to take wing and fly to another. They ufually flew very high in the air, and directly againft the wind; but, as foon as they faw a new crop of corn, they dropped together in a fwarm, and cleared it as they had done the firft. This practice they continued the whole day, and towards evening they fettled upon the ground, where they remained quiet till the heat of the following day raifed them again. When they had deftroyed all the corn in the country, they feized upon the vines, gardenherbs, and willows, and at laft upon hemp, whole fields of which they eat up, notwithftanding its great bitternefs. Towards autumn, they left off feeding, and were found in copulation, and foon after this, the females every-where feen laying their eggs, which they depofited in the ground, making a hole with their tail large enough to receive a goofe quill.

In thefe holes every female would lay forty or fifty eggs, each of the fize of a millet feed, and when they had finifhed the laying, they covered up the hole to keep out the water; after this they died a-pace, and the multitudes of their carcasses stunk intolerably, poisoning the air. The next year they hatched in April, and from this one swarm there were such prodigious numbers hatched, that fifteen tons of them were destroyed, while no bigger than flies, and nine tons of their eggs before the hatching, and yet there remained enough of them to destroy, in a great measure, the succeeding harvest. After this, they gradually decreased for several years, till they were not more numerous there than elsewhere. This was attributed to the industry of the farmers in killing them; but it is more probable, that unfavourable seasons destroyed them. *Philosophical Transactions*, N°. 182.

GRAVEL, in gardening.—Gravel and grass are naturally ornaments to a country-seat, and are the glory of the English gardens, and things by which we excel all other nations, as France, Holland, Flanders, &c.

There are different sorts of Gravel, but, for those who can conveniently have it, I approve of that Gravel on Black-heath, as preferrable to most we have in England; it consisting of smooth even pebbles, which, when mixed with a due quantity of loam, will bind exceeding close, and look very beautiful, and continue handsome longer than any other sort of Gravel, which I have yet seen.

Some recommend a sort of iron-mould Gravel, or Gravel with a little binding loam amongst it, than which nothing, they say, binds better, when it is dry: but in wet weather is apt to stick to the heels of one's shoes, and will never appear handsome.

Sometimes loam is mixed with Gravel that is over sandy or sharp, which must be very well blended together, and let lie in heaps; after which it will bind like a rock.

There are many kinds of Gravel which do not bind, and thereby cause a continual trouble of rolling, to little or no purpose: as for such,

If the Gravel be loose or sandy, you should take one load of strong loam, and two of Gravel, and so cast them well together.

There are many different opinions about the choice of Gravel: some are for having the Gravel as white as possible; and, in order to make the walks more so, they roll them well with stone-rollers, which are often hewn by the masons, that they may add a whiteness to the walks: but this renders it very troublesome to the eyes, by reflecting the rays of light so strongly; therefore, this should ever be avoided; and such Gravel as will lie smooth, and reflect the least, should be preferred.

If it be an old walk, that only wants coating over, it will be sufficient to lay it two or three inches thick: but, where there is plenty of strong reddish loam, you may lay it the full depth.

Some screen the Gravel too fine, but this is an error: if it be cast into a round heap, and the great stones only raked off, it will be the better.

Some are apt to lay Gravel-walks too round; but this is likewise an error, because they are not so good to walk upon, and, besides, it makes them look narrow: one inch is enough in a crown of five feet; and it will be sufficient, if a walk be ten feet wide, that it lies two inches higher in the middle, than it does on each side; if fifteen feet, three inches; if twenty feet, four; and so in proportion.

For the depth of Gravel-walks, six or eight inches may do well enough; but a foot thickness will be sufficient for any; but then there should always be a depth of rubbish laid under the Gravel, especially if the ground is wet; in which case there cannot be too much care to fill the bottom of the walks with large stones, flints, brick-rubbish, or any other materials, which can be best procured; which will drain off the moisture from the Gravel, and prevent its being poachy in wet weather.

In the making of Gravel-walks, there must be great regard had to the level of the ground, so as to lay the walks with easy descents towards the two parts of the ground, that the wet may be drained off easily; for, when this is omitted, the water will lie upon the walks a considerable time after hard rains, which will render them unfit for use, especially where the ground is wet or strong: but where the ground is level, and there are no declivities to carry off the wet, it will be proper to have sink-stones laid by the sides of the walks, at convenient distances, to let off the wet; and where the ground is naturally dry, that the water will soon soak away, the drains from the sink-stones may be contrived so, as to convey the water in sesspools, from which the water will soak away in a short time: but, in wet land, there should be under-ground drains, to convey the wet off, either into ponds, ditches, or the nearest place to receive it; for, where this is not well provided for, the walks will never be so handsome, or useful.

The month of March is the properest time for laying Gravel: it is not prudent to do it sooner, or to lay walks in any of the winter-months before that time.

Some indeed turn up Gravel-walks in ridges in December, in order to kill the weeds: but this is very wrong; for, besides that it deprives them of the benefit of them all the winter, it does not answer the end for which it is done, but rather the contrary; for, though it does kill the weeds for the present, yet, it adds a fertility to them, as to the great future increase of both them and grass.

If constant rolling them after the rains and frost will not effectually kill the weeds and moss, you should turn the walks in March, and lay them down at the same time.

In order to destroy worms that spoil the beauty of Gravel or grass-walks, some recommend the watering them well with water, in which walnut-tree leaves have been steeped, and made very bitter, especially those places most annoyed by them; and this, they say, as soon as it reaches them, will make them come out hastily, so that they may be gathered: but, if in the first laying of the walks, there is a good bed of lime-rubbish laid in the bottom, it is the most effectual method to keep out the worms; for they do not care to harbour near lime.

Grounds that are gravelly and sandy, easily admit both heat and moisture: but they are not much the better for it; because they let it pass too soon, and so contract no ligature; or else, if they have a clayey bottom, they retain it too long, and by that means either parch or chill too much, and produce nothing but moss, or cancerous infirmities: but, if the bottom be a Gravel, and there are two feet of good earth upon the surface, it is preferrable to most other soils for almost any sort of fruit; for, though this soil will not produce the fruit planted thereon, so large as a loamy soil, yet they will be much better tasted, and earlier ripe. *Miller's Gard. Dict.*

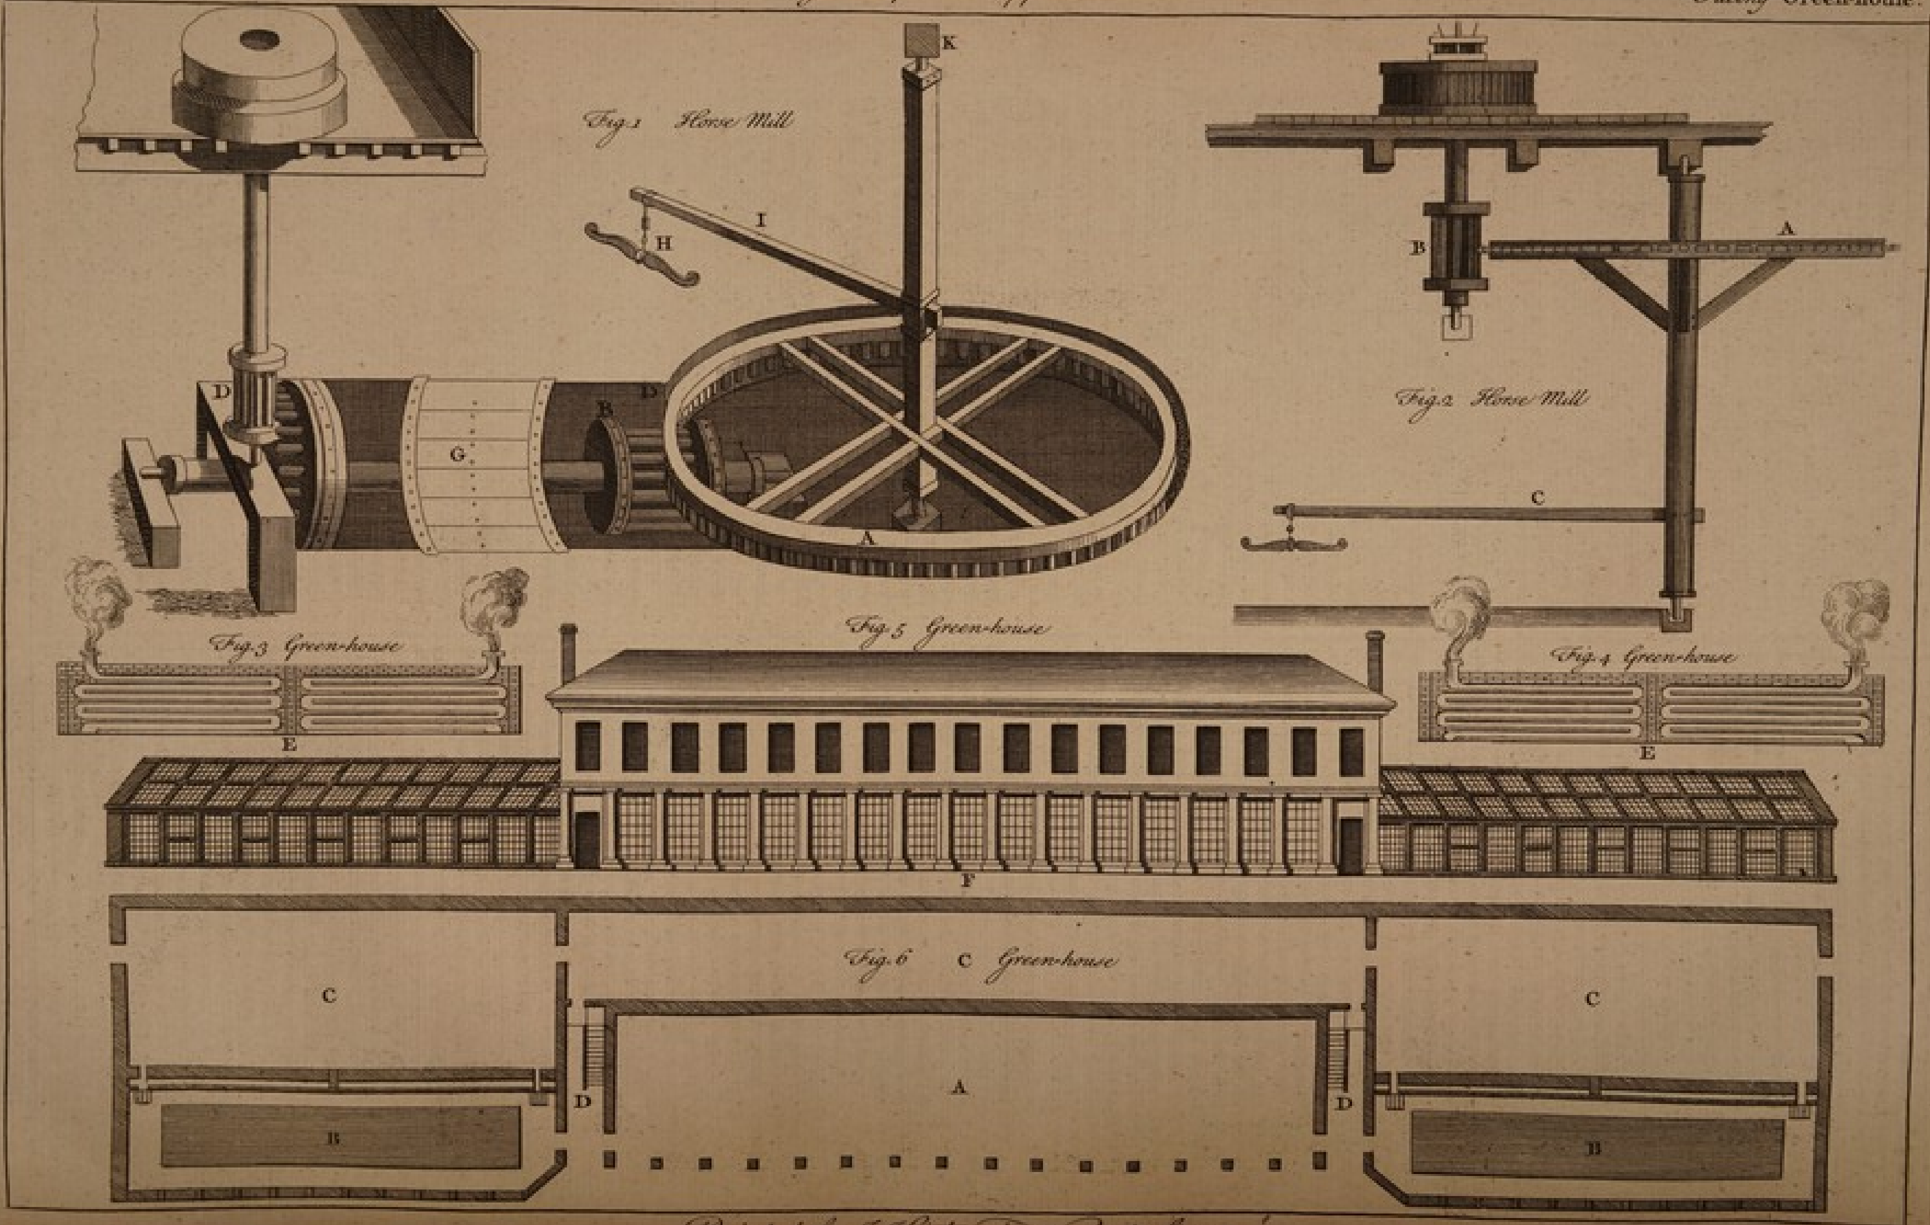
GREEN (*Dict.*).—The finest method of giving this beautiful colour to glass is this: take five pounds of crystalline metal, that has been passed several times through water, and the same quantity of the common white metal of polverine, four pounds of common polverined frit, and three pounds of red-lead; mix the red-lead well with the frit, and then put all into a pot in a furnace. In a few hours the whole mass will be well purified; then cast the whole into water, and separate, and take out the lead; then return the metal into the pot, and let it stand a day longer in fusion; then put in the powder of the residuum of the vitriol of copper, and a very little crocus martis, there will be produced a most lively and elegant Green, scarce inferior to that of the oriental emerald. There are many ways of giving Green to glass, but all are greatly inferior to this. *Neri's Art of Glass.*

GREEN-*house* (*Dict.*)—As, of late years, there have been great quantities of curious exotic plants introduced into the English gardens, so the number of Green-houses or conservatories has increased; and not only a greater skill in the management and ordering of these plants has increased therewith, but also a greater knowledge of the structure and contrivance of these places, so as to render them both useful and ornamental, hath been acquired: and, since there are many particulars to be observed in the construction of these houses, whereby they will be greatly improved, I thought it necessary not only to give the best instructions for this I was capable of, but also to give a design of one in the manner I would chuse to erect it, upon *plate* XXIV.

As to the length of these houses, that must be proportioned to the number of plants they are to contain, or the fancy of the owner; but their depth should never be greater than their height in the clear; which in small or middling houses may be sixteen or eighteen feet; but, for large ones, from twenty to twenty-four feet is a good proportion; for, if the Green-house is long, and too narrow, it will have a bad appearance both within and without; nor will it contain so many plants, if proper room be allowed for passing in front, and on the backside, of the stands on which the plants are placed: and on the other hand, if the depth of the Green-house is more than twenty-four feet, there must be more rows of plants placed to fill the house, than can with conveniency be reached in watering and cleaning; nor are houses of too great depth so proper for keeping of plants, as those of a moderate size.

The windows in front should extend from about one foot and an half above the pavement, to within the same distance of the ceiling, which will admit of a cornice round the building, over the heads of the windows. As it is necessary to have these windows so long, it will be impossible to make them in proportion as to their breadth; for, if in the largest buildings, the sashes are more than seven, or seven and an half feet broad, they will be so heavy and troublesome to move up and down, as to render it very difficult for one person to perform; beside their weight will occasion their soon decaying. There is also another inconvenience in having the windows too broad; which is, that of fixing proper shutters to them, in such a manner, as that they may fall back close to the piers, so as not to be incommodious; or, when open, to abstract any part of the rays of light from reaching the plants. The piers between these windows should be as narrow as possible to support the building; for which reason I should chuse to have them of stone, or of hard well burnt bricks; for, if they are built with fine rubbed bricks, those are generally so soft, that the piers will require to be made thicker, and the building will be in danger of falling in a short time; especially, if you have any rooms over the Green-house; which is what I would always advise, as being of great use to keep the frost out in very hard winters. If these piers are made of stone, I would advise them to be two feet and an half in front, and sloped off backward to about eighteen inches broad; whereby the rays of the sun will not be taken off or obstructed by the corners of the piers; which it would be, if they were square: but, if they are built with bricks, it will be proper to make them three feet in front, otherwise they

PLATE XXIV. *Engraved for the Supplement.* *Facing* Green-house.



Printed for J. Hinton in Newgate Street.

will be too weak to ſupport the building: theſe I would alſo adviſe to be ſloped off in the manner directed for the ſtone.

At the back of the Green-houſe, there may be erected an houſe for tools, and many other purpoſes; which will be extremely uſeful, and alſo prevent froſt from entering the houſe that way; ſo that the wall between theſe need not be more than two bricks and an half in thickneſs; whereas, were it quite expoſed behind, it ſhould be at leaſt three bricks in thickneſs; and, by this contrivance, if you are willing to make an handſome building, and to have a noble room over the Green-houſe, you may make the room over the tool-houſe, and carry up the ſtair-caſe in the back, ſo as not to be ſeen in the Green-houſe; and, hereby you may have a room twenty-five or thirty feet in width, and of a proportionable length: and, under this ſtair-caſe, there ſhould be a private door into the Green-houſe, at which the gardener may enter in hard froſty weather, when it will not be ſafe to open any of the glaſſes in the front. The floor of the Green-houſe, which ſhould be laid either with marble, ſtone, or broad tiles, according to the fancy of the owner, muſt be raiſed two feet above the ſurface of the ground whereon the houſe is placed; which, in dry ground, will be ſufficient: but, if the ſituation be moiſt and ſpongy, and thereby ſubject to damps, it ſhould be raiſed at leaſt three feet above the ſurface: and, if the whole is arched with low brick arches, under the floor, it will be of great ſervice in preventing the damps riſing in winter, which are often very hurtful to the plants, eſpecially in great thaws, when the air is often too cold to be admitted into the houſe, to take off the damps. Under the floor, about two feet from the front, I would adviſe a flue of about ten inches in width, and two feet deep, to be carried the whole length of the houſe, which may be returned along the back part, and be carried up in proper funnels adjoining to the tool-houſe, by which the ſmoke may paſs off. The fire-place may be contrived at one end of the houſe; and the door at which the fuel is put in, as alſo the aſh-grate, may be contrived to open into the tool-houſe, ſo that it may be quite hid from the ſight, and be in the dry; and the fuel be laid in the ſame place, whereby it will always be ready for uſe.

I ſuppoſe many people will be ſurpriſed to ſee me direct the making flues under a Green-houſe, which has been diſuſed ſo long, and by moſt people thought of ill conſequence; as indeed they have often proved, when under the direction of unſkilful managers, who have thought it neceſſary, whenever the weather was cold, to make fires therein. But, however injurious flues have been under ſuch management, yet, when ſkilfully managed, they are of very great ſervice: for, though, perhaps, it may happen, that there will be no neceſſity to make any fires in them for two or three years together, as, when the winters prove mild, there will not, yet, in very hard winters, they will be extremely uſeful to keep out the froſt; which cannot be effected any other way, but with great trouble and difficulty.

Withinſide of the windows, in front of the Green-houſe, you ſhould have good ſtrong ſhutters, which ſhould be made with hinges, to fold back, that they may fall back quite cloſe to the piers, that the rays of the ſun may not be obſtructed thereby. Theſe ſhutters need not to be above an inch and an half thick, or little more; which, if made to join cloſe, will be ſufficient to keep out our common froſt: and, when the weather is ſo cold as to endanger the freezing in the houſe, it is but making a fire in your flue, which will effectually prevent it: and without this conveniency it will be very troubleſome, as I have often ſeen, where perſons have been obliged to nail mats before their windows, or to ſtuff the hollow ſpace between the ſhutters and the glaſs with ſtraw; which, when done, is commonly ſuffered to remain till the froſt goes away; which, if it ſhould continue very long, the keeping the Green-houſe cloſely ſhut up will prove very injurious to the plants: and as it frequently happens, that we have an hour or two of ſun-ſhine in the middle of the day, in continued froſts, which is of great ſervice to plants, when they can enjoy the rays thereof through the glaſſes; ſo, when there is nothing more to do than to open the ſhutters, which may be performed in a very ſhort time, and as ſoon ſhut again when the ſun is clouded, the plants may have the benefit thereof, whenever it appears; whereas, where there is ſo much trouble to uncover, and as much to cover again, it would take up the whole time in uncovering and ſhutting them up, and thereby the advantage of the ſun's influence be loſt. Beſides, where there is ſo much trouble required to keep out the froſt, it will be a great chance if it be not neglected by the gardener: for, if he be not as fond of preſerving his plants, and as much in love with them, as his maſter, this labour will be thought too great by him; and, if he takes the pains to cover the glaſſes up with mats, &c. he will not care to take them away again, until the weather alters; ſo that the plants will be ſhut up cloſe during the whole continuance of the froſt.

There are ſome people who commonly make uſe of pots filled with charcoal to ſet in their Green-houſe in very ſevere froſts; but this is very dangerous to the perſons who attend theſe fires; and I have often known they have been almoſt ſuffocated therewith; and at the ſame time they are very injurious to the plants: nor is the trouble of tending upon theſe ſmall; and the many hazards, to which the uſe of theſe fires is liable, have juſtly brought them into diſuſe with all ſkilful perſons; and, as the contrivance of flues, and of the fires, are but ſmall charges, they are much to be preferred to any other method for warming the air of the houſe.

The back part of the houſe ſhould be either laid over with ſtucco, or plaiſtered with mortar, and white-waſhed; for otherwiſe the air in ſevere froſt will penetrate through the walls, eſpecially, when the froſt is attended with a ſtrong wind; which is often the caſe in the moſt ſevere winters. There are ſome perſons who are at the expence of wainſcoting their Green-houſes; but, when this is done, it is proper to plaiſter with lime and hair behind the wainſcot, to keep out the cold; and, when they are lined with wainſcot, they ſhould be painted white, as ſhould the ceiling, and every part withinſide of the houſe: for this reflects the rays of light in much greater quantity than any other colour, and is of ſignal ſervice to plants, eſpecially in the winter, when the houſe is pretty much cloſed, and but a ſmall ſhare of light is admitted through the windows: for, at ſuch times, I have obſerved, that in ſome Green-houſes which have been painted black, or of a dark colour, the plants have caſt moſt of their leaves.

Where Green-houſes are built in ſuch places as will not admit of rooms over them, or the perſon is unwilling to be at the expence of ſuch building, there muſt be care taken to keep out the froſt from entering through the roof. To prevent which, it will be very proper to have a thickneſs of reeds, heath, or furz, laid between the ceiling and the tiles: in the doing of which, there muſt be care taken in framing the joiſts, ſo as to ſupport theſe, that their weight may not lie upon the ceiling; which might endanger it: for theſe ſhould be laid a foot thick at leaſt, and as ſmooth as poſſible, and faſtened down well with laths, to prevent their riſing; and then cover it over with a coat of lime and hair, which will keep out the air, and alſo prevent mice, and other vermin, from harbouring in them; which, if left uncovered, they would certainly do. For want of this precaution, there are many Green-houſes built, which will not keep out the froſt in hard winters; and this is many times attributed to the glaſſes in front admitting the cold, when the fault is in the roof: for, where there is only the covering, either of tiles or ſlates, and the ceiling, every ſevere froſt will penetrate through them.

In this Green-houſe you ſhould have truſſels, which may be moved out and into the houſe; upon which you ſhould fix rows of planks, ſo as to place the pots or tubs of plants in regular rows one above another, whereby the heads of the plants will be ſo ſituated as not to interfere with each other. The loweſt row of plants, which ſhould be the forwardeſt towards the windows, ſhould be placed about four feet therefrom, that there may be a convenient breadth left next the glaſſes to walk in front: and the rows of plants ſhould riſe gradually from the firſt, in ſuch a manner, that the heads of the ſecond rows ſhould be intirely advanced above the firſt, the ſtems only being hid thereby: and, at the backſide of the houſe, there ſhould be allowed a ſpace of leaſt five feet, for the conveniency of watering the plants; as alſo to admit of a current of air round them, that the damps, occaſioned by the perſpiration of the plants, may be the better diſſipated, which, by being pent in too cloſely, often occaſions a mouldineſs upon the tender ſhoots and leaves; and, when the houſe is cloſe ſhut up, this ſtagnating rancid vapour is often very deſtructive to the plants: for which reaſon alſo, you ſhould never croud them too cloſe to each other; nor ſhould you ever place ſedums, euphorbiums, torch thiſtles, and other tender ſucculent plants, amongſt oranges, myrtles, and other ever-green-trees; for, by an experiment which I made anno 1729, I found that a ſedum, placed in a Green-houſe among ſuch trees, almoſt daily increaſed its weight, although there was no water given to it the whole time: which increaſe of weight was owing to the moiſture imbibed from the air, which, being replete with the rancid vapours perſpired from the other plants, occaſioned the leaves to grow pale, and in a ſhort time they decayed, and dropped off: which, I have often obſerved, has been the caſe with many other ſucculent plants, when placed in thoſe houſes which were filled with many ſorts of ever-green trees, that required to be frequently watered.

Therefore, to avoid the inconvenience which attends the placing of plants of very different natures in the ſame houſe, it will be very proper to have two wings added to the main Green-houſe; which, if placed in the manner expreſſed in the annexed plan, will greatly add to the beauty of the building, and alſo collect a greater ſhare of heat. In this plan, the Green-houſe is placed exactly fronting the ſouth; and one of the wings faces the ſouth-eaſt, and the other the ſouth-weſt; ſo that, from the time of the ſun's firſt appearance upon any part of the building, until it goes off at night, it is conſtantly reflected from one part to the other; and the cold winds are alſo kept off from the front of the main Green-houſe hereby: and, in the area of this place, you may contrive to place many of the moſt tender exotic plants, which will bear to be expoſed in the ſummer-ſeaſon: and, in the ſpring, before the weather will permit you to ſet out the plants, the beds and borders of this area may be full of anemonies, ranunculus's, early tulips, &c. which will be paſt flowering, and the roots fit to take out of the ground, by the time you carry out the

3 plants;

plants; which will render this place very agreeable during the spring season that the flowers are blown; and here you may walk and divert yourself in a fine day, when, perhaps, the air in most other parts of the garden will be too cold for persons not much used thereto, to take pleasure in being out of the house.

In the center of this area may be contrived a small bason for water, which will be very convenient for watering of plants, and add much to the beauty of the place: besides, the water, being thus situated, will be softened by the heat, which will be reflected from the glasses upon it; whereby it will be rendered much better than raw cold water for these tender plants.

The two wings of the building should be contrived so as to maintain plants of different degrees of hardiness; which must be effected by the situation and the extent of the fire-place, and the manner of conducting the flues; a particular account of which will be exhibited under the article of STOVES. But I would here observe, that the wing facing the south-east should always be preferred for the warmest stove; its situation being such, as that the sun, upon its first appearance in the morning, shines directly upon the glasses; which is of great service in warming the air of the house, and adding life to the plants, after having been shut up during the long nights in the winter season. These wings, being, in the draught annexed, allowed sixty feet in length, may be divided in the middle by partitions of glass, with glass doors to pass from one to the other. To each of these there should be a fire-place, with flues carried up against the back wall, through which the smoke should be made to pass, as many times the length of the house, as the height will admit of the number of flues; for, the longer the smoke is in passing, the more heat will be given to the house, with a less quantity of fuel: which is an article worth consideration, especially, where fuel is dear. By this contrivance, you may keep such plants as require the same degree of heat in one part of the house, and these will thrive in a much less warmth in the other part; but this will be more fully explained under the article of STOVES.

The other wing of the house, facing the south-west, may also be divided in the same manner, and flues carried through both parts, which may be used according to the seasons, or the particular sorts of plants which are placed therein: so that here will be four divisions in the wings, each of which may be kept up to a different degree of warmth: which, together with the Green-house, will be sufficient to maintain plants from all the several countries of the world: and, without having these several degrees of warmth, it will be impossible to preserve the various kinds of plants from the several parts of Africa and America, which are annually introduced into the English gardens: for, when plants from very different countries are placed in the same house, some are destroyed for want of heat, while others are forced and spoiled by too much of it; and this is often the case in many places, where there are large collections of plants.

In the building these wings, if there are not sheds running behind them, their whole length, the walls should not be less than two bricks thick; and, if they are more, it will be better; because, where the walls are thin, and exposed to the open air, the cold will penetrate them; and when the fires are made, the heat will come out through the walls; so that it will require a larger quantity of fuel to maintain a proper temperature of warmth in the house. The back part of these houses, having sloping roofs, which are covered either with tiles or slates, should also be lined with reeds, &c. under the covering, as is before directed for the Green-house; which will keep out the cold air, and save a great expence of fuel; for the closer and better these houses are built, and the glasses of the slope, as also, in front, well guarded by shutters or reeds in a hard frost, the less fuel will be required to warm the houses; so that the first expence of building these houses properly will be the cheapest, when the after expence of fires is taken into consideration.

The sloping glasses of these houses should be made to slide, and take off; so that they may be drawn down more or less, in warm weather, to admit air to the plants; and the upright glasses in front may be so contrived, as that every other may open as doors upon hinges; and the alternate glasses may be divided into two: the upper part of each should be contrived so as to be drawn down like sashes; so that either of these may be used to admit air, in a greater or less quantity, according as these may be divided into two: the upper part of each should be contrived so as to be drawn down like sashes; so that either of these may be used to admit air, in a greater or less quantity, according as there may be occasion.

But, besides the conservatories here mentioned, it will be proper to have a deep hot bed frame, such as is commonly used to raise large annuals in the spring; into which may be set pots of such plants as come from Carolina, Virginia, &c. while the plants are too small to plant in the open air; as also may other sorts from Spain, &c. which require only to be screened from the violence of the frosts, and should have as much free air as possible in mild weather; which can be no better effected than in one of these frames, where the glasses may be taken off every day when the weather will permit, and put on every night; and, in hard frosts, the glass may be covered with mats, straw, pease haulm, or the like, so as to prevent the frost from entering the pots to freeze the roots of the plants, which is what will, many times, utterly destroy them; though a slight frost pinching the leaves or shoots very seldom does them much harm: if these are sunk a foot or more below the surface of the ground, they will be the better, provided the ground is dry; otherwise they must be wholly above ground: the sides of this frame should be built with brick, with a curb of wood laid round on the top of the wall, into which the gutters, on which the glasses slide, may be laid: the back wall of this frame may be four feet high, and the front one foot and an half; the width about six feet, and the length in proportion to the number of plants.

GREE'NLAND *buck*, in natural history, a very thick and clumsy deer in comparison with our's in England, being, for proportion of its parts, more like a well grown calf than a deer; from the ground to the top of the shoulders, it is about three feet high, English measure; it hath a much shorter neck, and thicker legs, than is common in the deer kind; in summer time it is covered with smooth short hair of a mouse colour; against winter there springs from beneath this a second coat of long rough white hair, though it is a little brown on the back, and the lower part of the face; this long hair gives it a thick clumsy appearance; in the spring again, this rough winter cloathing is, as it were, thrust off by the succeeding summer's coat, which is smooth and short, and so it continues to change its coverings; what is most remarkable in this kind is the nose, which is wholly covered with hair in that part, which in other deer is bare skin, and moist: I suppose, had it been naked, it must necessarily have froze in those countries, so nature has given it this covering to defend it; the eyes are pretty large, standing a little out of the head; both male and female have horns, which is not common; its hoofs are not pointed, they part pretty much in the cleft, and are broad at the bottom, in order, I suppose, to keep them from sinking too far into the snow; it hath two small hoofs or claws behind the greater on each foot, placed pretty high; the hoofs are of a dark horn colour; the horns in this were not perfect, it being young; they were covered with a plush-like skin, of a brown colour, and shaped as in the figure.

I saw a head of perfect horns brought over with these deer, which had two large palmed branches over the eyes, conveniently placed as shovels, to remove the snow from the grass; a little above these were two other palms, but less, standing outward; above these, each horn spread itself into five round branches not at all palmed. A male and female of these deer were presented to Sir Hans Sloane, anno 1738, by captain Craycott, who brought them over. Sir Hans afterwards presented them to his grace the duke of Richmond, who sent them to his park in Sussex. I hear they are since dead, without any increase. This is by some supposed to be the rain-deer of the Laplanders and Russians. *Plate* XXV. *fig.* 3, represents it in its winter cloathing. *Edwards's History of Birds.*

GRENAI'LLE, a name given by the French writers to a preparation of copper, which the Chinese use as a red colour in some of their finest china; particularly for that colour which is called oil red, or red in oil. The china ware coloured with this is very dear. The manner in which they procure the preparation is thus: they have in China no such thing as silver coined money, but they use, in commerce, bars or masses of silver; these they pay and receive in large bargains, and, among a nation so full of fraud as the Chinese, it is no wonder that these are often adulterated with too great an alloy of copper. They pass, however, in this state in the common payments. There are some occasions, however, such as the paying the taxes and contributions, on which they must have their silver pure and fine: on this occasion they have recourse to certain people, whose sole business it is to refine the silver, and separate it from the copper and the lead it contains. This they do in furnaces made for the purpose, and with very convenient vessels. While the copper is in fusion, they take a small brush and dip the end of it into water; then, striking the handle of the brush, they sprinkle the water, by degrees, upon the melted copper; a sort of pellicle forms itself by this means on the surface of the matter, which they take off while hot with pincers of iron, and, immediately throwing it into a large vessel of cold water, it forms that red powder, which is called the Grenaille; they repeat the operation, every time they in this manner separate the copper; and this furnishes them with as much of the Grenaille as they have occasion for in their china works. *Observations sur les Coutumes de l'Asie.*

GROSSULA'RIA, *the gooseberry-tree*, in botany, a genus of plants whose characters are:

The leaves are laciniated, or jagged: the whole plant is set with prickles: the fruit grows sparsedly upon the tree, having

LATE XXV. *Engraved for the Supplement.* *Facing* Greenland *Buck*

Printed for J. Hinton in Newgate Street.

for the moſt part, but one fruit upon a footſtalk, which is of an oval or globular figure, containing many ſmall ſeeds ſurrounded by a pulpy ſubſtance.

There are ſeveral varieties of this fruit, which have been obtained from ſeeds in different parts of England, which differ either in the ſhape or colour of the berries: but, as theſe are only ſeminal variations, it is needleſs, in this place, to enumerate them, eſpecially ſince the number of theſe will be increaſed continually from ſeeds.

Theſe are propagated either by ſuckers taken from the old plants, or by cuttings; the latter of which I prefer to the former, becauſe thoſe plants which are produced from ſuckers are always more diſpoſed to ſhoot out a great number of ſuckers from their roots, than ſuch as are raiſed from cuttings, which generally form much better roots.

The beſt ſeaſon for planting theſe cuttings is in autumn, juſt before their leaves begin to fall; obſerving always to take the handſomeſt ſhoots, and from ſuch branches as generally produce the greateſt quantity of fruit; for, if you take thoſe which are produced from the ſtem of the old plants, which are commonly very luxuriant, they will not be near ſo fruitful as thoſe taken from bearing branches: theſe cuttings ſhould be about ſix or eight inches long, and muſt be planted in a border of light earth, expoſed to the morning ſun, about three inches deep, obſerving to water them gently, when the weather proves dry, to facilitate their taking root; and in the ſummer, when they put out, you ſhould rub off all the under ſhoots, leaving only the uppermoſt or ſtrongeſt, which ſhould be trained upright, to form a regular ſtem. In October following, theſe plants will be fit to remove; at which time you ſhould prepare an open ſpot of freſh earth, which ſhould be well dug, and cleanſed from all noxious weeds, roots, &c. and, being levelled, you ſhould proceed to take up your plants, trimming their roots, and cutting off all lateral ſide branches; then plant them at three feet diſtance row from row, and one foot aſunder in the rows, obſerving to place ſome ſhort ſticks to the plants, in order to train their ſtems upright and regular. In this place they may remain one year; being careful to keep them clear from weeds, as alſo to trim off all lateral ſhoots which are produced below the head of the plant, ſo that the ſtem may be clear about a foot in height above the ſurface of the earth, which will be full enough: and, as the branches are produced commonly very irregular in the head, you muſt cut out ſuch of them as croſs each other, or thin them where they are too cloſe; whereby the head of the plant will be open, and capable of admitting the air freely into the middle, which is of great uſe to all kinds of fruits.

After theſe plants have remained in this nurſery one year, they will be fit to tranſplant to the places where they are deſigned to remain; for it is not ſo well to let them grow in the nurſeries too large, which will occaſion their roots to be woody, whereby the removing of them will not only hazard the growth of the plants, but ſuch of them as may take very well, will remain ſtinted for two or three years, before they will be able to recover their check. The ſoil in which theſe plants thrive to the greateſt advantage, is a rich light ſandy earth; though they will do very well upon moiſt ſoils, which are not too ſtrong or moiſt, and in all ſituations: but where the fruit is cultivated, in order to procure it in the greateſt perfection, they ſhould never be planted in the ſhade of other trees, but muſt have a free open expoſure; the diſtance they ought to be planted is eight feet row from row, and ſix feet aſunder in the rows: the beſt ſeaſon for tranſplanting them is in October, when their leaves begin to decay; obſerving, as was before directed, to prune their roots, and trim off all lateral ſhoots, or ſuch as croſs each other; ſhortening all long branches, ſo as to make the head regular.

In the pruning of theſe ſhrubs, moſt people make uſe of garden-ſheers, obſerving only to cut the head round, as it is practiſed for ever-greens, &c. whereby the branches become ſo much crouded, that what fruit is produced, never grows to half the ſize as it would do, were the branches thinned, and pruned according to art; which ſhould always be done with a pruning-knife, ſhortening the ſtrong ſhoots to about ten inches, and cutting out all thoſe which grow irregular, and thinning the fruit-bearing branches where they are too thick; obſerving always to cut behind a leaf-bud: with this management your fruit will be near twice as large as thoſe which are produced upon ſuch buſhes as are not thus pruned, and the ſhrubs will continue in vigour much longer: but you muſt obſerve to keep the ground clear from weeds, and dig it at leaſt once a year; and every other year you ſhould beſtow a little rotten dung upon it, which will greatly improve the fruit.

It is a common practice with the gardeners near London, who have great quantities of theſe buſhes, in order to ſupply the markets, to prune them ſoon after Michaelmas, and then to dig up the ground between the rows, and plant it with coleworts for ſpring uſe, whereby their ground is employed all the winter, without prejudicing the gooſeberries; and in hard winters theſe coleworts often eſcape, when thoſe which are planted in an open expoſure are all deſtroyed; and theſe are generally pulled up for uſe in February or March, ſo that the ground is clear before the gooſeberries come out in the ſpring; which is a piece of huſbandry well worth practiſing where ground is dear, or where perſons are confined for room. *Miller's Gard. Dict.*

Gooſeberries, in the beginning, are green, and of an acid taſte, becauſe the acid ſalt, contained therein in a large proportion, is not yet encumbered with ſulphurs, and thus it can operate upon the nerves of the tongue very powerfully; inſomuch that this ſalt, being at that time united with nothing elſe but ſome proportion of earth, excites an aſtringent and ſtyptic ſenſation; whereas, afterwards, the little oil contained in the gooſeberries, which before was kept back by paſſive principles, gets looſe, riſes, and, by the help of fermentation, unites itſelf with the ſalts, and diveſts them partly of their ſtrength; then it is that gooſeberries are ripe, when they have a ſweet ſmell, and yellowiſh colour: from whence we may conclude, that, the riper gooſeberries are, they are ſo much the leſs aſtringent; and ſo, when you have a mind to have gooſeberries preſerved, the green are to be preferred before thoſe that are ripe.

The ſaid eſſential ſalt, wherewith gooſeberries abound, is the cauſe of the principal effects wrought by them. In ſhort, they would not create an appetite, were it not that this ſalt lightly pricks the little fibres of the ſtomach; they would not cool, and be good for people ſick of fevers, and be endued with the little virtues, but becauſe this ſalt, by imparting a little more conſiſtence to the humours, ſtops their violent and impetuous motion. *Lemery on Foods.*

GROTTO (*Dict.*)—A cement for artificial Grotto's may be made thus: take two parts of white reſin, melt it clear, and add to it four parts of bees wax; when melted together, add two or three parts of the powder of the ſtone you deſign to cement, or ſo much as will give the cement the colour of the ſtone; to this add one part of flower of ſulphur: incorporate all together over a gentle fire, and afterwards knead them with your hands in warm water. With this cement the ſtones, ſhells, &c. after being well dried before the fire, may be cemented. *Smith's Laboratory.*

Artificial red coral branches, for the embelliſhment of Grotto's, may be made in the following manner: take clear roſin, diſſolve it in a braſs pan; to every ounce of which add two drachms of the fineſt vermilion: when you have ſtirred them well together, and have choſen your twigs and branches, peeled and dried, take a pencil and paint the branches all over, whilſt the compoſition is warm; afterwards ſhape them in imitation of natural coral. This done, hold the branches over a gentle coal fire, till all is ſmooth and even, as if poliſhed.

In the ſame manner white coral may be prepared with white lead, and black coral with lamp-black.

A Grotto may be built with a little expence of glaſs, cinders, pebbles, pieces of large flints, ſhells, moſs, ſtones, counterfeit coral, pieces of chalk, &c. all bound or cemented together with the above deſcribed cement.

GROVES (*Dict.*)—Groves are the greateſt ornaments to a garden; nor can a garden be complete which has not one or more of theſe. In ſmall gardens there is ſcarce room to admit of Groves of any extent; yet, in theſe, there ſhould be at leaſt one contrived, which ſhould be as large as the ground will allow it: and, where theſe are ſmall, there is more ſkill required in the diſpoſition, to give them the appearance of being larger than they really are.

Groves are of two ſorts, viz. open and cloſe Groves; open Groves are ſuch as have large ſhady trees, which ſtand at ſuch diſtances, as that their branches may approach ſo near each other, as to prevent the rays of the ſun from penetrating through them: but as ſuch trees are a long time in growing to a proper ſize for affording a ſhade; ſo, where new Groves are placed, the trees muſt be placed cloſer together, in order to have ſhade as ſoon as poſſible: but, in planting of theſe Groves, it is much the beſt way to diſpoſe all the trees irregularly, which will give them a greater magnificence, and alſo form a ſhade ſooner, than when the trees are planted in lines; for, when the ſun ſhines between the rows of trees, as it muſt do ſome part of the day in ſummer, the walks between them will be expoſed to the heat, at ſuch times, until the branches of theſe trees meet; whereas, in the irregular plantations, the trees intervene, and obſtruct the direct rays of the ſun.

When a perſon, who is to lay out a garden, is ſo happy as to meet with large full grown trees upon the ſpot, they ſhould remain inviolate, if poſſible; for it will be better to put up with many inconveniencies, than to deſtroy theſe, which will require an age to retrieve; ſo that nothing but that of offending the habitation, by being ſo near as to occaſion great damps, ſhould tempt the cutting of them down.

Moſt of the Groves which have been planted either in England, or thoſe celebrated gardens in France, are only a few regular lines of trees; many of which join to the habitation, or lead to ſome building, or other object: but theſe do not appear ſo grand, as thoſe which have been made in woods, where the trees have grown accidentally, and at irregular diſtances; where the trees have large ſpreading heads, and are left at ſuch diſtance as to permit the graſs to grow under them, then they afford the greateſt pleaſure; for nothing is more noble, than fine ſpreading trees, with large ſtems, growing thro' grafs, efpecially if the grafs is well kept, and has a good verdure; befide, moft of thefe planted Groves have generally a gravel walk, made in a ftraight line between them; which greatly offends the fight of perfons who have a true tafte: therefore, whenever a gravel walk is abfolutely neceffary to be carried through thefe Groves, it will be much better to twift it about, according as the trees naturally ftand, than to attempt regularity: but dry walks under large trees are not fo ufeful, as in open places; becaufe the dropping of the trees will render thefe walks ufelefs, after rain, for a confiderable time.

Clofe Groves have frequently large trees ftanding in them; but the ground is filled under thefe with fhrubs, or underwood; fo that the walks which are made in them are private, and fcreened from winds; whereby they are rendered agreeable for walking, at fuch times when the air is too violent or cold for walking in the more expofed parts of the garden.

Thefe are often contrived fo as to bound the open Groves, and frequently to hide the walls, or other inclofures, of the garden: and, when they are properly laid out, with dry walks winding through them, and on the fides of thefe fweet-fmelling fhrubs and flowers irregularly planted, they have a charming effect: for here a perfon may walk in private, fheltered from the inclemency of cold or violent winds, and enjoy the greateft fweets of the vegetable kingdom: therefore, where it can be admitted, if they are continued round the whole inclofure of the garden, there will be a much greater extent of walk: and thefe fhrubs will appear the beft boundary, where there are not fine profpects to be gained.

Thefe clofe Groves are by the French termed bofquets, from the Italian word bofquetto, which fignifies a little wood: and in moft of the French gardens there are many of them planted; but thefe are reduced to regular figures, as ovals, triangles, fquares, and ftars: but thefe have neither the beauty or ufe which thofe have that are made irregularly, and whofe walks are not fhut on each fide by hedges, which prevents the eye from feeing the quarters; and thefe want the fragrancy of the fhrubs and flowers, which are the great delight of thefe private walks; add to this, the keeping of the hedges in good order is attended with a great expence; which is a capital thing to be confidered in the making of gardens. *Miller's Gard. Dict.*

GROUND *angling*, the art of catching fifh under water without a float, only with a plumb of lead, or a bullet. This method is moft expedient in cold weather, when the fifh fwim low. The bullet is to be placed nine inches from the baited hook; the top of the rod is to be very gentle, that the fifh may more eafily run away with the bait, and not be fcared with the ftiffnefs of it. The angler in this way is not to ftrike, as foon as he feels the fifh bite, but flacken his line a little, to give the fifh an opportunity to fwallow the hook.

The tackle here is to be fine and flender, ftrong and big lines being apt to fright the fifh. Morning and evening are the chief feafons for the Ground line for trout; but in a cloudy day, or a muddy water, you may fifh at Ground from morning to night. *Dict. Ruft.*

GROUND *plates*, in architecture, are the outermoft pieces of timber lying on, or near the Ground, and framed into one another with mortifes and tenifons. In thefe alfo, are mortifes made to receive the tenons of joints, the fummers and girders; and, fometimes, the trimmers for the ftair-cafe and chimney-way, and the binding joifts.

GROUND *timbers*, in a fhip, are thofe timbers which lie on her keel, and are faftened to it with bolts through the keelfon. They are fo called, becaufe the fhip lies at reft upon them, when fhe is aground.

GROUSE, in zoology, the name of the tetrao, or urogallus minor, called alfo the black game, and the heath-hen, and, by Turner, the moor-hen. It is a large bird of the gallinaceous kind. The male is all over black, but the edges of his feathers, efpecially on the neck and back, have a bluifh glofs mixed among the black, and its thighs very grey. The female is of the colour of the partridge, and is variegated with tranfverfe black lines on the back, and the breaft and belly are grey. Its beak is black and crooked. It is found in the mountainous and heathy parts of the kingdom, and is a very well tafted bird. The male and female differ fo much in colour, that fome very accurate writers on thefe fubjects have been deceived into an opinion of their being two different fpecies of birds; and Gefner has diftinguifhed them in this manner, calling the female of this the grygallus minor, and that of the great urogallus or cock of the mountain, the grygallus major. *Ray's Ornithol.*

GRO'WAN, in natural hiftory, a word ufed by the miners in Cornwall to exprefs a fort of coarfe and gritty ftone, which they are ufually obliged to dig through before they come at the veins of ore. This is ufually grey or whitifh, but fometimes it is of various colours, often yellowifh, and fometimes fpotted with iron colour, and an inky black; and often its texture is fo loofe and fpongy, that there are holes in it of the fize proper to receive a pea, or a horfe-bean; thefe are fometimes empty, but more ufually they are filled up either with chalk, or with fpar. Befide the ftrata of this ftone that lie over the ore, there is alfo a large quantity of it often placed by its fide. They have this, and two other forts of ftone, lying in their way to the tin ore in Cornwall. The firft of the others they call moor-ftone; a very uncertain name, as it is alfo given by fome to the common white granate of that country; but the miners only mean by it a loofe fort of freeftone, fomewhat fofter than that ufually employed in building. The other ftone is called killos. This is a grey ftone of the flate kind, eafily fplitting into thin plates, and is very full of talcky flakes. This killos is, however, a very indeterminate name, as well as the other; for the fame people fometimes ufe it alfo to fignify a white earth, common among them; this laft, however, they fometimes diftinguifh by the epithet white. The word Growan feems the only name they have kept to any determinate fignification, for they never exprefs by this word any other fubftance, than the ftone above defcribed.

GRUB, the Englifh name of the hexapode worms, or maggots, hatched from the eggs of beetles. Grubs are an excellent bait for many kinds of fifh. In angling for the grayling, the afh Grub is to be preferred to all others. This is plump, milk-white, but round from head to tail, and has a red head. There is alfo another Grub, which is very common, and is longer and flenderer than the afh Grub. It is yellower and tougher, and is known by having a red head, and two rows of legs along the belly. The trout and grayling ufually frequent the fame places, and it is not uncommon to take the trout, while fifhing for the other. Thefe Grubs are to be kept in bran, in which they will grow tougher than they were at firft; but the afh Grub is always fo tender, that it is difficult to make a good bait of it. The beft method is to wrap it in a piece of ftiff hair with the arming, leaving it ftanding out about a ftraw's breadth at the head of the hook, fo as to keep the Grub from totally flipping off, when baited. The horfehair that the hook is faftened to fhould be as white as poffible, that it may refemble the colour of the bait, and not be fufpected.

GRUB *of the box, or box puceron*, in natural hiftory, a name given to a fort of infect approaching to the nature of the puceron of the elder and other trees, but differing from that animal in fome effential characters, and being more properly of the fame genus with the fig-infect or falfe puceron.

GRU'BBING, a term ufed by our farmers, to exprefs the taking up the roots of trees out of the ground. Several occafions offer for the doing this; as, when trees are old and paft growing to any ufe, the roots muft be taken up, that young trees may be planted in their places. This is a chargeable operation in moft places, but, in fome countries, the farmers have devifed a machine, which does a great part of the work in a much fhorter time than in any other way can be done. It is a hook of iron, of about two feet and a half long, with a large iron ring faftened to its ftreight end or handle. The whole inftrument may be made for about three or four fhillings, and is to be ufed in this manner: the ground is firft to be cleared away about the root, and any ftraggling fide roots found running horizontally are to be cut off. Then they faften the point of the hook to fome part of the ftump or root, and, putting a long and ftrong lever through the ring, two men at the end of it go round forcing it every way, till they tear the root out, twifting the top roots off at fome diftance under ground. The digging down to which, in the common way, is one great article of the expence. It is very effectual in ftubbing up the roots of the underwood, but, when large tree roots are to be taken up by it, it is beft to cleave them firft with wedges into feveral pieces, and then pull them out feparately. *Mortimer's Hufbandry.*

GRYLLOTA'LPA, *the mole cricket*, in natural hiftory, a creature approaching to the locuft kind, and very properly called by this name by Moffet, as it has much of the form of the cricket, and makes a noife like it in the evening; and is, like the mole, continually employed in the digging the ground. It is an infect of a very unpleafant form. It is of the length and thicknefs of a man's little finger, and is of a brown colour; which is darker in the male than in the female. There are on each fide of the anus two hairy proceffes, refembling the tails of mice; its belly is compofed of eight joints, and is covered with as many fcales, which are of a pale flefh colour, and are covered with fhort hair. The back is covered by a pair of pointed wings, along each of which there runs a black ftreak or line. Thefe wings fold any way at the creature's pleafure, and, when fully expanded, are very large. Over thefe lie the antennæ; thefe are variegated alfo with black, and reach about half the length of the wings. It has only four legs; the hinder pair are long and fit for hopping; the anterior pair are fhort, and furnifhed with a fort of hands for digging in the manner of the mole. The breaft is covered with a cruftaceous fubftance which is blackifh, and hairy on the outfide, and fmooth and pale within. The eyes are very bright and black, and are very hard, and the mouth is wide, and has two tonfils, and teeth in both jaws. This creature lives under ground, and is principally found in damp and boggy places. There has for many years been a breed of them in the gardens of Lord Burlington, at Chifwick, under the grafs walk toward the lower end of the canal, where they are now very numerous. They come out in the dusk of the evening, and make a very loud noise, of the nature of that of the cricket.

GRY'LLUS, *the cricket*, in natural history, the name of a genus of insects nearly allied to the locust class. The two principal kinds are the house and field cricket. The first of these is smaller, and is of a brown colour spotted with black. The latter is more than an inch long, and has a great head and very large eyes. The antennæ in this species have no articulations.

GRY'PHIUS *pes*, *the griffon's claw*, a name of a chirurgical instrument described by Ambrose Parèy, and used for extracting moles from the uterus.

GRY'PHUS, in surgery, a sort of crooked pincers used by surgeons.

GUA'DUM, *woad*. See ISATIS.

GUAI'ACUM (*Dict.*)—*Analysis of* GUAIACUM.—Fill a clean glass retort, almost up to its neck, with the small raspings of the best, green, close, ponderous, and fresh Guaiacum, with care to prevent any of it from falling through the neck into the receiver. Set the retort in a sand furnace; apply a very large receiver, and lute the juncture close, with a luting of linseed meal. Distil, first, with a degree of heat not exceeding that of boiling water; and continue this carefully, so long as any moisture will be thereby driven from the wood. A liquid, tart, and sharply odorous water will thus come over, which is to be poured out, and kept apart. The receiver being now, again, luted on, increase the fire, by slow degrees; and, again, a considerably limpid, but somewhat more acid, unctuous, and reddish liquor will come over, which must carefully be urged with the same degree of heat, so long as it rises. This, also, may be kept separate, as being considerably strong, odorous, and smelling almost perfectly like red herrings. The fire, being now raised and kept up, drives over a red, unctuous, and highly acid liquor, together with a red oil floating in a considerable quantity therein: at length increase the fire to the utmost, that the bottom of the iron pot may begin to be red-hot; there will now ascend a smoke, and a thick, black, viscid oil, which sinks to the bottom of the former liquor. And, if this fire be continued as strong as the glass will endure without melting, the same fume will constantly continue to rise, how long soever the fire be kept up. In the last place, apply live coals upon the sand, all round and above the retort, which is called a fire of suppression; and keep this up, also, for some time, till no more oil comes over. Now suffer all to cool spontaneously, and, by this last extremity of the fire, a little very thick, black, and ponderous oil, like pitch, will be driven over.

Make a little filtre of cap-paper, put it into a glass funnel, and pour therein the water which first came over, without any oil, that the strainer, being thus well moistened, may transmit this pure water of the Guaiacum, which is to be kept separate. This water will be tartish, limpid, and penetrating, but have little of the smell or taste of the Guaiacum; but a somewhat burnt odour, a little resembling that of smoaked herrings. Then put the second water into the same filtre, and this will come through a little reddish, transparent, but more acid, and smelling stronger of smoaked herring; so as to prove somewhat empyreumatic, and much sharper than the former. And, if any oil was lodged in the second water, it will remain in the filtre; which, having been moistened by the preceding liquor, will not permit the oil to pass. Into the same filtre pour, likewise, the vinegar, and third spirit, together with its light oil; the vinegar will immediately pass through red, pellucid, sharp, acid, and empyreumatical, but leaves its oil behind, floating upon the liquor, in the filtre: for which purpose the filtre must always be kept filling up with more of the oily liquor, to prevent the oil from ever touching the lower part of the paper; for, thus, nothing of the oil will come through with the acid liquor. When, now, nearly all the liquor is come through, immediately remove the funnel, with the filtre, to another glass, before the oil begins to sink through the paper; which would happen, when the paper begins to grow dry. At this time, therefore, the light and thin oil may be poured, out of the filtre, into a vessel apart.

Pour the oil, which came over last, along with its highly acid, fetid, and unctuous liquor, into the same filtre, whilst it remains still wet with the former liquor; there will now come through a red, acid, transparent fluid; and a gross, black, pitchy, ponderous oil remains in the paper: this, also, is to be poured out, and kept separate.

If these acid liquors be preserved in clean glasses, they deposit, at the sides and bottom thereof, a small oily crust, which gradually increases, whereby the liquor gradually becomes less unctuous; whence it appears, that this distilled vinegar is a compound of water, acid, and oil, and may, therefore, properly be called a volatile, acid, oily, saponaceous salt. If this acid liquor, when become perfectly limpid, and affording no more visible oil, be poured upon clean chalk, it effervesces therewith, deposits its acid in the chalk, and becomes a water, which immediately throws the oil, before latent in it, to the surface, in a visible form: or, if the same liquor be again distilled with a gentle fire in a clean vessel, it also presently manifests its latent oil, and separates it from itself, and thus becomes pure and clear acid liquor.

If the oils be required in greater perfection, let a quantity of them be collected, and distilled by boiling water; whereby the purer part will be raised, and the grosser left behind; and, by often repeating this operation, these oils gradually come nearer to the perfection of the essential kind, and, by losing their more unactive and terrestrial part, become liquid, bright, beautifully red, penetrating, pure, thin, and not fetid. When thus all that is volatile has been drawn over from the subject, by the violent and long continued action of the fire, extremely black, light, insipid, and almost inodorous, and very brittle shavings remain in the retort, being the coal mentioned by Helmont, which can never, by the most continued force of fire, be calcined into white ashes, whilst the vessel remains close, but always continues black, and therefore inflammable; because this blackness is the fixed oil, tenaciously adhering to the earth, and subtly extended upon its surface; whence the coal becomes subject to take fire, and burn, so long as this oil remains unconsumed, for, if these black raspings be now put into a large open pan, and a small live coal be thrown into the middle of them, they will immediately burn and flame all over, till the whole blackness be ignited, after which the subject presently falls into white ashes; so that, in a short time, the whole body of the shavings may, by means of the smallest spark, be perfectly converted into ashes: nor could the wood itself be so easily and so readily fired, with a small spark, unless, by a like preparation, it were first brought to a coal, and then broke to powder. The white ashes, thus obtained from Guaiacum, are insipid, inodorous, and almost without any salt; though, if the wood were recent, they prove considerably rich in alcaline salt.

In making decoctions of Guaiacum, for medicinal uses, it is to be remarked, that the raspings of the fresh and green wood are much preferrable to those of that which is old and dry; and that, the longer it is boiled, the better.

Tincture of GUAIACUM.— Take the raspings of fresh, green, and ponderous Guaiacum wood, or the bark thereof, in powder; and put it into a tall chemical glass; pour thereon rectified spirit of wine, so as to float four inches above it, without any other addition: boil them together, in the manner abovementioned, for four hours, often shaking the glass; the liquor will thus become red, which is to be strained, after it is clarified by rest, through a linen strainer, to separate it from any impurities; then, pouring fresh spirits upon the remains, boil them again, and preserve the several tinctures pure. The liquor, thus obtained, will be of a pungent, aromatic, acrid, hot taste, and odour; but, if the alcohol, employed, was perfect, the tincture will always be the better.

If this tincture, prepared with pure alcohol, be distilled in a tall body, with a gentle fire, till only one fourth part be left behind, this will be a very rich tincture, fully impregnated with the virtue of the Guaiacum. But, if the spirit employed contained any water, the rosin would begin to fall, if the tincture was inspissated so high. But, when pure alcohol is used, the tincture will easily bear to be thickened, and thus increase in virtue, without growing turbid.

This tincture of Guaiacum, externally applied, is a wonderful remedy in malignant venereal ulcers, whether in the skin, fat, mouth, jaws, or throat.

When this tincture of Guaiacum, prepared with pure alcohol, and inspissated to an half, is mixed with four times its quantity of the syrup of the five opening roots, and taken upon an empty stomach, in the morning, lying in bed, it presently distributes itself over the whole body, which it thus warms, and promotes a copious sweat; and hence it is commended in the venereal disease, when it has seized upon the subcutaneous parts. *Boerhaave's Chemistry.*

GU'AJAVA, *the guava*, in botany, a genus of plants whose characters are:

The extremity of the pedicle passes into an ovary, of an oval figure, crowned, quinquefid, and like a calyx. The flower is rosaceous, pentapetalous, growing on the ovary within the crown, and furnished with numerous stamina. The ovary is furnished with a long tube, and becomes a fleshy fruit, full of very numerous small seeds.

The tree grows to the height of twenty feet, or more, in the West-Indies, and has a trunk as big as a man's thigh: in England it is preserved in stoves, and is rarely seen above six or seven feet high. *Miller's Dict.*

The fruit resembles our pears, with an umbilicus full of chaps, and covered with a thin whitish green rind. The pulp is of a pale bloody colour, in some whitish, and, when ripe, of a sweet and grateful taste, and a pleasant smell. The fruit has three different sorts of taste, according to its season. In the time of its ripening, before it is soft and yellow, it is austere and astringent, and is then good, when boiled, for the stomach; when it becomes a little riper, it is of a middle nature, and in its best state; but it is more adviseable, for health, to eat it either boiled or preserved in sugar, than raw; besides, it is of a more grateful taste and smell, when thus prepared. When it is come to perfect maturity, and is intirely soft and yellow, it has the taste and smell of raspberries, loosens the

belly,

belly, and is not so wholesome to be freely eaten, because it is easily corrupted, and breeds worms. The root, with its astringent bark, boiled in water, and drank, is an excellent remedy for the dysentery, where astriction and strengthening are indicated. The leaves are acid and astringent, and proper to be used in bathing. F. Hernandez adds, that the leaves used in lotions cure the itch, and that a decoction of the bark is good for swelled legs; that it cures fistulous ulcers, helps deafness, and removes pains in the belly: a syrup, also, made of the leaves, is very effectual against a flux of the belly. *Raii Hist. Plant.*

The fruit is refrigerating, and somewhat astringent: the roots are astringent, and therefore good for the dysentery, and to comfort the stomach: the leaves are vulnerary, resolvent, and used in bathing. *Hist. Plant. ascript. Boerh.*

GUAINU'MBI. See HUMMING *bird*.

GUANA'BANUS, *the custard apple*, in botany, a genus of plants whose characters are:

The empalement of the flower consists of three small pointed leaves: the flowers of some sorts have only three, but in others six petals; in the latter, three are alternately less than the others: from the empalement arises the pointal, which afterwards becomes an oval or round fleshy soft fruit, inclosing several oblong smooth hard seeds.

All these plants which are natives of the warm parts of America, are too tender to live in this country, if they are not preserved in warm stoves: they come up very easily from the seeds which are brought from America, if they are fresh: but the seeds must be sown on a good hot bed, or in pots of light earth, and plunged into an hot bed of tanners bark. These seeds should be sown as soon as possible when they arise, unless it is very late in the autumn, or in winter; in which case, they should not be sown till February; because, if the seeds receive much damp in the winter, they will rot; and, if the plants should come up at that season, it will be very difficult to preserve them till spring; so that, when these seeds come to England, pretty early in the spring, it is by much the best time; because the plants come up early, and will have time to get strength, before the cold comes on.

If these plants are kept in the bark stove, and carefully managed, they will make great progress; but in warm weather, they should have plenty of fresh air admitted to them; for, when the air is excluded from them too much, they are apt to grow sickly; when they will soon be attacked by vermin, which will multiply and spread over the whole surface of the leaves, and cause them to decay: but, if the plants are carefully managed, their leaves will continue green all the winter, and make a very good appearance in the stove at that season.

There are some of these plants in England, which are upwards of twelve feet high, and have produced flowers; so that they may probably produce fruit here. As these plants advance in their growth, so they become more hardy, and should have a greater share of air admitted to them, especially in the summer: but there should be great care taken, not to let them remain in the bark bed too long unremoved; because they are very apt to root through the holes of the pots into the tan; and then these roots will be torn off, whenever the pots are removed, and the plants seldom survive this; and, when they do, it is generally a long time before they perfectly recover their former vigour. These plants, when young, will require to be kept in the same degree of warmth with ananas; but, as they get more strength, so they will thrive with less warmth.

GUA'ZUMA, *bastard cedar-tree*, in botany, a genus of trees whose characters are:

It hath a regular flower consisting of five leaves, which are hollowed like a spoon at their base; but at their tops are divided into two parts, like a fork; the flower cup consists of three leaves, from whence arises the pointal, which afterward becomes a roundish warted fruit, which has five cells inclosing many seeds.

These plants may be propagated by seed, which should be sown early in the spring, in small pots filled with fresh light earth, and plunged into an hot-bed of tanners bark. When the plants appear above ground, they must be carefully cleared from weeds, and often refreshed with water; and the glasses must be raised to admit fresh air to them, otherwise they will draw up too weak: and, when they are about three inches high, they must be shaken out of the pots, and parted carefully, planting each into separate small pots filled with light fresh earth; and then plunge them into the hot-bed again, being careful to screen them from the heat of the sun, until they have taken new root. In this bed the plants may remain all the summer, being careful to keep them clear from weeds; and, when the plants have filled the small pots with their roots, they should be shaken out, and their roots trimmed, and then put into pots a size larger. About Michaelmas the plants must be removed into the stove, and plunged into the tan in a warm part of the stove. During the winter season, they will not require so much water as in summer: if their leaves should contract filth, it must be carefully washed off with a sponge; for, if it is suffered to remain on them, it will greatly injure the plants. These plants being very tender, they must constantly remain in the stoves, giving them a good share of fresh air in the summer; but in winter, they must be kept very warm, otherwise they will not live in this country; but, if they are carefully managed, they will thrive very well, and afford an agreeable variety in the stove, amongst other tender exotic plants of the same countries. *Miller's Gard. Dict.*

GU'DGEON, in ichthyology, the English name of the fish called by authors the gobio, and gobius fluviatilis. According to the new Artedian system, the word gobius is made the name of another genus of fishes, and the Gudgeon is reduced to the genus of the cyprini, of which, according to the distinctions and characters of that author, it is a true species.

GUDGEONS, *in a ship*, is used for the eyes driven into the stern-post, into which the pintles of the rudder go, to hang it on.

GUI'NEA *Pig*, the name given by our common people to a sort of animal, distinguished by authors by the name of mus porcelli pilis et voce, the rat with the hair and voice of a hog.

It is a very singular kind of animal, and there are three sorts of it, all very different from one another. 1. The porcellus Indicus, or common Guinea pig. 2. The aguti; and 3. The paca of the Americans. This creature seems to partake of the nature of several animals. Its hair and voice are like the hog's; its teeth and head resemble the rabbit's, as does also its general size; and its ears are wholly like those of the mouse and rat kind.

GUITA'RRA, *in the Italian music*, the name of a musical instrument of the string kind, with five double rows of strings, of which, those that form the bass, are in the middle, unless it be one for the burden, an octave lower than the fourth.

This instrument was first used in Spain, and the Italians give it the particular denomination of Spagnuola. It is found in Italy, and other countries, but more frequently in Spain. *Brass. Mus. Dict.*

GUM-*apples*, in Languedoc, and some other parts of France. The juice of apples will sometimes exsudate through their rind, and congeal all about them in form of a clear white gum, hard like ice, by reason of its being soon dried in the sun into a thin cake. The people call such an apple, pomme gelée, or a frozen apple. It is very common to see apples covered in part with this Gum in several specks; but it is more rare to meet with them wholly so. The Gum is insipid to the taste.

We have one plant cultivated in some gardens, which yields, in the heat of summer, such another white icy and tasteless Gum. This is the common rhubarb, of the stalks of the leaves of which tarts are made. The ribs of the larger leaves of this plant, in June and July, are covered with large transparent drops of this Gum, and an ounce of it may be sometimes collected from a single plant. *Phil. Trans.* N°. 224.

GUM-*boils*, a morbid affection of the Gums called by the writers of surgery parulides. These are of different degrees, and usually arise from pains in the teeth. They are to be treated by discutients or other inflammatory tumors, but if these fail, or the disorder is neglected, it usually terminates in an abscess or fistula. Sage, camomile, and elder flowers, boiled in milk and water, make a good gargarism to be held in the mouth, and the remaining herbs may be sewed up in a bag to be kept hot to the cheek. A half roasted fig is a very good internal application, and, when the softness of the tumor shews that the matter is suppurated, it ought immediately to be opened with the lancet, to prevent the matter's lodging there, and eroding the bone, and producing a fistula or caries. After it is opened, the matter should be gently pressed out with the fingers, and the mouth frequently washed with red wine mixed with a decoction of vulnerary herbs till it is well. When the ulcer has penetrated deep, it will be necessary to inject the same liquors with a syringe, and compress the part by a proper external bandage, to make the bottom part heal first; and, when it is already become fistulous, and has callous edges, it may then often be cured by injecting tincture of myrrh, and elixir proprietatis, continuing this for some time. If all these prove ineffectual, the fistula must be laid open by incision, and the caries removed by medicines, caustics, or the actual cautery. If this proceeds, as sometimes it does, from a carious tooth, this is first to be drawn before any thing else can be done; and it is a good rule in these cases always to be rather too soon than too late in laying them open. *Heister's Surg.*

GUN is also a name given by the miners to an instrument used in cleaving rocks with gun-powder. It is an iron cylinder of an inch and a quarter thick, and about six inches long, and having a flat side to receive the side of a wedge, and a hole drilled through it to communicate with the inside of the hole in the rock. The hole is made of about eight inches deep, and in the bottom of it are put about two or three ounces of Gun-powder; then this Gun is driven forcibly in, so as to fill up the hole, and the wedge is driven in on its flat side to secure it. The priming at the hole is then fired by a train, and, the orifice being so well stopped by this Gun, the force of the powder is determined to the circumjacent parts of the rock which it splits.

GUN-*room*, in a ship, is the apartment under the great cabbin, where the master gunner and his crew rendezvous, get ready their cartridges, &c. and do all things belonging to their business.

 GU'NNERY,

GUNNERY (*Dict.*)— Mr. Robins, from the experiments related in his New Principles of Gunnery, having concluded, that the force of fired gun-powder, at the instant of its explosion, is the same as that of an elastic fluid of a thousand times the density of the common air, and that the elasticity of this fluid, like that of air, is proportionable to its density, proposes the following problem:

The dimensions of any piece of artillery, the weight of its ball, and the quantity of its charge being given, to determine the velocity which the ball will acquire from the explosion, supposing the elasticity or force of the powder at the first instant of its firing to be given.

In the solution of this problem he assumes the two following principles: 1. That the action of the powder on the bullet ceases, as soon as the bullet is got out of the piece. 2. That all the powder of the charge is fired, and converted into an elastic fluid, before the bullet is sensibly moved from its place.

These assumptions, and the conclusions before-mentioned, make the action of fired gun-powder to be entirely similar to that of air condensed a thousand times; and from thence it will not be difficult to determine the velocity of the ball arising from the explosion. For the force of the fired powder diminishing in proportion to its expansion, and ceasing when the ball is out of the piece; the total action of the powder may be represented by the area of a curve, the base of which represents the space through which the ball is accelerated, and the ordinates to which represent the force of the powder at every point of that space. And these ordinates being in reciprocal proportion to their distance from the breech of the gun, because, when the spaces occupied by the fired powder are as 1, 2, 3, 4, &c. the force of the powder, or the ordinates representing it, will be as 1, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c. it appears that the curve will be a common hyperbola, and that the area intercepted between it, its asymptote, and the two ordinates representing the force of the powder at the first explosion, and at the muzzle of the piece, will represent the total action of the powder on the ball. But, if the ball were urged through the same space, by an uniform force equal to its gravity, the total action of this force would be represented by a rectangle, the base of which would be the base of the curve or intercepted portion of the asymptote before-mentioned, and the height of which would represent the uniform force of gravity. Hence the square of the velocity of the ball, resulting from the action of the gun-powder, will be to the square of the velocity resulting from the action of gravity, as the area of the hyperbolic space is to the area of the rectangle. But the velocity of the ball resulting from gravity is given, being the velocity it would acquire from a height equal to the space through which the powder accelerates it; and the proportion between the hyperbolic and the rectangle is also given, from the analogy of the hyperbolic spaces and logarithms; therefore the velocity of the ball arising from the action of the fired gun-powder will be given.

Mr. Robins has also given us an ingenious way of determining, by experiments, the velocity which any ball moves with, at any distance of the piece it is discharged from.

This may be effected by means of a pendulum made of iron, having a broad part at bottom, covered with a thick piece of wood, which is fastened to the iron by screws. Then having three poles joined together by their tops and spreading at bottom, such as are vulgarly used in weighing and lifting heavy bodies, and called by workmen triangles; on two of these poles, towards their tops, are screwed on sockets, on which the pendulum is hung by means of a cross piece, which becomes its axis of suspension, and on which it ought to vibrate with great freedom. Something lower than the bottom of the pendulum there should be a brace, joining the two poles to which the pendulum is suspended; and to this brace there is fastened a contrivance made with two edges of steel, something in the manner of a drawing pen; the strength with which these edges press on each other being diminished or increased at pleasure, by means of a screw. To the bottom of the pendulum should be fastened a narrow ribbon, which, passing between the steel edges, may hang loosly down by means of an opening cut in the lower piece of steel.

The instrument being thus fitted, if the weight of the pendulum, the respective distances of its center of gravity, and of its center of oscillation, from its axis of suspension, be known, it may from thence be found, what motion will be communicated to this pendulum by the percussion of a body of a known weight moving with a known degree of velocity, and striking it in a given point; that is, if the pendulum be supposed at rest before the percussion, it will be known what vibration it ought to make in consequence of such a blow; and if the pendulum, being at rest, is struck by a body of a known weight, and the vibration which the pendulum makes after the blow is known, the velocity of the striking body may from thence be determined.

Now, the extent of the vibration, made by the pendulum, may be measured by the ribbon. For if the pressure of the steel edges on the ribbon be regulated by the screw, so as to be free and easy, though with some minute resistance to hinder its slipping of itself: then, setting the pendulum at rest, let the part of the ribbon between the pendulum and the steel edges be drawn straight, but not strained, and fixing a pin in the part of the ribbon contiguous to the edges, the pendulum, swinging back by the impulse of the ball, will draw out the ribbon to the just extent of its vibration, which will be determined by the interval on the ribbon between the edges and the place of the pin.

The computation by which the velocity of the ball is determined from the vibration of the pendulum after the stroke, is founded on this principle of mechanics: that if a body in motion strikes on another at rest, and they are not separated after the stroke, but move on with one common motion, then that common motion is equal to the motion with which the first body moved before the stroke: whence, if that common motion and the masses of the two bodies are known, the motion of the first body before the stroke is thence determined. On this principle it follows, that the velocity of a bullet may be diminished in any given ratio, by its being made to impinge on a body of weight properly proportioned to it; and hereby the most violent motions, which would otherwise escape our examination, are easily determined by the retarded motions which have a given relation to them.

It is to be observed, that the length, to which the ribbon is drawn, is always near the chord of the arch described by the ascent; it being so placed, as to differ insensibly from those chords which most frequently occur; and these chords are known to be in the proportion of the velocities of the pendulum acquired from the stroke. Hence it follows, that the proportion between the lengths of the ribbon, drawn out at different times, will be the same with that of the velocities of the impinging bullets.

Now, from the computations delivered by Mr. Robins, it appears, that the velocity of the bullet was 1641 feet in one second of time, when the chord of the arch described by the ascent of the pendulum, in consequence of the blow, was $17\frac{1}{4}$ inches. Therefore, by the proportion of any other lengths of ribbon drawn out, by any percussion, to $17\frac{1}{4}$, the proportion of the velocity with which the bullets impinge, to the known velocity of 1641 feet in 1″, will be determined.

GUN-SHOT *wounds* are attended with much worse consequences than wounds made by sharp instruments, for the parts are more shattered and torn, especially when the shot falls upon the joints, bones, or any considerable part. Wounds of this kind have an eschar formed upon them, and are therefore attended with little or no hæmorrhage at first, unless some considerable vessel is wounded; but, as soon as this eschar falls off, the hæmorrhage is sometimes so violent, as to endanger the life of the patient, unless the ready assistance of a surgeon can be had. For the five or six first days there is little or no discharge of matter from these wounds; there is therefore no wonder that Gun-shot wounds exceed all others in violence of symptoms, such as inflammation, pain, gangrene, &c.

The eschar which is formed upon these wounds, is not occasioned so much by the heat of the bullets, as by the rapidity with which they destroy the parts; and the violence of the symptoms is owing chiefly to this manner of wounding. Neither is there any thing poisonous in these wounds, as has been by some imagined; for nothing poisonous enters the composition, either of powder or ball.

Gun-shot wounds are some deeper than others, and in some, the muscular parts alone are hurt; in others, the vessels, bones, or viscera, are wounded. Sometimes the ball passes clear through, and sometimes it remains fixed in the wound, and frequently carries part of the cloths or wadding with it. From the difference of these circumstances very different symptoms arise.

Gun-shot wounds in the cranium, even the lightest of them, are attended with very great danger, and frequently bring on terrible symptoms, by the concussion of the internal parts, which they occasion; insomuch that it is surprising to see how small an external wound upon this part will bring on death, if not prevented by the trepan. Internal wounds of this sort are also extremely dangerous; but if no large vessel is wounded, they are frequently cured.

When they are inflicted on the bones or joints, they are attended with very bad symptoms; for, in this case, it is next to impossible to escape inflammation, gangrene, caries, and dangerous fistulæ, which either require amputation of the limb, or leave it without sense or motion.

If any part of the cloths, wadding, or any other extraneous body, be forced into the wound, it must be removed before you can attempt to heal the wound; and the same caution is to be observed in regard to any splinters of bone: when these are removed, the hæmorrhage is to be stopped, then suppuration is to be promoted, and new flesh encouraged, and care taken to procure an even cicatrix.

Extraneous bodies are much easiest to be removed at first; for after some delay the tumor, and inflammation of the part, render it difficult and painful: besides, the bullets will by degrees work themselves deeper, and be buried under the muscles, which will occasion fistulæ, rigidity of the limb, and other inconveniencies. In extracting balls that lie deep, you

must

must take great care not to lay hold of blood-vessels or nerves; which accident will be best avoided, by introducing the forceps shut, and not opening them till you feel the ball.

Sometimes the orifices of these wounds are so narrow, that it is impossible to come at the body you are to extract, without making a larger opening; this then must be done on the most convenient side, always observing that no nerve, blood-vessel, tendon, or ligament, lies in the way. When the parts are very much inflamed and swelled, an opening of this kind is frequently of service; for by this means the obstructed blood is discharged, and the bad consequences of the inflammation are prevented. When the extraction of the ball is attempted, the patient must be put into the same posture and situation that he was in when he received the wound. When the ball has penetrated so deep, that it may be easily felt with the finger on the opposite side, it is sometimes better to make an incision there, and take it out in that place, than to attempt the getting it back the other way. If the wound cannot safely be inlarged, nor the ball extracted at first, without great pain and danger, it must be left in the wound, either till the pain is abated, or the wound is so inlarged by suppuration, that it either can work itself out, or be extracted with less danger. On the other hand, all other extraneous bodies are instantly to be removed, where there is danger of their bringing on pain, inflammation, and convulsions, by being left behind. If a ball has passed into the cavities of the body, it is best not to attempt to extract it, but to heal the wound, leaving it there. Persons have carried a ball in them thus, for many years, without inconvenience; and, at one time or other, it frequently happens that it will work itself into some part of the body, out of which it may be extracted with safety.

If a large artery is wounded by the ball, either in the arms or legs, which will be known by the loss of blood, the tourniquet must be applied, and, the blood being stopped, the vessel must be taken up by a crooked needle; but, if this cannot be done, or little hopes of a cure appear from future dressings, it will be prudent to take off the limb just above the wound.

When wounds of this kind have been well cleaned, and the blood stopped, the first intention is to use the utmost endeavours to prevent, or asswage the tumor and inflammation. The wound should be dressed with lint dipped in warm spirits of wine, and covered with a compress wetted with the same liquor; or with camphorated spirits of wine, either alone, or diluted with lime water. Having done this, the next intention is to forward the suppuration of the bruised and torn parts; to which end, it is common to use the common digestive made of turpentine dissolved in the yolk of an egg, or a mixture of basilicon and Arcæus's linament, softened with spirits of wine and oil; and, where there is a very great corruption of the parts, a little myrrh and aloes are to be added, as also Venice treacle, the brown ointment, and, where the occasion requires it, and the nerves do not lie bare, a little of the red precipitate.

In deep wounds, where the ball has gone quite through, a skein of thread being drawn through the eye of a blunt needle, and well saturated with the digestive ointment, is to be passed through the wound in the manner of a seton, and kept there till the wound is found in a condition to heal, and then the common methods are pursued to heal and cicatrize. *Heister's Surgery.*

GUNTER'S *Scale* (*Dict.*)— The line of numbers on these scales consists of two equal lengths, commonly called two radii; the first containing the logarithms of numbers from 10 to 100; and in the second are inserted those between 100 and 1000, or such of them as can conveniently be introduced.

These divisions are taken from a scale of equal parts; such, that 100 make the length of one radius; and from this scale the divisions for the sines, tangents, and versed sines, are also taken. Now, from this construction of the line of numbers, it is plain, that, as the numbers in one radius exceed those in the other, by one place in the scale of numeration, therefore the differences of their indices must also be unity: so that such numbers only, whose index differs by 1, can be estimated in a length of two radii: but, in a length of three radii, numbers, whose indices differ by 2, may be read; and a difference of 3 may be reckoned in a length of 4 radii, &c. The tables of logarithmic sines, tangents, secants, and versed sines, are generally computed for a circle, whose radius is 10,000,000: therefore,

	°	′	″		°	′	″	
In the sines, the index 9 belongs to all between	90	0	0	and	5	44	36	
The index 8	5	44	36	and	0	34	23	
The index 7 to all between	0	34	23	and	0	3	27	
6	0	3	27	and	0	0	21	&c.

	°	′		°	′	″
In the tangents, the index 9 belongs to all between	45	0	and	5	42	10

And the indices, 8, 7, 6, &c. fall as in the sines.

	°	′		°	′	
In the versed sines, the index 10 belongs to all between	180	0	and	90	0	
9	90	0	and	25	51	
8 belongs to all between	25	51	and	8	7	
7	8	7	and	2	34	
6	2	4	and	0	45	&c.

Now, as the length of the Gunter's scale admits of no more than two radii, or of such numbers only, whose index differs by unity; therefore, within this length, no more of the sines, tangents, or versed sines, can be introduced, than those whose index differs by unity: and as not only the greatest number among the sines and tangents, but also those more generally wanted, have the indices 9 and 8 differing by unity; therefore all the sines from 90° to 0° 34′, and all the tangents from 45° to 0° 34′, are those only, which are put on these scales; the divisions answering to the lesser sines and tangents being omitted for want of room. And this is the reason, why the sine of 90°, and the tangent of 45°, are limited by the same termination as the second radius on the line of numbers.

To construct the line of logarithmic sines on GUNTER'S *Scale*—From the scale of equal parts, take the numbers expressing the arithmetical complements of the log-sines of the successive degrees, and parts of degrees, intended to be put on the scale, descending orderly from 90°: then these distances, successively laid from the mark representing 90° at the right-hand end of the scale, will give the several divisions of a scale of logarithmic sines.

For, the ends of any scale being assigned, the progressive divisions of that scale are laid thereon from that end, which represents the beginning of the progression: or the same divisions may be laid from the other end, by taking the complements of the terms to the whole length of the scale.

Consequently the arithmetical complements of the sines are to be laid from the division representing 90 degrees.

To construct the line of logarithmic tangents on GUNTER'S *Scale.*— These are laid down in the same manner, and for the same reasons, that the sines were; the tangent of 45° standing against the sine of 90°.

The divisions for the tangents above 45° are reckoned on the same line from 45° towards the left hand; or any tangent and its cotangent are expressed by the same division.

Thus one mark serves for 40° and 50°, and the division at 30° serves also for 60°; that at 20° serves for 70°, &c. and the like is to be understood for the intermediate divisions.

For as the tangent of an arc is to a radius;

So is radius to the co-tangent of that arc.

Therefore the tangent is equal to the square of radius divided by the co-tangent.

And the co-tangent is equal to the square of radius divided by the tangent.

Now, the radius being unity, its square is also unity.

Therefore the tangent and co-tangent of any arc are the reciprocals one of the other.

But the reciprocals of numbers are correlatives to the arithmetical complements of their logarithms.

Therefore the logarithms of a tangent and its co-tangent are arithmetical complements one of the other, and consequently will fall at equal distances from 45 degrees.

Therefore, in the line of logarithmic tangents, the divisions to degrees under 45 serve also for those above, both being equally distant from 45 degrees.

To construct the line of logarithmic versed sines on GUNTER'S *Scale.* —As the greatest number of degrees will fall within the limits of the scale by beginning at 180°, therefore the termination of this line is at 180°, which is put against 90° on the sines: and, although the numbers annexed to the divisions increase in the order from right to left, yet they are only the supplements of the versed sines themselves.

Now subtract the logarithmic versed sines of such degrees and parts of degrees as are intended to be put on the scale, from the logarithm versed sine of 180°; then the remainder taken from the foresaid scale of equal parts, and laid successively from the termination of this line, will give the several divisions sought.

The following table to every 10 degrees was constructed in the foregoing manner, and are the numbers to be taken from the scale of equal parts, for the degrees they stand against.

Deg.	Supplements. of Versed Sines.	Deg.	Supplements. of Versed Sines.	Deg.	Supplements. of Versed Sines.
180	0,00000	120	0,12494	60	0,60206
170	0,00331	110	0,17327	50	0,74810
160	0,01330	100	0,23149	40	0,93190
150	0,03011	90	0,30103	30	1,17401
140	0,05402	80	0,38387	20	1,52066
130	0,08545	70	0,48282	10	2,21941

From this table it appears, that the least versed sine which can be introduced within the length of a double radius, falls between 10° and 20°, where the index changes from 1 to 2; which will happen about 11° 28′.

If a table of logarithm versed sines to 180° are wanting, they are easily made by the following rule:

"Take the logarithm sine of 30 degrees from twice the logarithm sine of (N) any number of degrees; the remainder is the logarithm versed sine of (2 N, or) twice those degrees."

For it is a well known geometrical property, that the sine of any arc (A) is a mean proportional between radius (R) and half the versed sine of twice that arc.

Therefore, puting *v* for the versed sine, and *s* for the sine;

The $v\,2\,A = \left(\frac{2\,s\,s\,A}{R} = s\,s\,A \times -\frac{2}{R} = s\,s\,A \times \frac{2}{10} = \right) s\,s\,A \times \frac{1}{5}$; radius being 10.

Or the log. $v\,2\,A = 2$ log. $s\,A$ — log. 5.

But, when radius is 10, the sine of 30° is 5.

Therefore the log. $v\,2\,A = 2$ log. $s\,A$ — log. sine of 30°.

Most of the writers on this subject give the following rule for laying down the divisions of this line:

"From the line of logarithmic sines, take the distance between 90° and any arc; that distance being twice repeated, from the termination of the line of versed sines, will give the division for twice the complement of that arc."

Thus the distance between 90° and 20° on the sines twice repeated gives the versed sine of 140°; or twice 70°, the complement of 20°. For the divisions, to be laid on this line, are the differences between the logarithm versed sine of 180°, and the logarithm versed sines of the successive arcs.

Now the difference between the logarithm versed sines of 180°, and of any arc 2 A, is log. ver. sine 180 — 2 log. sin. A + log. sin. of 30°.

Or, 10,30103 + 9,69897—twice log. sin. of A.

Or, 20,00000 — twice logarithm sine of A.

Or the arithmetical complement of twice logarithm sine of A.

That is, the difference between the logarithm versed sine of 180°, and the logarithm versed sine of any arc, is equal to double the arithmetical complement of the logarithm sine of half that arc, rejecting the indices.

But, as the differences give the divisions to the supplements of the real versed sines, therefore the arithmetical complement of the logarithm sine of any arc, being doubled, will give the distance of the division for the supplement of twice that arc on the line of versed sines.

Thus, for 70°, the logarithm sine is 9,97299.

The arithmetical complement is 0,02701.

Its double is 0,05402

Which is the number in the foregoing table standing against 140°, and is the supplement versed sine of twice 70 degrees.

Now, as the arithmetical complement of the log. sines of arcs are the distances on the line of sines between 90°, and the divisions to those arcs; therefore the distances between 90° and any arc, being twice repeated, will give the division of the supplemental versed sine to twice the co-sine of that arc. *Phil. Trans.* Vol. XLIX.

GU'NWALE, *or gunnel* of a ship, is that piece of timber which reaches on either side of the ship, from the half deck to the forecastle, being the uppermost bend, which finishes the upper works of the hull in that part, and wherein they put the stanchions which support the waste trees. This is called the Gunwale, whether there be guns in the ship or not. The lower part of any port, where any ordnance are, is also termed the Gunwale.

GUR, in minerology, a word used to express a fluid matter looking like milk, but reduced sometimes, by evaporation, to the consistence of honey, and appearing in form of a white sediment. It always contains more or less silver, and is common in the mines of Sweden, and in some other places.

GUTTA *rosacea*, in medicine, denotes a red or pimpled face; a distemper, which, though not always owing its original to hard drinking, is nevertheless most incident to tipplers of strong beer, wines, spirits, &c.

As to the cure, besides making a revulsion by bleeding, blistering, cupping, issues, &c. the diet ought to be moistening and cooling, as lettuce, purslain, sorrel, and spinach: the drink may be an emulsion of the cold seeds, milk and water, clarified whey, &c.

In the use, however, of this cooling regimen, great caution is necessary; for, if a person be taken off at once from his strong liquors, and allowed nothing but whey, or milk and water, it may cost him his life, by hastening a sudden decay of heat, palling his appetite, and bringing on a leucophlegmatia, or dropsy.

As for what concerns topics, much caution is likewise to be used. If there be only redness without pimples, and the disease recent, refrigerants and repellents take place: but, if pustules appear, discutients must be mixed; and if these pustules seem hard, and the disease be of long standing, there may be reason for emollients to ripen and digest the tough and viscid matter, which is afterwards to be let out.

If the disease be stubborn, and the tubercles grown hard, we are to begin with emollients, both fotus and ointment: such are the decoction of mallows, vervain, Solomon's seal, and linseed, also a cerate of sperma ceti, or Bates's white cerate. *James's Med. Dict.*

GYMNO'PYRIS, in natural history, the name of a genus of fossils, the characters of which are these: they are of the class of the pyritæ, and are compound, inflammable metallic bodies, found in detached masses, of no determinately angular figure; of a simple internal structure; not striated; and are naked, or not covered with any investient coat, or crust, in which they differ from the pyriplaces. *Hill's Hist. of Fossils.*

GYNA'NDRIA, in botany, a class of plants, in which the male and female parts of the flower are joined at their origin, the stamina or male parts of which grow to the pistillum or female part, and not to the receptacle of the seed.

The word is formed of the Greek γυνὴ female, and ἀνὴρ male. Among the plants of this class are the passion-flower, birthwort, &c.

The general character of this class of plants is very obvious: they are distinguished at first sight from all others, by the stamina being placed upon the style; or, in other words, the receptacle is elongated into the form of a style, and bears on it both the pistil and stamina.

H.

HADE, in mining, is where any ſhaft or turn goes deſcending like the ſide of a houſe, or like the deſcent of a ſteep hill. It is then ſaid to Hade. *Houghton's Compl. Miner.*

HALLE'RIA, African fly honey ſuckle, in botany, a plant ſo named by Dr. Linnæus, in honour to Albertus Haller, profeſſor of botany at Gottingen. The characters are:

The empalement of the flower is of one leaf, which is cut into three ſegments, the upper one being much broader than either of the others: the flower conſiſts of one leaf, and is in ſhape like the ſnap-dragon, having a tube, and the upper part joined, and reflexed, and at the brim is divided into four parts: in the center of the flower is ſituated the pointal, attended by four ſtamina, two of which are longer than the others: the pointal afterwards changes to a round berry having two cells, each having one ſeed.

This plant grows to the height of ſix or eight feet, having a woody ſtem, which is well furniſhed with branches: theſe have oval ſawed leaves, which are placed oppoſite by pairs, and continue green through the year: the flowers come out ſingly, and are of a red colour; but, being intermixed with the leaves, make but ſmall appearance: yet, as the leaves are green in winter, the plants make a variety in the green-houſe during that ſeaſon.

It may be propagated by cuttings, which, if planted in pots filled with light earth in the ſpring, and plunged into a gentle hot bed, will ſoon take root. Theſe plants may be expoſed in ſummer, and will require plenty of water: in winter they muſt be houſed with myrtles, and other hardy exotic plants.

HAMA'MELIS, *witch hazel*, in botany, a genus of trees whoſe characters are:

The empalement of the flower is of one leaf, which is cut into four ſegments to the bottom: the flower conſiſts of one leaf, which is cut into four narrow ſegments to the bottom, and turn backwards: the pointal is ſituated in the center of the flower, which is hairy, and attended by four ſtamina: the pointal afterwards changes into a capſule or huſk, having two cells, each containing one oblong ſmooth ſhining ſeed.

This is propagated by laying down the young branches in the autumn, which will take root in one year, provided they are duly watered in dry weather: but moſt of the plants which are in the gardens, have been produced from ſeeds which came from America. Theſe ſeeds always remain a whole year in the ground; ſo they ſhould be ſown in pots, which may be plunged into the ground in a ſhady part of the garden, where they may remain all the ſummer, and require no other care than to keep the pots clear from weeds, and in very dry weather to water them now and then: in autumn, the pots may be moved to a warmer ſituation, and plunged into the ground under a warm hedge; and, if the winter ſhould prove very ſevere, they ſhould have ſome light covering thrown over the pots, which will ſecure the ſeeds from being deſtroyed. In the ſpring the plants will come up; therefore, as the ſeaſon grows warm, the pots may be removed where they may have the morning ſun till eleven o'clock; and, if they are duly watered in dry weather, the plants will have made good progreſs by the autumn; when they ſhould be tranſplanted, either into ſmall pots, or in a nurſery bed; where in one, or at moſt two years time, they will be ſtrong enough to plant where they are deſigned to grow.

HÆMA'NTHUS, *blood-flower*, in botany, a genus of plants, whoſe characters are:

The empalement of the flower is large, compoſed of ſix oblong leaves, which grow in form of an umbel, and do not fall off: the flower is of one leaf, which is cut into ſix ſlender parts at top; but the bottom is tubulous and angular: in the center of each flower is ſituated the oblong pointal, attended by ſix ſtamina, which are inſerted at their baſe into the petals of the flower, but are ſtretched out much longer at the top: the pointal afterwards changes to a roundiſh berry, having three cells, each containing one triangular ſeed.

It is propagated by off-ſets, which ſhould be taken of in May, at which time theſe plants begin to loſe their leaves; for they are ready to put out new leaves in July, and continue growing all the autumn and winter; but, towards the end of May, the leaves begin to decay; at which time the plants ſhould be new potted; and, if they have any off-ſets which are ſufficiently rooted, they muſt be taken off, and planted in pots filled with light rich earth. In tranſplanting of theſe plants, there muſt be particular care to lay ſome ſtones and rubbiſh in the bottom of the pots to let the moiſture paſs off; for, if the wet is detained in the pots, it will ſoon cauſe the roots to periſh. During the ſeaſon of their inactivity, which is commonly from the beginning of May to the beginning of July, they muſt not have too much water, leſt it rot their roots; but, when they are in vigour, they will require a little more wet.

These plants muſt be conſtantly kept in the dry ſtoves; for they do not thrive well, if they are ſet abroad, even in the warmeſt part of the ſummer; ſo that it is much the better method to let them remain in the ſtove, with euphorbiums, and other tender ſucculent plants, which require a large ſhare of free air in warm weather; in which ſituation they will thrive exceeding well, and will annually produce their beautiful flowers, which make a fine appearance among other rare plants. During the winter ſeaſon, they muſt be kept in a moderate temperature of heat, and ſhould be frequently refreſhed with water; but it muſt not be given to them in large quantities, leſt it rot them. This plant is not conſtant in the time of its flowering, but the moſt uſual ſeaſon is in July or Auguſt; but, when it flowers in the ſpring, it frequently perfects ſeeds in this country; which, if ſown ſoon after they are ripe, and preſerved in the ſtove till ſpring, and then placed in an hot-bed of tanners bark, will grow very well; and, by this method, a much greater increaſe of the plants may be obtained in a year or two, than could be by off-ſets in many years.

HÆ'MORRHOIDS (*Dict.*) *Chirurgical treatment of the* HÆMORRHOIDS.—Though, ſome are deſirous of having this flux moderated or ſtopped, a ſkilful ſurgeon will be ſo far from complying, that he will lay before them many inconveniencies which muſt attend ſuch a practice. If, however, they perſiſt, or the flux is exceſſive, then he may, at the ſame time applying other proper remedies, ſtop up ſome of the mouths, leaving one or two open, according to the direction of Hippocrates. He muſt proceed in the following manner: firſt, bleed plentifully, then give gently cooling purges, and, laſtly, a clyſter, five or ſix hours before the operation.

The patient muſt be laid on his belly, either upon a bed, or table, ſo that his feet may touch the ground; or, according to ſome, on the ſide of a bed, as, for a clyſter; then, his legs and nates muſt be ſo diſtended, by two aſſiſtants, that the ſurgeon may have free acceſs to, and inſpection of the parts. Next, if there are no tubercles, he is to tie up the bleeding veins with a crooked needle and thread; if there are, he is to take hold of the parts preternaturally tumefied with his forceps, and cut them off, tying them up likewiſe; but he muſt be ſure to leave one vein, and that the ſmalleſt, ſtill open. Laſtly, if the profuſion does not ſtop ſpontaneouſly, in a ſhort time, he may apply ſtyptics, ſcraped lint, and compreſſes, with the T bandage. In the ſubſequent dreſſings he may uſe cicatrizing medicines; and, if any thing foreign ſtill remains, he muſt remove it by the ſciſſars, or a cauſtic. When theſe bleeding tubercles were ſeated very high in the rectum, the ancients recommended an actual cautery; but this was ſevere and dangerous: I, therefore, prefer the ſpeculum ani, which dilates the parts, in ſuch a manner, that the tubercles may be tied, or the open veins ſtopped by lint, impregnated with aſtringents: this, with the application of proper internal medicines, will reſtrain a profuſe Hæmorrhage in theſe parts; though it is ſeldom neceſſary to come to the laſt operation.

Sometimes the veins, diſperſed about the rectum and anus, are ſo much dilated with blood, as to be very painful, and raiſe tubercles as large as peas, grapes, or eggs; ſometimes, too, they extend to a finger's length. Theſe we call the blind piles, and diſtinguiſh them from other tubercles of the anus by their colour, and reſiſtance to the touch; for they appear livid, or black, from the ſtagnation of a thick blood; and, when preſſed by the fingers, feel like a bladder filled with liquor; which circumſtances are not obſerved in the others. Theſe diſtended veſſels vary; for ſome are ſoft, giving little or no pain; others hard, very painful, and inflamed, rendering the patient unable to ſit, ſtand, or walk, and ſometimes even bring on fainting-fits.

The blind piles generally occur in men of a coſtive, plethoric habit, and ſuch whoſe conſtitutions incline them to the bleed-

ing

ing piles; and women are moſt ſubject to them from a difficult labour, a ſuppreſſion of the menſes, geſtation, or a ſanguine habit. In all theſe, the veins ſometimes become ſo turgid as to diſcharge their blood, and from blind become bleeding piles, with ſo profuſe an hæmorrhage as to endanger the patient's health. The blind Hæmorrhoids are ſometimes attended with ſuch intenſe pains as to cauſe a ſpaſm of the anus, and a difficulty of ſitting, even to that degree as not to admit of the adminiſtration of a clyſter; ſometimes they produce troubleſome itching ulcers, eſpecially, if they do not burſt within three or four days; and very often give birth to an abſceſs, or ſtubborn fiſtula.

When the blind piles are neither large, nor troubleſome, they may be left to nature; but when they encompaſs the anus like a bunch of grapes, ſo that the patient can neither ſit, ride, nor go to ſtool without difficulty; if they do not ſubmit to ſpirits of wine, the moſt ſpeedy remedy is gradually to remove thoſe which are full and large, by a ligature; but, if there is a violent inflammation, it is proper, firſt, to bleed and give, internally, temperating and laxative medicines, preſcribing a regular diet, while diſcutient and emollient fomentations are externally applied. The ſame end is anſwered by the unguentum nutritum, unguentum linariæ, freſh butter, oil of ſweet almonds, and the like, applied to the parts.

But linen, dipped in warm ſpirits of wine, and emollient clyſters, are frequently of infinite ſervice; and, when they are not effectual, leeches may be applied to exhauſt the blood; if they are not at hand, or the parts inflamed, the lancet muſt be uſed; and, after bleeding in proportion to the patient's ſtrength, the dreſſings muſt be made of lint with compreſſes and the T bandage: theſe are to be renewed, till the diſorder is completely cured. Sometimes, the piles are ſo high in the rectum, as to render the uſe of the ſpeculum ani neceſſary. When the anus is properly dilated by this inſtrument, they muſt be ſcarified with a lancet, or divided with ſciſſars; for thus the inſpiſſated noxious blood will be diſcharged, and the pains relieved. Sometimes theſe wounds are ſo far from healing, that, of blind, they become bleeding piles, and the patients, eſpecially, if they are cauſtic, always, or very often at leaſt, diſcharge blood with their excrements; which flux, though not entirely free from trouble, ſhould not be ſuppreſſed while it is moderate, as it leſſens the pains, conduces to the patient's health, and prevents or removes many diſtempers, as the hypochondriac melancholy, diſorders of the kidnies and bladder, gout, and iſchiadic pains. For this reaſon, many moderns recommend and excite this evacuation. But, as this often induces many inconveniencies, and diſeaſes, I prefer other methods of cure.

The beſt method of preventing theſe piles is a regular, temperate diet, with bleeding twice or thrice in a year, and oftener, if required; for theſe evacuations will leſſen the quantity of blood, and conſequently remove the cauſe. Internally may be taken ſome temperating powder, or a decoction of yarrow, drank like tea, carefully avoiding all heating and aſtringent medicines, ſuch as aloes, myrrh, and ſaffron, and all aliments of the like quality, wine overloading the ſtomach, anger, violent exerciſe, profuſe venery, and riding. If, notwithſtanding this regimen, the hæmorrhoidal veins ſhould begin to ſwell, reſolvent and temperating medicines ſhould be given internally, while, externally, fomentations and cataplaſms may be applied; if the pains are acute, then recourſe muſt be had to leeches, or the lancet, as before directed. *Heiſter. Inſtitut. Chirurg.*

HÆ'MORRHOUS, *the blood-ſnake*, the name of a peculiar ſpecies of ſerpent; ſo called, becauſe it was ſuppoſed, that on a perſon being bit by it the blood flowed out of every part of the body. It is a ſmall ſerpent, ſeldom ariſing to more than a foot long; its eyes are remarkably vivid, bright, and ſparkling; its ſkin is very gloſſy, and its back variegated with a great number of black and white ſpots; its neck is very ſlender, its tail extremely ſharp, and it has a ſort of ſmall horns placed over its eyes; it is found in Egypt. There is alſo an American kind of this found in the ſouthern parts, and called by the natives a hucyatli, which is larger than the other, and reſembles the rattle-ſnake in many particulars, but wants the diſtinguiſhing characters of the rattle in the tail.

HAIR-*weed*, *conferva*, in botany, the name of a genus of moſſes, the characters of which are theſe: it is a water plant, deſtitute of flower and ſeed, ſo far as hitherto been obſerved, and compoſed only of ſimple and uniform filaments, which uſually extend to a great length, and are often branched, and uſually of a cylindric figure. The generality of authors have ſuppoſed that theſe are not produced of ſeeds, but are formed of ſome viſcous or gelatinous matter floating in the water, by mere oppoſition of parts; but this ſeems erroneous, and probably will be hereafter confuted by the diſcovery of their ſeeds, as has been already the caſe in the ſea-fucus's, and in many other genera of plants ſuppoſed formerly to want them. The confervæ are uſually divided into ſeveral orders, according to the nature of the filaments they conſiſt of. Some conſiſt of equable and even threads, others are knotted or jointed in the manner of a worm, or other ſuch inſect. Theſe are called the geniculated confervæ, to diſtinguiſh them from the other ſimple ones; and, finally, others are compoſed as it were of ſeveral globules joined one to another; theſe laſt are called the knotted confervæ. *Dillen. Hiſt. Muſc.*

HAND-*barrow*, in the military art, is commonly made of hard light wood. It is of great uſe in fortification, for carrying earth from one place to another, and in a ſiege, for carrying bombs, or cannon ball, along the trenches, and for ſeveral other uſes.

HAND-*ſpike*, a lever, or piece of aſh, elm, or other ſtrong wood, five or ſix feet long, cut thin like a wedge at one end, that it may get the eaſier betwixt things which are to be ſeparated, or any other thing that is to be raiſed; it is better than a crow of iron, becauſe its length allows a better poiſe.

HAND-*ſpikes* are frequently uſed in ſhips, as to traverſe the ordnance, to heave withal in a windlaſs, to weigh up the anchor, &c.

HANDLES *of a plough*, the name given by farmers to the two pieces of the plough faſtened to the earth-board, and to the ſheat, and ſerving the plough-man to reſt his force upon in the guiding of the plough. When they are conſiderably long, the plough is always guided the better, and the land is better tilled; but the lazy plough-men are apt to cut them off ſhorter, that, by bearing their whole weight upon them, they may, in a manner, ride, inſtead of walking. If they ſhould ride, in this manner, on the long handles, they would tilt up the end of the beam, and raiſe the plough out of the ground. *Tull's Huſbandry.*

HA'RBOUR (*Dict.*)—*A machine for cleanſing and deepening* HARBOURS, *and clearing ſea-ports*, &c.

There are a great variety of machines of this kind, but the following will be ſufficient for us, being that made uſe of at Toulon for this occaſion. See *plate* XXVI. *fig.* 1.

This machine conſiſts firſt of a barge, fifty-three feet in length from ſtem to ſtern; about eighteen feet and a half wide in the middle, and four feet and a half deep. Secondly, of two wheels, the firſt of twenty-two feet and a half diameter, the ſecond only twelve feet diameter. Thirdly, of two ſpoons which dig the bottom, and are filled alternately with ſand or gravel by the help of the wheels before-mentioned, which men turn different ways by the following method:

To the axis of the great wheel, are faſtened two iron chains CE and F, going on the wheels of the cranes CF; from thence, they come to the ſpoons, which they ſet at work. Obſerve the chain CE paſſes under the axis, and the other F G paſſes above it, that is, one lengthens, the other takes up and ſhortens, alternately, according to which ſide the great wheel turns, to oblige one ſpoon to deſcend while the other aſcends: the leſſer wheel contributes to this by the means of the two ropes Z Y, S D, called draw-backs, acting oppoſite, to the chains; each ſpoon is fixed to a long handle M N, which ſometimes bears againſt the roller H, ſometimes againſt the other I; and it is impoſſible this ſhould ſlip aſide, becauſe it is confined within the frame K L, where it acts in the following manner:
