SUPPLEMENT

TO THE

New and Universal

DICTIONARY

OF

ARTS AND SCIENCES.

LONDON:

Printed for the PROPRIETORS,

And Sold by JOHN HINTON, at the *King's-Arms* in *Newgate-Street*, *London*.

M.DCC.LIV.

GEORGE R.

GEORGE the Second, by the Grace of God, King of *Great-Britain*, *France*, and *Ireland*, Defender of the Faith, *&c.* To all to whom theſe Preſents ſhall come, Greeting: Whereas our Truſty and Well-beloved *John Hinton*, of our City of *London*, Bookſeller, hath by his Petition humbly repreſented to Us, That he hath been at very great Labour and Expence in purchaſing Books, and employing Mr. *John Barrow* to compile and write a Work, entitled, *A New and Univerſal Dictionary of Arts and Sciences, containing, Not only an Explanation of the various Terms made Uſe of in the following Arts and Sciences, but alſo, whatever elſe is requiſite to render theſe Branches of Literature themſelves, Eaſy and Familiar to the meaneſt Capacities,* viz. Agriculture, Algebra, Anatomy, Architecture, Arithmetic, Aſtronomy, Botany, Catoptrics, Chemiſtry, Chronology, Commerce, Conics, Coſmography, Dialling, Dioptrics, Ethics, Fluxions, Fortification, Gardening, Gauging, Geography, Geometry, Grammar, Gunnery, Handicrafts, Heraldry, Horſemanſhip, Huſbandry, Hydraulics, Hydrography, Hydroſtatics, Law, Levelling, Logic, Maritime and Military Affairs, Mathematics, Mechanics, Merchandize, Metaphyſics, Meteorology, Muſic, Navigation, Optics, Painting, Perſpective, Pharmacy, Philoſophy, Phyſic, Pneumatics, Rhetoric, Sculpture, Series, Statics, Statuary, Surgery, Surveying, Trigonometry, *&c.* With an Introductory Preface, tracing the Progreſs of Literature from the earlieſt Ages, and enumerating the various Improvements made therein at different Periods of Time; the whole being a complete Body of Arts and Sciences, as they are at preſent cultivated; illuſtrated with a great Number of Copper-Plates: In Two Volumes, in Folio: One Volume of which is already Publiſhed, and the other now Printing from the Manuſcripts of the ſaid *John Barrow*. Which Work the Petitioner apprehends will be of the greateſt Uſe and Benefit, by facilitating the Study of the Arts and Sciences. And being deſirous of enjoying the Profit and Benefit that may ariſe from Printing and Vending the ſame, without any other Perſon interfering in his juſt Property: He has therefore moſt humbly prayed Us, to grant him Our Royal Licence and Protection, for the ſole Printing, Publiſhing, and Vending the ſaid Work, in the ſame Manner as has been done in Caſes of the like Nature: We being willing to give all due Encouragement to this Undertaking, are graciouſly pleaſed to condeſcend to his Requeſt; and We do by theſe Preſents, ſo far as may be agreeable with the Statute in that Behalf made and provided, grant unto him the ſaid *John Hinton*, his Executors, Adminiſtrators, and Aſſigns, Our Licence for the ſole Printing, Publiſhing, and Vending of the ſaid Work, for the Term of Fourteen Years, to be computed from the Date hereof; ſtrictly forbidding all our Subjects, within our Kingdoms, or Dominions, to reprint, or abridge the ſame, either in the like, or in any other Size or Manner whatſoever; or to import, buy, vend, utter, or diſtribute, any Copies thereof reprinted beyond the Seas, during the aforeſaid Term of Fourteen Years, without the Conſent or Approbation of the ſaid *John Hinton*, his Executors, Adminiſtrators, and Aſſigns, under his or their Hands and Seals, firſt had and obtained, as they will anſwer the contrary at their Peril: Whereof the Commiſſioners, and other Officers of our Cuſtoms, the Maſter, Wardens, and Company of Stationers are to take Notice, that due Obedience may be rendered to Our Pleaſure herein declared.

Given at our Court at St. James's, *the Third Day of* December, 1753, *in the Twenty-Seventh Year of Our Reign.*

By His Majeſty's Command,

HOLDERNESSE.

PREFACE.

HAVING, in our preface to the Dictionary traced the progress of the Arts and Sciences from the earliest ages, we shall here endeavour to shew how these various branches of human knowledge form one regular system; for it is obvious upon reflection, that they have a certain connection with, and mutually assist each other; and, consequently, all form one general concatenation. But, if we find it no easy task to reduce any single Art, or Science, to a few rules or general principles, we shall find it equally difficult, at least, to reduce the various branches of human knowledge into a general system. In order, however, to see how far this may be effected, we shall previously enquire into the origin, generation, or production of human knowledge; its causes, signs, and the formation of ideas.

Human knowledge, in general, may be divided into direct and reflex. The former is what we receive directly by the senses without any exertion of the will; and flows to the mind spontaneously, and without obstruction. The latter is an acquisition of the mind attained by its operations upon the direct, in uniting, separating, arranging, or combining.

As we are indebted to the senses for all our direct knowledge, our ideas are all, consequently, derived from our sensations. This was a principle with the earliest philosophers; and, because of its antiquity, long held as an axiom among the ancient schoolmen; who would indeed have as warmly defended substantial forms, and occult qualities. Upon the revival of philosophy this truth, standing among a number of absurd opinions, was overlooked, and prescribed indiscriminately with them; nothing being more dangerous to truth, than its keeping company with error. The seducing doctrine of innate ideas, recommended the more strongly perhaps by its novelty, was adopted, and long prevailed over this axiom of the schoolmen; nor is it yet destitute of defenders; so difficult is it for truth to regain her seat, when once dethroned by prejudice or sophistry.

Nothing is more certain than the existence of our sensations; and, to prove that they alone are the foundations of all our knowledge, it will be sufficient for us to shew, that they possibly may be so; for, in sound philosophy, deductions, having facts and acknowledged truths for their bases, are preferable to what rests only on mere hypotheses, however ingenious.

The first thing taught us by our sensations is our own existence, which cannot be distinguished from them; and, consequently, our primary reflections revert back upon ourselves, or that thinking principle that constitutes our nature, and differs in nothing from ourselves.

The second thing taught us by our sensations is the existence of external objects, and among the rest, that of our bodies, which are, in a certain sense, external to us, even before we distinguish the separate nature of the thinking principle within us.

These innumerable external objects have upon us so strong, constant, and attractive an effect, that our ideas of reflection have no sooner called us into ourselves, than those of sensation, which entirely surround us, force us outwards; and detain us from that pensive solitude, in which we should otherwise continue.

The multiplicity of these sensations, the concurring agreement of their evidence, the degrees we observe in them, the involuntary affections they excite in us, compared with the voluntary controul we have over our ideas of reflection, which operate only upon our sensations; all this, we find, produces in us an irresistible impulse to acknowledge the real existence of external objects, and to regard them as the cause of our sensations. This impulse has by many philosophers been looked upon as the effect of the supreme Being, and the most convincing argument of an external world.

But, as we are ignorant of any relation between a single sensation and the object thus supposed to occasion it, we cannot reason from the one to the other: nor could any thing but a kind of instinct, more evident than reasoning itself, oblige us to draw so remote a conclusion. But this instinct is so strong, that, could it for a moment subsist, and all external objects be annihilated, their reproduction could add nothing to its strength. We may therefore surely conclude, that our sensations actually have the external cause supposed; since even the effect of that very cause would be the same with that we really experience.

Our own bodies, belonging more immediately to us than any other external objects, affect us most. We are no sooner sensible that our body exists, than we are convinced of the care requisite to guard it from surrounding dangers. It is not only exposed to a thousand wants, but so extremely sensible of the action of other bodies, that it would soon be destroyed, did not we exert our utmost attention to preserve it. All external bodies, indeed, do not produce disagreeable sensations; the action of some is attended with pleasure: but the condition of human nature is such, that we have a quicker sense of pain than of pleasure; and, therefore, the latter seldom compensates for the former.

Certain philosophers, indeed, maintained, that pain was no evil, and suppressed their cries in the midst of torments: others placed supreme happiness in voluptuousness, but avoided it for fear of its consequences. All of them however would have shewn themselves better acquainted with human nature, had they restrained the sovereign happiness of this life to exemption from pain; and allowed, that we can approach this happiness, only in proportion to our care and circumspection.

Reflections like these infallibly arise in the breast of every person, who has not imbibed the prejudices of wrong education or perverted study. They follow as consequences of the first impressions we receive from objects, and may be placed among those first emotions of the soul, which are so valuable to the truly wise, and so deserving of observation; though neglected, or rejected, by vulgar philosophers, whose principles they almost universally contradict.

As we are under a necessity of preserving our bodies from pain and destruction, we must examine what external objects may prove useful or hurtful to us, in order to secure the one, and avoid the other: but we no sooner begin to consider these objects than we discover among them numerous beings like ourselves, their form exactly resembling ours; and, having, in all appearance, the same perceptions, we justly conclude they labour under the same wants, have the same appetites, and the same desire of gratifying them; and, consequently, that we might, by uniting ourselves with others of our species, in discovering what things in nature to tend to our preservation, or detriment, reap very great advantages. The communication of ideas is the principle and support of this union, which necessarily requires the invention of signs: and upon this principle was society formed, and language introduced.

And surely the pleasure and advantage flowing from this communication, either by imparting our ideas to others, or by adding those of others to our own, should oblige us to an intimate union in society, and induce us to exert all our powers to render it as mutually useful as possible.

But as each member of society is chiefly sollicitous to procure his own personal advantage, and as an equal desire to do the same is implanted in others; all of us cannot possibly receive an equal share, though we have all undoubtedly an equal right: and hence a right, so justly founded, is presently invaded by that barbarous one of inequality, or the law of force; a law that reduces human nature almost to a level with the brutes, and is extremely difficult not to abuse. The strength nature has generously given to some, doubtless to be imployed for the support and protection of the weaker of our species, becomes the means of oppression: but the weak, in proportion to the violence of this oppression, the less patiently endure it: being persuaded that it is founded on no reasonable motive. And from hence flow our ideas of injustice, and of moral good and evil; the principle of which philosophers have so long endeavoured to discover; whereas it is truly the voice of nature, extending even to savages. This is the law of nature implanted in every human breast, and the true origin of the earliest laws formed by mankind. Nay, this sole voice of nature, unassisted by human laws, is often sufficient either to prevent oppression, or, at least, to confine it within certain bounds. Thus the vices of our own species produce in us the reflex knowledge of our opposite virtues.

Having acquired the idea of just and unjust, and the consequent moral nature of actions, we are led to examine, what that acting principle within us is, which wills and conceives. We easily discover, without a long research into the nature of our own bodies, and the idea we have of them, that they are very different from this principle, because the properties found in bodies are entirely different from the faculty of willing and thinking; consequently, we are composed of two principles, different in their nature; but so united, that the motions of the one are connected with the affections of the other, which we are absolutely unable either to suspend or alter: and this connection renders them reciprocally subordinate to each other.

This subordination so independent of us, added to the reflections continually flowing from the nature of these two principles, and their imperfections, raises us to a contemplation of an omnipotent intelligent being, to whom we are indebted for our existence and preservation, and who, consequently, demands our adoration: our internal sentiments, therefore, are sufficient to demonstrate the existence of an omnipotent Being; were we even deprived of the universal consent of others, and of all mankind. And thus our pure intellectual notions of virtue and vice, the principle and necessity of laws, the spiritual nature of our souls, the existence of God, and our duty towards him; in short, all the truths we have an absolute occasion for, naturally flow from our first ideas of reflection upon those of sensation.

But notwithstanding these first truths are of the greatest consequence, with regard to the more noble part of us, our soul; the body, to which that part is united, soon diverts our attention from them, to provide for its numerous wants. Its preservation obliges us either to prevent the dangers that threaten it, or to remove the evils it suffers. We have only two methods of performing this; the first is our own particular discoveries; and the second, those of others, which we acquire by intercourse. And from hence agriculture, medicine, and all those arts absolutely necessary, or the primitive arts of man, together with all the rest, though apparently very remote, derived their origin.

Men, in the earliest ages, either by mutually assisting each other with information, or by joint endeavours, seem soon to have discovered some particulars to which they might apply themselves. Eager in the pursuit of useful knowledge, they did not long amuse themselves with idle speculations, but examined the different objects of nature, and, discovering their most obvious and striking properties, applied them together.

This first application produced a more latent one, relating to man's necessities; consisting principally in examining more minutely some less single properties, in the alteration and decomposition of bodies, and the uses naturally flowing from thence.

But in whatever method the first of our species, and their successors, proceeded, instigated by an object so interesting as their own preservation; their experience and observation of this immense universe must have produced difficulties too great for their utmost efforts to surmount. But, having now accustomed their minds to meditation, and being desirous of drawing advantage from it, their only resource must be the discovery of some merely curious properties of bodies. And, indeed, were it possible for an immense number of agreeable facts to supply the place of a single useful truth, the study of nature would be abundantly sufficient; for, if it does not afford us necessaries, it at least furnishes us with a profusion of pleasures; and supplies, though very imperfectly, the place of what is truly essential, by a kind of barren superfluity.

Pleasure holds one of the first places in the order of our wants, and the objects of our passions; and curiosity is a want to the pensive mind, especially when animated by the flattering hopes of acquiring entire satisfaction. Hence, we owe numerous discoveries, whose only merit consists in pleasing, to an unhappy impotence of acquiring such as would be attended with real utility. But there is another motive to works of curiosity; we mean, a pretence of advantage. When we are convinced, that something real and advantageous has resulted from enquiries, where at first we had not the least reason to suspect it, it inspires us with hope that all curious enquiries may, in the end, prove useful: and shews the origin, cause, and progress of that vast science, called, in general, physics, or the study of nature, comprehending so many different parts; agriculture and medicine, which principally gave it birth, are now only branches of it; and, though the most ancient and most essential, have only been esteemed, in proportion as they happened to be more or less obscured by others.

In this study of nature, partly prosecuted from necessity, and partly for amusement, we are sufficiently convinced that bodies have numerous properties; but generally so united in the same subject, that, in order to study thoroughly each of them, we are obliged to consider them separately. And, by this operation of the mind, we soon discover properties apparently belonging to all bodies; as motion, rest, and the communication of motion: sources of the principal changes we observe in nature. Upon examining these properties by the senses, especially the last, we soon discover another property, whereon they depend, namely, impenetrability; or that kind of force, by which each body excludes all others from the space it occupies.

Impenetrability is the principal property by which we distinguish bodies from the parts of indefinite space, wherein we suppose them placed; at least, we are obliged by our senses to judge thus of them: and, if our senses in this particular deceive us, it is so metaphysical an error, that our existence and preservation have nothing thence to fear; our common manner of conceiving obliging us constantly, in spite of ourselves, to return to this notion. We are induced by every object that surrounds us to look upon space, as the real, or at least the supposed place of bodies: and it is, actually, by the means of the parts of space, considered as penetrable and immoveable, that we acquire the justest idea of motion we can possibly obtain: and are consequently obliged to distinguish, mentally at least, two kinds of extension; the one impenetrable, and the other constituting the place of bodies. Thus, though we include impenetrability in the idea we form of the parts of matter, yet, being a relative property, the idea of which we only acquire by examining two bodies together, we soon accustom ourselves to consider it as distinguished from extension; which we can mentally abstract from body.

In this new consideration we regard bodies only as figured and extended parts of space: which is the most general and abstract light they can be considered in: for extent, wherein we distinguish no figured parts, resembles only an obscure picture, whose several parts escape our notice; because we can distinguish nothing. Colour and figure, properties constantly, though differently, residing in bodies, help us to distinguish body from space. Indeed, one of these properties is sufficient for the purpose; and, in that case, figure is generally preferred to colour.

Hence, we are enabled to fix the properties of simple figured extension, which constitutes the object of geometry, which, the more easily to attain its end, considers extension as first limited by one, then by two, and lastly by three dimensions. These three dimensions constitute the essence of all bodies in the universe. Also, by the successive operations and abstractions of mind, we divest matter of almost all its sensible properties, in order to examine only its idea. This enquiry cannot fail of leading to discoveries of the greatest utility; especially, as it is here unnecessary to regard the impenetrability of bodies: for example, when we contemplate their motion, we need only consider them as figured and moveable parts of space, and distant from one another.

The examination of figured extension presenting a great number of possible combinations, it is necessary to invent a method of rendering these combinations easy. And as they principally consist in the calculation, and proportion, of the different parts which we imagine constitute geometrical figures; this enquiry leads us immediately to arithmetic, or the science of numbers. This art consists in finding a short and facile method of expressing a single relation, resulting from the comparison of several others. The different ways of comparing these relations give us the different rules of arithmetic.

By attentively considering these rules, we cannot help observing certain principles, or general properties, of relations; and, by expressing these relations in a general manner, we discover different possible combinations. The results of these combinations, being reduced to one general form, are in effect no more than arithmetical calculations indicated and expressed in the most concise manner, consistent with their generality. The art or science of representing these relations is what we term algebra. And though, properly speaking, it is impossible to perform any calculation, but by numbers; nor measure any magnitude but by extension (for without space we could not exactly measure time) we arrive, by constantly generalising our ideas, at that principal branch of the mathematics, and all the natural sciences, called the science of magnitude in general; being the foundation of all the possible discoveries relating to quantity; that is, whatever is susceptible of being increased or diminished.

This science is the ultimate end possible to be attained by the contemplation of the properties of matter; it being impossible to go farther, without entirely quitting the material universe. But such is the progress of the mind in its enquiries, that after having generalised its perceptions, so as to be unable to analyse them farther, it returns back by the same steps, recomposes its perceptions anew, and gradually forms ideas of such beings as are the immediate and direct objects of our sensations. These being immediately relative to our wants, we are under an absolute necessity of studying them; mathematical abstractions greatly facilitate this study, and by this application only prove useful in life.

Having now, as it were, exhausted the properties of figured extension by our geometrical speculations, we again restore to it impenetrability; which constitutes physical body, and is the last sensible property we divested it of by our abstractions. This new consideration is attended with another, the action of bodies upon each other; for bodies only act by means of impenetrability; whence we derive the laws of equilibrium and motion; the object of mechanics. And hence we extend our enquiries to the motion of bodies, propelled even by unknown powers, or moving causes; provided the law, regulating these causes, is either known or supposed.

Returning thus to the corporeal world, we immediately perceive the use of geometry and mechanics, in deriving, from the properties of bodies, the most sublime and interesting truths; and from whence, nearly, all those sciences, termed physico-mathematical, are derived. At the head of these sciences we justly place astronomy; a study, next to that of ourselves, the most worthy of cultivation, on account of the magnificent scene it presents to our view. Joining observation with calculation, and illustrating the one by the other, astronomy determines, to a surprising degree of exactness, the distances and most complicated motions of the celestial bodies; and even assigns the forces themselves, by which these motions are either produced or altered. So that this science may be justly regarded as a sublime and certain application of geometry and mechanics united; and its progress as an incontestable monument of the advantageous efforts of human sagacity.

The use of mathematical knowledge is no less considerable in examining the terrestrial bodies that surround us. All the properties observable in these bodies have certain relations to one another, more or less sensible to us: The knowledge, or discovery, of these relations is almost the only object we can arrive at; and, consequently, the only one we should propose to ourselves. The knowledge of nature can never be obtained from vague and arbitrary hypotheses: it must be acquired by considering phænomena, comparing them together, and reducing, as much as possible, many of them to one single cause, which should be regarded as a principle. In fact, the more we diminish the number of principles in a science, the more we increase their extent; for, the object of a science being necessarily determined, the principles applied to that object become so much the more pregnant, in proportion as they are rendered fewer, or more general. This reduction, which facilitates the discovery of principles, constitutes genuine theory; and should not be mistaken for the spirit of building systems; which is often a very different thing.

But this reduction becomes more or less difficult, in proportion as the object considered proves more or less abstruse, or extensive; and, accordingly, we are more or less intitled to require it of those who apply themselves to the study of nature. The magnet, for example, is a subject that has been greatly laboured; and surprising discoveries are already made in it; as its properties of attracting iron, and communicating the same virtue thereto; its turning to the north, with a variation subject to rules, and affording as surprising a phænomenon, as a more exact direction; and, in fine, its dip to the horizon, in an angle greater or less, according to the part of the earth it is placed upon. These are particular properties, probably depending upon some one general principle, or cause, hitherto unknown. And it is surely an enquiry worthy of philosophers to reduce, if possible, all these properties to one, by shewing the principle that connects them. But this discovery, however serviceable it might be to natural philosophy, is, we fear, not easy to make. We may say the same of many other phænomena, whose connection, perhaps, belongs to the general system of the universe.

The only method to be followed in such labdrious, necessary, and useful researches, is, to collect as many facts as possible; dispose them in a natural order; and reduce them under a certain number of principal facts, of which the lesser should appear as so many consequences. If at any time we presume to rise higher, it should be with a circumspection becoming so feeble an understanding as ours.

Such is the plan to be followed in this vast part of physics, generally called experimental philosophy. It differs from the physico-mathematical sciences, in being, properly, no more than a rational collection of experiments and observations; whereas the physico-mathematical sciences, by applying calculation to experience, sometimes, even from a single observation, draw numerous consequences, approaching, with certainty, to geometrical truths. Thus from one experiment upon the reflection of light, the whole science of catoptrics, or doctrine of mirrours, was produced; and, from another on the refraction of light, the theory of the rainbow, the doctrine of colours, and all dioptrics. From observing the pressure of fluids, we derive the laws of their equipollency and motion. In fine, from the single experiment of the acceleration of falling bodies, was derived their falling on inclined planes, and the whole doctrine of pendulums.

It must however be acknowledged, that some mathematicians have misapplied algebra to physics. Instead of proper experiments to ground calculation upon, they sometimes use hypotheses, commodious for their purpose, though often different from what is actually found in nature. Algebraists have been fond of reducing all to calculation, not excepting the healing art itself. That complicated engine, the human body, has been treated by algebraical physicians, as a simple machine, easy to analyse. For our own parts, either more cautious or more kind, we look upon the greatest part of such calculations, and vague suppositions, as the sport of fancy, to which nature is not in the least obliged to submit; and conclude, that the only true method of philosophising consists either in the application of mathematical calculation to experiments; or in simple observation, conducted by proper methods, and sometimes assisted by conjectures for further enquiry; scrupulously avoiding all arbitrary hypotheses.

From what has been said, we may observe that there are two limits, within which all our certain knowledge of nature appears to be confined; the one is, what we at first laid down, the idea of ourselves; which leads us to that of an almighty being, and our principal duties. The other is, that part of mathematics, which has for its object the general properties of body; we mean, extent and magnitude. Between these two limits, is an immense interval, wherein the supreme intelligence seems willing to exercise human curiosity, by the numerous clouds interspersed, and certain tracts of light breaking out here and there, as if to allure us. The universe may be compared to books written with sublime obscurity; where the author, sometimes levelling himself to the capacity of his readers, seems to persuade them they nearly understand the whole. Happy for us, who enter this labyrinth, if we do not mistake the path; for, if we should, the light, designed to conduct, will mislead us farther.

As the small acquisition of certain knowledge we can boast of, is incapable of conducting us beyond the two limits above-mentioned, it is far from being sufficient to supply our numerous wants. The study of human nature, so necessary, and so much recommended by Socrates, is an impenetrable mystery to man, who has only reason to direct him. The greatest genius, reflecting upon this important subject, seldom rises higher than to know less than the rest of mankind. And the same may be said of our present and future existence; the essence of that being to whom we owe them both; and of the kind of worship he requires of us.

A revealed religion is therefore absolutely necessary, to instruct us in essential points, and serve as a supplement to natural knowledge, by teaching us things otherwise impossible to be discovered. Revelation however has confined itself to what is absolutely necessary for us to know; the rest remains, and, perhaps, for ever will remain, concealed. A few truths to believe, a few precepts to practise, make the substance of revealed religion; but, by means of the light it has communicated to the world, we are more confirmed in many interesting points, than any of the sects of mere philosophers.

With regard to the mathematical sciences, which constitute the second limit of our knowledge, their nature and number should not deceive us. It is principally to the simplicity of their object, that they are indebted for their certainty. And, as the objects of the several branches of these sciences are not equally simple, demonstration, which is founded on self-evident principles, does not equally belong to them all. Many of them are founded on principles merely physical; that is, on experiments, or simple hypotheses; and, consequently, have only experimental or hypothetical certainty. Properly speaking, only those branches which treat of magnitude, and the general properties of extension, as algebra, geometry, and mechanics, can be called demonstrative. The light, acquired by the mind from these sciences, has a certain kind of gradation; and their principles become clearer, in proportion as their object is considered in a more abstract and general manner. Geometry is more simple and abstract than mechanics; and algebra more simple and abstract than either. This is no paradox to those who have philosophically studied these sciences; the abstractest notions, which the generality look upon as most confused, commonly afford the clearest light: our ideas become obscure, in proportion to the number of sensible properties we examine in an object. Impenetrability, joined to the idea of extension, seems like adding one mystery to another; the nature of motion is an ænigma to philosophers; the metaphysical principle of the laws of percussion is as little known: in a word, the more we compare our idea of matter with its properties, the more that idea becomes obscure, and seems to elude the utmost efforts of human perspicacity.

From what has been said it evidently follows, that all the mathematical sciences are not equally capable of giving satisfaction to the mind: let us next examine without prejudice, how far these sciences may be reduced. At first view, they appear extremely numerous, or almost inexhaustible; but, when ranged in order, and brought into a philosophical list, their number falls greatly short of expectation. There are numerous mathematical truths, of which little use, or application, is made. This, indeed, is no argument against them, considered in themselves; but even most of the axioms which geometry plumes itself with, what are they but expressions of the same simple idea, under two different signs, or words? Do we derive any more real knowledge from saying that two and two make four, than we should from saying that two and two make two and two? The ideas of a whole and a part, greater and less, are they, properly speaking, any more than the same individual simple idea; as we cannot have the one without the other's presenting itself at the same time? Certain philosophers observe, that many errors are owing to the abuse of words; and perhaps axioms are also owing to this abuse. We do not however absolutely condemn their use, but only propose to observe its limitation; which consists in rendering simple ideas more familiar by habit, and fitter for the different purposes to which they may be applied. The same, with proper restrictions, may be said of mathematical theorems; for, when they are considered without prejudice, they may be reduced to a few primitive truths. If we examine a train of geometrical propositions, so deduced the one from the other, that every contiguous two are linked together; we shall find, that they are all no more than the first proposition successively disguised, in passing from one consequence to the next; the original proposition not being in the least multiplied by this concatenation, but only appearing under different forms: as if successively expressed in a language, gradually changing by time, and employing a different phraseology, according to the different stages it passes through; whilst each stage remains discoverable by comparing it with that immediately preceding, but not so well by comparing it with one more remote one; though all the stages depend upon each other, and design to convey the same ideas. We may therefore consider the concatenation of a series of geometrical truths, as so many different translations of the same proposition, and often of the same hypothesis. Such translations, indeed, are often of the greatest use, as they enable us to make different applications of the theorem they express: and these applications are more or less valuable, in proportion to their importance and extent. But as the real merit of such mathematical translation originally resides in the proposition translated, how greatly are we indebted to those inventors, who, discovered any one of these fundamental truths, the source, or original from whence numerous others flow, as they have, by that means truly enriched, and greatly enlarged, the Science of Geometry. The same may be observed also of those physical truths, and properties of bodies, which form a concatenation; for all these properties, well ranged together, afford us only one simple truth. If numerous others appear to us detached, or separate, so as to form different truths, this melancholy advantage arises from the weakness of human understanding; our abundance here flowing only from our indigence. Electrical bodies, for example, wherein so many extraordinary, and apparently independent properties have been discovered, are perhaps, in one sense, the bodies we least understand; though we may think we know them the best. The virtue they acquire, by friction, of attracting lighter bodies, and of producing violent commotions in animals, appear at present two different things; but, could we discover their primary cause, we should be convinced of their unity. The universe itself, were it possible for us to reduce it to a single point of view, would be no more than a single pregnant fact, or immense verity.

We have yet mentioned only those Sciences which owe their origin to our wants; but these are not the only sort we are obliged to cultivate: there are others relative to these, which men have therefore studied at the same time with them. Both kinds might, indeed, have been described together; but we thought it more proper, and, at the same time, more suitable to the philosophical method of this discourse, first to consider it

2 without

without interruption, the general study men employ on bodies, and with which they originally commenced; though others were soon joined with it. These studies seem to have been pursued in the following order.

The advantages they found upon enlarging the sphere of their ideas, whether by the efforts of their own genius, or the assistance of others, must have pointed out to them the great utility of reducing the means of acquiring and communicating knowledge to an Art, which, being invented, was termed logic. It teaches us to range our ideas in the most natural order; to form them into a close concatenation, decompose such as comprehend too many simple ones, examine them on all sides, and, in fine, to communicate them to others in the most intelligible and perspicuous manner. In this consists the Science of reasoning, which may be justly called the key of knowledge, though it did not come first in order of discovery. The Art of reasoning is the free gift of nature to men of genius; and the books which treat of logic prove, in general, only of use to those who might reason well without their assistance.

The valuable Art of forming our ideas into a concatenation, and consequently of facilitating the transition from one to the other, furnishes us with a method of reducing nearly to an equality the abilities of every individual. For in fact, all our knowledge reduces itself primitively to sensations, which in all men are nearly the same; and the Art of combining and connecting our direct ideas is no more than arranging the same ideas in a series, more or less exact; whence they become more or less sensible to others. A man who readily combines his ideas, differs but little from another who combines them slowly; as he who judges of a picture at sight, differs but little from him who requires to be made successively sensible of all its parts: both, at the first glance, have the same sensations; but, as they do not sink so deep in the second, there is a necessity for him to dwell longer upon each, to render them strong and distinct. By this means, the reflex ideas of the former become as easy to the latter as the direct ones. And, perhaps, it would be difficult to find an Art or Science, that, by means of a well-adapted logic, may not be taught to persons of slow understanding; because there are few Arts, or Sciences, whose precepts, or rules, may not be reduced to simple notions, and disposed in so connected an order, that the chain need never be broken. But, in proportion as the mind is more or less slow in its operations, this connected order will become more or less necessary; and the advantage of a great genius is that of having less occasion for it, or rather of being able to form it in a rapid and almost imperceptible manner.

The Science of communicating our ideas is not confined to the method of arranging them in a proper order; it also teaches how to express each idea in the most exact and perspicuous manner, and consequently to perfect and ascertain the signs destined to convey them: this also the human species have, by degrees, endeavoured to perform. Those languages which had their origin at the same time with society, were, doubtless, at first only a confused collection of signs; and, consequently, natural bodies, as being objects of our senses, were first represented by names. And, as languages, at their first origin, were adapted only to the most pressing occasions, they were certainly very imperfect, confined, and subject to very few certain principles: and, therefore, the Arts and Sciences, of absolute necessity, might have made a great progress, before men attempted to form any rules for style or diction. The difficulty and imperfection attending the communication of ideas, during this want of rules, and scarcity of words, must have obliged every man to improve his knowledge, by his own resolute labour, without greatly depending on others for assistance. Too facile a communication of knowledge may doubtless sometimes benumb the faculties of the mind, or prevent the exertion of its force.

But, as a facile method of exchanging ideas by mutual commerce was attended by incontestable advantages, it is no wonder men should endeavour to render this exchange still more easy. In order to this, they began to reduce signs to words, which are marks or symbols, always ready at hand. The order of the generation of words, therefore, followed the order of the operations of the mind: after individuals, sensible qualities came next to be named, which, without having any existence of their own, except in individuals, belong in common to a great number; and hence, by degrees, men came to use certain abstract terms; some serving to connect ideas together, others to denote the general properties of bodies, and others to express mere mental notions. All these abstract terms, which children are so long in learning, doubtless required much time to discover. But, at length, the use of words being reduced to rule, grammar was formed; which we may consider as a branch of logic. Grammar, assisted by a subtle and refined metaphysics, determines the shades or degrees of our ideas; teaches us to distinguish these shades by different marks; affords rules for the more commodious use of such marks; and, by means of philosophical sagacity, in tracing the origin of things, often discovers the reasons of that apparently odd choice, which prefers one sign to another, and leaves as little as possible to that national caprice, called custom.

Men, at the same time that they communicate their ideas, endeavour also to communicate their passions. This is performed by means of eloquence. This speaks to the sentiments of the heart, as logic and grammar speak to the understanding, and can silence reason itself; and, perhaps, the great effects, which a single orator sometimes produces upon a whole people, are the most glaring instance of the superiority of one man over another. And here it is very surprising, that men should ever have thought of supplying the want of this prodigious talent by rules; can genius be reduced to precept? He who first pretended that orators were owing to Art, was either no orator himself, or very ungrateful to nature, which alone has the power of making an orator. There are but two books to be studied by orators; men are the first, and the greatest masters of the Art the second.

We are not contented to live with our cotemporaries alone. The mind of man, drawn by curiosity and self-love, eagerly endeavours to embrace, at once, the past, the present, and the future times. We desire to live both with our successors and predecessors. Hence the origin and intention of history, which unites us with past ages, by representing their vices, virtues, knowledge, and errors; and transmitting our own to posterity. It is by history we learn to esteem men only for their good actions, and not for the seducing pomp that surrounds them. Sovereigns, who are often unhappily excluded from truth on all sides, may here previously pass sentence upon themselves: for history is a tremendous, uncorrupt tribunal, which judges their resembling predecessors just as it will do them.

Chronology and geography are two appendages, or supporters of history: the one fixing the inhabitants of the earth, in point of time; and the other assigning their place upon our globe: they both derive great advantages from the history of the earth and the heavens; that is, from historical facts and celestial observations; and may therefore, in the language of the poets, be stiled, the daughters of astronomy and history.

One principal advantage resulting from the study of empires, and their revolutions, is to examine how mankind, separated, as it were, into numerous large families, formed different societies; how these societies gave birth to different kinds of government; and how each people endeavoured to distinguish themselves from the rest, both by laws, and particular signs, as the means of more easily communicating their thoughts: whence arose that great diversity of languages and laws, which, to our misfortune, is become a principal object of study. Hence, also, we see the origin of civil policy, as a particular and superior kind of morality; it being often difficult, without straining, to accommodate the principles of common moral duty to civil policy, which, entering into the principal motives of government, aims at discovering what may tend to preserve, weaken, or destroy a state. This study is perhaps the most difficult of any; for it requires not only a deep knowledge of mankind, in general, and of the people to be governed, in particular; but alſo a great compaſs, and variety of abilities: eſpecially if the politician would remember that the law of nature, being prior to all particular conventions, is the firſt law of the people; and that his being a ſtateſman does not exclude his being a man.

Theſe are the principal branches of that portion of human knowledge, which conſiſts either in the ideas we receive directly by the ſenſes, or in the combination or compariſon thereof: which combination is, in general, called philoſophy. Theſe branches ſubdivide themſelves into ſuch a prodigious number of others, that the enumeration of them rather belongs to the work itſelf than the preface.

We began with conſidering the firſt operation of reflection, which conſiſts in collecting and uniting our direct notions, and have mentioned the different Sciences reſulting from thence. The notions, formed by the combination of our primitive ideas, are not however the only ſort of which the mind is capable. There is another kind of reflex knowledge, which we ſhall now conſider. It conſiſts in the ideas we form to ourſelves, by imagining and comparing things, as they reſemble the objects of our direct ideas. This is what we term the imitation of nature, ſo well known, and ſo much recommended, by the ancients. As the direct ideas which ſtrike us with the moſt vigour are thoſe we remember beſt; ſo we the more earneſtly endeavour to reproduce them in ourſelves, by an imitation of their objects. Agreeable objects indeed ſtrike us ſtronger when real, than when barely repreſented; but this defect is, in ſome manner, ſupplied by the pleaſure we receive from their imitation. On the other hand, thoſe real objects which excite melancholy or diſtreſsful ſentiments, their imitation becomes more agreeable than the objects themſelves, by placing us at ſuch a juſt diſtance, that we receive the pleaſure of the emotion, without the diſorder. And in this imitation of all kinds of objects, capable of raiſing lively or agreeable ſentiments in us, conſiſts, in general, the imitation of beautiful nature; upon which ſo many authors have wrote, without being preciſe: perhaps becauſe it requires exquiſite ſentiments to determine what beautiful nature is; or becauſe the limits that diſtinguiſh what is arbitrary from what is juſt, are not hitherto properly aſcertained; and therefore leave ſome liberty to opinion.

At the head of the Arts of imitation painting and ſculpture are placed, as being thoſe wherein imitation comes neareſt to the objects they repreſent, and ſpeaking the moſt directly to the ſenſes. To theſe we may add that Art, which owes its origin to neceſſity, and its perfection to luxury; we mean architecture, as having riſen by degrees from cottages to palaces; and being, to a philoſophical eye, no more than an embelliſhed diſguiſe of one of our greateſt wants. The imitation of beautiful nature is here leſs ſtriking, and more confined, than in painting or ſculpture; which indifferently and with reſtriction expreſs all the parts of beautiful nature, by repreſenting her as ſhe is, either uniform, or with variety: whereas architecture is conſtrained, in diſpoſing and uniting the different materials it employs, to imitate that ſymmetry, which nature obſerving, more or leſs viſibly, in the ſtructure of each individual, produces ſo fine a contraſt with the beautiful variety of the whole.

Poetry, which occupies the next place to painting and ſculpture, employs, in its imitations, words ſo diſpoſed as to make agreeable harmony to the ear; but ſpeaks rather to the imagination than to the ſenſes; and thus preſents, after a ſtrong and lively manner, all the objects in the univerſe; and appears rather to create than paint, by the glow, motion, and life it gives to each.

The laſt among the Arts of imitation is muſic, which at once ſpeaks both to the imagination and the ſenſes. It is not becauſe its reſemblance is leſs perfect than theirs, with regard to the objects it would repreſent, that it is the laſt in the ſeries, but becauſe it has been confined to fewer images. Nor ſhould this perhaps be attributed ſo much to its nature, as to the want of invention and contrivance in moſt of its profeſſors.

And here we conclude our enumeration of the principal branches of human knowledge. If we conſider them all together, and ſearch for the general views that ſerve to diſtinguiſh them, we ſhall find, that ſome of theſe branches are entirely practical, and have the execution of ſome deſign for their end: that others are merely ſpeculative, or confine themſelves to the examination of their object, or the bare contemplation of its properties; and that a third ſort, from the ſpeculation of its ſubject, derives a practical uſe in theory and practice that principally diſtinguiſh Sciences from Arts; and accordingly one or other of theſe terms is applied to moſt branches of knowledge; but it muſt be confeſſed, that our ideas are, in this caſe, not hitherto ſufficiently preciſe. We are often at a loſs in naming ſuch branches of knowledge where ſpeculation is joined with practice; and it is frequently diſputed in the ſchools, whether logic be an Art or a Science: the queſtion might eaſily be ſolved, by ſaying it is both the one and the other. If words could be brought to a clear and preciſe ſignification, much time would be ſaved, and many diſputes avoided.

The term Art may, in general, be given to any branch of knowledge, capable of being reduced to determinate invariable rules, independent of caprice or opinion; and, in this ſenſe, ſeveral Sciences, conſidered in their practical uſe, may be termed Arts. There are rules for the operations of the mind, and others for thoſe of the body, the operations whereof, being confined to external ſubjects, require no more than the aſſiſtance of the hand to perform them. Hence proceeds the diſtinction between the liberal and mechanic Arts, and the preference given to the former, though very unjuſtly, in many reſpects. The mechanic Arts, depending upon manual operation, and confined to a certain beaten track, are aſſigned over to thoſe perſons whom prejudice has placed in an inferior claſs. Indigence, rather than taſte and genius, compelling them to this occupation, became, in time, a cauſe of contempt: ſo detrimental is it to thoſe it attends: whilſt the free operations of the mind were left to others, who thought themſelves greater favourites of nature. But the advantage of the liberal over the mechanic Arts, from employing the operations of the mind, and from the difficulty of excelling therein, is ſufficiently compenſated by the greater utility generally reſulting from the latter. This very utility reduces them to mere mechanical operations, in order to facilitate their practice among a greater number of men. Thus ſociety may have a juſt regard for its enlightening geniuſes, without debaſing the hands that ſerve it. The diſcovery of the mariner's compaſs is not leſs ſerviceable to mankind, than an explanation of the properties of the needle would be to philoſophy. In fine, if we divide the ſeveral branches of knowledge according to the grounds of diſtinction above-mentioned, how many of thoſe, termed Sciences, will be reduced to mechanic Arts? And what is the difference between a head furniſhed with a chaos of uſeleſs unconnected facts, and the inſtinct of an artiſan, diſplayed in mechanical execution?

The contempt thrown upon mechanic Arts has alſo, in ſome degree, been extended to their inventors. The names of theſe benefactors to mankind are rarely heard of; whilſt the great deſtroyers of our ſpecies, called conquerors, are univerſally known. Yet we find, among artiſans, many extraordinary proofs of ſagacity, genius, aſſiduity, and invention. Moſt Arts, indeed, are diſcovered by degrees; and ages have been employed in bringing ſome of them to perfection. And may not the ſame be ſaid of the Sciences? How many diſcoveries, which have immortaliſed their authors, were begun and continued by the labour of preceding ages, and ſome of them brought ſo near perfection, that little more than a ſingle addition was requiſite? Should not the inventors of the ſpring, the chain, and repeating parts of a watch, be equally eſteemed with thoſe who have ſucceſſively ſtudied to perfect algebra? But, though the gradual improvement of Arts ſhould be granted as a ſufficient reaſon for not ranking theſe artiſts in the claſs of inventors, yet there are certain machines ſo complicated, and all their parts ſo much depending upon one another, that it is difficult to conceive they ſhould have been invented by different perſons; and ſhould not ſuch extraordinary inventors, inſtead of having their names buried in oblivion, obtain a place among the few diſcoverers who ſtrike out new paths of Science?

Among

Among the liberal Arts reduced to principles, those that make the imitation of nature their end, are called fine Arts, or Arts of elegance, and have principally agreeableness for their object. But this is not the only particular that distinguishes them from the more necessary, or more useful liberal Arts, as grammar, logic, and morality. The latter have their fixed and determinate rules, capable of being transmitted from one man to another: whereas the practice of the Arts of elegance principally consists in invention, and derives its laws from genius. The rules laid down, with respect to these Arts, properly regard their mechanical part; and therefore, like telescopes, assist only those who have eyes.

From what has been said it follows, that the different ways, in which our mind operates upon objects, and the different uses it derives from thence, are the first means of distinguishing, in general, our different kinds of knowledge from each other; and that the whole of it relates to our wants, either of necessity, convenience, amusement, real use, or caprice. The more remote our wants are, or the more difficult to supply; the more slow is the progress of our knowledge. What improvement would the Art of physic have made, to the discredit of the speculative Sciences, were it founded on as certain principles as those of geometry? There are also other characters or differences, besides those we have enumerated, taken from the manner wherein our knowledge affects us, or the different judgments we form of our ideas. These judgments are denoted by the words evidence, demonstration, probability, sentiment, and taste.

Evidence belongs properly to those ideas, between which the mind immediately perceives a connection; and demonstration to those where the connection does not appear, without the assistance of intermediate ideas; or when the propositions are not found to have an identical agreement with the same self-evident principle, but by means of a chain of reasoning; and hence a proposition may appear different to different persons, according to the nature of their minds; for it may be self-evident to the one, and only demonstrative to the other. But, taking the term in a different sense, we might say that the former is the result of the mere operations of the mind, employed in metaphysical and mathematical speculations; and that the latter regards physical objects, our knowledge whereof flows from the constant and invariable relation of our senses. Probability principally relates to historical facts, and, in general, to all events, whether past, present, or future, which we usually ascribe to accident, for want of knowing the causes from whence they flow. But, though the history of present and past transactions rests solely upon testimony, yet it often produces as strong a persuasion in us as axioms. Sentiment is of two kinds; the one relates to moral truths, and is called conscience; which is a consequence of the law of nature, and of the ideas we have of good and evil; whence it might be called the evidence of the heart: for, though it differs greatly from the evidence of the understanding, which regards speculative truths, yet it equally affects us. The other kind of sentiment is restrained to the imitation of beautiful nature, and what is called the beauties of expression. This catches, with transport, all sublime and striking beauties; discovers, with elegance, such as lie concealed; and rejects all false appearances and pretensions. It often condemns at once, without assigning the motives; which, to render intelligible to others, would require much time to explain. To this kind of sentiment we owe what is called taste and genius; which only differ, as genius is creative, and taste judicial sentiment.

After this enumeration of the different parts of our knowledge, and the characters by which they are distinguished, it remains that we form them into a kind of genealogical tree, or systematical table of human knowledge, which may represent them all at one view, so as to shew their origin, relation, and mutual connection. The use of such a contrivance is evident; but the execution is attended with difficulties. The philosophical history of the origin of our ideas, given above, will, indeed, help us herein; though it would be absurd and impracticable severely to follow the series of that history, in forming our plan. A general system of Arts and Sciences is a kind of labyrinth, which the mind enters, without well knowing which path to take. Pressed by its own wants, and those of the body, to which it is united, it fixes on the first objects that present themselves; proceeds as far as it can in understanding them; but soon meets with difficulties to stop its progress; and, either in hope or despair of conquering them, strikes into a new track; returns afterwards by the way it went; but no sooner surmounts the first difficulties, than it is opposed by others; and, passing rapidly from one object to another, makes upon each a series of different attempts, which the very generation of its ideas necessarily interrupts. This disorder, however philosophical in the mind, is sufficient to disfigure, or even annihilate entirely any systematical plan of the Arts and Sciences.

Besides, we have already shewn, in that part of the preceding discourse relating to logic, the greatest part of those Sciences which include the principles of others, and therefore ought to have the first place in the philosophical order, must not have the same in the genealogical order of our ideas, because they were not first invented. The truth is, the primitive study of the human species must have been that of individuals; the particular obvious properties of these were first examined, and then, by the abstraction of the mind, their general properties; which formed metaphysics and geometry. Primitive signs were long in use, before mankind so far improved the method of using them, as to form it into a Science. A long series of operations on the objects of their ideas was necessary, before men could form, by reflection, rules for such operations.

In fine, the system of human knowledge is composed of different branches, many of which unite in one point. And as it is impossible, by beginning from the same point, to trace all the different branches; the choice of every man must be determined by the natural turn of his own mind: and, consequently, very few can pursue numerous branches to any advantage. Many, at first, applied themselves, in concert, to the study of nature, in order to supply their most pressing wants; but those parts of knowledge, not absolutely necessary, were divided, and each individual pursuing that which best suited his own genius, a number of them were almost equally improved at once. But, though several of the sciences were thus cultivated at the same time together, yet, in giving the historical order of the progress of the mind, they must necessarily be considered as successive.

It is not the same, with regard to the systematical order of our knowledge. This consists in contracting the whole of it into the smallest space possible, and placing the reader on an eminence above this vast labyrinth, so that he may at once take a view of all the principal arts and sciences; discover, by a single glance, the objects of each, and the operations to be performed upon these objects; distinguish the general branches of human knowledge, the points which separate or unite them, and, at the same time, perceive the secret paths that join them. Such a system would resemble a map of the world, on which the principal countries, their situation, and mutual relation, together with the direct roads that lead from one to the other, are delineated: though these roads are frequently interrupted, and so obstructed, that none but the respective inhabitants, or experienced travellers, can know them: nor is it possible for them to be delineated, except on the particular maps of each country. The different articles of our Dictionary and Supplement make such particular maps; and the philosophical tree, or systematical view annexed to this discourse, forms the general map of the world.

But as, in general maps of the globe, objects are placed nearer or more remote, and appear differently, according to the point wherein the eye is supposed to be placed; so the form of our philosophical tree will vary, according to the point from which we view the universe of literature. We may therefore consider the different systems of human knowledge, as general maps of different projections: and each system may have some advantage peculiar to itself over the rest. It is natural to think that every man would willingly place in the center of the whole his own favourite science; as the first men, being persuaded that the universe was made for them, placed this earthly globe in the center of it. And many of these pretensions, impartially considered in a philosophical light, might be justified by solid reasons.

Among all the various kinds of systematical plans of knowledge, that should doubtless be preferred, which takes in the most connections and relations between the sciences. But who can flatter themselves with having been fortunate enough to find it? Nature, as we have already observed, and which we cannot repeat too often, is wholly composed of individuals; which are the primitive objects of our sensations, and direct perceptions. We truly remark, in these individuals, certain common properties, by means whereof we compare them; and certain dissimilar properties, by which we distinguish them; and, by assigning abstract names to these properties, we are enabled to distribute objects under different classes. But as an object, which, on account of some properties, should be ranged in one class, has others which equally intitle it to another; it follows that all general divisions must needs be arbitrary. The most natural arrangement would be to make things succeed each other in gradual shades, or scarce discernible transitions; which at once might serve to separate and unite them: but the scanty number of the things we know, will not permit us to discern these shades. The universe resembles an immense ocean, where we see islands of different sizes above the surface, but cannot discern their connection with the continent.

A systematical plan of human science might be formed, by dividing it either into natural and revealed, or into useful and agreeable, or into speculative and practical, or into evident, certain, probable, and sensible; or into the knowledge of things, and the knowledge of signs; and so in infinitum: but we have chosen such a division as appeared, at the same time, most suitable both to the systematical and genealogical order of human knowledge. We principally owe this division to the immortal Sir Francis Bacon. But we are too sensible how arbitrary all divisions of the arts and sciences must ever be, to imagine ours the best or only system.

The objects which employ our minds, are either spiritual or material; and we are employed about them, either by direct or reflex ideas. Our stock of direct knowledge consists of a merely passive or mechanical collection of things treasured up in the memory. We have already observed that reflection is of two kinds, and either reasons upon the objects of our direct ideas or imitates them. Hence, there are three different methods, whereby the mind operates on the subject of its thoughts; which are memory, reason, properly so called, and imagination. We do not mean by imagination the mere faculty of recollecting sensible objects; this is no more than memory, which, were it not for the use of signs, must be in continual exercise; but we use the word in a higher and more explicit sense, to signify that faculty of the human mind which creates objects by imitation.

These three faculties form the three general divisions of our system, and the three general objects of human knowledge, viz. history, which relates to memory; philosophy, which is the product of reason; and the polite arts, which owe their origin to imagination. We place reason before imagination, because that order is more conformable to the natural progress of the operations of the mind; imitation is a creative faculty, but the mind, before it attempts creating, reasons upon what it sees and knows. Another motive for placing reason before imagination is, that reason and memory unite, to a certain degree, in forming the imagination. The mind creates, or imagines objects, only resembling those it already knows by direct ideas and sensations: The more it departs from these objects, the more strange and disagreeable objects it forms. Hence, in the imitation of nature, even invention is subject to certain laws; and these laws chiefly constitute the philosophical part of the polite arts; though, at present, it is but little known, as being only the work of genius, which rather delights in creating than discerning.

In short, if we examine the progress of our rational faculty, in its successive operations, we shall find it plainly precedes imagination; because the ultimate operations which reasoning performs upon objects, lead, in some sort, to imagination. For these ultimate operations consist in the formation of general notions, which, separated from their subject by abstraction, are no longer the immediate objects of our senses. And hence metaphysics and geometry, of all the sciences that derive their origin from reason, are those where imagination has the greatest share. The imagination of a geometrician who discovers, is as active as that of a poet who invents; though they operate differently on their respective objects. The former simplifies and analyses, whilst, the latter composes and adorns. These different operations also belong to different kinds of geniuses; whence, possibly, the talents of a great geometrician, and of a great poet, are impossible to be united. But, whether the one excludes the other, or not, they have doubtless no right to despise each other, as is too often the consequence. And, perhaps, among all the great geniuses of antiquity, Archimedes best deserves to be ranked with Homer.

The general distribution of subjects, into spiritual and material, forms the subdivision of the three general branches of our knowledge. History and philosophy equally regard both, whilst imagination wholly operates upon the plan of material objects: whence we have another reason for placing it last in the order of our faculties. At the head of spiritual beings is God; who holds the first place by his nature, and the necessity we have of knowing him. Next to this supreme being, come created spirits; the knowledge of whose existence we derive from revelation. In the next place comes man, composed of two principles, a soul, which is spiritual, and a body, which is material; and, lastly, comes this immense universe, which we call the corporeal world or nature.

History, as it relates to the supreme being, includes revelation and tradition; and is therefore divided into two parts, sacred and ecclesiastical. The history of man hath human actions and human knowledge for its object; and therefore is either civil or literary; treating of powerful nations and great geniuses; potentates and men of letters; conquerors and philosophers. Lastly, the history of nature is the history of the numerous productions we behold; and forms almost as many branches as there are different productions in nature; but among the rest is justly placed, with distinction, a history of arts; which is no other than a detail of the different purposes to which men have applied the productions of nature, either to satisfy their wants, or their curiosity.

Having considered the principal object of memory, we shall next proceed to that faculty of man which reflects and reasons.

Both spiritual and material beings, which are the objects of this faculty, having certain general properties, such as existence, possibility, and duration; the examination of these properties immediately forms that branch of philosophy, from which all the rest borrow some part of their principles; and is called ontology, the science of being, or general metaphysics. From ontology, in general, we descend to all the different particular beings; and the divisions, afforded by this science, of particular beings, form themselves on the same plan with the divisions of history.

Our knowledge of God, known by the name of theology, divides itself into two branches, natural and revealed. Natural theology, or the knowledge we have of God, by reason alone, is very confined; but revealed theology derives a more perfect knowledge of him from scripture. Man also owes his knowledge of created spirits to revelation.

The first part of the science of man, is that of the soul; consisting in the speculative knowledge of the soul itself, and of its operations. The speculative knowledge of the soul participates both of natural and revealed theology; and is a branch of metaphysics, called pneumatology. The speculative knowledge of the soul's operations is subdivided into two branches, as its object is either the discovery of truth, or the practice of virtue. The discovery of truth, which is the end of logic, constitutes the art of conveying truth to others: and hence the use we make of logic is partly for our own sakes, and partly for the sake of others. The rules of morality do not chiefly regard man in a solitary state, but suppose him necessarily linked with others in society.

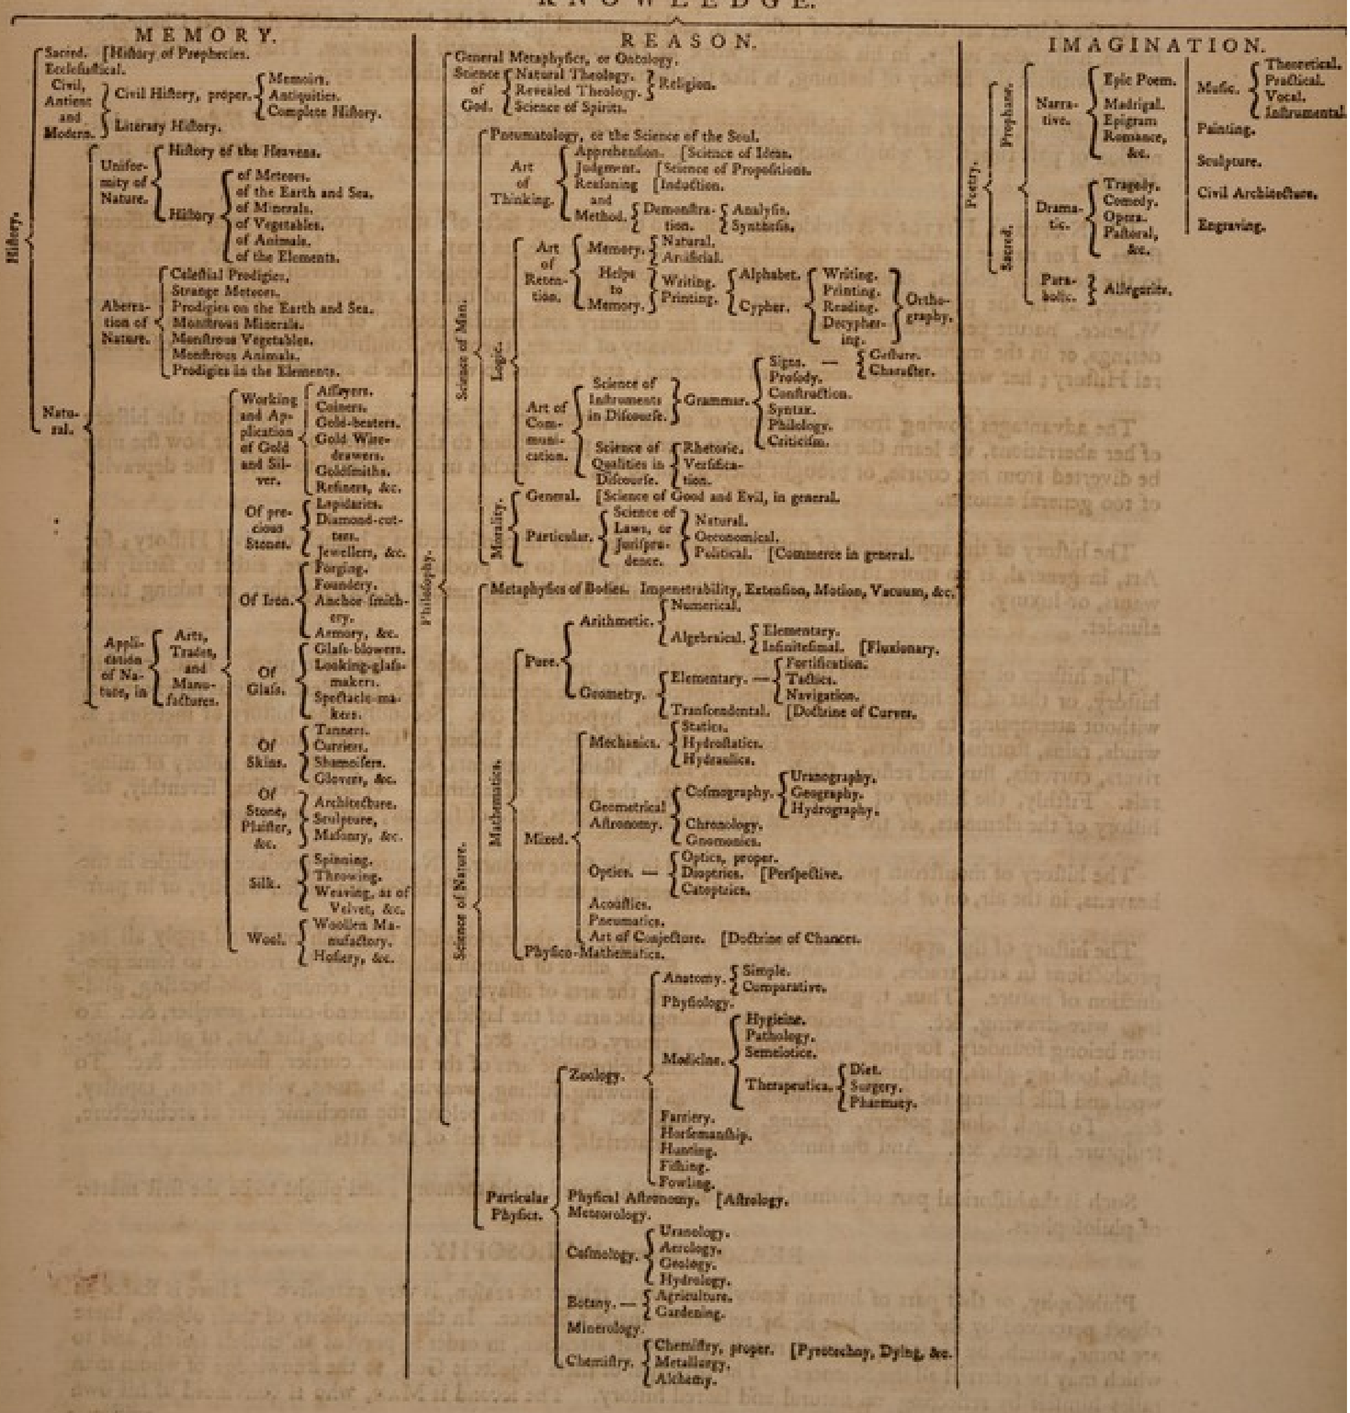
The science of nature is the knowledge of bodies, and their general properties; such as impenetrability, mobility, and extension, which are the first to be studied in natural philosophy. These general properties, being considered abstractedly, open an immense field for speculation; and, when considered materially, they become the objects of mensuration. Pure speculation belongs to general physics, or the metaphysics of body; and mensuration is the object of mathematics, the divisions and applications of which are almost infinite.

These two Sciences lead to particular physics, or natural philosophy, which considers bodies as they are in themselves, and has individuals for its object. Among these the human body is that whose properties we are principally concerned to know; and next after this come such as are necessary to our preservation: whence proceed anatomy, agriculture, medicine, and their different branches. In short, all the natural bodies, subject to our examination, furnish the other numerous branches of natural philosophy.

Painting, sculpture, architecture, poetry, and music, with their several branches, form the third general division, which refers to the imagination, and are all comprehended under the title of polite Arts. They might also be included under the general name of painting; because all the polite Arts are reducible to painting, and differ only in regard to the means they employ. Or, indeed, they might all be referred to poetry, taken, in its natural signification, for invention or creation.

In order farther to elucidate this systematical plan of the Arts and Sciences, we have added the following general view of the several branches of human knowledge.

A SYSTEMATICAL VIEW *of* HUMAN KNOWLEDGE.



Explanation of the preceding Syſtematical View of Human Knowledge.

Phyſical objects act upon the ſenſes; and their impreſſions excite perceptions in the mind. O theſe perceptions the mind employs itſelf three different ways, according to its three principal faculties, memory, reaſon, and imagination. The mind either takes a pure and ſimple review of its perceptions by memory; or it examines, compares, and digeſts them by reaſon; or elſe attempts to imitate or counterfeit them by imagination. And hence ariſes a proper general diſtribution of human knowledge into *Hiſtory*, which relates to memory; *Philoſophy*, which is produced from reaſon; and *Poetry*, which flows from the imagination.

MEMORY, whence proceeds HISTORY.

HISTORY relates facts; and theſe facts either regard God, man, or nature. The facts regarding God belong to ſacred Hiſtory: the facts regarding man belong to civil Hiſtory; and the facts regarding nature belong to natural Hiſtory.

HISTORY. I. SACRED. II. CIVIL. III. NATURAL.

I. SACRED HISTORY is divided into religious, or eccleſiaſtical, and the Hiſtory of prophecies, where the recital precedes the event.

II. CIVIL HISTORY is a branch of univerſal Hiſtory, to whoſe truſt are committed the examples of antiquity, the revolutions of things, the foundations of civil prudence, and the names and reputations of men. This is divided, according to its objects, into what is properly called *Civil Hiſtory*, and *Literary Hiſtory*.

As the ſciences are the produce of reflection, and the natural light of the human ſpecies, the great Chancellor Bacon had reaſon to ſay, in his admirable work *de Dignitate & Augmentis Scientiarum*, That the hiſtory of the world, without the hiſtory of learning, is like the ſtatue of Polypheme, without its eye.

Civil Hiſtory, proper, may be ſubdivided into *Memoirs*, *Antiquities*, and *Complete Hiſtory*. *Civil Hiſtory*, is a deliniation of paſt times, of which antiquities are damaged ſketches; and *Complete Hiſtory* a copy drawn from *Memoirs*.

III. NATURAL HISTORY is divided according to the different facts of nature, proceeding from her different ſtates. For nature is either uniform, and purſues a regular courſe, as may, in general, be obſerved, with regard to the heavenly bodies, animals, vegetables, &c. or appears to be oppoſed, or driven from her ordinary courſe, as in the production of monſters; or elſe conſtrained, and bent to various uſes, as in ſeveral Arts. Whence, nature performs the whole, either in her ordinary and regular courſe, or in her aberrations or wanderings, or in the manner ſhe is employed. Uniformity of nature, therefore, conſtitutes the firſt part of Natural Hiſtory; her wanderings or aberrations the ſecond; and the uſes to which ſhe is applied, the third.

The advantages flowing from the hiſtory of uniform nature are ſufficiently evident; and, from the hiſtory of her aberrations, we learn the tranſition from monſtrous productions to the wonders of Art; or how ſhe may be diverted from her courſe, or brought back again to it; and teaches us particularly to correct the depravity of too general axioms.

The hiſtory of the application of nature to various uſes may be conſidered as a branch of Civil Hiſtory; for Art, in general, is no more than the induſtry of man applied to the productions of nature, either to ſatisfy his wants, or luxury. And this application can only conſiſt in bringing natural bodies together, or taking them aſunder.

The hiſtory of uniform nature is divided, according to its principal objects, into five parts. Firſt, celeſtial hiſtory, or that of the heavenly bodies, their motions, ſenſible appearances, &c. conſidered only as phænomena, without attempting to explain the cauſes by ſyſtems, hypotheſes, &c. Secondly, the hiſtory of meteors; as winds, rains, ſtorms, thunders, auroræ boreales, &c. Thirdly, the hiſtory of the earth and ſea; as mountains, rivers, currents, flux and reflux, ſands, foreſts, lands, iſlands, continents, &c. Fourthly, the hiſtory of minerals. Fifthly, the hiſtory of vegetables. Sixthly, the hiſtory of animals. Whence reſults, ſeventhly, the hiſtory of the elements, or the apparent nature, ſenſible effects, &c. of fire, air, earth, and water.

The hiſtory of monſtrous productions is divided in the ſame manner. Nature may produce prodigies in the heavens, in the air, on or below the ſurface of the earth, at the bottom of the ſea, &c. either wholly, or in part.

The hiſtory of the application of nature is as extenſive as the various uſes to which mankind apply all her productions in arts, trades, and manufactures. Every effect of human induſtry may be referred to ſome production of nature. Thus, to gold and ſilver belong the arts of aſſaying, refining, coining, gold-beating, gilding, wire-drawing, &c. To precious ſtones belong the arts of the lapidary, diamond-cutter, jeweller, &c. To iron belong foundery, forging, anchor-ſmithery, armory, cutlery, &c. To glaſs belong the Art, of glaſs, plate-glaſs, looking-glaſs, poliſhing-glaſs, &c. To ſkins belong the arts of the tanner, currier, ſhamoiſer, &c. To wool and ſilk belong the Arts of ſpinning, milling, throwing, fulling, weaving, buttons, velvet, ſattin, tapiſtry, &c. To earth belong pottery, glazing, porcelain, &c. To ſtones belong the mechanic part of architecture, ſculpture, ſtucco, &c. And the ſame of all other materials, and the reſt of the Arts.

Such is the hiſtorical part of human knowledge, with regard to the memory; and ought to be the firſt matter of philoſophers.

REASON, whence PHILOSOPHY.

Philoſophy, or that part of human knowledge which relates to reaſon, is very extenſive. There is ſcarce an object perceived by the ſenſes, but is, by reflection, made a Science. In the multiplicity of theſe objects, there are ſome, which, by their importance, require particular attention, in order to prevent an endleſs ſearch, and to which may be referred all the Sciences. The principal of theſe objects is GOD, to the knowledge of whom man raiſes himſelf by reflecting on natural and ſacred hiſtory. The ſecond is MAN, who is convinced of his own exiſtence

existence by his conscience, or internal perception. And the third is NATURE, the history whereof we are taught by our external senses. GOD, MAN, and NATURE, will therefore furnish us with a general distribution of *Philosophy*, or *Science* (which are synonymous terms) into *the Science of God*, *the Science of Man*, and *the Science of Nature*.

PHILOSOPHY, or SCIENCE. } I. SCIENCE of GOD. II. SCIENCE of MAN. III. SCIENCE of NATURE.

I. The natural progress of the mind is to rise from individuals to species, from species to genera, from lower genera to higher, and at every step to form a Science; or, at least, to add a new branch to a Science already formed. Thus, our idea of an infinite, uncreated intelligence, recounted in nature, and revealed in sacred history; and that of a created, finite intelligence, as we find in man, lead us to the idea of a finite, created intelligence without body, whence we derive our general notion of spirit. And as the general properties of both spiritual and corporeal things are existence, possibility, duration, substance, attribute, &c. the examination of these properties produces ontology, or the Science of beings in general. And, by inverting the order, we have first the Science of ontology, and next the Science of spirit, or pneumatology, commonly called particular metaphysics; which Science is divided into the Science of God, or natural theology, which he has been pleased to rectify and sanctify by revelation; whence proceeds religion, or theology proper. Hence flows the doctrine of good and evil spirits, or angels and dæmons; whence divination, and that chimerical Art, called necromancy. Hence also proceeds the Science of the soul; which is divided into the Science of the rational soul, which thinks; and the Science of the sensitive soul, which is confined to sensations.

II. *The* SCIENCE *of Man.* The distribution of the Science of man is derived from his faculties, which are the understanding and the will; the former should be directed to truth, and the latter to virtue. The one is the end of logic, and the other that of morality.

Logic may be divided into the Art of thinking, the Art of retention, and the Art of communication.

The Art of thinking has as many parts as the mind has principal operations. We distinguish four principal operations in the mind, viz. apprehension, judgment, reasoning, and method. To apprehension belongs the doctrine of ideas, or perceptions: to judgment, the doctrine of propositions: to reasoning and method, the doctrine of induction and demonstration. But demonstration either ascends from the proposition to first principles; or descends from first principles to the proposition in proof; whence arise analysis and synthesis.

The Art of retention has two branches; the Science of the memory itself, and the Science of the helps to memory. The memory, before considered as a faculty purely passive, is now considered as an active power, improved by reason; and is either natural or artificial. Natural memory depends upon the organs. Artificial memory consists in prænotion and emblem. Without prænotion no particular object can be present to the mind; and emblem employs the imagination to assist the memory.

Artificial representations, as writing, &c. are helps to memory. In writing we use either common, or particular characters: of the first sort are the letters of the alphabet, and of the second are cyphers; whence proceed the Arts of reading, writing, decyphering, and the Science of orthography.

The Art of communication is divided into the Science of the instrument, and the Science of the qualities of discourse. The Science of the instrument of discourse is called grammar; the Science of the qualities of discourse is rhetoric.

Grammar is divided into the Science of signs, pronunciation, syntax, and construction. These signs are articulate sounds; pronunciation, or prosody, is the Art of articulating them: syntax is the Art of applying them, according to the different designs of the mind; and construction is the knowledge of the order they should have in discourse, founded upon custom and reflection. But there are other signs of our thoughts besides articulate sounds, viz. characters and gestures. Characters are either ideal, hieroglypic, or heraldic. Ideal characters are like those of the Indians, each of which denotes a particular idea; and must consequently be as numerous as the real beings they denote. Hieroglyphics were the writing of the world in its infancy: and heraldic characters from the Science of blazoning.

To this Art of communication belong criticism, pædagogy, and philology. Criticism restores corrupt readings, publishes authors, &c. Pædagogy treats of the choice of studies and the manner of teaching. Philology regards the knowledge of universal literature.

To the Art of embellishing discourse belongs versification, or the mechanical part of poetry. We omit the division of rhetoric, because no Art or Science is derived from it, except perhaps the pantomimic Art, from gesture, and declamation from the voice and gesture together.

Morality, which makes the second part of the Science of man, is either general or particular. Particular morality is divided into the law of nature, œconomics, and politics.

The law of nature is the Science of the duties of man, out of society. Œconomics is the Science of man's duties in a family. Politics is the Science of man's duties in society. But morality would be incomplete, unless preceded by the doctrine of the reality of moral good and evil; the necessity of discharging the duties of a good, just, and virtuous man, &c. which is the object of morality, in general.

As societies are under the same obligation of being virtuous, as particular persons; this leads to the duties of societies, or the natural law of society; the œconomies of societies; foreign and domestic commerce, by sea and land; and the doctrine of civil policy relative to each society.

The Science of nature is divided into natural philosophy and mathematics. This division naturally arises from reflection, and man's disposition to form general ideas. From our senses we receive the knowledge of real individuals, the sun, the moon, Sirius, &c.— Air, fire, earth, water, &c.—Rain, snow, hail, thunder, &c. and so of all natural history. At the same time we acquire the knowledge of abstract ideas; as colour, sound, found, taste, odour, density, rarity, heat, cold, soft, hard, fluidity, solidity, rigidity, elasticity, gravity, levity, &c. figure, distance, motion, rest, duration, extension, quantity, impenetrability.

We find by reflection, that some of these abstract ideas, as extension, motion, impenetrability, &c. correspond to all corporeal individuals, which are the object of general physics, or the metaphysics of bodies; and the same properties considered in any particular individual, together with the varieties that distinguish one individual from another, such as firmness, elasticity, fluidity, &c. are the object of particular physics. Another more general property of body, which supposes all the rest, viz. quantity, constitutes the object of mathematics. By quantity, or magnitude, we mean every thing capable of augmentation or diminution. Quantity, as the object of mathematics, may be considered, 1st, either alone, and independent both of the real and abstract individuals we know; or, 2dly, as existing in real and abstract individuals; or, 3dly, in effects fought for from real or supposed causes: and, in this view, reflection divides mathematics into pure, mixed, and physical.

Abstract quantity, the object of pure mathematics, is measured by number, or extension. Abstract quantity, measured by number, is the object of arithmetic; and abstract quantity, as extended, is the object of geometry. Arithmetic is divided into numeral, performed by figures; and algebra, or universal arithmetic, performed by letters; which is only the calculation of magnitudes, in general; its operations being no more than arithmetical operations, performed in a concise manner: for, properly speaking, there is no calculation but in numbers.

Algebra is either elementary or infinitesimal, according to the nature of the quantities to which it is applied. Infinitesimal or fluxionary algebra is either direct or inverse: direct when we descend from the expression of a finite quantity, or of a quantity considered as finite, to its instantaneous increment or decrement; and inverse when we ascend from this expression to that of the finite quantity.

Geometry has, for its primitive object, either the properties of right-lines, and the circle; or comprehends all the species of curves: and therefore is divided into elementary and transcendental.

Mixed mathematics has as many divisions and subdivisions as there are real beings, wherein quantity may be considered. Quantity, considered in bodies as moveable, or tending to motion, is the object of mechanics.

Mechanics has two branches, statics and projectiles. The object of statics is quantity considered in bodies that are in æquilibrio, and have only a tendency to motion; and the object of projectiles is quantity considered in bodies actually moving. Statics and projectiles are each divided into two parts. The former into statics proper and hydrostatics: statics has for its object solid bodies in æquilibrio, barely tending to motion: the object of hydrostatics is quantity considered in equipollent fluids tending to motion. The latter is divided into projectiles proper, which has for its object quantity considered in solid bodies, actually in motion; and hydraulics, whose object is quantity considered in fluids actually in motion. When quantity is considered in water actually in motion, hydraulics is sometimes called hydrodynamics. Navigation might be referred to hydraulics; and gunnery or the throwing of bombs to mechanics.

Quantity, considered in the motion of the heavenly bodies produces geometrical astronomy; whence arises cosmography or the description of the universe; which is divided into uranography, or the description of the heavens; hydrography, or the description of waters; and geography, or the description of the earth: from whence also proceed chronology and gnomonics, or the Art of dialling.

Quantity, considered in light, produces optics; and considered in the motion of light it produces the different branches of optics. Light, moving in straight lines, gives optics, proper; light, reflected in one and the same medium, gives catoptrics; and, as refracted in passing from one medium into another, it affords dioptrics. Perspective is a branch of optics.

Quantity, considered in the air, as to its gravity, motion, condensation, rarefaction, &c. produces pneumatics.

Quantity, considered in the possibility of events, gives the Art of conjecturing; whence the analysis of the games of chance.

The object of the mathematical Sciences being purely intellectual, we need not be surprised at the exactness of their divisions.

Particular physics should have the same distribution as natural history. From histories acquired by the senses, of the stars, their motion, sensible appearances, &c. reflection proceeds to enquire into their origin, the causes of their phænomena, &c. and thus produces the Science of physical astronomy; under which we also rank the Science of their influences, called astrology. From histories, given by the senses, of winds, rain, hail, thunder, &c. reflection proceeds to enquire into their origin, causes, effects, &c. and produces the Science called meteorology.

From natural histories of the earth, the sea, mountains, rivers, flux, reflux, &c. reflection enquires into their origins, causes, &c. and produces cosmology, or the Science of the universe; which is divided into uranology, or the Science of the heavens; aerology, or the Science of the air; geology, or the Science of continents; and hydrology, or the Science of waters.

From the natural history of mines, reason enquires into their formation, the ways of working them, &c. and thus proceeds minerology.

From the natural history of plants, reason enquires into their structure, propagation, culture, vegetation, &c. and thus produces botany, of which agriculture and gardening are two branches.

From the natural history of animals, reason enquires into the means of their preservation and propagation, their organisation, use, &c. and thus produces zoology: whence are derived physic, farriery, the manage, hunting, fishing, falconry, simple and comparative anatomy. Physic, according to the division of Boerhaave, is either employed upon the œconomy of the human body, and reaſoning upon the anatomy thereof; whence proceeds phyſiology; or upon the means of preventing diſeaſes; whence hygieine; or upon morbid bodies, and treats of the cauſes, differences, and ſymptoms of diſeaſes, their nature and effects, under the name of ſemeiotics; or upon the Art of curing diſeaſes, ſubdivided into diet, pharmacy, and chirurgery; which are the three branches of therapeutics.

Hygieine may be conſidered as relative to the health, beauty, and ſtrength of the body; and accordingly is ſubdivided into hygieine proper, coſmetics, and athletics. Coſmetics produces orthopœia, or the Art of procuring a juſt conformation of the limbs; and athletics produces gymnaſtics, or the Arts of exerciſe.

From an experimental hiſtory of the external, ſenſible, and apparent qualities, &c. of natural bodies, reflection riſes to an artificial examination of their internal and occult properties, by means of chemiſtry; which is an Art that imitates and rivals nature: its object being nearly as extenſive as nature itſelf. This Art either analyſes bodies, recompounds them, or transforms them. Chemiſtry gives riſe to alchemy, and natural magic. Metallurgy, or the Art of working metals for human uſes, is an important branch of chemiſtry. Whence alſo proceeds the Art of dying.

Nature has her errors, and reaſon its abuſes. We conſider monſters as errors or wanderings of nature; and the abuſe of reaſon produces thoſe Arts and Sciences, which only manifeſt avidity, malice, or ſuperſtition; and tend only to diſgrace the human ſpecies.

And this is the whole of philoſophy, or the grand branch of human knowledge belonging to reaſon.

IMAGINATION; *whence proceeds* POETRY.

Hiſtory has for its object ſuch individuals as actually exiſt, or have exiſted; and poetry only imaginary individuals, which the mind creates in imitation of the hiſtorical. No wonder therefore if poetry falls under one of the diviſions of hiſtory. But the different kinds of poetry, and the difference of its ſubjects, preſent us two very natural diſtributions. The ſubject of a poem is either ſacred or prophane. The poet therefore relates things paſt, or makes them appear as preſent, by repreſenting them in action; or elſe gives bodies to mere abſtract intellectual beings. The firſt kind is narrative, the ſecond dramatic, and the third parabolic poetry. Epic madrigal, epigram, &c. are generally of the narrative; tragedy, comedy, opera, eclogue, &c. of the dramatic; and allegory, &c. of the parabolic kind.

POETRY. I. Narrative. II. Dramatic. III. Parabolic.

We here underſtand, by poetry, fiction only. As there may be verſification without poetry, and poetry without verſification; we conſider verſification as a quality of ſtyle, and refer it to rhetoric. On the other hand, under poetry we rank architecture, muſic, painting, ſculpture, engraving, &c. for a painter may as juſtly be called a poet, as a poet be called a painter. A ſculptor, or engraver, is a painter in relievo or in creux; as a muſician is a painter in ſounds. The poet, the painter, the ſculptor, the muſician, &c. imitate or counterfeit nature; but the poet employs diſcourſe, the painter colours, the ſculptor, marble, braſs, &c. and the muſician his inſtrument, or his voice. Muſic is either theoretical, practical, inſtrumental, or vocal. Architecture imitates nature but imperfectly in the ſymmetry of its productions, as we have already obſerved.

Poetry has, as well as nature, its monſtrous productions, flowing from a diſordered imagination; and, in all the ſpecies of poetry, ſuch productions may happen.

This is the whole poetical branch of human knowledge, flowing from the imagination; and finiſhes our ſyſtematical view, or genealogical table of the Arts and Sciences.

Thus have we endeavoured to ſhew how the various branches of human knowledge form one regular ſyſtem; nothing therefore remains but to ſay ſomething of the enſuing work, that the reader may form an idea of its utility; and the manner we have purſued in its execution.

We have, in the firſt place, carefully connected the Supplement with the Dictionary, in order to render them both as one work; and thoſe articles which have the ſyllable *Dict.* annexed to it are additions to thoſe under the ſame word in the Dictionary; ſo that what is ſaid on that head in the Dictionary ought firſt to be conſulted.

As it has been our principal view to render this work uſeful to the reader, thoſe branches of learning, which are of more immediate uſe in life, are more largely treated of than thoſe of mere curioſity. Particularly agriculture, gardening, chemiſtry, dying, and the reſt of the mechanic Arts are fully conſidered.

And, as little help in the mechanic Arts could be acquired from books, we were obliged to have recourſe to workmen themſelves, obſerve them at their work, learn their various terms, and clear up and methodiſe what they delivered; and as many of them were unable to explain, in an intelligent manner, the machines they employed in their various Arts, we were obliged alſo to take their machines to pieces, in order to explain their conſtruction, and ſhew the uſes they are applied to.

Every perſon muſt be ſenſible that an attempt of this kind could not be executed without the aſſiſtance of copper-plates; and accordingly the reader will find in the Dictionary and Supplement *One Hundred* and *Seven* folio plates, engraved by the beſt hands. And ſeveral of thoſe relating to mechanic Arts are actually perſpective views of places where their reſpective works were carried on, and the men are repreſented in their proper attitudes, as they perform the various operations. By this method a mechanic Art, which it would be almoſt impoſſible to convey an adequate idea of by words, is eaſily apprehended.

But as there are objects ſo familiar that it would be ridiculous to give drawings of them; and, on the other hand, ſome of the mechanic Arts have machines ſo complicated, that no figures could uſefully repreſent them; we have therefore, in the firſt caſe, truſted to the reader's underſtanding and experience, and in the laſt referred to the objects themſelves. In ſhort, we have endeavoured to obſerve a proper medium, and repreſent that only which was neceſſary, and, at the ſame time, could be uſefully conveyed by figures. To treat any one Art at full length, and give it all the possible plates, would alone require numerous volumes. It would, for instance, be unnecessary to represent in plates the several stages a piece of iron passes through before it is formed into an anchor. The whole process indeed must be described; but we have represented in our figures only the most momentous actions, or address of the artists, which are easy to draw, but very difficult to explain by words. We have, in short, chiefly confined our plates to essential circumstances; which, when once well represented, necessarily shew the rest.

The various branches of natural history are carefully attended to, and those of the greatest use largely treated of; and, in order to convey an idea of the most curious and useful plants, animals, &c. we have represented them in their proper colours on eleven copper-plates; a circumstance not to be found in any other Dictionary of this kind.

With regard to the Sciences and liberal Arts, the method we have pursued in their execution has been mentioned in our Preface to the Dictionary, and therefore need not be repeated here; all that seems necessary to be added is, that those articles which were either omitted or defective are here supplied or completed, and all the discoveries since made in these various branches of literature inserted.

To conclude, neither care, nor expence, has been wanting in our attempts to render this work a complete body of Arts and Sciences; and we shall always enjoy the internal satisfaction of having spared no pains to succeed. But, in surveying so extensive and intricate a labyrinth, who can flatter themselves with having accurately described and delineated the whole? The best performances, even on a single Science, have their errors and defects. The great number of both which we have corrected and supplied in our extracts, has sufficiently convinced us of this; and doubtless several have escaped our circumspection. Nor can we flatter ourselves that those articles, additions, and observations of our own, interspersed through the whole work, are entirely free from errors; but we dare say there are no fundamental ones; and, with regard to others, we hope for the candour and indulgence of the reader.

A List of the Cuts in the Supplement, with Directions to the Binder, for placing them in the Book.

SUPPLEMENT

TO THE

NEW and UNIVERSAL DICTIONARY

OF

ARTS and SCIENCES.

A symbolic letter, was used as an hieroglyphic by the ancient Egyptians, who, for their first characters, made use either of the figures of animals, or signs that denoted some of their properties: The Ibis is supposed to have been represented by an A, on account of the analogy between its triangular shape and the gait of that bird. Also, when the Phœnician characters, attributed to Cadmus, were adopted in Egypt, the letter A was a character of the symbolic writing consecrated to religion, at the same time that it was used in the common writing for transacting the business of life.

A, among modern writers, is commonly used for anno, as A. D. anno Domini, in the year of our Lord; in England, A. M. stands for artium magister, master of arts.

A, in the Julian calendar, is also the first of the seven dominical letters.

The Romans made use of it long before the time of our Saviour, as the first of the eight nundinales literæ, in imitation whereof it was that the first dominical letters were introduced.

A B, the eleventh month of the civil year of the Hebrews, and the fifth of their ecclesiastical year, which began in the month Nisan. The month Ab answers to the moon in July and the beginning of August, and consists of thirty days. The Jews observe the first day of this month as a fast, on account of Aaron's death, as they likewise do the ninth, for several reasons; first, because both the temple of Solomon, and the second temple built after the captivity, were burnt on that day, the first by the Chaldeans, and the second by the Romans; secondly, from a belief that the spies which were sent into the land of Canaan, after their return, engaged the people in rebellion on this day; and thirdly, in commemoration of the Emperor Adrian's edict, whereby they were prohibited from staying any longer in Judea; wherefore, they on this day always turn their faces towards Jerusalem, and bemoan its fate.

A'BACUS, in accounts and calculations, among the ancients, was a long square, divided by several parallel brass strings, on each of which was strung an equal quantity of small, moveable, wooden or ivory balls, like a pair of beads, by the disposition whereof, and according to the relation which the lower had to the upper ones, they divided the numbers into several classes, and thereby performed all sorts of calculations. This arithmetical table, which was used by the Greeks, was not unknown to the Romans: We find it described by Fulvius Ursinus and Ciaconius, from some antique monuments; but, as some difficulty attended the use of it, they preferred the method of reckoning by counters. In China, and some parts of Asia, the merchants still compute by the help of a set of balls, made either of ebony or ivory, threaded upon brass wire, which they tie to their girdle, and carry about with them.

ABACUS *Logisticus*, a name given by some mathematicians to a rectangled triangle, whose sides, forming the right-angle, contain the numbers from one to sixty; and its area, the product of each two of the numbers perpendicularly opposite. It is also known by the name of a canon of sexagessimals.

A'BAS, a weight used in Persia for weighing pearls. It is an eighth part lighter than the European carat.

A'BASSI, a silver coin in Persia, in figure and size very much like the antient pieces of fifteen sols in France. The Abassi takes its name from Shah-Abas the Second, king of Persia, who ordered the coinage of it. It has on one side, for legend, the profession of the Mahometan faith, There is no God but God, and Mahomet is his prophet; and on the other the king's name, and that of the city where it was coined.

This coin, which has a great currency in Persia, is worth two mammoudis or four chayes; the chaye being estimated at the rate of nine sols six deniers of French money, makes the Abassi worth thirty-eight sols, or seventeen sols of Holland.

ABE'LLIO, or ABELLION, the name of a heathen deity, supposed to be the God of the air; two altars have been discovered, one in Italy, and the other near Nantz in France, inscribed to this God; he was particularly worshipped by the ancient Gauls and Britons, the latter of whom called him diw. Awelion. G. Vossius is mistaken, in supposing him to have been the same with Belinus, or the Apollo of the ancient Gauls, as is Bouchier in asserting, that he had his name from that of the place in which he first was worshipped.

ABE'LMOCH. See MUSK-SEED.

A'BIB, a name given by the Hebrews to their first month of the holy year; it was afterwards called Nisan, and answered to our March. Abib, in the Hebrew, signifies green ears of corn, or fresh fruits, according to St. Jerom's translation, mense novarum frugum. Exod xiii. 4.

ABLACTA'TION *(Dict.)* — As nature has taken care to provide an aliment suitable to the tender stomachs of new-born infants, so has it given us plain directions when to change it for a diet that is more solid and difficult of digestion.

It is well known to observers of nature, that exercise and motion are the grand promoters of digestion, insomuch that a labourer of a moderate strength and constitution shall digest aliment of any kind without difficulty; whereas sedentary people, though much more robust originally, shall in time scarcely be able to sustain a diet of the most innocent food without the symptoms of indigestion. Digestion then seems to be, cæteris paribus, in proportion to motion.

Whilst, therefore, a child is incapable of sufficient exercise and motion to digest solid food, a thin fluid is provided for his sustenance, which is almost converted into nourishment, before it is taken into the stomach of the infant. And, for fear the mother should be so imprudent as to offer it improper aliment, providence seems to have secured the tender stomach, in some degree, from the mischiefs of indigestion, by a singular artifice, that is, by denying the child the use of teeth for the first months.

From these observations it will appear, that a child ought not to be weaned, till nature points out the proper time, by giving it teeth, and making it capable of motion sufficient to comminute, and afterwards to digest an aliment more solid, and more difficult to dissolve, than the milk of its mother.

But, because an infant is furnished by degrees with the instruments of mastication, and the power of using exercise, the transition from milk to solid food should not be sudden.

Agreeable to this are the directions given by authors for the nourishment of young children. They tell us the milk of the parent should be the only food of children, for the first two or three months, provided a sufficient quantity can be supplied without inconvenience; that afterwards pap, panada, and bread boiled with milk, must prudently and gradually be introduced into their diet, till their abilities for mastication and motion render them capable of digesting more solid aliment, and at last flesh.

Hence, it appears, how little those mothers consult the health of their children, who wantonly, and without any necessity, take them from the breast soon after they are born, and substitute a diet not to be digested in their tender stomachs, in the room of that which nature has provided for them, and accommodated to their constitutions.

A very few observations on the usual food of infants will set this in a clearer light.

The milk of a healthy woman, in the flower of her age, is the most easily digestable of any aliment whatever, provided she uses moderate exercise, and a proper diet; and, for that reason, is the greatest restorative in nature. Many instances occur in authors, of grown people, reduced by distempers to the utmost degree of weakness, who have been restored by sucking the milk of women provided for that purpose.

The salutary effects of milk are very easy to be accounted for, if we consider the stomach as the laboratory of health, and milk as a fluid, either secreted from the mass of blood in the glands of the breast, or else communicated immediately to the breast from the receptacle of the chyle, by some ducts not yet discovered. When this is taken warm as it comes from the breast, it gives the stomach very little trouble to digest it, having lately passed the digestive organs of the woman. It is therefore easily convertible again into chyle, from which it differs but very little.

But I must not omit observing, that milk, like all animal fluids, loses most of its virtues when it has been suffered to grow cold; and this irretrievably; for warming it again will not restore them. But, if milk is boiled, the qualities that rendered it an eligible food, are utterly destroyed, and from that moment it becomes an improper aliment for weak and tender stomachs.

Bread boiled in water is a food for children frequently substituted for milk, but is not by far so proper; for bread, thus boiled, will grow glutinous and viscid, if not well fermented, but, if well fermented, it soon turns sour. In both these cases a considerable action of the stomach is required to convert it into chyle; for, otherwise, violent gripings, difficulty of breathing, inflammations of the belly, convulsions, and death, must be the consequence.

It is not possible to lay down rules for the weaning children, adapted to every case that may occur. Regard is to be had to the strength and health of the mother, as well as of the child. Upon the whole we are to pursue the method which nature seems to point out, unless some circumstances interfere, which make it impracticable. Rules may be drawn from what has been represented above, which may, with a little variation, be accommodated to particular cases. *James.*

ABLE'GMINA, in antiquity, were first-fruits, or the choicest and principal parts of victims offered to the Gods; they were first sprinkled with wheat and flour, and then put in little baskets by the persons offering sacrifice, after which, being placed on the altar, and wine poured on them, they were burnt. They were likewise called prosecta, prosiciæ, and magmenta.

ABORI'GINES, *(Dict.)* —The term Aborigines is famous in antiquity. Though at present taken as an appellative, it was originally a proper name of a certain people of Italy, the etymology whereof is greatly disputed among the learned. Aborigines then denoted a nation in Italy, which inhabited the ancient Latium, or country now called Romania or Campagna di Roma. In which sense the Aborigines are distinguished from the Janigenæ, who, according to the false Berosus, were settled in the country before them; from the Siculi, whom they expelled; from the Grecians, whom they descended from; from the Latins, whose name they assumed after their union with Æneas and the Trojans; and lastly from the Ausonii, Volsci, Oenotrii, &c. neighbouring nations in other parts of the country. Whence this people came by the appellation, whether, first, as belonging to any of the species of Aborigines above recited; or, secondly, from their having been Aborigines, i. e. wanderers; or, thirdly, from their inhabiting the mountains, or on what other account, is much disputed.

St. Jerom says, they were so called as being absque origine, the primitive inhabitants of the country after the flood. Dion. Halicarnasseus says, that the name signifies the founders and first fathers of the inhabitants of that country; others think them so called, as being originally Arcadians, who claimed to be earth-born, and not descended from any people.

Aurelius Victor, and after him Festus, derive Aborigines by corruption from Aberrigines, wanderers, or vagabonds, and pretend that the Pelasgians, another name sometimes given them, is of the same import, and denotes vagabonds. Pausanias rather thinks they were thus called, ἀπὸ ὀρέων, from the mountains which they inhabited; which opinion seems confirmed by Virgil, who, speaking of Saturn, the legislator of his people, says,

> *Is genus indocile, ac dispersum montibus altis*
> *Composuit, legesque dedit.*

The Aborigines were either the original inhabitants of the country, settled there by Janus, as some imagine, or by Saturn or Cham, as others, not long after the dispersion, or even, as some think, before it; or they were a colony sent from some other nation, who, expelling the ancient inhabitants the Siculi, settled in their place. About this mother nation there is great dispute: Some maintain it to be the Arcadians, parties of whom were brought into Italy at different times; the first under the conduct of Oenotrius, son of Lycaon, four hundred and fifty-five years before the Trojan war; and others under the conduct of Hercules: Some derive this colony from the Lacedæmonians, who fled from the severe discipline of Lycurgus. All these, uniting, are said to have formed the kingdom or nation of the Aborigines. Others will have them of Barbarian, rather than Grecian origin, and to have come from Scythia, others from Gaul, and lastly, others will have them to be Canaanites, who were expelled out of their country by Joshua.

ABO'RTION, *(Dict.)* — Astringent medicines and applications, and an astringent regimen, as they prevent hæmorrhages in general from the uterus, are particularly recommended for that reason, as preservatives against Abortion.

For this reason, all those medicines that are found effectual in moderating a profuse flux of the menses, are also serviceable in this case.

For this purpose tincture of roses is frequently prescribed, and Sydenham directs the following electuary:

Take conserve of dried roses two ounces. Troches of Lem-nian earth, a drachm and half. Pomegranate peel and red coral, of each two fcruples. Blood-ftone, dragon's blood, and Armenian bole, each a fcruple. Syrup of coral, a fufficient quantity to make an electuary.

Let the patient take the quantity of a large nutmeg in the morning, and at five in the afternoon, drinking after it fix fpoonfuls of the following julap. Take of the fimple water of oak-buds and plantain, each three ounces. Of barley, cinnamon-water, and fyrup of red rofes, each an ounce. Spirit of vitriol enough to make it agreeably acid.

Reftringent plaifters are ordered to be applied to the region of the loins by Sydenham, made of equal parts of diapalma and the rupture-plaifter. Others direct the fame, with an addition of the red-lead plaifter, or plaifters of other reftringent ingredients, as dragon's blood, Armenian bole, maftic, galls, biftort-root, and red coral, made up, with Cyprus turpentine, into the confiftence of plaifter.

It would be endlefs to give forms of medicines, frequently prejudicial, becaufe they are capable of being mifapplied, unlefs particular regard is had to the caufes of the diforder they are intended to remove, to which they muft be adapted, as circumftances fhall direct. The reader will be more inftructed by the following cautions.

1. Let nothing reftringent be either given internally, or applied, when an approaching mifcarriage is fo far advanced as to make the preventing it improbable, or impoffible; for whatever then retards it is pernicious. Reftringents then are particularly prejudicial, as they oppofe the relaxation of the internal 'office of the uterus, at this time fo neceffary to the expulfion of the fœtus and fecundines.

2. When there is reafon to believe the fœtus is dead, let no aftringents of any kind be made ufe of, becaufe whatever then prevents a mifcarriage does harm.

3. When a tenfion and ftricture of the uterus make it incapable of a fufficient dilatation, and thereby endanger a mifcarriage, aftringents are improper, as they increafe the tenfion, and confequently the danger. I am fenfible fome authors are of opinion, that aftringents are fometimes neceffary, even in the cafes laft mentioned, to moderate a violent flux of blood. But they cannot anfwer the end propofed, fo long as the fœtus, placenta, or any part of it, or the clotted blood, keep the uterus diftended, and the blood-veffels thereof open; and, when thefe are brought away, they are generally fuperfluous, becaufe the hæmorrhage ufually ceafes without any further affiftance, unlefs a laceration of the uterus, or fome extraordinary accident, render both a prudent regimen and medicines neceffary.

The precautions that are taken againft a mifcarriage, during the time of pregnancy, are feldom fo effectual as thofe which are taken in the interval betwixt a mifcarriage and the next impregnation. Thefe confift in reftoring to the woman a perfect ftate of health in general, particular regard being had to the diforders of the uterus.

If, from the fymptoms of great pain, tenfion, and hardnefs about the region of the uterus it is too tenfe to admit of fufficient dilatation, the general habit of body muft be relaxed, or the fibres of the uterus may be foftened by emollient fomentations, cataplafms, injections, or peffaries. *Jame's Dict.*

ABRA'SA, in furgery, ulcers attended with abrafion of part of the fubftance; or ulcers where the fkin is fo tender and lax as to be fubject to abrafion.

ABRI'DGEMENT, epitome, fummary, fubftance, &c. An Abridgement is a difcourfe, in which we reduce to fewer words the fubftance of what is elfewhere treated of more at large, and more circumftantially.

Abridgement, in the common law, fignifies, particularly, the making a declaration or account fhorter, by fevering fome of the fubftance from it. A man is faid to abridge his plaint in affize, and a woman her demand in an action of dower, where any land is put into the plaint or demand, which is not in the tenure of the defendant: For, if the defendant pleads non-tenure, joint tenancy, &c. in abatement of the writ, the plaintiff may leave out thofe lands, and pray that the tenant may anfwer to the reft. The reafon of this Abridgement of the plaint is, becaufe the certainty is not fet down in fuch writs, but the run in general; and, though the demandant hath abridged his plaint in part, yet the writ will be good for the remainder.

ABRI'DGING, in algebra, implies a method of reducing a compound equation to a more fimple expreffion. When there are feveral known quantities in the fame term, mathematicians generally exprefs them by a fingle letter. Thus in the equation $x^3 - axx + abx - abc = o$; by putting $n = a$, $p = ab$, and $q = abc$, we fhall have $x^3 - nxx - px - q = o$, inftead of the propofed equation. This abridged equation is called a formula.

ABROTONI'TES, a wine mentioned by Diofcorides impregnated with abrotanum or fouthernwood, in this manner:

Take of fouthernwood bruifed and fifted a hundred ounces, (an ounce is eighteen penny-weights five grains $\frac{1}{4}$ troy) inclofe it in a linnen bag, and put it into a veffel containing about feven gallons of muft. It is good in diforders of the ftomach, lofs of appetite, and in a jaundice, for it is diuretic. Diofcorides. l. 5. c. 62.

ABROTA'NUM. — There are two very different plants defcribed by botanical writers under the fame general name of Abrotanum, and diftinguifhed by the addition of mas and fœmina. The male Abrotanum is the plant we call fouthernwood, and the female is what we call lavender cotton.

Southernwood, or *male Abrotanum*, is one of the *fyngenefia polygamia fuperflua* of Linnæus, and one of the *herbæ corymbiferæ floribus non radiatis* of Ray. It is defcribed by all the botanical writers under the name of Abrotanum vulgare, Abrotanum mas, and Abrotanum anguftifolium majus. It grows to four or five feet high, and is a fhrubby and ftrong plant. Its ftalks are hard and woody, but not tough; they are of a reddifh colour, and lightly ftriated on the furface, and have a hollow filled with a whitifh medullary fubftance within. The leaves are very numerous; they are of a whitifh green colour, very finely divided into fegments, and of a ftrong, and to fome people very difagreeable fmell; though there are others who are fond of it.

Their tafte is acrid and bitter; the flowers ftand thick together, about the tops of the branches, and are of a yellowifh colour, and much like thofe of the common wormwood, but fmaller; they are compofed of a number of fmall and hollow flofcules, which are divided into five fegments at the end. Thefe are all contained in one common cup, and each of them ftands on an embryo feed, which afterwards ripens and is oblong, and like the feed of wormwood, but fmaller, and has no downy matter annexed to it. In the whole it greatly approaches to the nature of the wormwood kind, in all things but its external appearance. It grows in great abundance on the Pyrenean mountains, and on moft of the mountains of France and Italy. With us it is not found wild, but is cultivated in the gardens about London for its fmell, and to fupply the fhops.

A pound of frefh tops of fouthernwood, diftilled by the retort, yields firft about two ounces and a half of a limpid phlegm, of the fmell and tafte of the plant; after this about ten ounces of a ftronger-fcented liquor, of an acid, and with it of fomewhat of the volatile alkaline tafte; after this, about half an ounce of a brownifh liquor, of an empyreumatic fmell, and of a ftrongly volatile alkaline tafte, but with fomewhat alfo of the acid yet in it; after this comes over about half an ounce of an oil partly fluid, and partly thick as butter. The remainder in the retort, calcined in an open fire and lixiviated, yields two drachms of a fixed alkaline falt.

The ftrong fmell and tafte of fouthernwood, as well as the active principles it is refolved into by analyfis, plainly fhew that it is a powerful medicine; and it has been very juftly lamented by Etmuller, that it is not brought more into ufe. It is evidently of the tribe of attenuants, and would be ferviceable in all obftructions of the vifcera. It deftroys worms by its bitter effential oil, and at the fame time acting as an attenuant on the foul vicious matter in the bowels, without which worms cannot live or breed there, it prevents a return of the complaint.

It is recommended by fome in fuppreffions of urine, a drachm of it in powder for a dofe. But S. Pauli, who recommends it moft ftrenuoufly on this occafion, orders fome nitre to be added to it, and perhaps the effects that he found from that compound powder, were as much owing to the nitre, as to the plant. A decoction of it is in repute with fome as a lotion for the recovering hair upon the head when fallen off; and others recommend its juice as a great cleanfer and healer of old ulcers. We fometimes meet with a diftilled water of it in the fhops; but few make it, and fewer ufe it when made. It poffeffes but a fmall fhare of the virtues of the plant; an infufion in water, or a conferve made of the young tops in fpring, feems much better calculated to anfwer the purpofes intended by it.

Lavender cotton, or the *female Abrotanum*, is a plant of the fame clafs with the former, but is extreamly different from it in its manner of growth and general external figure. It is defcribed by the botanical writers under the name of *fantolina*, *chamæcypariffus*, and *Abrotanum fœmina*. Tournefort calls it *fantolina foliis teretibus*, and C. Bauhine, *Abrotanum fœmina foliis teretibus*.

It grows in form of a thick and low bufh; its main ftalks are woody and hard; they grow to two or three feet high, and are divided into a number of flender branches which are whitifh or hoary. The leaves are about an inch long, very thick and narrow; they are minutely ferrated round the edges, or, more properly fpeaking, they are befet in all parts with rows of little tubercles, four in a feries. They are more white and hoary than the ftalks, and have a very ftrong and fragrant fmell, and are of an acrid and bitter tafte. At the extremity of every branch there ftands a fingle flower, moderately large and of the flofculous kind, or compofed of a number of little tubular flofcules, cut into five fegments at the edges, and feparated by feveral imbricated leaves. They are of a bright yellow colour, and when in their perfection, and a great number open upon the plant at once, they make a very beautiful appearance. The whole clufter of flofcules that compofe one flower, are contained in one common cup of the fquammous kind, and each of them is fucceeded by a fmall oblong and ftriated feed of a brown colour. Its root is hard, woody, and

and is often divided into a great number of branches. It is common in many parts of Italy, and in France wild by the road sides, in mountainous places; with us it is cultivated in gardens for its beauty more than for its medicinal use, though it is rather of the number of those plants which escape our notice, than of those that do not merit it.

A pound of the fresh tops of lavender cotton, distilled in a retort, yield first about two ounces or a little more of a limpid and colourless phlegm, smelling and tasting of the plant, but, in taste, somewhat obscurely acid. This is in quantity about seven, or between seven and eight ounces; after this come over about two ounces of a reddish liquor, partly acid and partly alkaline, and, after this, about eight grains of a volatile alkaline salt, in a solid form; and finally near an ounce of a thick oil like butter. The remainder in the retort, calcined in an open fire and lixiviated, yields about a drachm and half of a fixed alkaline salt.

The virtues, ascribed to the santolina or female Abrotanum, are in general the same with those of the male; it is, however, particularly recommended in uterine complaints. The seed of this plant is accounted little inferior to the semen santonicum for destroying worms, and is not unfrequently sold by the druggists as a succedaneum for it.

Matthiolus recommends the powder of the dried leaves, half a drachm for a dose, and to be continued a considerable time, as a remedy for the fluor albus. And Garidelli tells us of the same dose having been given with great success in pleurisies and peripneumonies.

A'BSCESS, *(Dict.)*—Mr. Petit has presented to the royal academy of surgery a very important paper on tumors of the gall-bladder, which have often been mistaken for Abscesses in the liver, and, by the many curious remarks wherewith that memoir is replete, has enriched pathology with an accurate account of a new species of disease. He gives us the diagnostic signs which distinguishes the tumors of the gall-bladder, when distended by the bile retained in it, from Abscesses of the liver; compares that retention of the bile, and the biliary stone, with the retention of urine, and the stone in the bladder; and proposes the performing operations on the gall-bladder similar to those made in the vesica. See Mem. de l'Acad. de Chirurgie, tom. 1. Very considerable Abscesses often happen in the fundament, and occasion fistula's. See the article FISTULA *in ano.*

Mr. Littre observes, Hist. de l'Academie, an. 1701, p. 29, on occasion of an inflammation of the parieties of the left ventricle of the heart, that the ventricles of the heart must be less subject to Abscesses than inflammations; because an Abscess consists in an extravasated fluid, which coagulates, corrupts, and turns into pus; and an inflammation in a swelling of the vessels, caused by too great a quantity of fluid. If then we suppose, that from the coronary arteries, which nourish the substance of the heart, it extravasates, and diffuses the blood that does not at first enter the coronary veins destined to receive it, it will be difficult that the continual motion of the contraction, and dilatation of the heart, does not force it to re-enter therein, or at least break and attenuate in such manner, as to escape into the ventricles across the parietes. With regard to an inflammation, the heart has no other remedy than what it receives from some other part of the body, either to prevent it, or deliver itself from it.

We have, in the history of the royal academy of sciences for the year 1730, p. 40, the history of a cure of an Abscess in the liver, which ought to be publickly known. Mr. Soulier, surgeon at Montpellier, was called to a youth of about thirteen or fourteen years of age, who, after having been violently heated, had put his feet into cold water, and thereby contracted a fever, which was attended with no less dreadful a consequence than that of a very large tumor in the liver, which Mr. Soulier opened; he found the liver considerably imposthumated on the outside, and convex, and in it a hole capable of receiving half of an hen's egg; at each dressing there was discharged a bloody, thick, yellow, bitter, and inflamed matter, which he soon discovered to be the gall, accompanied with flakes of the substance of the liver.

In order to discharge the matter from this Abscess, Mr. Soulier contrived a silver canula, blunted at the end, so that it might be introduced into the liver without injuring it, and pierced with several lateral apertures to receive the peccant humour, and bring it off externally, where it fell upon a plate of lead, which he had applied to the wound, so that the matter could not excoriate the skin: This expedient had the wished-for success; the fever lessened, a good habit of body came on, the wound cicatrised, and the patient was cured.

ABSCI'SSA, *(Dict.)*—In the parabola, the Abscissa is a third proportional to the parameter and semiordinate; and the parameter a third proportional to the Abscissa and semiordinate.

In the ellipsis, the square of the subordinate is equal to the rectangle of the parameter into the Abscissa, subtracting another rectangle of the same Abscissa into a fourth proportional to the axis, parameter, and Abscissa.

In the hyperbola, the squares of the semiordinates are to each other, as the rectangles of the Abscissa into another line composed of Abscissa and the transverse axis.

ABSINTHI'TES *Vinum.* Dioscorides describes several ways of making the vinum Absinthites. The best way, in the opinion of Fuchius, is to bruise an ounce of the best wormwood, and, tying it up in a thin linnen rag, infuse the same in nine gallons of wine. Then put must (wine never fermented) to it and let it work, leaving a hole open, that it may not burst the vessel.

The vinum Absinthites is good for the stomach, excites urine, accelerates concoction, relieves such as labour under distempers of the liver, the stone, or yellow jaundice, removes a nausea, and helps infirmities of the stomach. It is effectual also for an inveterate distension of the hypochondria, and all inflammations; kills round worms, restores the suppressed menses, and is an antidote against the poison of the white chamæleon, provided it be drank in a large quantity, and returned by vomit.

ABSO'RBENT *Vessels*, in anatomy, those minute vessels which imbibe the nutritious and other juices of the human body.

The learned Dr. Mead, in his Monita & Præcepta, has given us the following remarkable case of the vessels absorbing the water in a dropsical person.

I attended a certain merchant for an ascitical dropsy, with another physician of great experience: And, after trying the usual remedies to no purpose, we resolved upon the paracentesis, as the ultimate resource. Accordingly the operation was performed, and about twenty pints of clear water were drawn off. In a few weeks his belly filled again. Whereupon we agreed to meet the surgeon next morning, in order to draw off the water by a second tapping. As we came to the patient, he looked at us, and smiled; saying that he had no occasion for any sort of assistance; and, stripping off the cloaths, he shewed his abdomen, which was soft and relaxed. At this we were vastly surprized, and, having asked him if he had any kind of evacuation in the night, he assured us that he had had none, either by stool, or urine, or sweat, more than usual. Wherefore all the water must have been absorbed by the glands and capillaries of the peritonæum and adjacent membranes. But afterwards this patient very imprudently committed himself to the care of a certain quack, who, to prevent a return of the disease, gave him very strong cathartics, which so exhausted him that he soon died consumptive. Yet upon dissection there was little or no water found in the Abdomen.

Anatomists have long since discovered, that water is absorbed from the belly into the circumjacent parts: for, if a pint of warm water be injected, through a small wound, into the abdomen of a live dog, and his abdomen be laid open a few hours afterwards, not a single drop of the water will be found therein. Thus, as Hippocrates has justly observed, every part of the body, both outward and inward, are perspirable. But I refer the reader to the perusal of what the learned Dr. Abraham Kaav has published on this subject; who demonstrates that the humours are admitted into, and transude through, all the membranes of the body, both in health and sickness.

ABSTRACTI'TIUS, *Abstractitius*, a name given to the native spirits of aromatic vegetables, to distinguish them from spirits produced by fermentation. *Castellus*, from *Libavius*.

ACA'CIA, in botany, the name of a genus of trees, of which M. Tournefort has enumerated twelve, and Mr. Miller twenty-four species.

The characters of the tree are these:—It hath a tubulose flower consisting of one leaf, with many stamina, or threads, which are many of them collected into a kind of sphere or globe: the pointal of the flower afterwards becomes a pod, in which are included several seeds, each of which is separated by transverse diaphragms, and are generally surrounded by a whitish pulp. *Miller's Dict.*

ACA'DEMY *(Dict.) Royal* ACADEMY *of Sciences and Belles Lettres of Prussia.* Frederic the First, king of Prussia, founded it in the year 1700, and appointed M. Leibnitz to be the first president thereof: the list of the members of this Academy was, at its first establishment, adorned with some of the greatest names in the republic of letters. This Academy, in the year 1710, published the first volume of its transactions under the title of Miscellanea Berolinensia; and, though Frederic's successor gave but little encouragement to letters, the Academy continued to publish new volumes in the years 1723, 1727, 1734, 1737, and 1740. At length, Frederic the Second, the present king of Prussia, thought proper to give new vigour to the Academy; for which purpose he invited to Berlin such strangers as were of the most distinguished merit in literature, and encouraged the best of his subjects to prosecute the study and cultivation of it, by giving them ample rewards; so that, in the year 1743, there appeared a new volume of the Miscellanea Berolinensia, in which the new force that the Academy had acquired plainly appeared. However, that prince did not think fit to confine himself there: he thought that the Royal Academy of Sciences of Prussia, in which, till that time, some minister, or great nobleman, had presided, would find an advantage from having a man of letters at its head, and accordingly he made choice of M. Maupertius, a gentleman well known all over Europe, and engaged him to settle at Berlin; he himself, at the same time, giving

giving a new regulation to the Academy, and taking upon him the title of its protector. This Academy has, since the year 1743, published three volumes of memoirs, wrote in French, and nearly upon the same plan as the history of the Royal Academy of Sciences at Paris, but with this difference, that, in the second of these volumes, the extracts of the memoirs are suppressed, as they are intended to be in the future volumes, one of which is to be published every year. The academists hold two public assemblies in the year; one in January, on the present king's birth-day, and the other in May, on the day of his accession to the throne. At the latter of these assemblies is given a prize, consisting of a gold medal of the value of fifty ducats: the subject for this prize is successively natural philosophy, mathematics, metaphysics, and erudition. This Academy has this in particular, that it includes metaphysics, logic, and morality, which are not the objects of any other Academy: there is a particular class which is engaged in these matters, and is called the class of speculative philosophy.

The Imperial ACADEMY *of Petersburg.* — Czar Peter the First, sirnamed the Great, by whose means Russia shook off the yoke of barbarism, which had reigned for so many ages in that kingdom, coming into England and France, in the year 1717, and observing the great utility of literary societies and Academies, resolved to establish one in his capital; and had actually taken the necessary measures for that purpose, when he was taken off by death in the year 1725. His successor, the czarina Catharine, being fully informed of his intentions, laboured upon the same plan, and, in a short time, formed one of the most celebrated Academies in Europe, composed of the most considerable foreigners, some of whom came and settled at Petersburg. This Academy, which is employed in cultivating the sciences and polite literature, hath, since the year 1726, published ten volumes of memoirs, which are all wrote in Latin, and are highly valuable, particularly for the mathematical part, which contains a great number of excellent pieces. Most part of the foreigners who composed that Academy being either dead, or retired out of the kingdom, it was in a very desponding and languishing condition upon the czarina Elisabeth's accession to the throne; but that princess, happily for herself, named count Rasomouski to be president; gave the Academy a new body of statutes; and left nothing neglected which could re-establish its ancient splendor. This Academy has this modest motto, *Paulatim.*

ACÆ'NA, ἄκαινα, in antiquity, a ten-feet rod, used by the Greeks in measuring their land.

ACAJOU', the name of the tree which produceth the cashew-nut, or anacardium. See ANACARDIUM in the dictionary.

ACANTHOPTERY'GII *, in natural history, a term used to express one of the general classes of fishes, the rays of whose fins are bony, and some of them sharp or pointed.

* The word is Greek, ἀκανθοπτερύγιοι, and formed from ἄκανθα, a thorn, and πτερύγιον, a fin.

ACATALE'PSIA (*Dict.*) — The Pyrrhonists, or Sceptics, asserted an absolute Acatalepsia: all human science and knowledge, according to them, went no farther than to appearances and verisimilitude: they declaimed much against the senses, and charged them with a principal share in seducing and leading us to error.

Arcesilas was the first assertor of the Acatalepsia, and reasoned as follows: We can know nothing, said he, not even so much as what Socrates advanced, that we are ignorant of our knowing nothing. This impossibility proceeds both from the nature of things, and of our faculties, and even more from the nature of our faculties, than from that of things.

We must then either deny or assert any thing whatsoever; for it is unworthy of a philosopher both to approve of any thing that is false, or uncertain, and to pass his judgment without being instructed. But every thing having almost the same degrees of probability, pro and con, a philosopher may then declare himself against that which he either denies or affirms, whatever it be; being sure at length either of finding the truth of what he seeks for, or fresh reasons to believe that it is not made for us. In this manner Arcesilas searched after it, during his whole life, perpetually quarrelling with the philosophers of his own time: but, says he, if neither sense nor reason are sufficient to be attended to in the schools of philosophy, they are at least so in the conduct of life, when there is no danger of following probabilities; since we live among such people as have not themselves any better means to determine them.

ACATA'STATOS, a physical term, signifying inconstant, and is applied to irregular fevers, where the periods of exacerbation are uncertain, and the appearances in the urine perpetually changing. It is applied also to shivering fits in fevers, which return at irregular periods, sometimes every day, sometimes every other day, or every third day; or it is applied to urines which are turbid, but do not deposit any regular sediment.

A'CCENT (*Dict.*) — It is a question whether these Accents and aspirates are now to be marked upon Greek words. F. Sanadon, in his preface to Horace, tells us, that he writes the Greek without Accents. This is certain, that we pronounce the words of the dead only according to the inflections of living languages: we do not touch the quantity of the Greek and Latin, except upon the penultima, though the word consists of more than two syllables; but, with regard to the tone, or accent, we have lost the ancient pronunciation: yet, not to lose the whole, and, as it often happens that two words have no other difference between them than in the Accent, we think, with the author of the Greek method of P. R. that we ought to preserve the Accents in writing the Greek; but must add, that we are to look upon them as signs of a pronunciation which is now disused; and I am persuaded, that the learned, who would, at present, regulate their pronunciation by these Accents, would be hissed at by the Greeks themselves, were it possible that they should hear them.

As for the Latins, it is commonly thought that the Accents were only made use of in writing, to fix the pronunciation, and make it easy to strangers. At present, in the Latin grammar, they give the name of Accent only to the three signs (see CHARACTER in the dictionary) the grave, the acute, and circumflex, and this last is never marked but thus [ˆ], and not as in the Greek.

The ancient Latin grammarians had not restrained the name of Accent to these three signs. Priscian, who lived in the sixth century, and Isidore, who flourished a little time after him, both say that the Latins have ten Accents: these ten Accents, according to those authors, are,

1. The acute.
2. The grave.
3. The circumflex.
4. The long line, used to mark a long vowel — longa linea, says Priscian; longa virgula, says Isidore.
5. The mark of the shortness of a syllable, brevis virgula [◡].
6. The hyphen, which served to join two words, as antetulit; they marked it, according to Priscian, thus [◡], and, according to Isidore, thus [◠]. The French use the tiret, division, or stroke of union, for that purpose; porte-manteau, arc-en-ciel.
7. The diastole, on the contrary, was a mark of separation; they marked it thus [ↄ], under the word supposita versui. Isid. de sig. accentuum.
8. The apostrophe, which we still make use of: the ancients placed it also at the top of the word, to shew the suppression of a letter; as tho' for though.
9. The δασεῖα. This was the sign of the aspiration of a vowel, RAC. δασὺς, hirsutus, hairy, rough: they marked it over the letter thus [c]; it is the rough aspirate of the Greeks, which the copyists have turned into an h, in order to a facility of writing quick, without the trouble of raising the pen to mark the aspirate upon the aspirated letter.
10. Lastly, the ψιλή, which shewed that the vowel was not to be aspirated: it is the soft aspirate of the Greeks, which was wrote in contradistinction to the rough aspirate.

They likewise had, as well as we, the asterisk, and several other notes, which Isidore mentions, Orig. l. 1. and says that they were very ancient.

As to the Hebrews, towards the fifth century, the doctors of the famous school of Tiberias laboured upon the criticisms of the books of the holy scriptures, that is to say, to distinguish the apocryphal books from those which were canonical; afterwards they divided them by sections and verses, and fixed their reading and pronunciation by points, and other marks, which the Hebreans call Accents; so that they give this name not only to signs which mark the elevation and depression of the voice, but also to the signs of punctuation.

These doctors were called massorets, from the word massore, which signifies tradition; because those doctors stuck close in their operations to preserve, as much as was in their power, the traditions of their fathers, in the manner of reading and pronouncing.

As for our part, we give the name of Accent primarily to the inflection of the voice, and to the manner of pronunciation of particular countries. Thus we say of the French Accent, &c. that man has a foreign Accent, i. e. that he has some inflection of voice, and a manner of speaking, which is dissimilar to that of persons born in the capital; in this sense Accent comprehends the elevation of the voice, and the quantity, and particular pronunciation, of each word, and of each syllable.

In the second place, we have kept the name of Accent to each of the three signs of tone, which is either acute, grave, or circumflex: but these three marks have lost, among us, their ancient destination; they are no more, on that account, than printed Accents: this is the use we make of them in Greek, Latin, and French.

As to the Greek, we pronounce it our own way, and place Accents according to the rules that grammarians give us, without using those Accents as guides for raising or lowering the tone. As for the Latin, we at present distinguish the quantity of words only in respect to the penultima, though the word consists of more than two syllables; for the words which have but two syllables are pronounced equally, whether the first be long or short: for example, in verse, the a is short in pater, and long in mater; yet we pronounce both as if they were of the same quantity.

In books designed for public reading, the acute Accent is made use of, and placed differently, according as the penultima is either short or long; for instance, in matutinus we perceive the quantity only on the penultima ti, and, because this penultima is long, we place an acute Accent thereon, matutínus.

On the contrary, this penultima ti is short in serótinus, in which case we put the acute Accent on the antepenultima ró, whether that penultima be short or long. In verse, this acute Accent then serves to shew us, that we must rest upon that accented antepenultima, in order to pass more easily on the penultima, and to pronounce it short.

As the method of accenting, though used but by few authors, is of great use, it were to be wished that this practice equally prevailed as to classical books, thereby to accustom young people to pronounce the Latin regularly.

ACCE'PTOR, in commerce, the person who accepts a bill of exchange.

The Acceptor, who is generally the person on whom the bill is drawn, becomes personal debtor by the acceptance, and is obliged to pay, even though the drawer happens to fail before the bill becomes due.

A'CCIDENT, in logic, is when we join a confused and indetermined idea of substance with a distinct idea of some mode: that idea is capable of representing all things, wherein that mode will be, as the idea of prudent, prudent men, and the idea of round, all round bodies. That idea, expressed by an adjective term, prudent, round, gives the fifth universal, which is called Accident, because it is not essential to the thing to which we attribute it; for, if it was, it would be difference, or proper. But here it is to be observed, that, when we consider two substances together, we may consider one of them as the mode of the other; thus, a dressed man may be considered as a whole, composed of that man and of his clothes; but, to be dressed in respect to that man, is only a mode, or fashion of being, under which we consider him, though his habits may be substances.

ACCIPE'NSER, a name given, by Linnæus, to a genus of fishes, whose characters are, that the mouth is tubulated, and without teeth, and the gills have only one hole, or aperture, on each side.—The sturgeon, among others, belongs to this genus.

ACCI'PITER, in zoology, the hawk. Linnæus has given this name to an order of birds, the distinguishing character of which is, their having a crooked beak. There are three genera belonging to this order, the owl, the hawk, and the falcon.

ACCLAMA'TION, a token of joy, or applause, whereby the public testifies its esteem, or approbation. Antiquity has transmitted to us several sorts of Acclamations. The Hebrews were accustomed to cry hosanna; and the Greeks ἀγαθῇ τύχῃ, good fortune, good luck. The historians speak of some magistrates of Athens who were elected by Acclamation, which was not manifested by calling out, but by holding up the hands. The Barbarians testified their approbation by a confused noise, or clashing of their arms. We have a more circumstantial knowledge of the customs of the Romans on this head, which may be reduced to three different kinds of Acclamations, those of the people, those of the senate, and those of the assemblies of the learned.

The Acclamation of the people took place upon the public entries of emperors and generals, at the shews given by the princes, or magistrates, and of triumphs of conquerors; this was originally no more than a confused outcry of a multitude transported with joy, and a simple undisguised expression of public approbation; plausus tunc arte carebat, says Ovid. But, under the emperors, and even under Augustus, this impetuous motion, to which the people abandoned themselves, as it were by enthusiasm, became an art, and a studied harmony; a musician set the tune, and the people, giving two chears, alternatively repeated the form of Acclamation. On the false report of Germanicus's recovery being spread over Rome, the people flocked to the capitol, with torches and victims, singing, Salva Roma, salva patria, salvus est Germanicus. Seneca and Burrhus were the first in their Acclamations to Nero (who was passionately fond of music) when he played upon the harp in the theatre, and these were followed by five thousand soldiers, called augustales, who roared out his praises, which the rest of the spectators were obliged to repeat. These musical Acclamations were continued to the reign of Theodoric. Applauses in cadence were also sometimes joined with these Acclamations; the most common formula's were, feliciter, longiorem vitam, annos felices; those of triumph, were verses in praise of the general, and the soldiers and people cried out, at certain intervals, io triumphe; though the soldiers sometimes mingled with these praises very sharp and satyrical railleries upon the conqueror. The Acclamations of the senate, though they were more serious, yet had the same end, that of honouring the prince, and often of flattering him. The senators testified their consent to his propositions by these formula's, omnes, omnes, æquum est, justum est. We have had instances of the elections of emperors made by Acclamation, without any preceding deliberation. Men of learning either recited their compositions, or declaimed in the capitol, or in the temples, and in the presence of a numerous assembly; and Acclamations were then given nearly in the same manner as at the public shews, as well in respect of the music, as of the accompaniments. As those Acclamations ought to be suitable to the subject, as well as to the persons to whom they were given, they had several of them, some adapted to the philosophers, others to the orators, others to the historians, and others again proper for the poets. One of the most common of these formula's was the saphos, which they repeated three times; neither were comparisons or hyperboles spared in the least, especially by those admirers who were hired to applaud; for there were people of this sort, as we learn from Philostratus.

ACCO'MPAGNAGE, a term used in silk manufactories, and signifies a fine woof of the same colour with the gilding, whereof the stuff is wrought, helping to enrich the ground under which it passes, and to hinder it from striking cross the gilding itself, which would diminish its gloss and lustre. All rich stuffs, the warps whereof are of a different colour from the gilding, ought to be accompanied.

ACCO'MPANIMENT, in music, is the execution of a complete and regular harmony upon any instrument, as the organ, harpsichord, theorbo, guitar, &c. we shall, in this place, consider it in respect to the harpsichord.

Here we have one of the parts of music, which is commonly the bass, for our guide. The bass is touched on the left hand; and on the right the harmony is pointed out, either by the movement of the bass, the tone of the other parts which we hear at the same time, the divisions which we have before our eyes, or by the figures which are commonly added to the bass. The Italians shew no regard to the figures, the quickness and nicety of their ear supplying the want of them, and they accompany extremely well without that apparatus; a faculty of playing, for which they are entirely indebted to their own natural genius. Other people, who are not, like them, born for music, when they come to practice, find infinite difficulties in Accompaniment, and require ten or twelve years to succeed tolerably well in it. What then can be the causes that retard the progress of the scholar, and embarrass even the masters themselves, for so long a time, as the difficulty alone of that art cannot occasion it?

There are two which are the principals; the one is in the manner of figuring the bass, and the other in the methods of Accompaniment. The signs which are used to figure the basses are too numerous. If there are so few fundamental concords, why must there be a multitude of figures to express them? The very signs are equivocal, obscure, and insufficient; for instance, they scarce ever determine the nature of the intervals which they express; or, what is still worse, point them out quite contrary: the one is barred to have the place of diesis, and the other is barred to hold the place of *b* flat: the greater intervals, and even the lesser ones, are often expressed in the same manner. When the figures are doubled, they are too confused, and, when single, they scarce ever give us any more than the idea of only one interval, so that we always have several others of them to understand and express. What method then must be taken to remedy these inconveniencies? Must the signs be multiplied, in order to express the whole? To this it may be answered, that we complain, that there are too many of them already. Must we then reduce them? Why, if we do, we shall then leave more things to be guessed at by the accompanier, who is already too much taken up. What then is to be done? We must invent new signs, perfect the fingering, and make signs of fingering two ways combined, which at the same time concur to help the accompanier. This is what M. Rameau has, with great sagacity, attempted in his dissertation on the different methods of Accompaniments.

As the ancient music was not so well composed as ours is, either for harmony or singing, and had scarcely any other bass than the fundamental, all the Accompaniments consisted in a series of perfect concord, wherein the accompanier from time to time substituted a sixth to a fifth, as the ear guided him: this was all the ancients knew; but, of late years, since we varied the modulations, and overcharged, and perhaps spoiled the harmony by a croud of dissonances, we are constrained to follow other rules. M. Campion conceives, it should be that which we call the rule of the octave; and it is by that method that the major part of the present masters shew the Accompaniments.

The concords are determined by the rule of the octave, relatively to the rank which the notes of the bass take up in any given tone. Thus, the tone being known, the note of the bass continues the rank of that note in the tone, the rank of the note that immediately precedes it, and the rank of that which follows it; and the player will not be much mistaken in accompanying by the rule of octave, if the composer has followed the most natural and simple harmony; but this is what we must not scarce expect in the modern music: besides, how can we have all these things present? And, notwithstanding that the accompanier is well acquainted with them, what must become of his fingers? He is scarce got at one

one concord but another presents itself; the instant of reflection is precisely that of execution; so that there is nothing but a consummate habitude of music, a reflected experience, and a facility of reading a line of music at first sight that can help him; and yet, even with this assistance, the most skilful musicians are often guilty of blunders.

Suppose, that, before we attempt Accompaniment, we have waited till the ear is formed, till we know how to read music fast, and that we are able to unravel a division upon opening the book; yet we shall still be at a loss, because we still want a habit of fingering, founded upon other principles of Accompaniment than those hitherto laid down by M. Rameau.

The most zealous masters have been perfectly sensible of the insufficiency of their principles; and, in order to remedy them, they have had recourse to enumeration, and the knowledge of consonances, whose dissonances are prepared and preserved. This is a prodigious detail, as is sufficiently apparent by the multitude of dissonances.

There are some who advise us to learn composition before we attempt Accompaniment, as if Accompaniment was not composition itself, exclusive of the talent to which we ought to join the practice of the other. And, on the contrary, how many people are there that would have us begin by Accompaniment to learn composition?

The movement of the bass, the rule of the octave, the manner of preparing and keeping dissonances, and composition in general, occur only to point out the succession of one concord to another; so that at each concord there is a new object and a fresh subject for reflection. What labour is here for the mind? When will it be sufficiently instructed, and the ear so thoroughly exercised, that the fingers may be no longer stopped?

It is to M. Rameau (who, by his invention of new signs, and the perfection of fingering, has shewn us the means of facilitating Accompaniment) that we are indebted for a new method, which secures us from the inconveniences of all the others that we have hitherto followed; and it is he who was the first that brought us acquainted with the fundamental bass, and discovered the true foundations of an art in which every thing had appeared arbitrary.

We shall, in a few words, lay before the reader the principles upon which his method is founded.

In harmony there are only consonances and dissonances; so that there are no more than consonant and dissonant concords. Each of these concords is fundamentally divided by thirds (this is M. Rameau's system). The consonant is composed of these notes, as *ut*, *mi*, *sol*; and the dissonant of four, as *sol*, *si*, *re*, *fa*.

Whatever distinction or distribution may be made of the consonant concord, there always must be in it three notes, *ut*, *mi*, *sol*; whatever distribution is made of the dissonant concord, we shall always find in it four notes, *sol*, *si*, *re*, *fa*, setting aside the supposition and suspension, which others of them introduce in the harmony, as it were, *per licentiam*. Either the consonant concords succeed each other, or the dissonant concords are followed by other dissonants, or the consonants and dissonants are intermingled.

The perfect consonant concord agrees only with the tonic, the succession of concords furnish so many tonics, and consequently the alterations of sound.

The dissonant concords commonly succeed each other in the same tone. The dissonance connects the harmonic sense. A concord makes us wish for another, and gives us to understand that the phrase is not finished. If the tone changes in that succession, the alteration is always declared by a diesis or by a *b* flat. As to the third succession, to wit, the intermingling of consonant and dissonant concords, M. Rameau deduces that succession to two cases, and asserts, in general, that a consonant concord cannot be preceded by any other dissonant than that of the seventh predominant, or that of the sixth fifth of the subpredominant, excepting in a broken cadence and suspensions; and he further pretends, that there are no exceptions as to the ground. It appears to us, that the perfect concord may still be preceded by a concord of the seventh diminished, and even by that of the sixth superfluous; two original concords, the latter whereof never defeats itself.

Here then are three different temperatures of harmonic phrases; of tonics that succeed themselves and occasion a change of tone; of consonances and dissonances which intermingle with each other, and where the consonance is, according to M. Rameau, necessarily preceded by the seventh of the predominant, or the sixth fifth of the subpredominant; what then remains to be done for the facility of Accompaniment, if it is not to indicate to the accompanier, that it is that of those temperatures which reigns in that which he accompanies?

This is what M. Rameau would have executed by characters: one single sign might easily indicate the tone, tonic, and its concord.

From thence we gather the knowledge of the diesis and of the *b* flats, which ought to enter into the series of the concords of one tonic into another.

The fundamental succession, either by fifths or thirds, as well in ascending as in descending, gives the first temperature of harmonic phrases intirely composed of consonant concords.

The fundamental succession by thirds or fifths, in descending, gives the second temperature, composed of dissonant concords, to wit, of concords of the seventh, and that succession gives the descending harmony.

The principal harmony is furnished by a succession of fifths in ascending, or fourths in descending, accompanied by the dissonance proper to that succession, which is the sixth added; and this is the third temperature of harmonic phrases, which has not hitherto been observed by any one; though M. Rameau has found the principle and origin of it in the irregular cadence. Thus by the ordinary rules harmony, which springs from a succession of dissonances, always descends, though, according to its true principles, and to reason, it ought to have in ascending a progression intirely as irregular as in descending.

The fundamental cadences give the fourth temperature of harmonic phrases, where the consonances and dissonances intermingle together.

All these temperatures may be denoted by single, clear, and few characters, which will at the same time indicate when the dissonance in general is necessary; for its place is always determined by the temperature itself.

We begin by exercising ourselves upon these temperatures taken separately, since we make them succeed each other upon each tone and upon each mode successively. With these precautions M. Rameau asserts, that we may make a greater progress in Accompaniments in six months, than before in six years, as he himself found by experience. *Diderot's Encycl.*

ACCOMPANIMENTS, in painting, are those objects which are added either by way of ornament or probability; it is natural to see guns, dogs, game, &c. in an hunting-piece; but it is not necessary, for the sake of probability, to put all sorts of them in; when we do introduce them, they are the Accompaniments which always greatly ornament a picture. We say of a picture that represents sportsmen, this piece should have some Accompaniment, as guns, games, &c. We say fine Accompaniments; that thing accompanies that part, group, &c. very well.

ACCOUNT, or ACCOMPT, *(Dict.)*—Is used collectively for the several books which merchants, traders, and bankers, keep, and in which they enter all their business, traffic, and bargains with each other. Hence they say, to make out an Account, to pass Accounts, &c.

To open an Account, is to enter it for the first time into the ledger. This is done by writing in large characters the christian name, firname, and place of abode of the person with whom an Account is thus opened: Afterwards the articles are posted to it, either on the debit or credit side, as affairs occur.

When an Account is opened in the ledger for any one, his name must be entered at the same time in the alphabet, and the folio of the book set down, where the Account is entered, for the more easily referring to it.

Merchants, who keep open Accounts with each other, sometimes agree to honour the bills of exchange, which they draw reciprocally.

To post a sum to Account, is to enter into the ledger, either on the debit or credit side, the articles for which persons become either debtors or creditors.

Order of an Account, is its division into three heads, of receipt, expence, and defalcation; that is, the deduction of such sums as are taken into the Account, and not received or admitted. The French call it reprise.

To examine an Account, is to read it exactly, to point the articles of it, and prove the computation, in order to know if there be no errors, and whether the balance be right. I have examined your Account, it is right, there is nothing to except against it.

To settle an Account, is to cast up, and calculating every article of it, and balancing the same. In the like sense are used the words to shut, to balance, to close, to make up an Account. Accounts are balanced upon the ledger on two occasions; the one, when traders settle or adjust affairs with some debtor or creditor, in order to know what they owe, or what is due to them: The other, when it is necessary, to carry over Accounts to some new folio's in the same book, or into another, in order to continue them, for want of room in the former.

Prudent merchants ought to settle their Accounts at the end of every year, in order to open new ones in the beginning of the next.

To place to Account, is to give one credit for a sum received, either of him, or for him. It signifies also to make him debtor for a sum paid to him, or for him. Thus, in a bill of exchange, the drawer puts sometimes these words after the sum, Which you will place to my Account, or to the Account of, &c.

Balance of an ACCOUNT, is the sum in which the debt exceeds the credit, or the credit the debt, when the Account is duly examined and settled, and the balance taken. I owe you 300 l. for the balance of our Account. There is so much due to me for the balance of our Account.

ACCOUNT *in bank*, is a fund which merchants, traders, bankers, and

and other private perſons, if they think fit, depoſit into the common caſh of ſome bank, to be employed in the payment of bills of exchange, promiſſary notes, bonds, debts contracted, either in trade or otherwiſe, as by buying eſtates in land, &c.

ACCOUNT *in company*, is a ſpecies of Account between two merchants, or traders, in conſequence of a kind of aſſociation, or partnerſhip between them.

ACCOUNT *of ſales*, is an Account given by one merchant to another, or by one factor to his principal, of the diſpoſal, charges, commiſſion, and net proceeds of certain merchandizes ſent for the proper, or company Account of him, who conſigned the ſame to ſuch factor or vender. When the like Account is inland or domeſtic, the ſame is tranſmitted in the current money of that country, wherein the buſineſs is tranſacted. As from a Blackwell-hall factor to the clothiers in the country, or from the warehouſe-men in town, who deal by commiſſion for the country manufacturers, as baiz-factors, drugget and duroy-factors, and the like.

The following is the natural form of a Blackwell-hall factor's Account of ſales to a clothier.

Account of ſales, charges, and net proceeds (or produce) C | D | of 20 pieces of ſuperfine cloth, received per A B's 1 a 20. waggon of — —, conſigned to me by C. D. of Wiltſhire, for his Account, marked and numbered as per margin.

	l.	*s.*	*d.*
January 5th, 1754. Sold to E. F. draper, 6 pieces of ſuperfines, per A B, quantity — yards at — per yard, to pay in 6 months.			
January 12th, 1754. Sold to G. H. 14 pieces, ditto, quantity — yards, at — per yard, to pay in 6 months.			
Charges.			
Paid carriage to London — —			
Porterage and warehouſe room —			
Poſtage of letters — —			
Commiſſion at — per cloth — —			
Deduct charges from the ſales.			

The net proceed is paſt the credit of your Account, without my prejudice.

London, February 10th, 1750. E. E. N. O.

An example of a foreign Account of ſales.

Account of ſales, and net proceeds of 2 bales of druggets, received per the Hollandia, Cap. Jan. Roeloff Smith, for the Account of M. P. of London.

November 4th, 1750. Conſigned the above two bales of druggets, quantity 112 pieces, quantity 4875 yards, as per factory (i. e. invoice which is frequently ſtiled ſo) which, at 3 ½ palms per yard, are palms 18280 net, at ſols 9 s. 4 d. per palm, to pay in two months — —	8530	13	4
Sold and conſigned 2 pieces of white druggets for wrappers as above, for	140	00	0
	8670	13	4
Charges, viz.			
Freight and primage — —	106	5	0
Porters landing and carrying to warehouſe	6	0	0
Opening to viſit, aſſorting and making up	4	0	0
Warehouſe room — —	8	0	0
Brokerage 2 ½ per cent — —	43	7	0
To commiſſion, and ſtanding to bad debts at 4 per cent.	346	16	4
	514	8	4
	8156	5	0
Aggio deducted at 118 ½ per cent	1283	0	2
Genoa, November 30, 1750. E. E. * Bco.	6873	4	10

* *E. E.* ſignifies errors excepted in the Account rendered, and *Bco.* ſignifies the bank money of Genoa. *Poſtlethwayt.*

ACENTE'TUM, a name given by the ancients to the fineſt ſort of rock cryſtal.

A'CER, in botany, the maple. See MAPLE.

ACE'RRA, in antiquity, and particularly among the Romans, was a ſort of altar erected near the bed of a dead perſon, and upon which the parents and friends of the deceaſed continually burnt incenſe till the inſtant of the funeral.

Acerra, more properly, ſignifies a little pot which held the incenſe and perfumes for ſacrifices, ſuch as are now made in the form of a ſmall boat, and are uſed in the church of Rome at this day. The rich, ſays Horace, offered boxes full of the fineſt perfumes to the deities:

Et plena ſupplex veneratur Acerra:

And the poor, according to Lucian, were excuſed for making a bow, and throwing ſome incenſe into the fire that burnt upon the altars. They were alſo placed, according to Feſtus, before dead bodies, and were quadrangular, like the greater arks or cheſts called κιβωτοί.

ACERSECO'MES, a name of Apollo; it ſignifies long-haired, becauſe they commonly repreſented this God with a head of hair like that of a young man.

ACE'STIDES, in foundery, a name given by the ancients to the chimnies of their furnaces, wherein braſs was made. They diminiſhed or narrowed from the bottom to the top, in order that the fumes of the metal when in fuſion might be collected therein, and that the cadmia might be formed there in great quantities.

ACETA'BULUM, in natural hiſtory. The Acetabulum has been formerly claſſed among the marine plants, but is now known to belong to the animal kingdom, and to be produced by ſea inſects: This production, by its ſubſtance, which is ſtony, does not appear to be analogous to plants, and is much leſs ſo when we conſider the figure. It is a ſmall baſon, formed in the ſhape of a cone reverſed, which, at its point, adheres to a very thin, longiſh pedicle: There are ſeveral of theſe pedicles, which ſeem to come out of a ſtone, ſhell, or ſome other hard body, to which they are faſtened. This appearance, together with other circumſtances, had introduced a miſtake in regard to the nature of the Acetabulum, as well as of many other pretended ſea plants, which was currently received till Mr. Peyſſonel diſcovered that they were animal productions. *Diderot's Encyclop.*

ACETO'SA, in botany, ſorrel. See the article SORREL.

ACE'TOUS, or ACETOSE, ſomething relating to vinegar: We ſay an Acetous taſte, Acetous qualities, &c. wine, and all other vinous liquors, are rendered Acetous, by exciting their ſalts, and tempering or abating their ſulphurs. Chemiſts give the preparation of divers aceta or Acetous liquors.

ACHA'NE, ἀχάνη, in antiquity, an ancient Perſian corn meaſure, containing forty-five Attic medimni. *Arbuthn. Diſſertat.* p. 104.

ACHA'TES. See AGAT.

ACHE'LAA, the name of one of the harpies: her ſiſters were called Alope and Ocypete.

ACHI'LEA, a name given by the ancient phyſicians to that ſpecies of gum called at preſent *ſanguis draconis*, or dragon's blood.

A'CHIA, a kind of cane, preſerved or pickled in vinegar with pepper, ſpices, and other ingredients: It is about the ſame length and conſiſtence with our girkins, of a yellow colour and fibrous texture. The Dutch import it from the Eaſt-Indies in earthern jars.

ACHI'LLEID, or ACHILLEIS, in polite literature, a celebrated poem of Statius, in which that author propoſed to deliver the whole life and exploits of Achilles; but, being prevented by death, he has only treated of what concerns the infancy and education of his hero, and that hiſtory has remained imperfect. We call it a hiſtory, though we are not ignorant, that ſome celebrated authors have called it an epic poem; and that Julius Scaliger has even given Statius the preference to all the Greek and Roman heroic poets. But it is at preſent generally agreed, that Statius has treated his ſubject rather as an hiſtorian than as a poet, without attaching himſelf to that which makes the eſſence and conſtitution of a true epic poem; and that, as to diction and verſification, in endeavouring to raiſe himſelf, and appear great, he has fallen into bombaſt.

An epic poem is not the hiſtory of the whole life of a hero.

ACHIO'TTE, a red drug imported from America, generally called anatta. See ANATTA.

A'CHITH, in natural hiſtory and botany, a ſort of wine that grows in the iſland of Madagaſcar, and yields a fruit, which is called voachit, about the ſize of a green grape, and ripens in December, January, and February.

ACHO'ROU, is a ſpecies of laurel which grows in America, and is called Indian wood. This Indian wood grows to a large ſize, is hard, red, and uſed in works where ſolidity is required; its leaves and fruit are aromatic; the decoction of its leaves is taken in diſorders of the nerves, and in dropſies. Its fruit, which is in ſhape of a grape, and whoſe berries are rather oval than round, is of a deep violet colour, covered with a pellicule, which is thin and full of juice. It incloſes purple-coloured ſeeds, ſhaped like a kidney; the fleſh of thoſe birds who eat theſe ſeeds, is purple-coloured, and of a very bitter taſte.

ACHTE'LING, a liquid meaſure made uſe of in Germany; thirty-two Achtelings make an heemer, and four ſchiltens make an Achteling.

ACHTENDEE'LEN, or Achteling, a corn meaſure uſed in ſome parts of Holland; two hoeds of Gurmiheug make five Achtendeelens; twenty-eight Achtendeelens of Aſpeſen make thirty-two of Rotterdam, but there muſt be but twenty-ſix of thoſe of Worcum; twenty-nine Achtendeelens of Delft make twelve viertels of Antwerp; four Achtendeelens 1⁄2 of Delft make the hoed of Bruges.

A'CIDS, (*Dict.*)— Acids are, with great reaſon, looked upon by phyſicians, as one of the general cauſes of diſeaſes, and they undoubtedly occaſion ſeveral accidents, according to the part which they affect, while they are contained in the ſtomach.

mach. They cauſe ſour belchings, ſenſations of hunger, and painful prickings, which bring on the cardialgia, or heart-burn: When they get into the inteſtines, they, in the duodenum, diminiſh the action of the bile, and in others produce ſpaſmi, and the iliac paſſion; by cloſing up the lacteal veſſels they give birth to chronical diarrhœas, which often terminate in dyſenteries; when they mingle with the blood, they alter its quality, and produce a thickening in it, to which the lymph that ſhould ſupply matter for the ſecretions likewiſe finds itſelf ſubject; from thence ariſe obſtructions in the glands of the meſentery, a diſeaſe common to young children, the fibres, of which their parts are compoſed, being as yet too ſoft to blunt the points of the Acids which they meet in moſt parts of the aliments that they take. Sedentary perſons and ſtudents are often attacked with diſeaſes, of which the Acid acrimony is productive; diſſipation and exerciſe are very neceſſary to prevent thoſe diſorders, by promoting and augmenting perſpiration. The green ſickneſs to which girls are ſubject, either before the menſes have appeared, or on their being by any accident ſtopped, are likewiſe owing to an Acid acrimony; and this occaſions that depraved appetite which they have for coals, chalk, the plaiſter of walls, and other things of that ſort; all which are abſorbent, and reſiſt the Acids.

We attain the end in deſtroying the Acids, and ſtopping the ravages which they make, when we are ſo happy as to find their exiſtence in the ſtomach, by partly evacuating them by the help of emetics, which muſt be followed by the uſe of abſorbents, and aperitive and martial remedies, which are very proper to give a ſpring to the ſolids, and fluidity to the liquids: In ſhort, by making uſe of thoſe remedies that, readily fermenting with the Acids, form ſalts of a particular nature, and which have a ſtimulating and diaphoretic virtue, and are capable of reſolving obſtructions.

All theſe remedies muſt be adminiſtered with great caution, and we muſt always have a regard to the ſtrength, age, conſtitution, and ſex of the patient. *James's Med. Dict.*

ACI'DULATED, in pharmacy, ſignifies in general whatever has an acid juice mixed with it, in order to render certain refreſhing liquors of an agreeable taſte; as limonade, gooſberry water, verjuice, juice of barberries, and the tincture of roſes, in which they put ſome drops of ſpirit of vitriol, juſt to give them an agreeable acidity.

Mineral ſpirits, dulcified with ſpirit of wine, muſt here find a place, ſuch as ſpirit of vitriol, ſulphur, nitre, and ſea ſalt. This name is ſuitable to cold water; and ſome phyſicians have given them that appellation, to diſtinguiſh them from Bath waters, which are hot.

ACME'LLA, in botany, a plant which comes from the iſland of Ceylone, where it is very common. P. Hotton, profeſſor of botany at Leyden, gives this account of it. The flowers of this plant grow on the extremities of the ſtalks, and are compoſed of a great many tubulous yellow floſculi, which by their union form a head ſuſtained by a perianthium of ſix leaves; when theſe floſculi fall off, the ſeeds appear, which are of a dark grey, long and ſmooth, except that at the top, immediately under the floſculi, they are furniſhed with a double beard, which make them forked; the ſtalk is ſquare, and cloathed with leaves that grow by pairs like thoſe of the lamium or dead-nettle, but longer and more pointed.

The great reputation it has obtained in diſſolving and curing the ſtone has rendered it famous. In the year 1690, a Dutch officer affirmed to the Dutch Eaſt-India company, that he had cured upwards of a hundred perſons of the ſtone and nephritic complaints, only by the uſe of this plant, and this teſtimony was confirmed by that of the governor of Ceylon. In 1699, the firſt ſurgeon of the hoſpital in the city Columbo wrote the ſame things of the Acmella to P. Hotton; that ſurgeon, in his letter, diſtinguiſhed three ſorts of Acmella, differing from each other, particularly in the colour of the leaves, and he recommends that ſort with a black ſeed and large leaves, as the beſt; the leaves are gathered before the flowers appear; they are dried in the ſun, and taken in powder, in tea, or ſome other convenient vehicle. A ſpirit is alſo prepared by diſtillation from the root, ſtalks, and branches, infuſed in ſpirits of wine; they likewiſe uſe the flowers, the extract of the root, and the ſalt of this plant, in pleuriſies, cholics, and fevers.

As a plant of ſo great an importance and uſe cannot be too well known, we ſhall, to the preceding deſcription, add that of Breynius; that author ſays, the root is fibrous and white, its ſtalk ſquare, and about a foot in height, dividing itſelf into ſeveral branches; that its leaves are long, pointed, rough, and a little dented, and that its flowers grow at the extremity of its branches.

The ſame author adds, that the tincture of Acmella made with ſpirits of wine, or in ſome antinephritic decoction, may be taken twice or three times in a day to facilitate the voiding of gravel and ſtones.

We cannot too much excite the naturaliſts to ſearch into the properties of this plant: What happineſs might there redound to mankind, if upon a ſtrict examination thoſe virtues which are attributed to it, ſhould be diſcovered: And what man would better merit immortality, than he who ſhould undertake the taſk? Perhaps indeed he might be obliged to make a voyage to Ceylon.

Animal ſubſtances acquire ſingular qualities by the uſe which animals make of certain aliments, rather than of others; and why may it not be the ſame with vegetable ſubſtances? If this induction be reaſonable, it follows, that any given plant, gathered on one ſide of a mountain, will have a virtue that is not to be found in a plant of the ſame ſort, gathered on the other ſide; that ſuch a plant had formerly a property, which it has not at preſent, and perhaps will never regain; that fruits, vegetables, and animals, are in perpetual viciſſitude, in reſpect of their qualities, forms, and elements; that our anceſtors, who lived four thouſand years ago, did not, or rather that our poſterity ten thouſand years hence will not, perhaps, know thoſe fruits which we now have, by comparing them with the moſt exact deſcriptions, which we have made of them; and, conſequently, that we ought to be extreamly reſerved in the judgments we paſs on thoſe paſſages, wherein the ancient hiſtorians and naturaliſts treat of form, virtues, and other qualities, which are in a perpetual motion of alteration.

It may indeed be ſaid, if ſalubrious aliments degenerate into poiſons, on what muſt animals live? There are two anſwers to this objection; firſt, that, the form and conſtitutions of animals altering in the ſame proportion, and by the ſame ſenſible degrees, the one is always ſuitable to the other. Secondly, that, if a ſubſtance happen to degenerate with too great rapidity, animals will abandon the uſe of it. We are told, that the malum Perſicum, or peach, was firſt brought to us from Perſia as a poiſon; however, it is in our climate an excellent fruit, and a very wholſome food.

A'CORN, in natural hiſtory and agriculture, the fruit produced by trees of the oak kind. For the method of planting acorns, &c. ſee t he article OAK.

A'CRIMONY, in the humours, is a malignant quality, which they contract by a great number of cauſes, as too much agitation, &c. This quality conſiſts in looſening the ſalts, and ſome tendency to alkalization, in conſequence of the extream diſſipation of the aqueous vehicle that envelops them; from whence we plainly ſee, how hurtful long abſtinence muſt be to the generality of conſtitutions.

A'CTION, is a term ſometimes made uſe of in mechanics, to denote the effort which one body or power makes againſt another body or power, and ſometimes the effect itſelf of that effort.

It is in order to conform ourſelves to the common language of mechanics, and natural philoſophers, that we give this double definition: For if we are aſked, what we ought to underſtand by Action, by attaching to that term clear ideas only, we anſwer, that it is a motion that a body really produces, or tends to produce, in another, that is to ſay, ſuch a motion as it would have produced if nothing had hindered it. See MOTION in the dictionary.

In effect, all power is no more than a body which is actually in motion, or which tends to move itſelf, that is to ſay, a body which would move itſelf, if nothing hindered it. Whence it follows, that, in a body which actually moves, or that tends to move, we clearly ſee the motion only which it has, or that it would have, if it had no obſtacle. The Action therefore of body manifeſts itſelf to us by its motion only, and, therefore, we muſt not fix any other idea of the word Action, than that of an actual motion, or a ſimple tendency; and it is only confounding that idea to join thereto that of I know not what metaphyſical being, which we imagine reſides in the body, and of which no one can have a clear diſtinct notion; it is to the ſame miſtake that we are indebted for the famous queſtion of living forces, which, according to all appearances, had never been a ſubject of diſpute, if we had thoroughly obſerved, that the only preciſe and diſtinct notion that one can give to the word force, reduces it to its effect, that is, to the motion it produces or tends to produce.

ACTION, in the military art, is an engagement between two armies, or between different bodies of troops belonging thereto. The word is likewiſe uſed to ſignify ſome memorable act done by an officer or commander of a body of troops.

ACTION, in law, is a judiciary demand, founded upon a title or law, whereby the plaintiff ſummons the defendent to ſatiſfy him for that to which he is obliged, in virtue of the one or the other, and, for defect whereof, he requires that he ſhould be condemned by the judge.

Actions are divided, by Juſtinian, into two general kinds; real, or thoſe againſt the thing, and perſonal, or thoſe againſt the perſon; for whoever brings an Action, either does it againſt one obnoxious to him, in reſpect either of contract or of offence; in which caſe ariſe Actions againſt the perſon, which require to do or give ſomething; or he does it againſt one not obnoxious, yet with whom a controverſy is riſen, touching ſome matter; as if Caius holds a field, which Julius claims as his property, and brings his Action for the ſame. See the Inſtitut. l. 4. tit. 4. where the principal Actions introduced by the Roman law are ſummarily explained.

C There

There is also a third kind of Action, which arises out of the two former classes of real and personal Actions, and which is called a mixed Action.

Real Action, is that whereby the plaintiff sues for the right which he has to lands, tenements, rents, or other payments; and of this there are two sorts, either the possession or demand. An Action is merely real when it singly attacks the thing, and the detainer is clear upon giving it up; but, if he is personally obliged to the restitution of fruits or interests, in that case it is mixed.

Personal Action, is that which one man has against another, in consequence of a contract, whereby he is obliged to pay or do something, or by reason of an offence done by him, or by some other person for whose fact he is answerable. In the first case the Action is civil, and in the other it is or may be criminal.

Mixed Action, is that which is either laid against the person of the detainer of the thing, or for the thing detained, being thus called, because it hath a mixed respect, both to the thing and to the person.

They generally reckon three sorts of mixed Actions, the Action of partition between coheirs, of division between associates, and limitations between neighbours.

Actions, are also divided into civil, penal, or criminal: The civil Action, is that which tends only to the recovery of that which belongs to a man, by virtue of a contract, or of some some such-like cause; as if any one should endeavour to recover, by way of Action, a sum of money which he has lent.

Penal or *criminal* Action, tends to the punishment of the party accused or prosecuted, either corporally or pecuniarily.

French Actions, in commerce. There are at present three sorts of them, to wit, simple Actions, rentiere Actions, and interested Actions.

The simple Actions, are those which have a share in all the profits of the company; and are likewise liable to bear all losses, having no other security than the funds of the company.

The rentiere Actions, are those which are intitled to a sure profit of two per cent. for which the king is surety, as he was for the rents upon the city.

The interested Actions hold, if I may say so, the middle place between the other two: They have two per cent. fixed income with the king's warrantry, in the same manner as the rentiere Actions; and, besides which, they are also to share the overplus of the dividend with the simple Actions. These last Actions have been created in favour of ecclesiastical communities. *Savary's Dict. Com.*

A'CULER, in the menage, is used for the motion of a horse, when in working upon volts he does not go far enough forward, at every motion, so that his shoulders take in too little ground, and his croupe comes too near the center of the volt.

ADA'MICA *Terra*, in natural history. The bottom of the sea is covered with a salt, glutinous, fat, and mucilaginous mud, like a jelly, as is easily discovered after the tide is out. This mud makes those places it has abandoned so slippery, that it is difficult to walk upon them; it appears to be a settlement of all the most slimy and unctuous parts contained in the waters of the sea, which is continually precipitating themselves in the same manner as the sediment which fresh water insensibly throws down to the bottom of those vessels wherein it is contained, from a kind of slime or silt, which is called Adamica terra. It is conjectured, that, besides the great quantity of fish and plants which continually die and perish in the sea, the air still contributes something to the augmentation of that mud we are speaking of, for it is observed that the Adamic earth is found in greater quantities in such vessels as are only covered with a cloth, than in those which have been hermetically sealed. Memoirs of the Royal Academy of Sciences, for the year 1700, page 29.

A'DAR, in ancient history and theology, the twelfth month of the holy year of the Hebrews, and the sixteenth of their civil year. It consists but of 29 days, and answers to our February; sometimes it enters into the month of March, according as the moon's course falls out.

As the lunar year, which the Jews followed in their calculations, is shorter than the solar year by eleven days, which, at the end of three years, makes one month, they then intercalate a thirteenth month, which they call Veadar, or the second Adar, which has twenty-nine days.

A'DDER, in natural history, a venomous reptile of the serpent kind, generally called a viper. See VIPER in the dictionary.

A'DDER's *Tongue*, in botany. See OPHIOGLOSSUM.

ADDI'TIONS, in distillation, a general name for whatever is added to the wash in the time of fermentation, in order to increase the vinosity of the spirit, procure a larger quantity, or give it a particular flavour.

These Additions may be included under the four heads of salts, acids, aromatics, and oils. A little finely powdered tartar, nitre, or common salt, may be thrown into the fermenting liquor, at the beginning of the operation: or in their stead a little of the vegetable, or fine mineral acids, may be dropt in, at different times, where they are found necessary: As particularly in the case of treacle, honey, and other sweet and rich vegetable juices, which either want a natural acid, have been robbed of it, or hold it but in a small proportion. To this end may be used juice of lemon, oranges, &c. spt. sal. Glaub. ol. sulphur. per campan. &c. But the most effectual thing for the purpose is a particular aqueous solution of tartar; a succedaneum for which may be tamarinds, or the robs of some very acid fruits; or, better still, the media substantia vini. On which foundation stands the ingenious practice of constantly using a suitable proportion of the still-bottoms, or remaining wash, in the subsequent brewing. The Additions are manifestly designed to give a vinous acidity, or improve that naturally afforded by the subject, without any expectation of considerably increasing the quantity of the spirit; which is the more immediate use and design of aromatics and oils; at the same time that they give, alter, or improve a flavour.

All the pungent aromatics have a surprizing property of increasing the quantity of spirit; but their use requires a close or compressed fermentation; and, if the quantity intended be large, that the Addition be not made all at once, lest the oiliness of the ingredients should hinder the operation. But, if flavour be the only thing required from them, these Additions should be delayed till towards the end of the fermentation. After the same manner a very considerable quantity of any essential vegetable oil may, by the proper encheiresis, be converted into a surprisingly large quantity of inflammable spirit; but great care must here again be had not to drop it in too fast, or too much at a time; which might easily damp the fermentation; and is one of the known ways of checking, or totally stopping this operation at any point of time required. The best method of introducing the oil, so as to avoid all inconvenience, is to bring it into an elæosaccharum; which will readily enter the body of the liquor, and directly ferment along with it. In the like prudent manner of proceeding, a large proportion of brandies, or highly rectified spirit of wine, may be introduced into any fermenting liquor. *Shaw's Distil.*

A'DDITIVE *Equations*, in astronomy, are those which are to be added to the sun's mean anomaly, in order to discover the true anomaly.

ADENO'GRAPHY, in anatomy, a description of the glands. This word is compounded of the Greek ἀδὴν, a gland, and γράφω, to describe.

We have a book wrote by Wharton, intituled Adenography, printed in 12°. at London, in 1650, and another work under the same title wrote by Nucke printed in octavo at Leyden, in 1691 and 1722.

ADHE'SION, in philosophy.—The Adhesion of leaden balls is so very considerable, that with two (not weighing above a pound each, nor touching upon more than $\frac{1}{50}$ of a square inch surface) I have lifted above 150 pounds weight. In order to this, the surfaces by which they touch, must be finely planed with the edge of a sharp penknife, and equally pressed together with a considerable force, with a gentle turn of the hand at the same time; and thus two common leaden bullets will adhere so firmly together, as to require upwards of 50 pounds, to separate them.

In polished surfaces that are very hard, as glass, brass, &c. It is impossible to bring them into such close contact as to cohere without the interposition of water, or something humid to fill the pores by expelling the air contained therein, which prevents the planes coming together while dry; the humidity in this case proves a cement which holds the planes together by all its force of attraction on either side.

This force of attraction between the brass planes is greater with oil than with water; and greater with any sort of grease or fat that will harden with cold, than with oil. I never yet could meet with two men strong enough to separate planes thus put together, which are but four inches and a half diameter; and, therefore, they cohere with a force much superior to the force or pressure of air on such a surface, which contains about 14 square inches, and, allowing 15 pounds for pressure to every inch, it will amount to but 210 pounds, which is not near equal to the strength of two men pulling against each other to the best advantage.

Professor Muschenbroeck has made many experiments to shew the force of cohesion between planes of various substances, and about 2 inches diameter, well polished, having first heated them in boiling water, and then besmeared them first with a cold tallow-candle, and afterwards with boiling grease, and the weights to separate them were as in the following table:

	cold grease	hot grease
Planes of glass ——	130 lb.	300 lb.
of brass ——	150	800
of copper ——	200	850
of marble ——	225	600
of silver ——	150	250
of iron ——	300	950

These

These planes adhere by other sorts of matter with forces, as in the table below, where the weights necessary to separate them are specified:

With water	— —	12 ounces.
With oil	— —	18 ounces.
With Venice turpentine		24 ounces.
With rosin	— —	850 pounds.
With tallow candle	—	800 pounds.
With pitch	— —	1400 pounds.

Though these experiments would not always give the same numbers, yet they sufficiently shew the vast attractive forces, and the very great difference between them.

After this he gives us an account of his experiments made, to find the force with which bodies cohere naturally, or what is the absolute force of cohesion in various bodies, which he estimates by the weights required to pull them asunder, drawing according to their length; this he tried first in wood, and afterwards in metal. His pieces of wood were of a long square form, of which each side was $\frac{26}{100}$ of an inch, and by weights suspended they were drawn asunder, according to the several sorts, as mentioned below:

Wood of linden-tree	— —	1000 lb.
of alder	— —	1000
of fir	— —	600
of oak	— —	1150
of elm	— —	950
of beech	— —	1250
of ash	— —	1250

The trial he made with metals, was of weights suspended to wires of each sort, whose diameter was $\frac{1}{10}$ of a Rhindland inch; or, because the Rhindland foot is to ours as 139 to 135, the wire was $\frac{103}{1000}$ part of an inch English.

The metals and weights were as follow:

Of copper	—	299$\frac{1}{4}$ lb.
Of yellow brass		360
Of gold	— —	500
Of silver	—	370
Of iron	— —	450
Of tin	—	40$\frac{1}{2}$
Of lead	— —	29$\frac{1}{4}$

These experiments shew the absolute force of cohesion in bodies. That which he calls the relative force, is that by which any body resists the force of any other body, acting upon it in a direction perpendicular to its length; and this he estimated in the same pieces of wood as before, by putting one end into a square hole of a metal plate, and hanging weights towards the other end sufficient to break each piece of wood at the hole. These weights and distances from the hole were in his experiments as follow:

	distances.	weights.
Fir	— 9 inches	40 ounces.
Oak	— 8$\frac{1}{2}$	— 48
Elm	— 9	— 44
Pine	— 9$\frac{1}{2}$	— 36$\frac{1}{2}$
Alder	— 9$\frac{1}{4}$	— 48
Beech	— 7	— 56$\frac{1}{4}$

Such as would see more on this subject, may consult the author's admirable *Essai de Physique*; and his treatise of the cohesion of bodies, altogether on the subject.

ADIA'NTUM. See the article MAIDENHAIR in the dictionary.

A'DMIRAL, a name given a very beautiful shell of the voluta kind. (See *Plate* III. *fig.* 1.) The enamel which covers it is very bright and elegant, and variegated with bands of yellow, representing, in some measure, the flags of a ship of war; whence it obtained its name. Its distinguishing character is a fine denticulated line, running along the center of the large yellow band.

There are four species of these shells. 1. The grand admiral. 2. The vice admiral. 3. The orange admiral, and 4. The extra admiral. But the first is by far the most valuable.

ADRA'STIA, in antiquity, an epithet given to the goddess Nemesis, or revenge; because king Adrastus first erected a temple to that Deity.

ÆGAGRO'PILA, or ÆGAGROPILUS, in natural history; see the article *German* BEZOAR, in the dictionary.

A'EM, or AM, a liquid measure used in most parts of Germany, and contains generally 20 vetals, or 80 masses. At Heidelberg it is 12 vertels, and the vertel 4 masses, which reduces the Aem to 48 masses: and in Wirtemberg the Aem is 16 yunes, and the yune 10 masses, which makes the Aem amount to 160 masses.

AERO'GRAPHY *, a description of the air or atmosphere, its properties, limits, dimensions, &c.

* The word is compounded of the Greek ἀὴρ, air, and γράφω, to describe.

AFFECTA'TION, in language and conversation, is a very common fault in those who pass under the denomination of fine speakers. It consists in using far fetched terms and hard words, those too, sometimes ridiculously chosen, in speaking of trivial or common subjects: for this reason fine speakers are so intolerable to men of genius, who are more ambitious of thinking than speaking well, or rather because men of genius are of opinion, that in order to speak well it is sufficient to think well; that a thought, which is new, strong, just, and clear, carries its own expression along with it; and that a common thought should never be dressed above itself, that is to say, higher than in common language.

AFFECTATION, in style, is nearly the same thing as Affectation in language, but with this difference, that what we write must naturally be more correct, than what we speak, because we are supposed to think more accurately on what we write; whence it follows, that those who are sometimes affected in their conversation, are not always so in their writing.

AFFE'CTION, in a physiological sense, may be taken in general for the impression that internal or external Beings make on the soul. But Affection is taken more commonly for that lively sense of approbation or dislike, which objects, whatever they are, create in us; thus we say of a picture, which represents things offensive in nature to the senses, that we are shocked, or disagreeably affected at it. We say of an heroic action, or rather of its recital, we are delightfully affected by it.

Such is our frame and the construction of our bodies, that, when the soul is in a disposition to conceive love or hatred, pleasure or aversion, there arise in the body certain muscular motions, on which, in all probability, the intenseness or relaxation of these conceptions depends. Joy is attended with a great dilatation of the heart, the pulse beats high, the heart palpitates in a very sensible degree, the transpiration is so extraordinary as often to have been followed by swoonings, and sometimes even death itself. Anger either suspends or increases all the motions in the body, especially the circulation of the blood, which makes the body hot, red, trembling, &c. Now it is evident, these symptoms are more or less violent, according to the disposition of the parts and the mechanism of the body. The mechanism of the body is rarely such, that it can suspend the free action of the soul by the force of its impressions. But, that this has sometimes happened, there is no room to doubt; it is in the mechanism of the body we must seek the cause why different men are so differently affected by the same object. In this we resemble musical instruments which have strings of a different extension. External objects perform on us the office of bows on these strings, and we all give sounds more or less sharp. Our constitutions, our education, our principles, our systems, our prejudices, all modify our Affections, and the motions of the body, which are the consequences of them. An Affection may be so instantaneous and so strong, that what causes the Affection may seem to produce effects which make free agency a question. But it is evident by what has been said above, that the first motion is more or less durable, according to the difference of constitutions and in infinite number of other circumstances. Let us therefore be very cautious how we judge of those actions that proceed from violent passions. It is better in these cases to be favourable than severe in our sentence; to suppose that the weakness rather than the wickedness of men may have carried them beyond themselves: we pity weakness, abhor wickedness; and surely pity is more suitable to the human character than hatred.

A'GATE, see ACHATES in the Dictionary.

Agate and jasper stones are easily tinged, but such of these stones as are naturally smooth, are for the same reason composed of so many heterogeneous parts, that the colour will not strike uniformly, so that we can only make spots, to compleat the regularity of those we find in them; but not entirely change their colour, as we can in the white Agate called the chalcedony. If you put a solution of silver in spirit of nitre, on a piece of the white Agate, or chalcedony, and expose it to the sun, you will find it tinged at the end of some hours, of a brown colour, approaching to red; and, if some fresh solution be applied, it will pierce deeper still, and the tincture will entirely penetrate the stone. If the Agate exceeds not the thickness of two twelfth parts of an inch, and the tincture be applied on both sides, it does not act uniformly. There are in this sort of Agate, and the generality of other hard stones, veins, which, tho' almost imperceptible, are more easily penetrated by the tincture than by the other parts, become more deeply tinged, and form a very agreeable variety. If you add to the solution above one fourth of it's weight, or thereabouts, of soot and red tartar mixed together, the colour will be brown of a grey cast. Instead of soot and tartar if you apply the same quantity of allum, the colour will be a deep violet, approaching to black. A solution of gold only gives the Agate a light brown, which penetrates very little; of tin, a colour that in a direct light looks of a darkish white, but brown in a side-light. Other solutions of metals and minerals applied in the same manner have no effect.

To succeed in this operation, it is necessary to expose the Agate to the sun. Monsieur Du Fay tried some under a muffle, but the colour struck very weak and imperfectly. He has frequently observed even that those exposed to the sun have taken less colour in the course of the whole first day, than in half an hour of the second, without adding any fresh solution, which made him suspect that a humidity of air is requisite to make the metalline particles penetrate. In short, he made

made Agate take their tinge very readily, by carrying them into a damp place, as soon as the sun had dried the solution, and then exposing them to the sun again.

To trace figures of some regularity on the chalcedony, or white Agate, the best way is to take the solution of silver on a feather or little cleft stick, and trace the contour or outlines with a pin; if the Agate be unpolished, the stroke is never very fine, because the solution soon spreads itself; but, if it be well charged with silver, and the Agate immediately exposed to the sun, there is no great risk of too much diffusion, and the strokes will be neat enough; they will not, however, be so fine as those drawn by a pencil, and, consequently, inferior to those little trees which we see so delicately formed in the dentrite.

Supposing, however, we could find a method of imitating them, there are two ways of distinguishing the natural from the artificial; first, if you heat the Agate coloured by art, it loses a great quantity of its colour, which it will not recover without a fresh application of solution of silver. The second, which is, indeed, the easiest and most simple way, is to put a little aqua fortis, or spirit of nitre, on coloured Agate, keep it from the sun, and, in one night's time, it will take the tinge entirely out: after the experiment is made, the colour may be restored by exposing the Agate several days following in the sun; but we must not depend much on this, as you will see in the sequel.

It is very well known, we can change the colour of most precious stones by fire; thus you may make sapphires and amethists white: put these stones into a crucible, surround them with sand, or steel filings, and they lose their colour in proportion as they receive heat; they are sometimes taken out perfectly white. If you heat the common chalcedony in the same manner, it becomes a darkish white; if you make spots in it with a solution of silver, they turn into a yellow citron, on which aqua fortis effects no mutation. Solution of silver put on the chalcedony, blanched in this manner, and set in the sun several days following, makes brown spots in it.

Solution of silver gives the oriental Agate a deeper black than the common chalcedony. To the Agate interspersed with yellow spots it gives a purple. See Mem. of the Acad. 1728, by M. Du Fay. I have observed before, speaking of the method to discover whether the colour of Agate be natural or artificial, we should not trust too much to aqua fortis. In short, M. De la Condamine put two natural dendrites into aqua fortis three or four days, and they suffered no mutation; the same dendrites, on which the experiment had been made, being accidentally left in a window fourteen or fifteen days, in a wet season, a little rain casually got into the aqua fortis, by which means the branches and lines in the dendrites were totally effaced; the same thing happened to another, at least, as much of it as had been dipped in the aqua fortis.

A'GRICULTURE *(Dict.)*—To cultivate lands to advantage, we must be previously acquainted with the nature of the soil; this requiring one culture, that another; this is better adapted to one kind of grain, that to another. Under the articles LAND and SOIL the reader will find what generally relates to this subject; and, under the names of the different species of corn and plants, their proper soil and culture: we shall here only consider Agriculture or tillage in general. This consists in dividing the ground by the spade, plough, hoe, or other instruments, which divide by a sort of attrition, or contusion, as dung does by fermentation. See DUNG.

Every time the earth is broken by any sort of tillage, or division, there must arise some new superficies of the broken parts which never has been open before: for, when the parts of earth are once united and incorporated together, it is morally impossible that they, or any of them, should be broken again, only in the same places; for, to do that, such parts must have again the same numerical figures and dimensions they had before such breaking, which, even by an infinite division, could never be likely to happen; as the letters of a distich, cut out and mixed, if they should be thrown up never so often, would never be likely to fall into the same order and position with one another, so as to recompose the same distich.

Although the internal superficies may have been drained by a preceding crop, and the next plowing may move many of the before-divided parts, without new breaking them, yet such as are new broken, have, at such places where they are so broken, a new superficies, which never was, or did exist before; because we cannot reasonably suppose, that any of those parts can have in all places (if in any places) the same figure and dimensions twice.

For, as matter is divisible ad infinitum, the places or lines whereat it is so divisible must be, in relation to number, infinite, that is to say, without number; and must have at every division superficies of parts of infinite variety in figure and dimensions.

And, because it is morally impossible the same figure and dimensions should happen twice to any one part, we need not wonder how the earth, every time of tilling, should afford a new internal superficies (or artificial pasture;) and that the tilled soil has in it an inexhaustible fund, which, by a sufficient division (being capable of an infinite one) may be produced.

Tillage, as well as dung, is beneficial to all sorts of land. Light land, being naturally hollow, has larger pores, which are the cause of its lightness: this, when it is by any means sufficiently divided, the parts being brought nearer together, becomes, for a time, bulk for bulk, heavier, i. e. the same quantity will be contained in less room, and so is made to partake of the nature and benefits of strong land, viz. to keep out too much heat and cold, and the like.

But strong land, being naturally less porous, is made, for a time, lighter, as well as richer, by a good division; the separation of its parts makes it more porous, and causes it to take up more room than it does in its natural state; and then it partakes of all the benefits of lighter land.

When strong land is plowed, and not sufficiently, so that the parts remain gross, it is said to be rough, and it has not the benefit of tillage, because most of the artificial pores, or interstices, are too large; and then it partakes of the inconveniences of the hollow land untilled.

For, when the light land is plowed but once, that is not sufficient to diminish its natural hollowness, or pores; and, for want of more tillage, the parts into which it is divided by that once (or perhaps twice) plowing, remain too large; and consequently the artificial pores are large also; and, in that respect, are like the ill-tilled strong land.

Light land, having naturally less internal superficies, seems to require more tillage or dung to enrich it; as when the poor, hollow, thin downs have their upper part (which is the best) burnt, whereby all, except a caput mortuum, is carried away; yet the salts of this, spread upon that barren part of the staple which is unburnt, divide it into so very minute particles, that their pasture will nourish two or three good crops of corn: but then the plough, even with a considerable quantity of dung, is never able afterwards to make a division equal to what those salts have done; and therefore such burnt land remains barren.

Artificial pores cannot be too small, because roots may the more easily enter the soil that has them; quite contrary to natural pores; for these may be, and generally are, too small, and too hard for the entrance of all weak roots, and for the free entrance of strong roots.

Insufficient tillage leaves strong land with its natural pores too small, and its artificial ones too large. It leaves light land with its natural and artificial pores both too large.

Pores that are too small, in hard ground, will not easily permit roots to enter them.

Pores that are too large, in any sort of land, can be of little other use to roots, than only to give them passage to other cavities more proper for them; and, if in any place they lie open to the air, they are dried up and spoiled before they reach them.

For fibrous roots (which alone maintain the plant, the other roots serving to receive the chyle from them, and convey it to the stem) can take in no nourishment from any cavity, unless they come into contact with, and press against, all the superficies of that cavity which includes them; for it dispenses the food to their lacteals by such pressure only: but a fibrous root is not so pressed by the superficies of a cavity whose diameter is greater than that of the root.

The surfaces of great clods form declivities on every side of them, and large cavities, which are as sinks to convey, what rain and dew bring, too quickly downwards below the plowed part.

The first and second plowings with common plows scarce deserve the name of tillage; they rather serve to prepare the land for tillage.

The third, fourth, and every subsequent plowing, may be of more benefit, and less expence, than any of the preceding ones.

But the last plowings will be most advantageously performed by way of hoeing. See HOEING.

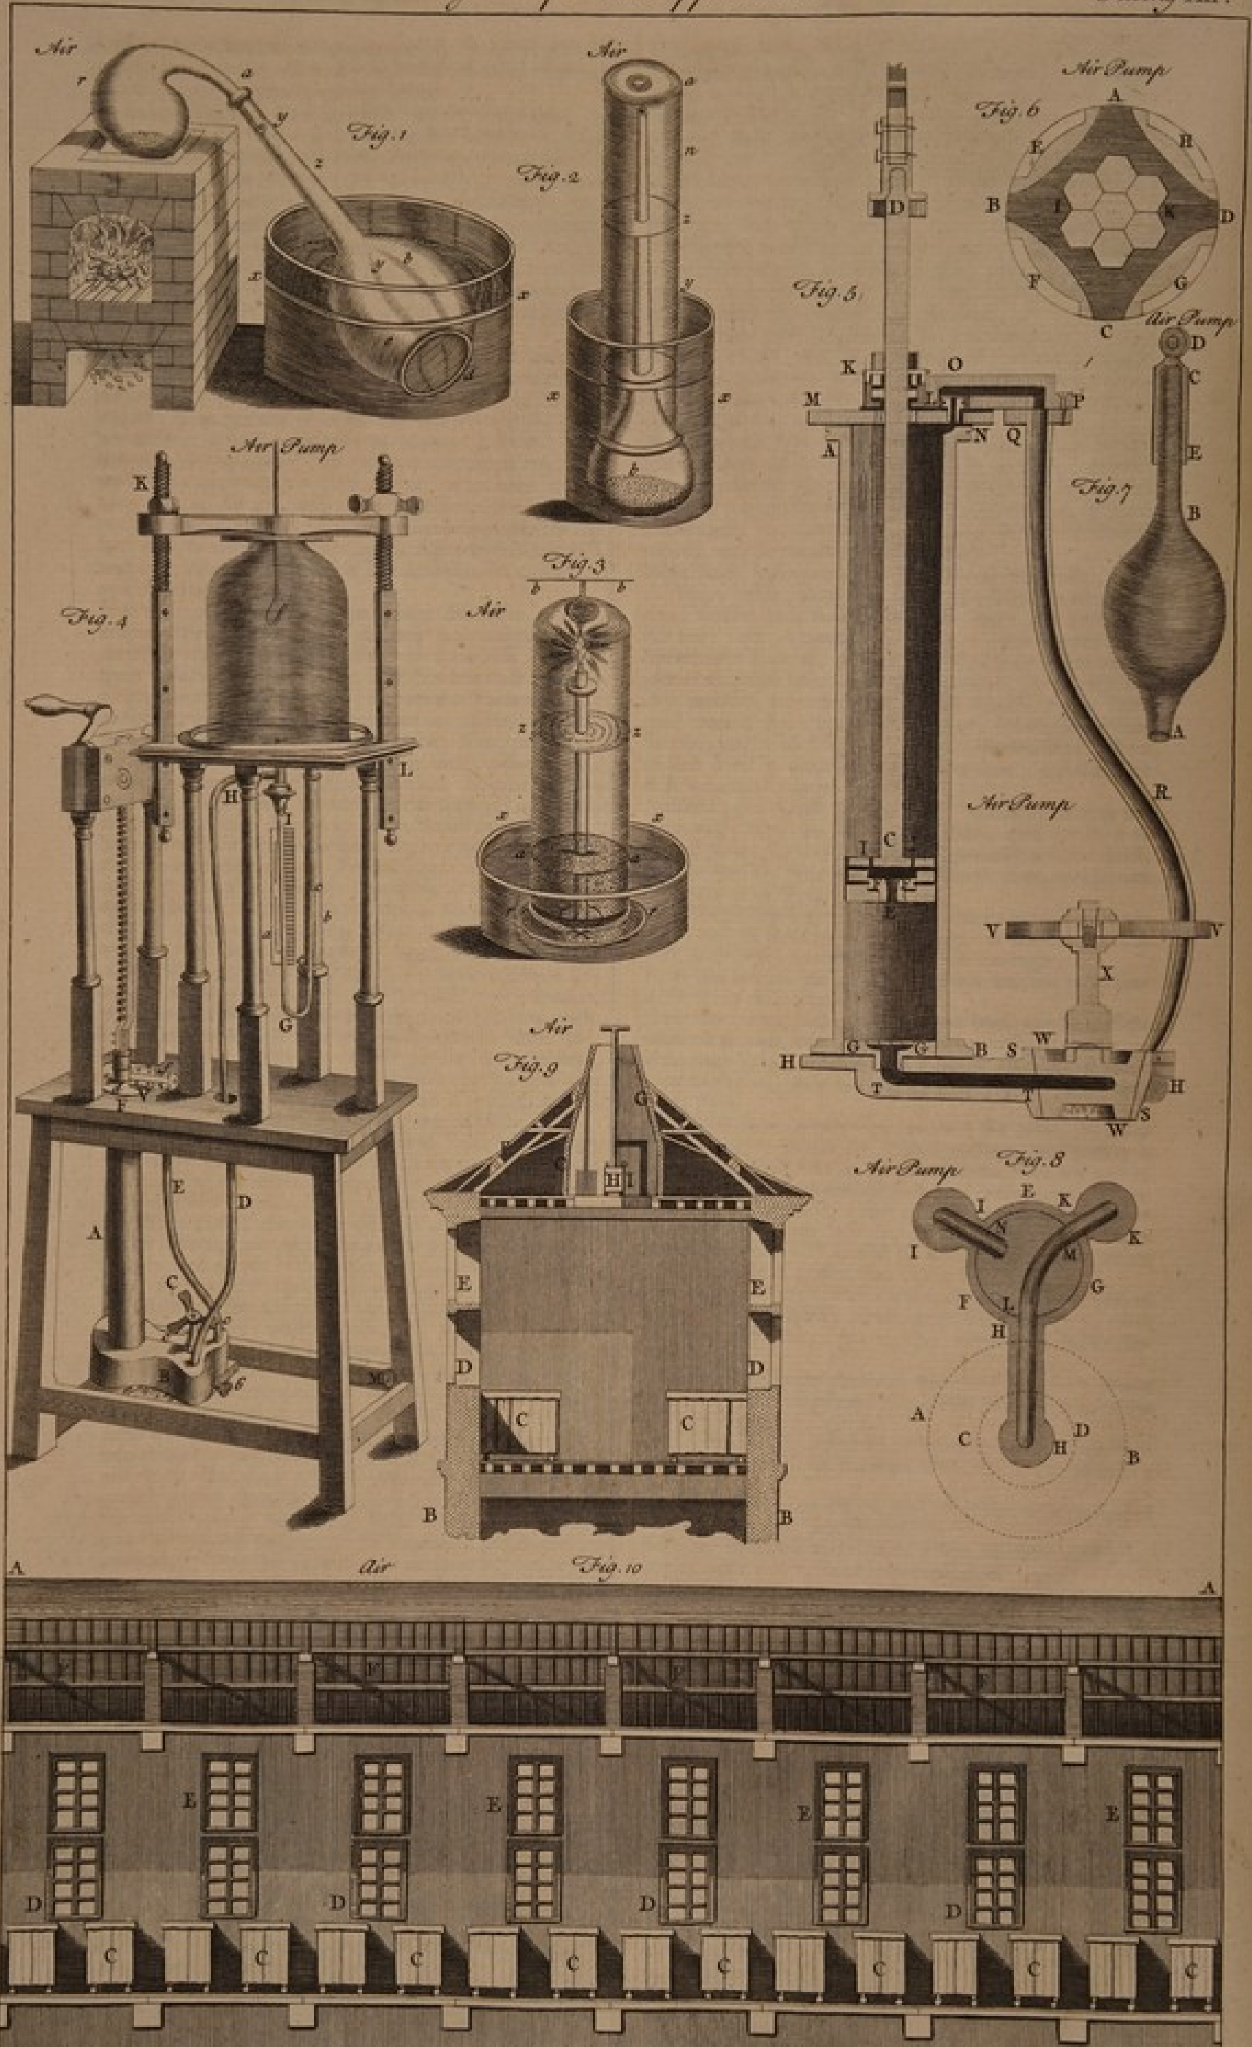
For, the finer land it is made by tillage, the richer will it become, and the more plants it will maintain.

It has been often observed, that when part of a field has been better tilled than the rest, and the whole ground constantly managed alike afterwards for six or seven years successively; this part that was but once better tilled, always produced a better crop than the rest, and the difference remained very visible every harvest.

One part being once made finer, the dews more enriched it; for they penetrate in and beyond the superficies, whereto the roots are able to enter: the fine parts of the earth are impregnated, throughout their whole substance, with some of the riches carried in by the dews, and there reposited; until, by new tillage, the insides of those fine parts become superficies; and, as the corn drains them, they are again supplied as before; but the rough large parts cannot have that benefit; the dews not penetrating to their centers, they remain poorer.

I think nothing can be said more strongly to confirm the truth of this, than what is related by the authors quoted by Mr. Evelyn, to this effect, viz.

'Take of the most barren earth you can find, pulverize 'it well, and expose it abroad for a year, incessantly agita- 'ted; it will become so fertile as to receive an exotic plant 'from



Printed for J. Hinton in Newgate Street.

"from the fartheſt Indies to cauſe all vegetables to proſper in "the moſt exalted degree, and to bear their fruit as kindly "with us as in their natural climates."

This artificial duſt, he ſays, will entertain plants which refuſe other violent applications; and that it has a more nutritive power than any artificial dung or compoſt whatſoever: and further that, by this toil of pulverizing, "it is found, "that ſoil may be ſo ſtrangely altered from its former nature, as "to render the harſh and moſt uncivil clay obſequious to the "huſbandman, and to bring forth roots and plants, which "otherwiſe require the lighteſt and holloweſt mould."

It is to be ſuppoſed, that the Indian plants had their due degree of heat and moiſture given them; and I ſhould not chuſe to beſtow this toil upon the pooreſt of earth in a field or garden, though that is the moſt proper wherein to make the experiment.

I never myſelf tried this way of pounding or grinding, becauſe impracticable in the fields.

But I have had the experience of a multitude of inſtances, which confirm it ſo far, that I am in no doubt, that any ſoil, be it rich or poor, can ever be made too fine by tillage.

For it is beyond diſpute, that one cubical foot of this minute powder may have more internal ſuperficies, than a thouſand cubical feet of the ſame, or any other earth tilled in the common manner; and, I believe, no two arable earths in the world exceed one another in their natural richneſs twenty times; that is, one cubical foot of the richeſt is not able to produce an equal quantity of vegetables, cæteris paribus, to twenty cubical feet of the pooreſt; therefore it is not ſtrange, that the pooreſt, when by pulverizing it has obtained one hundred times the internal ſuperficies of the rich untilled land, ſhould exceed it in fertility; or, if a foot of the pooreſt was made to have twenty times the ſuperficies of a foot of ſuch rich land, the pooreſt might produce an equal quantity of vegetables with the rich. Beſides, there is another extraordinary advantage, when a ſoil has a larger internal ſuperficies in a very little compaſs; for then the roots of plants in it are better ſupplied with nouriſhment, being nearer to them on all ſides within their reach, than it can be when the ſoil is leſs fine as in common tillage; and the roots in the one muſt extend much farther than in the other, to reach an equal quantity of nouriſhment; they muſt range and fill perhaps above 20 times more ſpace to collect theſame quantity of food. But, in this fine ſoil, the moſt weak and tender roots have free paſſage, to the utmoſt of their extent, and have alſo an eaſy, due, and equal preſſure every-where, as in water.

Hard ground makes a too great reſiſtance, as Air makes a too little reſiſtance, to the ſuperficies of roots.

Farmers, juſt when they have brought their land into a condition fit to be further tilled to much greater advantage, leave off, ſuppoſing the ſoil to be fine enough, when, with the help of harrows, they can cover the ſeed; and afterwards with a roller they break the clods, in order, that, if the crop ſucceed, they may be able to mow it, without being hindered by thoſe clods: by what I could ever find, this inſtrument, called a roller, is ſeldom beneficial to good huſbandry, it rather untils the land, and anticipates the ſubſiding of the gound, which in ſtrong land happens too ſoon of itſelf.

But more to blame are they, who neglect to give their land due plowing, truſting to the harrow to make it fine; and, when they have thrown in their ſeed, go over it twenty times with the harrows, till the horſes have trodden it almoſt as hard as a highway, which in moiſt weather ſpoils the crop; but, on the contrary, the very horſes, when the earth is moiſt, ought all to tread in the furrows only, as in plowing with a hoe-plough they always do, when they uſe it inſtead of a common plough. *Tull's Horſe-hoeing Huſbandry.*

AGROSTOGRA'PHIA *, in phyſiology, the hiſtory or deſcription of gramens, or plants of the graſſy kind.

* The word is formed from the Greek, ἄγρωστις, graſs, and γράφω to deſcribe.

AIR, *(Dict.)*—— Air is a principal cauſe of the vegetation of plants, an inſtance of which we have from Mr. Ray, in the Philoſophical Tranſactions, of lettice-ſeed, that was ſown in the glaſs receiver of the Air-pump, which was exhauſted and cleared from all Air, which grew not at all in eight days time; whereas ſome of the ſame ſeed that was ſown at the ſame time in the open Air, was riſen to the height of an inch and an half in that time; but, the Air being let into the exhauſted receiver, the ſeed grew up to the height of two or three inches in the ſpace of one week.

Another inſtance of the uſefulneſs of the Air in vegetation, is the ſedum, which will puſh out roots without earth and water, and live for ſeveral months: and ſome ſort of aloes, if hung up in a room entirely ſecured from froſts, will remain freſh for ſome years, though they will ſenſibly loſe in their weight.

Air is capable of penetrating the porous and ſpongy parts of plants, and being there contracted, and dilating itſelf again.

The Air operates alſo within the bowels of the earth, and, by its ſubtilty perſpiring thro' the pores, aſſiſts in the rarefaction of the crudities of the earth, and in the diſpelling all ſuperfluous moiſture entering into the very pores and veins of the trees, plants, herbs, &c. carrying along with it thoſe ſalts contained either in itſelf, or lodged in the earth; which ſalts or juices are altered according to the ſeveral figures or dimenſions of the different ſtrainers or veſſels of thoſe ſeveral plants which grow upon the ſame ſpot of earth, which is ſo impregnated with theſe ſalts: and thence thoſe varieties in taſte and ſmell proceed, notwithſtanding they all receive their nouriſhment from the ſame ſtock that is lodged in the earth.

The Air alſo affects the branches, leaves, and flowers of trees, plants, and herbs, entering and perſpiring through them, and even thro' the bark and body of trees; and by the ſame kind of ſubtilty it does, by its refreſhing breezes, moderate the intenſeneſs of the ſun-beams, cooling, chearing, blowing, opening, and extending all the offspring of nature. The Air fixes and inſinuates its aereal ſubſtance into the liquid ſap of vegetables: and, as all the agitations in nature proceed from the contrariety of parts inhabiting together, in this aereal and liquid ſubſtances, being mixed, cauſe the agitation and motion in vegetables, or, more properly, ſet it all into a ferment, whether it be in the roots, or in the ſtem; and it riſes by co-operation of the ſun, which is the third agent in vegetation, up to the top of a tree, &c. as liquids riſe by fire to the top of the containing veſſel.

The Air, we find, produces a vibratory motion in ſeveral bodies; and, particularly in plants, the Air-veſſels thereof perform the office of lungs: for the Air contained in them, ſometimes contracting, and ſometimes expanding, according as the heat is increaſed or diminiſhed, preſſes the veſſels, and eaſes them again by turns; and thus promotes a circulation of their juices, which could ſcarce be otherwiſe effected.

Air, ſays the learned Dr. Hales, is a fine elaſtic fluid, with particles of very different natures floating in it, whereby it is admirably, fitted by the great author of nature, to be the breath or life of vegetables, as well as animals, without which they can no more live nor thrive than animals can. As a proof of the great quantities of Air in vegetables, he refers to the third chapter of his excellent treatiſe of vegetable ſtatics, where, he ſays, in the experiments on vines, the great quantity of air was viſible, which was continually aſcending through the ſap in the tubes; which manifeſtly ſhews what plenty of it is taken in by vegetables, and is perſpired off with the ſap through the leaves.

He adds ſeveral experiments, as to an apple-branch, apricot-branch, birch, and other plants, to prove the ſame thing.

And Dr. Grew has obſerved, that the pores are ſo large in the trunks of ſome plants, as in the better ſort of thick walking-canes, that they are viſible to a good eye without a glaſs; but, with a glaſs, the cane ſeems as if ſtuck at top full of holes with great pins, ſo large as very well to reſemble the pores of the ſkin in the ends of the fingers, and ball of the hand.

In the leaves of pines, they likewiſe, through a glaſs, make a very elegant ſhew, ſtanding almoſt exactly in rank and file thro' the length of the leaves. Whence it may be thought probable, that the Air freely enters plants, not only with the principal fund of nouriſhment by the roots, but alſo through the ſurface of their trunks and leaves, eſpecially at night, when they are changed from a perſpiring to a ſtrongly imbibing ſtate.

Dr. Hales likewiſe tells us, that, in all thoſe experiments that he tried to this purpoſe, he found that the Air entered very ſlowly at the bark of young ſhoots and branches, but much more freely through old bark; and that in different kinds of trees it had different degrees of more or leſs free entrance.

And likewiſe, that there is ſome Air both in an elaſtic and unelaſtic ſtate, mixed with the earth (which may well enter the roots with the nouriſhment) he found by ſeveral experiments, which he gives in the above-mentioned treatiſe.

The excellent Mr. Boyle, in making many experiments on the Air, among other diſcoveries found, that a good quantity of Air was produceable from vegetables, by putting grapes, plums, gooſeberries, peaſe, and ſeveral other ſorts of fruits and grain, into exhauſted and unexhauſted receivers, where they continued for ſeveral days emitting great quantities of Air.

This put the curious Dr. Hales upon further reſearches to find out what proportion of Air he could obtain out of the vegetables in which it was lodged and incorporated; this he performed by divers chymico-ſtatical experiments, which he gives in many inſtances, in his treatiſe of the analyſis of the Air, plainly ſhewing in what manner he performed them.

One of which was by diſtillation; another by fermentation.

That by diſtillation is as follows: The matter to be diſtilled is put into the retort *r (plate I. fig. 1.)* and then at *a* is cemented very faſt the glaſs veſſel *a b*, which was very capacious at *b*, and had an aperture *c d*, or hole at the bottom. The bolt-head *a b* being immerſed in water, with one leg of an inverted ſyphon put up as far as *z*, the water would riſe in the bolt-head, and drive out the Air through the ſyphon, which being taken out, the water will remain in the veſſel to the part *z*; at the ſame time, while the bolt-head is under water, it is placed in the veſſel *x x*, which, with the bolt-head and retort, is carried to the chymical furnace, where the retort has the heat and fire gradually communicated to it, and the bolt-head *a b* and veſſel *x x* well ſkreened from the heat of the fire.

As the matter diftilled, all except the Air, would go down into the water of the bolt-head and veffel; the Air that was generated or deftroyed by the procefs, would be fhewn by caufing the furface of the water in the bolt-head to ftand below or above the point *z*, as at *y*, when all was fet afide till it became quite cold. Thus, if the body diftilling generates Air of an elaftic quality, that added to the former will not permit the water *y* to rife fo high as *z*, and the fpace between *z* and *y* below will fhew how much Air was produced from its fixed ftate.

But if, when all is cold, the furface of the water *y* be feen above the point *z*, it then fhews that the diftilled body did deftroy, that is, imbibe or abforb, a part of the natural air above *z*; and the fpace between *z* and *y*, filled with water, will fhew what quantity was changed from a repellent elaftic to a fixed ftate, by the ftrong attraction of the abforbing particles of the diftilled body. This quantity of generated or abforbed Air it is eafy to meafure in cubic inches, by ftopping the end of the bolt-head with a cork, and then from a quantity of water of a known weight to fill it firft to *z*, and afterwards to *y*; and the difference of weight in the two bulks of water gives the number of cubic inches, from a table of fpecific gravities.

The other method which the doctor made ufe of for eftimating the furprizing effects of fermentation, from various mixtures of folid and fluid fubftances, in generating and abforbing Air, was as follows: He put the ingredients into the bolt-head *b*, (*fig.* 2.) and then run the long neck thereof into a tall cylindric glafs *ay*, and inclining both almoft horizontally, in a large veffel of water, the water ran into the veffel *ay*, and, driving out part of the Air, would poffefs its place upon turning them up, and placing both in a veffel of water *xx*, as you fee in the figure, where the furface of the water ftands in the inverted glafs *a y* at the point *z*.

If the ingredients generated Air, then the water would fall from *z* to *y*, and the empty fpace *zy* was equal to the quantity of generated Air; but, if on fermentation they abforbed or fixed the active particles of Air, then the furface of the water would afcend from *z* to *n*; and the cylinder *z n* would be the bulk of Air abforbed, which is eafily known in cubic inches.

When the fubjects for trying thefe experiments were a burning candle, burning brimftone, nitre, gun-powder fired, living animals, &c. the doctor ufed to make ufe of a pedeftal, on the top of which was a plate, whereon he laid the matter to be fired; then inverting the tall cylindric glafs over it, and drawing the water up to *zz* (*fig.* 3.) with an inverted fyphon, he fet fire to the matters lying on the plate, by means of a burning-glafs, concentering the fun's rays in its focus upon the fame. See the figure.

But the beft way is, inftead of having the cylindric glafs clofe upon the top at *bb*, to have it open by a fmall neck, on which a brafs cap is cemented with a female-fcrew to receive a ftop-cock, to take off the communication of the external Air, when occafion requires. Thus the ufe and trouble of the fyphon is fuperfeded; and in cafe of noxious fumes, vapours, &c. from aquafortis, burning brimftone, &c. a fyringe fcrewed on to the ftop-cock will draw off the Air, and raife the water to what height you pleafe, without the cumberfome ufe of a large pair of bellows, as the doctor made ufe of.

From half a cubic inch, or 135 grains of heart of oak, frefh cut from a growing tree, he found there were 108 cubic inches of Air generated, which is a quantity equal to 216 times the bulk of the piece of oak; that the weight of it was above 30 grains, one quarter part of the weight of 135 grains.

And he adds, that he took the like quantity of thin fhavings from the fame piece of oak, and dried them at fome diftance from a gentle fire, for 24 hours; in which time they evaporated 44 grains of moifture; which 44 grains being deducted from 135 grains, there remain 91 grains for the folid part of the oak: then 30 grains will be one-third of the weight of the folid part of the oak.

He gives us another experiment of Indian wheat, which grew in his own garden: he took 388 grains of it, when it was not come to its full maturity, and there were generated from it 270 cubic inches of Air; the weight of which Air was 77 grains, viz. one-fourth of the whole weight of the wheat.

He alfo found, that a cubic inch, or 318 grains, of peafe generated 396 cubic inches of Air, or 113 grains, i. e. fomething more than one-third of the weight of the peafe.

And again, that from one ounce, or 437 grains of muftard-feed, 270 cubic inches of Air were generated, or 77 grains, which is more than one-fixth part of the ounce weight.

He likewife adds, that there is a great plenty of Air incorporated into the fubftance of vegetables, which, by the action of fermentation, is roufed into an elaftic ftate, as is evident from thefe experiments following.

On the fecond day of March, he poured 42 cubic inches of ale from the tun, which had been there fet to ferment 34 hours before, into a bolt-head; and from that time, to the 9th of June, it generated 639 cubic inches of Air, with a very unequal progreffion, more or lefs, as the weather was warm, cool, or cold; and fometimes, upon a change from warm to cool, it reforbed Air, in all 32 cubic inches.

From the 2d of March to the 16th of April, 12 cubic inches of Malaga raifins, with 18 cubic inches of water, generated 411 cubic inches of Air; and then, again, it reforbed 35 cubic inches in two or three cold days. From the 21ft of April to the 16th of May, it generated 78 cubic inches; after which, the 9th of June, it continued in a reforbing ftate, fo as to reforb 13 cubic inches: that there were at that feafon many hot days, with much thunder and lightning, which deftroy the elafticity of the Air: there were generated in all 489 cubic inches, of which 48 were abforbed. The liquor was at laft vapid.

On the 10th of Auguft, 26 cubic inches of apples being mafhed, they generated 986 cubic inches of Air in 13 days time, which is a quantity equal to 48 times their bulk; after which they reforbed a quantity equal to their bulk, in three or four days, notwithftanding the weather was then very hot; after which time they were ftationary for many days, neither generating nor abforbing.

From the above-mentioned experiments on raifins and ale, the ingenious author concludes, that wine and ale do not turn vapid in warm weather by imbibing the Air, but by fermenting and generating too much; by which means they are deprived of their enlivening principle, the Air: for which reafon, thefe liquors are beft preferved in cool cellars, whereby this active invigorating principle is kept within due bounds; which when they exceed, wines are upon the fret, and are in danger of being fpoiled. Upon thefe, and many other experiments, which the learned author has given in his aforefaid treatife, he obferves, that the Air which arifes in fo great quantities from fermenting and diffolving vegetables, is true permanent Air; which is certain, by its continuing in the fame expanded and elaftic ftate for many weeks and months; which expanded watery vapours will not do, but foon condenfe, when cold.

Upon the whole, he concludes, that Air abounds in vegetable fubftances, and bears a confiderable part in them: and, if all the parts of matter were only endowed with a ftrongly attracting power, all nature would then immediately become one unactive cohering lump.

Wherefore it was abfolutely neceffary, in order to the actuating this vaft mafs of attracting matter, that there fhould be every-where mixed with it a due proportion of ftrongly repelling elaftic particles, which might enliven the whole mafs by the inceffant action between them and the attracting particles.

And fince thefe elaftic particles are continually in great abundance reduced by the power of the ftrong attracters, from an elaftic to a fixed ftate, it was therefore neceffary, that thefe particles fhould be endued with a property of refuming their elaftic ftate, whenever they were difengaged from that mafs in which they were fixed, that thereby this beautiful frame of things might be maintained in a continual round of the production and diffolution of vegetable, as well as animal bodies.

The Air is very inftrumental in the production and growth of vegetables, both by invigorating their feveral juices, while in an elaftic active ftate, and alfo by greatly contributing, in a fixed ftate, to the union and firm connection of the feveral conftituent parts of thofe bodies, viz. their water, fire, falt, and earth.

To conclude, by reafon of thofe properties of the Air beforementioned, it is very ferviceable to vegetables, in that it blows up and breaks open the clouds, thofe treafures of rain, which nourifhes the vegetable tribe.

The Air alfo helps to waft or difperfe thofe foggy humid vapours which arife from the foil, and would otherwife ftagnate, and poifon the whole face of the earth.

The Air, by the affiftance of the fun, affumes and fublimates thofe vapours into the upper regions; and thefe foggy humid vapours are, by this fublimation, and the coercive power of the Air and fun, rarefied, and made again ufeful in vegetation.

And, on the contrary to the benign quality of the Air, which is fo many ways fubfervient to vegetables, it is alfo fometimes, and upon fome accounts, injurious and pernicious to them; not only to the ligneous, herbaceous, and flowery parts above, but alfo to the roots and fibres below: for, becaufe the Air penetrates into the earth, it is eafy to be concluded, that a dry, hufky, fcorching Air may be very prejudicial to the tender fibres of new-planted trees.

It may be likewife fuppofed, that all bodies of earth are more or lefs capable of imbibing the fluid air, and of attracting fuch falts as either can give, or the earth is capable of receiving.

In chymiftry, it is by no means indifferent whether the procefs be made in the Air or out of it, whether in a confined or open Air. Thus camphire, burnt in a clofe-ftopped veffel, goes all into falts; inftead of which, during the procefs, if you open the veffel and approach it with a wax taper, it all diffipates into fmoke. In like manner, to make fulphur inflammable, there muft be an open Air. In a clofe cucurbit you may fublimate it even a thoufand times without its taking fire. If fulphur be put under a bell glafs with fire underneath it, a fpirit of fulphur will arife; but, if there be the leaft crack in the glafs, to permit a communication between

 the

the interior and exterior Air, the ſulphur will immediately take fire. An ounce of charcoal, incloſed in a well-luted crucible, will remain there without decay fourteen or fifteen days in the middle of a furnace with a ſtrong fire, though, in open Air, the thouſandth part of the fire would have reduced it into aſhes in a minute; Van Helmont even adds, that all this time the charcoal keeps its black colour, but, on the intromiſſion of a little Air, it immediately changes into white aſhes. The ſame thing may be ſaid of all animal and vegetable ſubſtances, which can only be calcined in open fire, but in ſtopped veſſels can only be reduced to black coals. The Air can effect infinite mutations in ſubſtances, not only with regard to its mechanical properties, as gravity, denſity, &c. but alſo on account of the heterogeneous parts which enter into all ſubſtances. As, for example, where there is a great many, the Air is impregnated with a biting vitriolic ſalt, which deſtroys every thing on the earth round about, and frequently appears on the ſurface of the ground in a kind of whitiſh efflorescence.

At Fohlun, in Sweden, a town famous for its copper mines, which have procured it the name of Copperburgh, the mineral exhalations affect the Air ſo ſenſibly, that the ſilver and copper money people carry in their pockets, changes colour by the means of it; and M. Bayle was informed by a gentleman of property in thoſe parts, that from the veins of metals and minerals, frequent in that country, columns of a kind of ſmoke or ſteam frequently aroſe, ſome of which had a very bad ſcent, others none at all, and ſome an agreeable one. In Carniole and other places, where there are mines, the Air is at ſome ſeaſons very unhealthy: from whence proceed ſeveral epidemical diſtempers. We ſhall add, that, about the cape of Good-hope, the mines of arſenic, which are numerous in that neighbourhood, emit ſuch noxious vapours, that no animal can live, and they were therefore obliged to ſhut them up again, after having been opened ſome time. Dr. Hales has lately contrived a machine for evacuating foul Air. We are not yet ſufficiently acquainted of what importance it is, that the Air we breathe ſhould be pure and free from all mixture of nauſeous and offenſive particles; but, if ſuch a quality of Air is ſo much to be deſired by every body, how much more eſſentially neceſſary is it for thoſe whom ſickneſs has made ſuſceptible of every external impreſſion, and thoſe who, pent up in a ſhip, during the courſe of a long voyage, are obliged to live between decks, and are forced to hard labour in different places of the lower part of the veſſel, which receive very little Air from without, and where it is always motionleſs, and as it were ſtagnated? What renders this ſtill more deplorable, is thoſe very places into which we would chuſe to have pure Air are in general filled with the contrary; the Air of hoſpital-rooms is almoſt always mixed with the vapours that continually exhale from the bodies of the ſick, their cloſe-ſtools, and the different remedies adminiſtered to them: the terrible ſickneſſes ſome people of the ſtrongeſt conſtitutions have been attacked with, on their entering into theſe places at firſt, are a proof paſt contradiction of the impurity of the Air and its effects. The ſame thing happens in ſhips, where the exhalations that ariſe from the proviſions, from the pores of the men and living creatures on board, produce effects nearly like to thoſe obſerved in hoſpitals.

In order to prevent the accidents, which Air mixed with theſe noxious vapours may occaſion more certainly, it will be right, firſt, to examine into the nature of theſe vapours. The leaſt attention will convince us, they are almoſt entirely volatile; we muſt conclude, therefore, they will always naturally riſe toward the ceiling of the rooms, and this motion upward muſt be increaſed by the motion of the Air, which aſcends in proportion to its rarefaction.

If this propoſition wanted proof, it is eaſy to demonſtrate it; only raiſe a ladder againſt the wall of a room in an hoſpital, and you will find, as you advance towards the ceiling, the ſmell, which you could ſupport below, grow continually more offenſive, and the Air hotter; this being admitted, it will be eaſy to let out the foul Air and introduce freſh, only by placing windows cloſe under the ceiling, and leaving the top ſquares always open; for the hot and putrified Air would continually go off, and a circulation of freſh Air be promoted every moment.

The ſame effect might be produced by erecting a cupola or dome at each extremity of a ward in an hoſpital; the Air would naturally be drawn to them, and paſs off by them; this has been practiſed at Lyons with ſo much ſucceſs, that you can ſcarce perceive any ſmell at all in the hoſpital, but, if you ſhould go up on the inſide of the cupola, the ſtench is inſupportable.

However certain the means we have mentioned, of renewing Air in hoſpitals, may appear to be and really are, they can only be uſed in new fabrics of this kind; to attempt it in the old, would be often impracticable, and always expenſive.

Monſieur Duhamel has found out a method of remeding this inconvenience; he, in the room at one end, makes a large fire-place, like one of your great kitchen chimnies; the opening of this ſtock is on a level with the cieling, and abuts above on a funnel, like thoſe of common chimnies; but three or four times as large, and this is ſufficient to procure a circulation of Air; one of this kind built in a ſtable entirely freed ſome neighbouring apartments from the ſmell of the dung, which before affected them: but to increaſe the draught of Air, and determine it in a more certain manner to take this courſe, put a ſtove within the chimney, the funnel of which muſt go out at its opening, and the mouth diſcharge itſelf in the garret; light a fire in it ſufficient to heat the Air contained within the chimney; the rarefied Air will aſcend in the funnel, and the draught conſequently become quicker. The hotter the weather, the more this adventitious help will be required, becauſe the difference between the ſuperior and inferior Air will become ſo much leſs; and the machine will introduce new Air in proportion as the fire is increaſed.

As we ſhall be obliged to increaſe the draught in ſummer, it will ſometimes perhaps be neceſſary to leſſen it in winter; it might pump too powerfully, and the room be chilled by it. For this, however, M. Duhamel has contrived a very eaſy remedy, that is, by putting a kind of cover either on the chimney or its funnel, which you may open or ſhut at pleaſure, and ſo increaſe or diminiſh the draught, as ſhall be found neceſſary.

But there is no danger of rendering the Air of the room too chilly, even by the briſkeſt draught, if we make funnels behind the ſtock or underneath the hearth, for through theſe a ſufficient quantity of Air will paſs to fill the ſpace that is diſſipated by the chimney; or it will be the ſame thing if the funnels are made near the ſtove in which a continual fire is kept, ſomething after the manner propoſed by M. Gauger in his treatiſe on mechanics by fire, for thus, in whatever quantity this Air enters, it will ſupply the place of the Air in the room, without chilling it.

But how are we to apply theſe means to the under decks of ſhips, in which we can neither build cupola nor chimney? M. Duhamel propoſes a very eaſy method, notwithſtanding the ſeeming difficulty of applying them to theſe purpoſes; with very little alteration in the machine, he places, under the hearth of the chimney in the cook-room, a great box of hollow iron, the top of this ſerves for the fire-place. This box has two funnels, one goes down toward the under decks, the other is carried directly up in the brick-work, and diſcharges itſelf above; the Air, being continually rarefied in the box, by the action of the fire becomes lighter and goes off through the aſcending funnel, which is continually ſupplied by that which the deſcending funnel draws from the under decks; by this contrivance a circulation of Air is obtained by a draught through the ſcuttles and other openings of the veſſel, and the Air which otherwiſe would have ſtagnated, is carried off through the aſcending funnel: thus we ſhall find ourſelves delivered from the accidents that might happen from corrupted Air, without expence, or any inconvenience to the veſſel.

Plate I. *fig.* 9, 10, repreſents two profiles of the ward of an hoſpital, the one A A, the length; the other B B, the breadth; C C, beds of the patients, D D, uſual poſition of the windows, E E, a better poſition, F F, timbers of the roof. In the ſecond profile, the correſponding places are marked by the ſame letters. G, G, the fire-place, on the floor of the garret, at one of the ends of the ward. H, a ſtove in the fire-place, the tube of which riſes above it, and is carried above the funnel. I, the place where the ſtove is to be faſtened to one of the ſides of the fire-place, for lighting the fire by an aperture at the other ſide of this wall.

Dr. Deſaguliers and Dr. Hales have invented two different machines for the ſame uſe, the former of which the reader will find under CENTRIFUGAL *Wheel*, and the latter under VENTILATOR.

AIR-*bladder*, a ſmall bladder or veſicula, found in the bodies of fiſhes. Its uſe is to enable them to either riſe or ſink in the water, or ſuſtain themſelves at any depth.

A bubble of Air, immerſed in a fluid, dilates itſelf in proportion as it approaches the ſurface; becauſe the weight or preſſure of the incumbent water thereon continually decreaſes; and from hence the diſcovery of the uſe of Air-bladders took its riſe. For the Air in the bladder is like the bubble, more or leſs compreſſed according to the depth the fiſh ſwims at, and takes up more or leſs ſpace; and, conſequently, the body of the fiſh, part of whoſe bulk this bladder is, is greater or leſs according to the ſeveral depths, though it retains the ſame weight. The rule of hydroſtatics is, that a body heavier than ſo much water, as is equal in quantity to the bulk of it, will ſink; a body lighter will ſwim: a body of equal weight will reſt in any part of the water. By which rule, if the fiſh in the middle region of the water be of equal weight with an equal bulk of the water, the fiſh will reſt there, without any tendency either upwards or downwards; and, if the fiſh be deeper in the water, its bulk becoming leſs by the compreſſion of the bladder, and yet retaining the ſame weight, it will ſink and reſt at the bottom: on the other ſide, if the fiſh be higher than the middle region, the Air dilating itſelf, and the bulk of the fiſh conſequently increaſing, without any increaſe of the weight, the fiſh will riſe and reſt at the top of the water.

Perhaps the fish by some action, can emit Air out of the bladder, and afterwards out of its body; and also, when there is not enough, take in more Air, and convey it to this bladder; in which case it will be no wonder, that there should be always a fit proportion of Air in the bodies of all fishes, to serve their use, according to the depth of water they live in: perhaps also, by some muscle, the fish can contract this bladder beyond the pressure of the weight of water; and perhaps it can by its sides, or some other defence, keep off the pressure of the water, and give the Air leave to dilate itself. In these cases, the fish will be helped in all intermediate distances, and may rise or sink from any region without moving a fin. *Phil. Transf.* N°. 114. p. 310.

If the Air-bladder of a fish be pricked or broken, the fish presently sinks to the bottom, unable either to support or raise itself up again. Flat fishes, as soles, plaise, &c. which always lie groveling at the bottom, have no Air-bladder.

In most fishes there is a manifest channel, leading from the gullet, or upper orifice of the stomach, to the Air-bladder, which doubtless serves for conveying Air into it. In a sturgeon, Mr. Willoughby observed, that, upon pressing the bladder, the stomach presently swelled; so in that fish it seems the Air passes freely both ways. Possibly the fish, while alive, may have a power to raise up this valve, and let out Air on occasion.

Air-*pump*. Under this article in the dictionary we have given an account of the structure of the common Air-pump, and also that of a portable one; we shall here add an account of a very great improvement made in that machine, by the ingenious Mr. Smeaton, from the *Philos. Transact.* vol. 47. pag. 415.

The principal causes of imperfection in the common pumps arise, first, from the difficulty in opening the valves at the bottom of the barrels; and, secondly, from the piston's not fitting exactly, when put close down to the bottom; which leaves a lodgment for Air, that is not got out of the barrel, and proves of bad effect.

In regard to the first of these causes, the valves of Air-pumps are commonly made of a bit of thin bladder, stretched over a hole generally much less than one tenth of an inch diameter; and to prevent the Air from repassing between the bladder and the plate, upon which it is spread, the valve must always be kept moist with oil or water.

It is well known, that at each stroke of the pump the Air is more and more rarefied, in a certain progression, which would be such, that an equal proportion of the remainder would be taken away, was it not affected by the impediments I have mentioned: so that, when the spring of the Air in the receiver becomes so weak, as not to be able to overcome the cohesion of the bladder to the plate, occasioned by the fluid between them, the weight of the bladder, and the resistance that it makes by being stretched, the rarefaction cannot be carried farther, though the pump should still continue to be worked.

It is evident, that the larger the hole is, over which the bladder is laid, a proportionably greater force is exerted upon it by the included Air, in order to lift it up; but the aperture of the hole cannot be made very large, because the pressure of the incumbent Air would either burst the valve, or so far force it down into the cavity, as to prevent its lying flat and close upon the plate, which is absolutely necessary.

To avoid these inconveniences as much as possible, instead of one hole, I have made use of seven, all of equal size and shape; one being in the center, and the other six round it: so that the valve is supported at proper distances, by a kind of grating, made by the solid parts between these holes: And to render the points of contact, between the bladder and grating, as few as possible, the holes are made hexagonal, and the partitions filed almost to an edge. As the whole pressure of the atmosphere can never be exerted upon this valve, in the construction made use of in this pump; and as the bladder is fastened in four places instead of two; I have made the breadth of the hexagons three tenths of an inch, so that the surface of each of them is more than nine times greater than common. But as the circumference of each hole is more than three times greater than common, and as the force, that holds down the valve, arising from cohesion, is, in the first moment of the Air's exerting its force, proportionable to the circumference of the hole; the valve over any of these holes will be raised with three times more ease than common. But as the raising of the valve over the center-hole is assisted on all sides by those placed round it; and as they altogether contribute as much to raise the bladder over the center-hole, as the Air immediately acting under it; upon this account the valve will be raised with double the ease, that we have before supposed, or with a sixth part of the force commonly necessary.

It is not material to consider the force of the cohesion, after the first instant: for, after the bladder begins to rise, it exposes a greater surface to the Air underneath, which makes it move more easily. I have not brought into this account the force, that keeps down the valve, that arises from the weight of the bladder, and the resistance from its being stretched; for I look upon these as small, in comparison of the other.

I was not however contented with this construction of the valves, till I had tried what effect would be produced, when they were opened by the motion of the winch, independent of the spring of the Air: and though the contrivance I made use of seemed to me less liable to objection than any thing I was acquainted with, that had been designed for that purpose; yet I did not find it to answer the end better than what I have already described; and therefore laid it aside, as it rendered the machinery much more complex, and troublesome to execute.

But, supposing all those difficulties to be absolutely overcome, the other defect, that I mentioned in the common construction, would hinder the rarefaction from being carried on beyond a certain degree. For, as the piston cannot be made to fit so close to the bottom of the barrel, as totally to exclude all the Air; as the piston rises, this Air will expand itself; but still pressing upon the valve, according to its density, hinders the Air within the receiver from coming out; hence, were this vacancy to equal the 150th part of the capacity of the whole barrel, no Air could ever pass out of the receiver, when expanded 150 times, though the piston was constantly drawn to the top; because the Air in the receiver would be in æquilibrio with that in the barrel, when in its most expanded state. This I have endeavoured to overcome, by shutting up the top of the barrel with a plate, having in the middle a collar of leathers, through which the cylindrical rod works, that carries the piston. By this means, the external Air is prevented from pressing upon the piston; but that the Air, that passes through the valve of the piston from below, may be discharged out of the barrel, there is also a valve applied to the plate at the top, that opens upwards. The consequence of this construction is, that, when the piston is put down to the bottom of the cylinder, the Air in the lodgment under the piston will evacuate itself so much the more, as the valve of the piston opens more easily, when pressed by the rarefied Air above it, than when pressed by the whole weight of the atmosphere. Hence, as the piston may be made to fit as nearly to the top of the cylinder, as it can to the bottom, the Air may be rarefied as much above the piston, as it could before have been in the receiver. It follows therefore, that the Air may now be rarefied in the receiver, in duplicate proportion of what it could be upon the common principle; every thing else being supposed perfect. Another advantage of this construction is, that, though the pump is composed of a single barrel, yet, the pressure of the outward Air being taken off by the upper plate, the piston is worked with more ease than the common pumps with two barrels: and not only so, but when a considerable degree of rarefaction is desired, it will do it quicker; for the terms of the series expressing the quantity of Air taken away at each stroke do not diminish so fast, as the series answering to the common one.

I have found the gages, that have been hitherto made use of, for measuring the expansion of the Air, very unfit to determine in an experiment of so much nicety. I have therefore contrived one of a different sort, which measures the expansion with certainty, to much less than the 1000th part of the whole. It consists of a bulb of glass something in the shape of a pear, and sufficient to hold about half a pound of quicksilver. It is open at one end, and at the other is a tube hermetically closed at top. By the help of a nice pair of scales, I found what proportion of weight a column of mercury, of a certain length, contained in the tube, bore to that, which filled the whole vessel. By these means I was enabled to mark divisions upon the tube, answering to a 1000th part of the whole capacity, which, being of about one tenth of an inch each, may, by estimation, be easily subdivided into smaller parts. This gage, during the exhausting of the receiver, is suspended therein by a slip-wire. When the pump is worked as much as shall be thought necessary, the gage is pushed down, till the open end is immerged in a cistern of quicksilver placed underneath: the Air being then let in, the quicksilver will be driven into the gage, till the Air remaining in it becomes of the same density with the external; and as the Air always takes the highest place, the tube being uppermost, the expansion will be determined by the number of divisions occupied by the Air at the top.

The degree, to which I have been able to rarefy the Air in experiment, has generally been about 1000 times, when the pump is put clean together: but the moisture, that adheres to the inside of the barrel, as well as other internal parts, upon letting in the Air, is in the same succeeding trials worked together with the oil, which soon renders it so clammy, as to obstruct the action of the pump upon a fluid so subtile as the Air is, when so much expanded; but in this case it seldom fails to act upon the Air in the receiver, till it is expanded 500 times, and this I have found it to do, after being frequently used for several months, without cleaning. I have also generally found it to perform best, the first trial at each time of using; though nothing had been at it from the time preceding; which, after a great many trials made with this view, I also attribute to the vapours of the

Air

Air mixing with the oil. An experiment, where the Air was expanded 1000 times, was tried about two years fince in your prefence; at which were prefent alfo Dr. Knight and Mr. Canton; and I lately did the fame thing with Mr. Watfon. The pump, which I intend myfelf the honour of fhewing the Society, is the fame, that I juft now mentioned, and the fecond that I made, with a view to improve upon this principle.

The degree of rarefaction, produced by the beft of the three pumps, that you procured the trial of, and which you efteemed good in their kind, and in complete order, never exceeded 140 times, when tried by the gage above defcribed.

I have alfo endeavoured to render the pneumatic apparatus more fimple and commodious, by making this Air-pump act as a condenfing engine at pleafure, by fingly turning a cock. This not only enables us to try any experiments under different circumftances of preffure, without changing the apparatus, but renders the pump an univerfal engine, for fhewing any effect, that arifes from an alteration in the denfity or fpring of the Air. Thus, with a little addition of apparatus, it fhews the experiments of the Air-fountain, wind-gun, &c.

This is done in the following manner: the Air above the pifton being forcibly driven out of the barrel at each ftroke, and having no-where to efcape, but by the valve at the top; if this valve be connected with the receiver, by means of a pipe, and at the fame time the valve at the bottom, inftead of communicating with the receiver, be made to communicate with the external Air, the pump will then perform as a condenfer.

The mechanifm is thus ordered. There is a cock with three pipes placed round it, at equal diftances. The key is fo pierced, that any two may be made to communicate, while the other is left open to the external Air. One of thefe pipes goes to the valve at the bottom of the barrel; another goes to the valve at the top, and a third goes to the receiver. Thus, when the pipe from the receiver, and that from the bottom of the barrel, are united, the pump exhaufts: but turn the cock round, till the pipe from the receiver, and that from the top of the barrel, communicate, and it then condenfes. The third pipe, in one cafe, difcharges the Air, taken from the receiver into the barrel; and, in the other, lets it into the barrel, that it may be forced into the receiver.

The figures delineated on *plate* I. will fufficiently explain this inftrument.

Fig. 4. Is a perfpective view of the principal parts of the pump together. A is the barrel. B the ciftern, in which are included the cock, with feveral joints. Thefe are covered with water to keep them air-tight. A little cock to let the water out of the ciftern, is marked 6. C *c c* is the triangular handle of the key of the cock: which, by the marks on its arms, fhews how it muft be turned that the pump may produce the effect defired. D H is the pipe of communication between the cock and the receiver. E is the pipe that communicates between the cock and the valve, on the upper plate of the barrel. F is the upper plate of the pump, which contains the collar of leathers *d*, and V the valve, which is covered by the piece *f*. G I is the fiphon-gage, which fcrews on and off, and is adapted to common purpofes. It confifts of a glafs tube hermetically fealed at *c*, and furnifhed with quickfilver in each leg; which, before the pump begins to work, lies level in the line *a b*; the fpace *b c* being filled with Air of the common denfity. When the pump exhaufts, the Air in *b c* expands, and the quickfilver in the oppofite leg rifes, till it becomes a counter-balance to it. Its ufe is fhewn upon the fcale I *e*, by which the expanfion of the Air in the receiver may be nearly judged of. When the pump condenfes, the quickfilver rifes in the other leg, and the degree may be nearly judged of by the contraction of the Air in *b c*: marks being placed at $\frac{1}{2}$ and $\frac{1}{3}$ of the length of *b c* from *c*; which fhews when the receiver contains double or treble its common quantity. K L is a fcrew-frame to hold down the receiver, in condenfing experiments, which takes off at pleafure; and is fufficient to hold down a receiver, the diameter of whofe bafe is 7 inches, when charged with a treble atmofphere: in which cafe it acts with a force of about 800 pounds againft the fcrew-frame. M is a fcrew, that faftens a bolt, which flides up and down in that leg, by means whereof the machine is made to ftand faft on uneven ground.

Fig. 5. Is a perpendicular fection of the barrel and cock, &c. where A B reprefents the barrel. C D the rod of the pifton, which paffes through M N the plate, which clofes the top of the barrel. K is the collar of leathers, through which the pifton-rod paffes. When the pifton is at the bottom of the cylinder, the upper part of K is covered by the cap at D, to keep out duft, &c. L is the valve on the upper plate, which is covered by the piece O P, which is connected with the pipe Q R, which makes the communication between the valve and cock. C E is the pifton; and E F F is the pifton-valve. I I are two little holes to let the Air pafs from the pifton-valve into the upper part of the barrel. G G K is the principal valve at the bottom of the cylinder. H H is a piece of metal, into which the valve G G K is fcrewed, and clofes the bottom of the cylinder; out of which alfo is compofed S S the cock, and K T T the ducts from the cock to the bottom of the barrel. W W is the key of the cock. X the ftem; and V V the handle.

Fig. 8. Is an horizontal fection of the cock, through the middle of the duct T T. A B reprefents the bignefs of the circular plate, that clofes the bottom of the barrel. C D reprefents the bignefs of the infide of the barrel. E F G is the body of the cock; the outward fhell being pierced with three holes at equal diftances, and correfponding to the three ducts H H, I I, K K, whereof H H is the duct that goes to the bottom of the barrel. I I is the duct that communicates with the top of the barrel; and K K is the duct that paffes from the cock to the receiver. L M N is the key, or folid part of the cock, moveable round in the fhell E F G. When the canal L M anfwers to the ducts H H and K K, the pump exhaufts, and the Air is difcharged by the perforation N. But, the key L M N being turned till the canal L M anfwers to I I and K K, the perforation N will then anfwer to H H; and in this cafe the pump condenfes. Laftly, when N anfwers to K K, the Air is then let in or difcharged from the receiver, as the circumftance requires.

Fig. 6. Is the plan of the principal valve. A B C D reprefents the bladder faftened in four places, and ftretched over the feven holes I K, formed into an hexagonal grating, which I fhall call the honey-comb. E F G H fhews where the metal is a little protuberant, to hinder the pifton from ftriking againft the bladder.

Fig. 7. Reprefents the new gage, which I call the pear-gage. It is open at A; B C is the graduated tube, which is hermetically clofed at C, and is fufpended by the piece of brafs D E, that is hollowed into a cylinder, and clafps the tube.

AIR-*Shafts*, in minerology, imply fhafts or holes cut from the furface to the adits, in order to furnifh frefh Air.

AIR-*Veffels*, in plants, are certain ducts or canals, whereby a kind of refpiration is performed in vegetable bodies. See PLANT in the Dictionary and Supplement.

AI'RING *of horfes*. Airing brings feveral advantages to horfes. Firft, it purifies their blood, if the Air be clear and pure; it purges the body from many grofs and fuffocating humours, and by that means fo hardens a horfe's fat, that it is not near fo liable to be diffolved by ordinary exercife.

Secondly, it teaches him how to let his wind rake equally, and keep time with the other actions and motions of his body.

Thirdly, it fharpens the appetite, and provokes the ftomach, which is of great advantage both to gallopers and hunters, which are apt to lofe their ftomach either through excefs or want of exercife, for the fharpnefs of the Air will drive the horfes natural heat from the outward to the inward parts, which heat, by furthering concoction, creates an appetite.

Markham directs, if a horfe be very fat, to Air him before fun-rife, and after fun-fetting; and another author fays, that nothing is more wholefome than early and late Airings: others again do not approve of this, and urge, that all things that any ways hinder the ftrength and vigour of nature, are to be avoided; now that extremity of cold and being out early and late do fo, is evidently feen by horfes that run abroad all winter, which, however hardily bred and kept with the beft care and fodder, yet cannot by any means be advanced to fo good cafe in winter, as an indifferent pafture will raife them to in fummer; and, as this holds true of nocturnal colds, it muft needs be verified in fome proportionate meafure of the morning and evening dews, and that piercing cold which is obferved to be more intenfe at the opening and clofe of the day, than any part of the night.

Befides that, the dews and moift rimes do as much injury to a horfe as the fharpeft colds or frofts, and, if a horfe is any ways inclinable to catarrhs, rheums, or any other cold diftemper, he is apt to have the humours augmented, and the difeafe fenfibly increafed by thefe early and late Airings.

But, if he be not had forth to Air till the fun be rifen, it will chear his fpirits; and it is feen that all horfes love the fun's warmth, as in thofe that lie out at nights, who will repair to thofe places where they can have moft benefit of the beams of the fun, after he is rifen, to relieve them from the coldnefs of the preceding night.

And, befides the benefit of the fun, the Air will be more mild and temperate, as that it will rather invigorate than prey upon his fpirits, and more increafe his ftrength than impair it.

And, as for bringing down a horfe's fat, we need not be at a lofs for that, and to keep him from being purfive, and too high in flefh, to reduce him to cleannefs, and a more moderate ftate of body: for it is but keeping him out fo much longer at a time, both morning and evening, and you will undoubtedly obtain your end by fuch long Airing, joined with true found heats; and it is from the length of Airings that you muft expect to bring your horfe to a perfect wind and true courage. *Markham's Farriery.*

ALABA'STER, *Alabaftrum, (Dict.)*— This is of a fubftance that may be calcined, being lefs hard than marble. It is of different colours, fome white, but moft commonly of a dirty yellowifh yellowish white, some reddish, some variegated with different colours, red, brown, &c. In some are discovered veins or streaks which may be compared to those of the onyx stone. In this sense we may say there is onyx Alabaster; and there is some found with little spots and branches, in such a manner as to resemble the dendrite. Alabaster is somewhat transparent, and its transparence so much the more sensible, as its colour approaches nearer to white. They polish it: but it is by no means capable of so fine and lively a polish as marble, because it is more soft; besides, when it has been polished, its surface looks as if it had been rubbed with grease. This cast obscures its polish, and, as it is but little transparent, it in some sort resembles wax. Though Alabaster be so soft, and takes no fine polish, yet it is employed in different uses; tables, chimney-pieces, vases, statues, *&c.* are made of it. There are two sorts of Alabaster, the oriental and common; the oriental is much the best, finest and hardest, as well as that its colours are more lively, which makes it more valuable and more sought after than the common, but this is scarce; we meet with it indeed in France, about Cluny, and other places. There is some in Lorain and Germany, but especially in Italy about Rome. It is however more common than one would imagine.

ALABASTRI'TÆ, or *alabasters*, in natural history, the name of a genus of fossiles, composed of large separate concretions, of great brightness, and an elegant, but stately structure, not very hard, soluble in acids, and easily calcinable.

ALA'RM, the name of an instrument for awaking persons at a certain hour. The weavers use a very simple contrivance of this kind. See WEAVER's *Alarm*.

ALATE'RNUS, in botany, the name of a genus of plants, whose characters are: the flower has no empalement, and consists of one leaf, which is divided into four parts; this is succeeded by a round berry, resting upon part of the flower, which is divided into three cells, each containing a single seed. To which may be added, the leaves growing alternately upon the branches, by which, at any time of the year, it may be distinguished from the phillyrea.

Mr. Miller has enumerated six pieces of Alaternus, and Tournefort eight.

ALBU'GO, (*Dict.*) ——This is a troublesome disease, which is more or less offensive to the sight, according to the greater or less portion of the transparent part of the cornea affected by it. For sometimes it fixes on the exterior surface only of this membrane, sometimes on the interior, and sometimes it runs more or less deep into it.

It is most commonly the consequence of inflammations, by the extravasation of humours, between the membranes of this tunicle; and particularly in the small-pox, by the suppuration of pustules upon this part.

I have made use of two methods of cure for this disorder of the sight; the one in the outward sort, the other in the inward. In the former case I ordered the following powder:

Take of common glass any quantity. Pound it in a mortar, into very fine powder; then add an equal quantity of white sugar-candy, and levigate the mixture on a marble with great labour, till it becomes quite impalpable.

A little of this powder, put into the eye with a quill, every day, gradually absterges and wears off the spot by its inciding quality. The other method above-mentioned of removing this speck is, to order a dexterous surgeon to pare it cautiously every day with a knife; for this tunicle is composed of several lamellæ one over another, and has thickness enough to bear paring off some of its parts. I have seen several instances of cures by the eye-powder; but the paring of the coat has not succeeded with me above once or twice. However, it is better to try a doubtful remedy than none. *Mead's Monita & Præcepta.*

ALCA'NNA, or *Alcana*, a drug used in dying, being the leaves of the Egyptian privet. The colour extracted from the leaves is either red or yellow, according to the menstruum made use of; yellow, when infused in common water, and red, when steeped in vinegar or allum-water.

ALCE'A, in botany, *vervain mallow*, a genus of plants whose characters are: it hath the whole habit of the mallow or althæa, but differs from both in having its leaves deep divided, somewhat like the vervain.

Tournefort has enumerated twenty species of Alcea. It is sometimes used in medicine as an emollient, its virtues being much the same with those of the mallow, but in a less degree.

ALCHIMI'LLA, *ladies mantle*, in botany, the name of a genus of plants, of which Mr. Miller has enumerated 13 species. The characters are these: The leaves are serrated: the cup of the flower is divided into eight segments, which are expanded in form of a star: the flowers are collected into bunches upon the tops of the stalks: the seed-vessels contain, for the most part, two seeds in each.

ALCHIMILLA, in the Linnæan system of botany, the name of a genus of plants, the characters of which are these: the cup is a tubular perianthium, remaining till the seed ripens; it is composed of one leaf, divided at the extremity into eight segments alternately larger and smaller; it has no petals; the stamina are four very small erect, pointed filaments, inserted in the rim of the cup; the antheræ are roundish; the germen of the pistillum is of an oval figure; the style is slender, of the length of the stamina, and inserted on the basis of the germen; the stigma is of a globose figure. The neck of the cup, shutting together, makes it serve in the place of a fruit, containing a single compressed seed of an elliptic figure. *Linnæus, Gen. Plantar.*

AL'CORAN, (*Dict.*) ——The Alcoran is allowed to be written with the utmost elegance and purity of language, in the dialect of the Koreishites, the most noble and polite of all the Arabians; but with some mixture of other dialects. It is the standard of the Arabic tongue, and, as the orthodox believe, and are taught by the book itself, inimitable by any human pen; and therefore insisted as a permanent miracle, greater than that of raising the dead, and alone sufficient to convince the world of its divine original; and to this miracle did Mahomet himself chiefly appeal, for the confirmation of his mission, publickly challenging the most eloquent schoolmen in Arabia to produce a single chapter comparable to it. A late ingenious and candid writer, who is a very good judge, allows the style of the Alcoran to be generally beautiful and fluent, especially when it imitates the phrophetic manner, and scripture phrase; concise, and often obscure; adorned with bold figures, after the eastern taste; enlivened with florid and sententious expressions; and, in many places, especially where the majesty and attributes of God are described, sublime and magnificent. *Sale.*

The most elegant passage in the whole Alcoran, in the judgment of all the commentators, is that in the chapter of Hud, wherein God, to put a stop to the deluge, says, "O earth, "swallow up these waters! and thou, O heaven, withdraw "thy rain! And immediately the waters abated; the decree "was fulfilled; the ark rested on the mountain, and a voice "was heard, Woe to the ungodly". *Alkor.* c. 11. p. 180. *Herbel. Bibl. Orient.*

The Alcoran, besides the inconveniencies to which all books of revelation are subject, viz. to be differently understood and interpreted, has some peculiar ones. Mahomet placed the stress and merit of his Alcoran on the excellency of the style. This is subject to inconveniencies; the composition and argument of words admit of infinite varieties, and it can never be absolutely said, that any one is the best possible. Accordingly Hamzah Benahmed wrote a book against the Alcoran, with at least equal elegancy; and Moselema another, which even surpassed it, and occasioned a defection of a great part of the mussulmen.

AL'DER *Tree.* See ALNUS.

A'LIMENT.—The health of the human body evidently depends upon the quantity and quality of the blood and juices; whence it is plain, that all those Aliments which preserve and maintain a just temperament, and a due quantity of these, are beneficial to health, and that such as have a contrary tendency are to be reckoned unwholsome.

For blood of a just temperament, and neither exceeding nor falling short in quantity, as it circulates most easily through the body, and is clear of all foreign particles, is admirably adapted to nourish the parts and increase strength; so that it may be called the real treasure of life.

Blood of a due temperament, and benign quality, by its progressive as well as intestine motion, which continues during the whole course of life, is not only continually wasted, but likewise requires a morbid disposition, and degenerates into an impure and excrementitious mass.

Experience proves, that the blood of those who have fasted long is converted into saline and bilious excrements, which are discharged by stool, urine, and sweat, and even loses that natural balsamic quality which is necessary to health, and the mass of humours is by this means rendered so thin and fluid, that it becomes intirely unfit for nourishing the parts. This appears still more plainly from continual fevers, and hectic disorders, the nature of which diseases is to waste the juices, and convert the most benign humours into useless, salt, and bilious excrements. Labour also, and exercise, because they augment the intestine and progressive motion of the blood considerably, lessen the quantity of superfluous humours, as persons of full plethoric habits experience, to the no small advantage of their health.

Because the blood, by its continual motion, is wasted and converted into an excrementitious mass, utterly unfit to nourish the solids, or recruit that fine fluid which supplies the body with sense and motion, it is plain that life and health cannot be preserved, unless these natural motions be continually repaired, and new juices substituted in the room of those thrown out of the body as excrementitious.

The reason is therefore plain, why people stand in need of continual ingestion and egestion, or, in other words, of eating, drinking, and evacuations; for health cannot long be preserved, unless the place of the corrupted humours discharged be supplied by new juices.

Solid foods of a good quality, as well as liquors, recruit the lost juices; and, therefore, all those Aliments that are nearly of the same nature with the blood, and easily mix with it, ought to be reckoned amongst wholesome Aliments.

Blood and juices, fit for nourishment, are of a benign quality, of a due temperament, and resemble a jelly, consisting of

small

ſmall earthy, aqueous, oily, and eaſily moveable particles, thoroughly mixed with each other: hence all thoſe Aliments, which abound with a mucilaginous juice of a due temperament, are moſt fit for ſanguification, or the production of new blood.

The fleſh of young animals, their juices, and broths made of them, eſpecially of young beef, veal, and mutton, afford a large quantity of jelly, and on that account are juſtly reckoned among the Aliments which are moſt quickly turned into blood. All ſorts of the hen kind and pigeons, with their young, are likewiſe well diſpoſed for nouriſhment, becauſe they afford a more ſubtile jelly than the animal-fleſh abovementioned, though in a ſmaller quantity.

It is worth while to obſerve, that the clean animals, which, according to Moſes, were uſed by the Iſraelites in their ſacrifices, were principally ſuch as afforded a good and wholeſome nouriſhment, ſince they abounded more than others with nutritive mucilaginous juices.

Broths and jellies made of fleſh are, therefore, not without reaſon, preſcribed for recruiting the ſtrength of thoſe who either by large hæmorrhages or violent fevers have ſuſtained a loſs of blood; and people who feed much on theſe mucilaginous Aliments, which the French above all other people in the world do, can bear to have blood taken from them more frequently, and in larger quantities, than people who are not ſo much accuſtomed to them.

The chyle is the immediate matter of the blood, and reſembles a natural emulſion, made of ſoft, oily, inſipid, watery, and mucilaginous particles; for this reaſon all thoſe Aliments, into the compoſition of which parts, reſembling chyle, enter, are proper for nouriſhing the parts, and producing lymph and blood.

Milk, which is nothing but chyle, is an univerſal Aliment, and, in reſpect of nouriſhment, to be preferred to all others.

And, for this reaſon, milk is given as the firſt Aliment, not only to children, but to robuſter animals, that their bodies may grow the faſter, and acquire ſtrength and maturity the ſooner; for food that is ſolid, of a firm coheſion, or hard digeſtion, does not well agree with young and tender bodies, becauſe the ſtomach and inteſtines have not that ſtrength and force which are neceſſary for the digeſtion and expulſion of ſolid foods. Hence, a reaſon may be aſſigned, why ſome people, eſpecially the Swiſs, who are great lovers of milk, and make much uſe of it in food, grow ſo very large and tall, that ſcarce any nation in Europe can ſurpaſs them in that particular.

All mild ſeeds which abound with a milky juice are to be reckoned among the claſs of nouriſhing Aliments.

Hence appears the reaſon, why ſeeds and grains of moſt kinds, ſuch as barley, wheat, oats, rye, beans, peaſe, almonds, cheſnuts, pine-nuts, peſtachia-nuts, rice, maiz, and Turkiſh corn, are extremely proper for nouriſhing animals, and why the meals of theſe baked into bread are the principal and moſt general Aliments made uſe of; from this likewiſe one may account for people's being able to live tolerably on bread and water only.

Among all other Aliments, bread holds the principal place, nor can we poſſibly want it without injuring health. Its uſe is proper at all ſeaſons, and accommodated to all conſtitutions, and may therefore properly be called an univerſal Aliment; nor can fleſh and other ſubſtances be taken alone, and without it, ſince in that caſe they create a nauſea.

The texture of the parts of bread is admirably adapted to the nature of the nutritious juices; for it is mixed with mild, oily, and mucilaginous particles, and likewiſe with a ſubtile acid ſalt, which are very grateful to the ſtomach, and quicken the diſſolving power of the ſalival and fermentative juices. But, as all bread is not made of one and the ſame grain, ſo one kind of bread is preferrable to another with regard to its healthful qualities. The beſt and moſt nouriſhing bread is made of dry rye-meal, not very white, but mixed with the ſmaller and finer parts of the bran. For, by a chymical analyſis, blackiſh coarſe bread upon diſtillation affords more oil, which diffuſes a more agreeable flavour, and more effectually recruits ſtrength, than that which is drawn from fine bread. But that which is made of barley, oats, Turkiſh corn, or even of acorns or cheſnuts, is heavier on the ſtomach, nor is it ſo effectual for repairing loſt ſtrength.

Eggs, becauſe they contain a very fine, balſamic, pellucid lymph, which approaches neareſt to the immediate matter of nouriſhment, therefore afford a very ſpeedy nouriſhment to the parts.

Eggs afford a very ſpeedy nouriſhment, if they are new laid and ſoft, according to that maxim of the Scola Salernitana, Si ſumas ovum, molle ſit atque novum, *i. e.* If you incline to eat an egg, let it be ſoft and new laid. The yolk contains many unctuous, fat, and ſulphureous parts; the white, on the other hand, conſiſts of moiſt, balſamic parts like thoſe of the ſerum, ſo that, if any food is univerſal, this is certainly ſuch, and is in a peculiar manner adapted to increaſe the ſeminal liquor. Eggs are particularly proper, when the body, either weakened by an effuſion of blood, or waſted by the ſhocks of a fever, requires a very ſpeedy ſupply of nouriſhment.

Cheeſe and butter are univerſal and moſt excellent Aliments. Since milk is reſolved into butter and cheeſe, and ſince the butter contains its oily, and the cheeſe its mucilaginous and terreſtrial parts, it is therefore plain that theſe two, eſpecially with the addition of bread and water, muſt be a very valuable and univerſal nouriſhment, fit for perſons of all ages and conſtitutions. The newer butter is, it is of conſequence at once the more grateful to the ſtomach, and the more conducive to health; but, when long kept, it grows fœtid and rancid. The too great or too frequent uſe of it, by relaxing the fibres of the ſtomach, weakens its tone, and excites nauſeas. Butter joined with cheeſe is likewiſe very nouriſhing; but cheeſe ſhould be neither too new nor too old. If too new, it loads the ſtomach, and binds the belly; if too old, it increaſes the acrimony and impurity of the humours, as it is endowed with a poignant taſte, and a fœtid ſmell.

As the blood, the nutritive juice, and in general all the parts of the body, are made up of three elements, viz. Firſt, of one white, ſulphureous, oily, and inflammable: Secondly, one of an earthy, ſubtile, alcaline nature, which is nevertheleſs more fixed: Thirdly, one of an aqueous; ſo the ſeveral kinds and virtues of Aliments may be moſt commodiouſly reduced to theſe three claſſes.

Aliments of theſe three ſeveral qualities, duly mixed with one another, afford a proper nouriſhment for the human body.

The fleſh of animals, eſpecially when roaſted, affords the body its principal ſupply of the ſulphureous part; but it is to be obſerved, that wild animals are preferrable in this reſpect, to thoſe of the tame and domeſtic kind, becauſe their oils and ſalts are exalted by their habitual exerciſe.

That the fleſh of animals contains more of a ſubtile oil, than vegetables, is plain from this, that in the ſummer fleſh very ſoon turns putrid and offenſive, which is not found to be the caſe with reſpect to vegetables.

Vegetables have an acid in their compoſition, and their oils, excepting ſome of the hotter herbs, are for that very reaſon ſo much the milder. Animals, on the other hand, have no acid in their compoſition; for all the parts of them, ſubjected to diſtillation, yield a ſubtile oil, and a volatile ſalt; and this hot oil is what principally excites an inteſtine and fermentative motion in the blood, and proves the occaſion of the penetrating and diſagreeable ſmell which is felt upon putrefaction.

The roaſted fleſh either of wild beaſts, or wild fowls, furniſh the blood with a greater ſtore of a light ſulphureous ſubſtance, than boiled fleſh, or thoſe of tame animals.

The fleſh of wild animals, and wild fowls, is undoubtedly lighter, more ſubtile and oily, but fraught with a ſmaller quantity of mucous balſamic matter, than the fleſh of tame animals; becauſe wild animals uſe more violent exerciſe, breathe a freer and purer air, and feed upon drier Aliments. Add to this, that by the very roaſting much of the humidity is evaporated, by which means the oily principle, diſentangling itſelf from the reſt of the component parts, and being exalted by the fire, enjoys its full liberty, and has the aſcendant over the other parts.

Among the Aliments which furniſh the blood with its humid parts, of animals fiſh, and of vegetables pot-herbs, the milder roots, and ſome ſummer-fruits, are reckoned the principal.

Fiſh ſubjected to diſtillation yields much phlegm, little oil, and very little volatile ſalt.

Becauſe fiſh contains only a very ſmall quantity of oil and volatile ſalt, it does not ſo eaſily turn putrid as fleſh, and for this reaſon is generally leſs hurtful in fevers than fleſh.

To the third claſs of Aliments which ſupply the blood with its fixed and earthy parts, belong all kinds of grains, as the ſeveral kinds of bread, rice, peaſe, beans, lentils, cheſnuts, almonds, cacao, cheeſe, &c.

From what has been ſaid it will appear, that all ſuch Aliments that are of a mild quality, and reſemble the chyle and blood, are fit for nouriſhment.

All ſuch Aliments therefore, as either recede from, or are quite oppoſite to the chyle and blood, are unfit for nouriſhing the parts.

All Aliments in which there is too much of an acid, are improper for nouriſhment; becauſe milk and blood will not mix with an acid, which is quite oppoſite to their natures, and induces a coagulation of the circulating juices.

Hence the reaſon is plain, why the too liberal uſe of ſallads, ſummer fruits, eſpecially whilſt crude and unripe, vinegar, ſour ale, and wines that abound with an acid, are ſo remarkably prejudicial to health.

No ſalt whatever can be mixed with the blood, chyle, and milk, for which reaſon all ſalts, and all foods too high ſalted, muſt be improper and unfit for nouriſhment.

Blood and chyle never incorporate with ſpirituous liquors, but rather ſeparate from them; whence it is eaſy to judge how detrimental the free uſe of them is, both to health and nouriſhment.

All ſweet things, as ſugar and honey, have no affinity with the blood and chyle, but rather recede from their nature, ſince they

they have an exquiſite taſte which the blood, chyle, and nutritive juices have not.

Though ſweet ſubſtances conſiſt of a temperate mixture of parts, and may on that account ſeem proper for nouriſhment, yet the ſweet particles are ſalts of a peculiar kind, which are diſſoluble in water; hence they cannot be joined to the ſubſtance of the parts, ſince they are liable to be diſſolved by the circulating fluids.

Aliments proper for preſerving health ought not only to contain a laudable juice, but ſhould likewiſe be eaſily diſſolved by the ſtomach. Hence it is plain, that all thoſe kinds of food, which on account of the cloſeneſs and compactneſs of their texture are with difficulty diſſolved, are for that very reaſon leſs conducive to health.

The fleſh of old animals, fleſh dried in the ſmoak, hard eggs, ſea fiſh almoſt of all kinds, and very coarſe bread, on account of the rigid and complicated texture of their parts, are for that very reaſon with ſome difficulty concocted by the ſtomach, and converted into juice and blood.

As theſe hard and compact foods require much warmth, abundance of fermentative and ſalival lymph, and a ſtrong ſtomach to disjoin and break their complicated textures, ſo they do not agree but with robuſt conſtitutions, and people that labour hard; for this reaſon the inhabitants of ſome northern countries, ſuch as the Swedes, the Norwegians, the Laplanders, the Finlanders, the Weſtphalians, and the Pomeranians are not eaſily injured by foods of this kind, becauſe their ſtomachs, being not only naturally vigorous, but likewiſe ſtrengthened by cuſtom, eaſily diſſolve and digeſt them.

Of vegetables, roots, fruits, and herbs, eſpecially if eat crude, and before they are ſufficiently ſoftened by boiling, are difficultly concocted by the ſtomach, becauſe their fibrous textures are hard to be diſſolved.

Aliments of the vegetable kind are for that reaſon likewiſe heavy on the ſtomach, ſince they produce many flatulences which diſturb and diſorder the primæ viæ.

To this claſs belong all unripe fruits, peaſe, beans, turnips, rape, bulbous roots, the ſeveral kinds of cabbage, garlic, onions, radiſhes, ſallads prepared of lettices and other herbs, pears, apples, prunes; honey and water, honey, muſt, and all ſweet fruits of whatever kind; for ſuch is the nature of theſe that they eaſily run into a fermentation, or even become ſour, and by reaſon of their viſcid tenacity are reſolved into fumes and vapours.

The tenacious and glutinous parts of animals, among which are the ſtomach, the inteſtines, the ſpleen, the kidnies, the beaks, the vulvæ, the ears, the ſkins, and the claws, are of hard digeſtion, and with difficulty yield to the menſtruum of the ſtomach.

Fat ſubſtances are with difficulty digeſted by the ſtomach, for, if an acid, with which vegetables principally abound, be added to them, they run into a coagulum.

Fat foods require an alcaline liquor for breaking and disjoining their complicated textures; for which reaſon a good deal of bile is requiſite to prevent their proving hurtful to the ſtomach; for, when an acid in the ſtomach attempts the ſolution of fat ſubſtances, hot ſulphureous vapours and eructations are cauſed, which are very troubleſome to the alimentary tube.

The more viſcid, rancid, and old fat ſubſtances are, they are for that reaſon ſo much the worſe. The new and recent are better, and ſooner yield to ſolution and digeſtion..

Hence the reaſon is plain, why the fat of beef is not ſo hurtful, when uſed in the preparation of food, as the fat of mutton, or that of the kid, the ſow, or the gooſe. Hence likewiſe, may a reaſon be aſſigned, why old fleſh ſuch as is hardened in the ſmoak, becauſe of the rancidity which fat contracts, and bacon which has acquired a ruſtineſs and yellow colour, are highly improper for the preſervation of health.

In order to the performance of the office of nutrition, it is neceſſary that the ſmall mouths of the internal rough coat of the inteſtines abſorb the chyle, and convey it to the blood; for which reaſon none of thoſe Aliments, which either obſtruct, or too much corrugate its mouths, can be uſed, without in ſome meaſure injuring health.

Since the effete maſs of Aliments, drained and exhauſted by the ſeparation of the chyle from it, ought by the expanſive and contractive motion of the inteſtines to be thrown off from them, it muſt of courſe follow, that all thoſe Aliments are prejudicial to health, which either paſs through the inteſtines with difficulty, ſtop their motions, or weaken their tone, and impair their ſtrength, by ſuppreſſing excretion ſo neceſſary to health.

All Aliments that are acid, aſtringent, mouldy, glutinous, viſcid, auſtere, or ſuch as eaſily run into a coagulum, are for this reaſon prejudicial to health, becauſe they weaken the tone of the inteſtines, and by that means prevent the ſuperfluous fæces from being diſcharged.

This characteriſtic of unwholeſomeneſs belongs to all unripe ſummer fruits, pears, quinces, pomegranates, medlars, the fruits of the thorn and myrtle, ſea biſcuits, the cruſt of bread; bread that is mouldy, hard, too coarſe, or taken warm from the oven; all farinaceous ſubſtances, gruels made of peaſe, beans, lentils, and millet, cakes or bread not ſufficiently fermented, cheeſe eat too freely, ſheeps milk, and in fine all milky and fat ſubſtances; all which Aliments do ſtill more remarkably hurt the conſtitution, if wine, acids, or cold liquors, are uſed along with them; for by this means they are reduced into a firm coagulum, which adheres immoveably to the coats of the inteſtines, and incruſtates the orifices of their ſmall abſorbent veſſels, whence proceed copious flatulences and ſpaſms.

The unwholeſomeneſs of Aliments is to be eſtimated from their impairing the fermentative and ſolutive powers of the ſtomach, ſince by that means crudities are generated.

The action of the fermentative juice is impaired and weakened by all fat, oily, and very ſweet ſubſtances; by honey, hydromel, or honey and wine, new grapes, ſummer fruits, green figs. All pulſes, farinaceous ſubſtances, gruels made of millet, lukewarm Aliments, the fibrous roots of pot-herbs, cheeſe, and curdled milk, all which are the more prejudicial to health, the greater quantities of them are taken into an empty ſtomach.

Every acid, and every putrefaction, are prejudicial to health; and, for that reaſon, all Aliments which eaſily grow ſour or putrid in the ſtomach, may be juſtly reckoned unwholeſome.

An acid is equally injurious to the primæ viæ and to the blood, for it deſtroys the alcaline and balſamic quality of the bile, coagulates the chyle, and retards the expulſion of the excrement. Add to this, that, when it is mixed with the blood, ſtagnations of the juices and infarctions of the viſcera are generated. And, when the firſt organs of digeſtion are affected by putrified Aliments, and the putrefaction extends itſelf towards the more internal parts, it communicates its own bad diſpoſition to the moſt wholeſome juices. Among thoſe foods which by their long continuance in the primæ viæ grow acid, may be reckoned all ſummer fruits, milk, honey, almoſt all ſorts of tarts, ſweet wines of ſeveral kinds, muſt, hydromel, and fermented bread; and thoſe Aliments which ſooneſt grow putrid by a long ſtay in the primæ viæ, are boiled fleſh; for, of all Aliments uſed by us, none have a greater tendency to putrefaction than fleſh. Wherefore it is for very valuable purpoſes, that nature in acute diſeaſes, and in habits abounding with impure juices, does of her own accord loath and abhor fleſh; and thoſe phyſicians laudably aſſiſt nature in carrying on her deſign, who in caſes of that nature forbid their patients the uſe of nouriſhing broths; for Aliments of this kind wonderfully add to the putrefaction, which is the formal cauſe of the malignity. For this reaſon, when peſtilences or other epidemical diſeaſes rage, it is adviſable to abſtain from fleſh, and uſe acidulated liquors, which ſtrongly reſiſt putrefaction, and by that means prove remarkably ſerviceable; but this is to be underſtood of thoſe conſtitutions which are infirm, weakened with fevers, or loaded with impure juices; ſo that Hippocrates was very juſt in his obſervation, that, the more bodies abounding with impure juices are nouriſhed, the more they are injured. Corrupted fiſh, putrid fleſh, or that of animals which laboured under any diſeaſe, have of all other kinds of food the ſtrongeſt and more direct tendency to produce a putrefaction in the body. *Hoffman's Medicina Rationalis Syſtemat.*

ALLIGATION *Alternate* (*Dict.*)—When two kinds of things only are given to be mixed, the rule of Alligation will give but one anſwer; for inſtance, ſuppoſe it were required to mix brandy, at 8 ſhillings per gallon, with cyder, at 1 ſhilling per gallon, ſo as to make the mixture worth 5 ſhillings per gallon? The operation would ſtand as follows:

$$5\left\{\begin{matrix}8\\1\end{matrix}\right.\left|\begin{matrix}4\\3\end{matrix}\right.$$

And the anſwer will be, 4 gallons of brandy, and 3 of cyder. Nevertheleſs, let it be obſerved, that any other two numbers, that are in the ſame proportion to each other as 4 to 3, will alſo anſwer the queſtion. Thus, 8 and 6, 12 and 9, 16 and 12, &c. are anſwers to the queſtion; for in theſe the quantity of the mixture is the double, triple, quadruple, &c. of the quantity in the former; and ſo are the parts of which it is compoſed. If three kinds of things are given to be mixed, the rule of Alligation will give but one anſwer; but then, as before, all numbers that are in the ſame proportion between themſelves as the numbers which compoſe that anſwer, will alſo ſatisfy the queſtion.

But this is not all, for, by the help of an artifice, now to be explained, innumerable other anſwers may be obtained, the numbers compoſing which are not in the ſame proportion as above.

Let it be required to mix brandy, at 8 ſhillings per gallon, with wine, at 7 ſhillings per gallon, and cyder, at 1 ſhilling per gallon, ſo that the mixture may be worth 5 ſhillings per gallon? The work, by the rule of Alligation, will ſtand as follows:

$$5\left\{\begin{matrix}8\\7\\1\end{matrix}\right.\left|\begin{matrix}4\\4\\3{,}2\end{matrix}\right.\left|\begin{matrix}4\\4\\5\end{matrix}\right.$$

Which ſhews, that 4 gallons of brandy, 4 of wine, and 5 of cyder will anſwer the queſtion.

For

For 4 galls. of brandy,	at 8 s. per gall.	are worth	32 s.
4 galls. of wine,	at 7 s. per gall.	are worth	28 s.
5 galls. of cyder,	at 1 s. per gall.	are worth	5 s.
Therefore 13 galls. of the mixture are worth		—	65 s.
And 1 gall. of the mixture is worth $\frac{65}{13}$ s. =			5 s.

Now let us suppose, that it should be determined to use 5 gallons of cyder in the mixture constantly, but to use any quantities of brandy and wine that will answer the question.

Then may the quantity of brandy be increased or diminished by 2, the difference between the prices of the wine and mixture; if, at the same time, the quantity of the wine be diminished or increased by 3, the difference of the prices of the brandy and mixture.

That is to say, to (4) the quantity of brandy, given by the above answer, add 2; and, from (4) the quantity of wine, take 3; so shall the sum 6, and difference 1, be respectively quantities of brandy and wine, which, mixed with 5 gallons of cyder, will answer the question.

For 6 galls. of brandy,	at 8 s. per gall.	are worth	48 s.
1 gall. of wine,	at 7 s. per gall.	is worth	7 s.
5 galls. of cyder,	at 1 s. per gall.	are worth	5 s.
Therefore 12 galls. of the mixture are worth		—	60 s.
And 1 gall. of the mixture is worth $\frac{60}{12}$ s. =			5 s.

Again; if, from (4) the quantity of brandy given in the first answer, 2 be subtracted; and if, to (4) the quantity of wine, 3 be added; then will 2 and 7, the remainder and sum, be respectively quantities of brandy and wine, which will answer the question.

For 2 galls. of brandy,	at 8 s. per gall.	are worth	16 s.
7 galls. of wine,	at 7 s. per gall.	are worth	49 s.
5 galls. of cyder,	at 1 s. per gall.	are worth	5 s.
Therefore 14 galls. of the mixture are worth		—	70 s.
And 1 gall. of the mixture is worth $\frac{70}{14}$ s. =			5 s.

Now, if, instead of the numbers of the first answer 4, 4, and 5, larger numbers, in the same proportion, viz. 12, 12, and 15, were taken, the following eight answers would be found, by increasing and diminishing the quantities of brandy and wine as above directed, the quantity of cyder remaining constantly 15, viz.

Brandy	18.	16.	14.	12.	10.	8.	6.	4.	2.
Wine	3.	6.	9.	12.	15.	18.	21.	24.	27.
Cyder	15.	15.	15.	15.	15.	15.	15.	15.	15.

And if, instead of these, still larger numbers in that proportion, or in proportion as any of the last found answers, be assumed, a greater number of other answers may be found.

If, instead of supposing the quantity of cyder invariable, the quantity of brandy be taken for such; then an infinite number of answers may be found, by continually increasing the quantity of wine by (4) the difference between the prices of the cyder and mixture; and the quantity of cyder by (2) the difference between the price of the wine and mixture.

Thus, assuming the second answer 6, 1, and 5, as the basis of our work, and esteeming the 6 gallons of brandy as invariable, the following system of answers will arise:

Brandy	6.	6.	6.	6.	6.	6.	6.	6.	6, &c.
Wine	1.	5.	9.	13.	17.	21.	25.	29.	33, &c.
Cyder	5.	7.	9.	11.	13.	15.	17.	19.	21, &c.

Lastly, esteeming the quantity of wine as invariable, the quantity of brandy must be increased by (4) the difference of the prices of the cyder and mixture; and the quantity of cyder must be increased by (3) the difference of the prices of the brandy and mixture.

Thus, taking the third answer 2, 7, and 5, as the basis, and making 7 invariable, these answers arise:

Brandy	2.	6.	10.	14.	18.	22.	26.	30, &c.
Wine	7.	7.	7.	7.	7.	7.	7.	7, &c.
Cyder	5.	8.	11.	14.	17.	20.	23.	26, &c.

When there are four kinds of things to be mixed, and two of them are of greater value, and the other two of lesser value than the mixture, the rule of Alligation will give three answers; with either of which, or with any numbers that are in the same proportion among themselves as those, as a basis, innumerable other answers, consisting of numbers which are in different proportions among themselves, may be found, by making any two of them invariable, and changing the rest in the manner as above.

Note. 1. That the number by which the quantity of any simple is to be varied, is always the difference between the price of the mixture, and the price of the other simple, which, in any operation, is considered as variable.

Note. 2. That if the simples, which, in any operation, are considered as variable, be both of greater, or both of less value than the mixture, then, while the one is increased, the other must be diminished; but, if the one be of greater value than the mixture, and the other lesser, then they must be both increased or both diminished.

Let it be required to mix brandy at 8 shillings, wine at 7 shillings, cyder at 1 shilling, and water at nothing per gallon together, so that the mixture may be worth 5 shillings per gallon? The three answers, by the rule of Alligation, are as follow:

5	8	5		5	8	4		5	8	5,4	9
	7	4			7	5			7	5,4	9
	1	2			1	3			1	3,2	5
	0	3			0	2			0	3,2	5

Now, taking the last answer for the basis of our operation, and making the quantities of wine and cyder invariable, we shall have

Brandy	9.	14.	19.	24.	29.	34.	39, &c.
Wine	9.	9.	9.	9.	9.	9.	9, &c.
Cyder	5.	5.	5.	5.	5.	5.	5, &c.
Water	5.	8.	11.	14.	17.	20.	23, &c.

Making the brandy and cyder invariable.

Brandy	9.	9.	9.	9.	9.	9.	9, &c.
Wine	9.	14.	19.	24.	29.	34.	39, &c.
Cyder	5.	5.	5.	5.	5.	5.	5, &c.
Water	5.	7.	9.	11.	13.	15.	17, &c.

Making the wine and water invariable.

Brandy	9.	13.	17.	21.	25.	29.	33, &c.
Wine	9.	9.	9.	9.	9.	9.	9, &c.
Cyder	5.	8.	11.	14.	17.	20.	23, &c.
Water	5.	5.	5.	5.	5.	5.	5, &c.

Making the brandy and water invariable.

Brandy	9.	9.	9.	9.	9.	9.	9, &c.
Wine	9.	13.	17.	21.	25.	29.	33, &c.
Cyder	5.	7.	9.	11.	13.	15.	17, &c.
Water	5.	5.	5.	5.	5.	5.	5, &c.

Making the brandy and wine invariable.

Brandy	9.	9.	9.
Wine	9.	9.	9.
Cyder	10.	5.	0.
Water	1.	5.	9.

Or taking 4 other numbers in the same proportion, as 9, 9, 5 and 5, viz. 36, 36, 20 and 20.

Brandy	36.	36.	36.	36.	36.	36.	36.	36.
Wine	36.	36.	36.	36.	36.	36.	36.	36.
Cyder	40.	35.	30.	25.	20.	15.	10.	5.
Water	4.	8.	12.	16.	20.	24.	28.	32.

Lastly, make the cyder and water invariable.

Brandy, &c.	44.	42.	40.	38.	36.	34.	32.	30.	28, &c.	
Wine, &c.	24.	27.	30.	33.	36.	39.	42.	45.	48, &c.	
Cyder, &c.	20.	20.	20.	20.	20.	20.	20.	20.	20, &c.	
Water, &c.	20.	20.	20.	20.	20.	20.	20.	20.	20, &c.	

Not only the sets of numbers thus found, but their sums and differences will also be answers:

	Brandy.	Wine.	Cyder.	Water.	
Thus, from or to	42	27	20	20	
Take or add	9	9	10	1	
The remainder	33	18	10	19	will be answers to the question.
And sum	51	36	30	21	

Desson.

A'LLUM, or rather ALUM (*Dict.*)—The configurations of this salt, examined by the microscope, are very beautiful and prove more or less perfect, according to the strength of the solution, and the degree of heat employed in making the experiment; to judge of which a little experience will be found needful.

The solution, however, sated with Allum, will not be found over strong after standing some days, for, in that time, it will have precipitated many crystals to the bottom, whereby the liquor is sometimes left too weak for our purpose; but then, by holding the phial over or near a fire, the crystals will again dissolve, and be taken up a-new into the fluid. It is not, however, adviseable to make use of it, as soon as this is done, unless we want to produce nothing else but crystals; for if, after this, it be employed before it has had a little time to cool and settle, it is very apt to form into crystals only; but, when it has stood about half an hour, a drop placed on a slip of glass, and heated properly, exhibits commonly, at the beginning, a dark cloud, which appears in motion somewhere near the edge, and runs pretty swiftly both to the left and right, until it is either stopped by the intervention of some regular crystals, or else proceeds onward both ways at once, and nearly of the same height; till, having surrounded the whole drop, the two ends rush together and join: the progress towards which is attempted to be shewn (*plate* III. *fig.* 2.) at *a a*.

This cloudy part of the drop, that seems violently agitated, whilst it is running round, appears, on a strict examination, to consist of salts, shot into long and very slender lines, much finer than the smallest hair, which cross one another at right angles, and form, as they go along, from their internal edges, rows of solid crystals, composed of many oblique plain sides, *b b*.

But it happens frequently, that, in some parts of the drop, many minute and circular figures are seen, rising at some little distances at the edge, whilst the abovementioned operations are performing in other places thereof; which minute figures, enlarging themselves continually, appear at last of a star-like form, or with lines radiating and diverging from its center, in the manner represented at *c c*.

After the business is over about the edges, a good deal of patience will be requisite to wait for the configurations in the middle of the drop, which seldom begin till the fluid seems almost wholly evaporated; when, on a sudden, many straight lines appear pushing forwards, whose sides or edges are jagged, and from which other similar straight lines and jagged shoot out at right angles with the first; these again have other small ones of the same kind shooting likewise from themselves, and compose, all together, a most beautiful and elegant configuration; the order of which is attempted to be shewn at D.

Each of these lines, increasing in breadth towards its end, appears somewhat club-headed, as *e e e*.

Sometimes, instead of sending branches from their sides, many of these lines rise parallel to each other, resembling a kind of pallisadoe, and having numberless minute transverse lines running between them, as at F.

But the most wonderful part of all, though not produceable without an exact degree of heat and right management, is the dark ground-work shewn at G, which consists of an almost infinity of parallel lines, having others crossing them at right angles, and producing a variety scarce conceivable from lines disposed in no other manner: the direction of the lines (which are exquisitely straight and delicate) being so frequently and differently counter-changed, that one would think it the result of long study and contrivance.

During the time this ground-work is forming, certain lucid points present themselves to view (on one side thereof most commonly) which points grow larger continually, with radiations from a center, and become star-like figures, in the manner of those before mentioned. Several of them likewise shoot out long tails, which give them the appearance of comets: and, at the end of all, a dark lineation, in various directions, darts frequently through, and occupies all or most of the spaces between them, making thereby no ill representation, when viewed by candle-light, of a night-sky illuminated with shining stars, and tailed comets, and rendering the whole scene extremely whimsical and pretty.

Nor do these configurations break away, or dissolve, soon after their being formed, as many others do; but may be preserved on the glass in good perfection for weeks or months, if care be taken neither to exclude the air wholly from them, nor put them in a moist place: for in either case they will be soon destroyed. *Baker's Employment for the Microscope.*

A'LMOND-TREE, *Amygdalus*, in botany, a beautiful tree, which produces the Almonds. See the article ALMONDS, in the dictionary.

The characters of this genus are, it hath leaves and flowers very like those of the peach-tree; but the fruit is longer, and more compressed: the outer green coat is thinner and drier, when ripe, and the shell is not so rugged.

The species are: 1. Amygdalus sativa, fructu majore. C. B. P. The common large Almond. 2. Amygdalus dulcis, putamine molliore. C. B. P. The sweet Almond, with tender shells. 3. Amygdalus amara. C. B. P. The bitter Almond. 4. Amygdalus sativa, flore albo. The white-flowering Almond.

The first, second, and third sorts are chiefly cultivated in England for the beauty of their flowers, which are produced early in the spring, when few other things appear; which renders them worthy of a place in the best gardens, where being intermixed with other flowering trees, either in wilderness quarters, or in walks, they make a very fine appearance.

They are propagated by inoculating a bud of these trees into a plum, Almond, or peach-stock, in the month of July (the manner of this operation, see under the article of GRAFTING, *Dict.* The next spring, when the buds shoot, you may train them up either for standards, or suffer them to grow for half standards (according to your own fancy) though the usual method is to bud them to the height the stems are intended to be; and the second year, after budding, they may be removed to the places where they are to remain. The best season for transplanting these trees (if for dry ground) is in October, as soon as the leaves begin to decay; but, for a wet soil, February is much preferrable; and observe always to bud upon plum-stocks, for wet ground; and Almonds or peaches, for dry.

The Almond with white flowers is a greater curiosity than either of the former, and, being intermixed with the other sorts, and a few of the cherry-plum-trees, which flower all together, add very much to the beauty of these plantations: this sort with white flowers is more difficult to increase than either of the former, and will not take upon a plum-stock, but must be either budded on a peach, or Almond.

The sort with large fruit produces almost every year large quantities with us in England, which, if eaten before they are too dry, are little inferior to those we receive from abroad; but, if kept too long, they are very apt to shrivel up, and lose their plumpness; but in other respects are very good.

The Jordan Almonds, which are annually brought to England, seem to be the same as ours with white flowers, by some plants which I have raised from the nuts, which retain the same appearance in leaf and shoot, as those with white flowers; but they have not as yet flowered with me, although the trees are grown to a large size.

The bitter and sweet Almonds are only varieties, which will come from the same seeds; but there is a manifest difference between these and the white-flowering sort, both in leaf and shoot, so as to be distinguished thereby at all seasons; yet by later botanists they are made but one species.

The white sort, coming out earlier in the spring than the other, is in greater danger of suffering from the frost in the spring, whereby few fruit are ever seen upon the trees in this country. *Miller's Dict.*

ALMOND *Furnace*, a small furnace in which the refiners of silver out of lead melt flags of the litharge left in this operation, and, with the help of charcoal, reduce them into lead again.

A'LNUS, *the alder-tree*, in botany, the name of a genus of trees, whose characters are these: the flower is of the amentaceous kind, being composed of several apices, arising from four-leaved cups; these are affixed in a clustering manner to an axis, but these are barren. The young fruit appears in a different part of the tree, and is of a squamose structure, and loaded with embryo seeds; this finally increases in size, and becomes a regular fruit, containing a number of compressed seeds. *Miller's Dict.*

There are eight species of this plant enumerated by botanical authors; but the common alder is generally meant by the name.

There is a peculiar beneficial property belonging to this plant, for no beast will crop it, be it young or old, which saves the great charge and trouble of fencing it after planting. Their propagation is the same as the poplar, and, where a place is too wet for that, the alder will flourish and become large trees, pollards, or poles for hedges; in short, there is none of the aquatic tribe will raise more money and sooner than the alder, in wet meadow hedges, and in boggy, moorish ground, nor make stronger and quicker fences, than this excellent plant.

This aquatic will thrive but poorly when raised from truncheons, nor much better from the wild set or sucker, which it produces but few of. But there is a way to do this much more to the purpose, and that is thus: first prepare a bed of well manured fine mould; then lay the full ripe seed at a due distance from the fire, or in the sun, and it will cause them to open like the fir pine-apple; then sow the seeds in the bed, and you will have abundance of young plants, that on setting out will be sure to grow, if rightly managed: at midsummer cut away the small side shoots of this tree, which will prevent their second growth; but, if they are large, you must not do it, because it will then make the sap run out too much, and damage the tree. This is of great consequence, for, by so doing, the large side arms are prevented in their growth, which often causes knobs and wens that lessen the value of their wood. *Ellis's Timber-tree improved.*

A'LOE, in botany, the name of a genus of plants, of which Mr. Tournefort has enumerated 14, and Mr. Miller 38 species. The characters of this genus are these: the flower is liliaceous, and consists of one petal, which is of a tubular form, and is divided into six segments at the edge. In some species of this genus, the cup, and in others the pistil, finally becomes a fruit, or seed-vessel, of an oblong cylindric form, divided into three cells, and containing flat and semicircular seeds. The soil in which these plants thrive best, is on half fresh light earth from a common (and if the turf is taken with it, and rotted, it is much better) the rest should be white seasand, and sifted lime-rubbish, of each of these two a fourth part; mix these together six or eight months at least before it is used, observing to turn it over often in this time.

The first species of Aloes is very hardy, in respect to cold; and has, in mild winters, endured abroad, being planted in a very dry soil, and under a south wall; but, as they are liable to be killed in hard frosts, they generally are kept in pots or tubs in a common green-house with oranges, myrtles, &c. but must have very little moisture in winter. Most of the other sorts are better preserved in an airy glass-case, in which there is a stove to make a little fire in very bad weather; to dry and warm the air in foggy, cold, or wet weather, and to prevent the frost from entering the house.

The fifth, sixth, seventh, eighteenth, thirty-fourth, and thirty-fifth sorts, require a greater share of heat to preserve them in winter, and should be set in a good stove, and kept nearly to the degree of heat marked (upon Mr. Fowler's Botanical Thermometers) temperate. Indeed, most of the other sorts may be kept in the same temperature of heat in winter; but then you must observe, that, the greater the heat is in winter in which you keep them, the more water they will require: and, if they are well managed in this heat, they will grow very much in winter; therefore, great care must be taken in the severe cold, that it doth not enter the house, nor that the heat be at that time lessened; as also how you begin to give them air in the spring; for the extreme parts of the plants will be rendered very tender, by their growing freely in winter; and the least check to their growth, at that season, is very often their destruction.

Most of the African sorts of Aloes produce flowers with us annually, when grown to a sufficient size, which is generally the

the ſecond, and ſeldom more than the third year, after planting from off-ſets; but the American Aloes (which, for the moſt part, produce their flower-ſtems immediately from the center of the plant) ſeldom flower till they are of a conſiderable age, and this but once during the life of the plant; for when the flower-ſtem begins to ſhoot from the middle of the plant (which, for the moſt part, is of a large ſize, and grows to a great height) it draws all the moiſture and nouriſhment from the leaves, ſo that, as that advances, the leaves decay; and, when the flowers are fully blown, ſcarce any of the leaves remain alive; but, whenever this happens, the old root ſends forth a numerous quantity of off-ſets for increaſe; and it is not till this time that ſome of theſe ſorts can be increaſed, eſpecially the ſecond, third, fourth, fifth, ſixth, and ſeventh ſorts, which never produce any young plants until they flower; at which time, the flower-ſtem of the ſeventh ſort is beſet with ſmall heads from bottom to top, which, being taken off, and planted, will grow as well as ſuckers from the roots.

This Aloe, which, with us, ſeldom makes a very large plant, hath yet produced flower-ſtems of a conſiderable ſize, and fifteen feet in height. The flowers are little leſs than thoſe of the large ſort. I cannot here forbear taking notice of a vulgar error relating to the large American Aloe; which is, that it never flowers till it is an hundred years old; but this is a miſtake; ſince we have had ſeveral of them flower in England, ſome of which were known not to exceed fifty years old; and others, which flowered many years ago, cannot be ſuppoſed to have been in England ſo long as to arrive at that age, ſince they were thought too tender for our climate at that time, when green-houſes were not known; as may be ſeen by looking into Gerrard's and Parkinſon's Herbals.

Thoſe who are deſirous to have this ſort of Aloe flower, may, by giving the plants large tubs for their roots to ſpread, greatly promote their growth, and, in proportion to the growing of the plants, their flowering is haſtened. For, the bud being formed in the center of the plants, when the number of leaves which enfold it are thrown off, the ſtem will advance; ſo that in Spain and Portugal, where the plants grow faſt, they produce flowers in eighteen or twenty years; and in the Weſt-Indies, where they grow faſter, in ſeven or eight.

The African Aloes, for the moſt part, afford plenty of ſuckers, by which they are increaſed; but thoſe few that do not, may be moſt of them propagated, by taking off ſome of the under-leaves, laying them to dry for a week or ten days, as was directed for the off-ſets; then plant them in the ſame ſoil as was directed for them, putting that part of the leaf which did adhere to the old plant, about an inch, or an inch and an half (according to the ſize of the leaf) into the earth, giving them a little water to ſettle the earth about them: then plunge the pots into a moderate hot-bed, obſerving to ſcreen them from the violence of the ſun, and give them gentle refreſhings with water: the beſt ſeaſon for this is in June, that they may puſh out heads before winter. See the article ALOE, in the Dictionary. *Miller's Dict.*

Lignum ALOES, a medicinal wood imported from the Eaſt-Indies, where it is called calambac, or calamba. See CALAMBAC.

ALVE'OLI, among naturaliſts, ſignifies thoſe little waxen cells in the combs of bees, wherein the honey is depoſited. See BEE, *in the Dictionary*.

A'LUM. See the article ALLUM.

ALYSSOI'DES, in botany, a genus of plants, whoſe characters are theſe: it hath a flower in form of a croſs, conſiſting of four leaves, out of whoſe flower-cup riſes the pointal, which afterwards becomes an elliptical thick fruit, divided into two cells by an intermediate partition, which is parallel to the demi-elliptical turgid valves, and filled with round flat ſeeds, having borders round them.

AMARA'NTA, a military order of knighthood, inſtituted, in 1653, by Chriſtina queen of Sweden, daughter of Guſtavus Adolphus, on the following occaſion. At Stockholm, the metropolis of Sweden, is yearly celebrated a feaſt, called wirtſchaft, or feaſt of pleaſure, conſiſting of rich dreſſes, balls, maſquerades, &c. Chriſtina, ambitious of imitating the feaſts of the gods, ordered the nobility to come magnificently apparelled, and repreſent the gods and goddeſſes at the feaſt. The queen took the name of Amaranta, *i. e.* immortal, and joining the young nobles, clad like nymphs and ſhepherds, waited upon the gods at the tables, which were covered with the moſt ſumptuous repaſts. The hall where this feaſt was made, was hung with the richeſt tapeſtry, repreſenting the delightful country of Arcadia, adorned with ſtatues, vaſes, and other ornaments, and ſcented with the moſt agreeable perfumes. Theſe pleaſures laſted a day and night; when the queen, ſuddenly changing her habit, ordered thoſe who had repreſented the gods and goddeſſes to throw away their diſguiſes, and put on their own dreſſes again; and, in memory of ſo elegant a feaſt, inſtituted the order of the Amaranta, from the name which ſhe herſelf had taken.

Aſhmole, in his Hiſtory of the Garter, and Guillim, in his Diſplay of Heraldry, erroneouſly place the inſtitution of this order in the year 1645. Aſhmole ſay that Chriſtina abdicated the crown of Sweden in 1645, in favour of her couſin Charles Guſtavus, on account of her abjuring the Lutheran for the Roman catholic religion; whereas ſhe did not reſign the crown till 1654, nor did ſhe embrace the Catholic religion till 1656; and it was a year before her abdication, that ſhe inſtituted the order of the Amaranta. *Juſtinian's Hiſt. of Military Orders, cap.* 85. 9.

The ceremony of the inveſtiture of the knights of this order is as follows: the queen being ſeated in ſtate, the perſon to be knighted kneels down before her, and, holding his hands between the queen's, takes an oath to defend her perſon from harm, and the perſons of his brother-knights; to incite juſtice, virtue, and piety, and diſcountenance its oppoſers; after which the queen puts about him a crimſon ſilk ſcarf, with the enſign of the order faſtened thereto.— To an abſent prince, or other perſonage, ſhe ſends the jewels, accompanied with her letter, which ſupplies the place of a perſonal inveſtiture.— There have been ſeveral knights and princes of this order.

The chief enſign of this order is a circle of laurel, in which is a cypher compoſed of an A and a V, or two A's, one of which is reverſed. The leaves of the laurel are wreathed about with a white ribbon, upon which is this motto, *Dolce nella memoria.* The whole incircling a gold medal, which hangs to a collar, and is alſo embroidered upon the garment. (See *plate* III. *fig.* 4.) *Trevoux. Hiſt. de Mil. Ord.*

AMARANTHOI'DES *, *globe amaranthus*, or *everlaſting flower*, a genus of plants whoſe characters are theſe: the flowers are ſmall, and cut into four ſegments, which are collected into ſquamoſe heads: from each of theſe ſcales is produced a ſingle flower; the ovary in the bottom of the flower becomes a roundiſh crooked ſeed, which is contained in a thin pellicule, or ſkin.

* The word is formed from the Greek *ἀμάϱανθος* and *εἶδος*, reſemblance.

Theſe plants are ſome of the greateſt beauties amongſt the whole annual tribe: they muſt be ſown very early in a good hot-bed, and treated as will be hereafter directed for the amaranths; with this difference only, that theſe muſt have a greater ſhare of heat, and be forwarded more in the ſpring.

If the autumn ſhould prove cold or wet, it will be very neceſſary to remove the pots, with theſe plants, into ſhelter, otherwiſe they will not perfect their ſeeds, eſpecially if they were not ſown very early in the ſpring. If theſe pots are preſerved in a good green-houſe, their flowers will make a pretty variety amongſt other plants, and will continue until the middle or latter end of November, provided the weather proves not too cold: but what flowers you intend to preſerve, ſhould be gathered ſoon after they arrive at their proper bigneſs; for, if they are ſuffered to remain very long after, the under part of their heads will change brown, and decay.

AMARA'NTHUS, in botany, the name of a genus of plants. The characters are: the flowers have ſeemingly no petals: the cup of the flower is dry and multifid: the ſeeds are included in membranaceous veſſels, which, when come to maturity, burſt open either tranſverſely or horizontally, after the manner of purſlane and pimpernel, in each of which are contained one or more roundiſh ſeeds.

There is a vaſt variety of theſe plants, both in the Eaſt and Weſt-Indies, many of which are extremely beautiful, and as much deſerve our care as any of the flowery tribe. Mr. Miller has enumerated 11, and Tournefort 36 ſpecies of this genus.

All the ſorts of Amaranthus muſt be ſown on a good hot-bed in February, or the beginning of March at fartheſt; and in about a forthnight's time (if the bed is in good temper) the plants will riſe; when you muſt prepare another hot-bed, covered with good rich light earth, about four inches thick; then raiſe up the young plants with your finger, ſo as not to break off the tender roots, and prick them into your new hot-bed about four inches diſtance every way, giving them a gentle watering to ſettle the earth to their roots: but, in doing this, be very cautious not to bear the young plants down to the ground by haſty watering, which rarely riſe again, or at leaſt ſo as to recover their former ſtrength, in a long time, but very often rot in the ſtems, and die quite away.

The Amaranthus tricolor and bicolor muſt be kept longer under the frames than the cock's combs; and, in order to have them very beautiful, it will be proper to make a freſh hot-bed in a glaſs caſe; or, where ſuch a conveniency is wanting, to erect ſome of the lights which were placed over cucumbers, round an hot-bed, and cover thoſe with the ſame lights on the top, ſo as to reſemble a glaſs-ſtove. On this hot-bed you ſhould place your Amaranths, at ſuch a diſtance from each other, as to allow them room to ſpread; obſerving to refreſh them often with water, and in warm weather let them have plenty of freſh air. With this management, the plants may be raiſed five or ſix feet high, and their leaves will come to the moſt beautiful colours; after which they may be expoſed to the open air, and removed to adorn the ſeveral parts of the garden. *Miller's Dict.*

AMBARVA'LIA, in antiquity, the feaſt of perambulation, or proceſſion they made about the plowed and ſown fields

fields in honour of the goddefs Ceres; like the proceffion of the papifts at this day, celebrated upon the feaft of St. Mark and rogation days, with larger or fhorter litanies. There were two feafts at Rome of this name, one in April, or, according to other authors, at the end of January, and the other in July.

Twelve priefts went before a public proceffion of the citizens, who had lands and vineyards without the city. The fame ceremony was practifed in the country by other priefts among the inhabitants of the villages; they went three times round the ground, every one being crowned with leaves of oak, and finging hymns in honour of Ceres, the goddefs of corn: this ceremony was called Ambervalia, ab ambiendis arvis: the facrifices which they offered, after this proceffion, they called ambarvales hoftes.

There were three forts of them, viz. a fow, a fheep, and a bull, which is the reafon that this threefold facrifice was called fuovetaurilia, which is a word compounded of Sus, Ovis, and Taurus. In the firft facrifice they prayed to the goddefs Ceres and the god Mars, that they would preferve their corn from mildew and hail, and bring it to perfect ripenefs; and, in that of the month of July, they prayed to them to blefs their harveft.

Cato has left us the form of prayer ufed on this occafion, in cap. 141. De Re Ruftica; but this prayer was made to Mars only. The fame author hath alfo left us another form of prayer, which was made in the fecond feaft of perambulation in the month of July, in which they facrificed a fow. Before they began their harveft, which they called porca precedanea, this prayer was put up to Janus, Jupiter, and Juno, and not to Ceres, any more than the former. We find likewife that this ceremony was performed by the mafter of the family, accompanied with his children and fervants, every one of them being crowned with oak leaves as well as the facrifice, which they led three times round the lanes and vineyards, finging hymns to the gods; after which they facrificed to them fweet wine, with honey and milk, as we may fee by the verfes of Virgil, Georg. lib. 1.

This manner of proceffion was always ufed in the country where they had no arval priefts, as at Rome. Virgil, Georg. lib. 1. ver. 343, defcribes, in a moft natural and lively manner, the rejoicing of the country people at this feaft. *Danet's Antiq.*

A'MBER, *Analyfis of* AMBER. Take a capacious glafs retort, with its neck cut off, fo as to leave an orifice two inches wide or more; put into it pieces of common Amber, well cleanfed from fand, duft, or other foulnefs, fo that it fill two-thirds of the cavity. Apply a large receiver, and lute the juncture with the common luting; diftil in a fand furnace, with a degree of heat a little greater than that of boiling water; thus there will come over a copious, thin, limpid oil: continue this degree of heat, fo long as any oil comes over, and keep it feparate. Then apply the receiver again, and cautioufly raife the fire, till a fecond oil begins to rife, which will be yellow, large in quantity, and ftill tranfparent: proceed patiently with the fame degree of heat, fo long as this oil comes over, which it continues to do a confiderable time; but, for the elegance of the operation, this alfo might be kept feparate. Now, again, raife the fire gradually, till a white, faline, woolly matter appears in the receiver, but particularly in the neck; then gradually raife this fire a little, and continue it increafing, till no more of this matter comes over; but the fire muft not be increafed too quick, otherwife the volatile falt would mix with the grofs oil, that fhould follow after, and thus be in a great meafure loft therein. It is beft to remove the receiver, take out the productions, and keep them feparate; but during the whole time, that this volatile falt runs, a red oil alfo comes over, ftill almoft tranfparent. The fire being now increafed to the utmoft, there comes over a grofs, vifcous, fat oil, thick like turpentine. When this is rifen, if a fire of fuppreffion be given, the whole black matter now becomes flatulent, rifes into the neck of the retort, and thus comes into the receiver, in form of a hard black mafs; fo that, if the neck of the retort be not left wide, it will be thus blocked up, and the glafs be burft in a dangerous manner, with a loud noife, and often a firing of the matter. But if, before the fire of fuppreffion was ufed, a large quantity of fand were thrown upon this laft remainder, it will divide the matter, and caufe it to come over, without danger, in a black and dry form. There remains, at the bottom of the retort, a very fmall quantity of brittle fæces, of fcarce any fignificance, fo that the whole is volatile. If the operation be carefully performed, fo many different productions are obtained, which may be purified by a new diftillation, and be rendered thin and limpid; but the volatile falt, collected by itfelf, is perfectly acid, and this is the only method, that I know, whereby a true acid is obtained in a folid faline form; for we have no inftance thereof in any other vegetable, animal, or foffil fubftance. Tartar indeed is acid, but, as it is fcarcely diffolvable in water, does not deferve the name of a falt. Oil of vitriol, brought to an extreme degree of purity, fhoots, in winter-time, into tranfparent folid cryftals; but immediately diffolves again, and appears fluid, as foon as the cold is a little diminifhed; but the falt of Amber long continues the fame.

Remarks.

Amber thus appears to be a very particular body; its oil refembles the foffil oils of petroleum, naphtha, and the like; but the remainder, after the firft and fecond are come over, nearly refembles jet, and the acid falt feems fomewhat vitriolic. But the fame thing, concreted, wonderfully differs from thofe parts, into which chymiftry refolves it. Who would think, that Amber, its powder, its liquid folution in alcohol, the powder precipitated from its tincture with water after diftillation, and then wafhed; the oils, falt, and colophony after diftillation; proceeded from the fame matter? Who could know the proper virtues of each, and who, by joining them together again, could recompofe Amber? The oils, being purified by a repeated diftillation, have a fharp, balfamic, exciting, diaphoretic, dieuritic, emmenagogic, and anti-hyfteric virtue, and when externally ufed, by way of linament, are very ferviceable in reftoring contracted, weak, paralytic, torpid limbs: the volatile falt is gratefully acid, balfamic, unctuous, penetrating, prefervative, and ftimulating to the nerves and fpirits, being a true, volatile, acid, oily falt, and therefore a capital anti-hyfteric, and diuretic, efpecially, if purified by a fecond diftillation. *Boerhaave's Chymiftry.*

The fhootings of the falt of this bitumen obferved by the microfcope are exceedingly entertaining, though its progreffions are fo very flow, that fome patience is neceffary to wait for and attend to the whole courfe of its configurations: but a curious obferver will find from it at laft a pleafure fufficient to reward his attention.—Its firft fhootings at the edge of the drop, after it has been held for a few feconds over the flame of a lamp or candle, appear irregular, as at *a a* (*plate* III. *fig.* 3.) Some figures pufh out foon after, beyond the reft, and are carved and tapering to a point, as *b b*. Very elegant figures will be feen forming themfelves in other places at the fame time, and refembling fprigs of fir or yew: numbers of thefe rife together, each having a main ftem very thickly befet with little fhootings from top to bottom, in fome on both fides, but, in others, on one fide only; which difference will be underftood by a view of the figures *c c*. The downy feathers of birds appear in the fame kind of form, when examined by the microfcope. As the progreffion goes on, branches will be found iffuing from the fides of the former fhootings, vid. *d*: and, in fome places of the drop, feveral gradations of branchings will be perceived to fucceed one another, to divide and fubdivide after a moft wonderful order, reprefenting at the laft a winter fcene of trees without leaves, a fpecimen of which is fhewn at *e*.— The laft action of this curious falt produces figures exquifitely delicate, bearing no refemblance to any thing that preceded, but appearing like the flourifhes or engravings of a mafterly hand, in the manner reprefented at *f f*. This part of the operation begins not till the water is nearly exhaled, and, whilft it is performing, the fcene appears a good deal confufed; but, after waiting till the water is intirely dried away, a thoufand beauties will prefent themfelves perfectly diftinct and clear; for the configurations of this falt do not break away, or melt in the air, as moft others do, but may be preferved on the glafs flip for a long while afterwards, if nothing is fuffered to rub them off. *Baker's Employment for the Microfcope.*

AMBRO'SIA, in botany, a genus of plants, whofe characters are: it hath male flofculous flowers, which are produced on feparate parts of the fame plant from the fruit, and have no vifible petals: the fruit, which fucceeds the female flowers, is fhaped like a club, and is prickly, containing one oblong feed in each.

The feeds of this plant fhould be fown on a moderate hot-bed in March, and, when the plants are come up two inches high, they muft be tranfplanted into another moderate hot-bed, allowing each plant three or four inches fquare; obferving to water them pretty well, and fhade them until they have taken new root; afterwards they muft have a large fhare of frefh air every day, when the weather is warm, and frequent waterings; for they are very thirfty plants. When the plants are grown pretty ftrong, they muft be taken up with balls of earth to their roots, and planted in large pots filled with rich earth; and, if they are placed on a very moderate hot-bed until they are well rooted, it will generally forward their flowering. Toward the latter end of May they fhould be placed abroad with other hardy annual plants, among which they will make a variety. *Miller's Dict.*

A'MBURY, a kind of wen, or fpongy wart, growing upon any part of a horfe's body, full of blood.

The manner of curing this excrefcence is, to tie it about hard with a thread, or rather with a horfe-hair, and in eight days it will fall off; then ftrew upon it the powder of verdigreafe to kill it at the root, and heal it up again with green ointment; but, if it be flat that nothing can be bound about it, then take it away with an incifion-knife clofe to the fkin, or elfe burn it with a fharp hot iron, cutting it round-about fo deep as to leave none of the root behind, and, after having applied turpentine and hog's-lard melted together, heal it up as before: but if this wart grows in a finewy part, where a hot iron is improper, eat out the core with oil of vitriol, or white fublimate; then ftop the hole with flax dipped in the white of an egg

egg for a day or two, and at laſt dry it up with unſlaked lime and honey. *Markham's Farriery.*

For theſe warts put three ounces of powder of copperas in a crucible, with one ounce of arſenic powdered; place the crucible in the middle of a charcoal fire, ſtirring the ſubſtance, but carefully avoiding the malignant ſteams: when the matter appears ſomewhat reddiſh, take the crucible off the fire, and, after it is cool, break and beat the matter into a very fine powder, incorporate four ounces of this powder, five ounces of album Rhaſis, and make an ointment to be applied cold to warts, anointing them lightly every day, and they will fall off like kernels of nuts, without cauſing any ſwellings in the legs, if the application be ordered ſo as only the warts be anointed, and the horſe be not worked or ridden, during the cure; and, after the warts fall off, dreſs the ſore with the common application called the counteſs's ointment. *Soll. Syſ.*

AMENTA'CEOUS, in botany, a term applied to the flowers of certain trees and plants, which are compoſed of a vaſt number of apices, or antheræ, hanging down in form of a rope; ſuch as the hazel, and the like.

A'METHYST *(Dict.)* — Amethyſts may be counterfeited with glaſs, to which the proper colour or ſtain is given. There were fine ones made in France, about the year 1690, which may even impoſe on connoiſſeurs, unleſs the ſtone be taken out of the collet.

The method of giving this colour to glaſs is as follows: take cryſtal-frit, made with the moſt perfect and fine tarſo; then prepare a mixture of manganeſe in powder, one pound; zaffer prepared, one ounce and a half; mix theſe powders well together, and add, to every pound of the frit, an ounce of this powder. Let it be put into the pots with the frit, not into the already made metal. When the whole has ſtood long enough in fuſion to be perfectly pure, work it into veſſels, and they will reſemble the colour of the Amethyſt. *Neri's Art of Glaſs*, p. 92.

AMMONI'ACUM *(Dict.)* — Some of this ſalt diſſolved in water and a drop thereof placed on a ſlip of glaſs, to be examined by the microſcope, will be found to ſhoot with a ſmall degree of heat; which muſt be very carefully obſerved, for, if more heat than juſt enough be given to it, the configurations will run into one another, and make the whole appear in great confuſion.

It begins with ſhooting from the edges great numbers of ſharp, but thick and broad ſpiculæ, from whoſe ſides are protruded, as they riſe, many others of the ſame ſhape, but very ſhort, parallel to each other, but perpendicular to their main ſtem, as at 1. *(Plate* III. *fig.* 5.) Theſe ſpiculæ arrange themſelves in all directions, but for the moſt part obliquely to the plain from whence they riſe, and many are ſeen frequently parallel to one another: which particulars the figure endeavours to expreſs at 1. 1.— As they continue to puſh forwards (which they do without increaſing much in breadth) ſome ſhoot from them the ſmall ſpiculæ only, as at 2. Others, after they are nearly come to their full growth, divide into two branches in a manner different from all other kinds of ſalt I have ever ſeen, by the ſplitting of the ſtem, longitudinally, from the top almoſt to the edges of the drop, but without any ſhootings from the inſide, as is repreſented at 3.— Other branches, beſides the ſmall ſpiculæ mentioned above, protrude longer ones of the ſame form, from whence others alſo proceed: which others ſhoot alſo ſmaller ones from them, and ſo on to many gradations, at at 4.

Before the middle of the drop begins to ſhoot, ſeveral exceedingly minute bodies may be diſcerned at the bottom of the fluid. Theſe riſe to the top in a little while, and as ſoon as their form can be diſtinguiſhed, whilſt yet extremely ſmall, they plainly wear the ſame ſhape exactly, which they afterwards appear in when grown much larger, as is ſhewn at 5.— Their growth is very quick, and pretty equal for a time, but at length ſome one branch gets as it were the maſtery, and, ſhooting farther than the reſt, forms the figure at 6. The other branches enlarge but little afterwards, all the attraction ſeeming biaſſed to this alone, from which more branches being protruded, and they again protruding others, the whole appears as at 8.

It is not uncommon to ſee in the middle of the drop ſome different configurations, where, inſtead of the ſtraight ſtems deſcribed above, there is formed a kind of zigzag, with ſpiculæ like thoſe in the other figures, as at 7.

To obtain the cryſtals of this ſalt, it is neceſſary to place a drop of a freſh ſolution (made in warm water) before the microſcope, without giving it any other heat than the warmth of the water. The regular cryſtals will then appear as repreſented at the ſide of the drop A, B, C, *fig.* 6, 7, 8. The laſt of which figures C is produced from the ſecond B, by new formations at each corner of the croſs branches, when the whole proceſs is nearly ended: but the cryſtals are rarely ſeen, unleſs the ſolution be examined, as ſoon as made. *Baker's Employment for the Microſcope.*

AMPHITHE'ATRES, in gardening, are great ornaments to a large and noble garden. If this hill, or riſing ground, is of a ſemicircular figure, it will be ſtill the better.

Theſe Amphitheatres are formed of ever-greens, as hollies, phillyrea's, lauruſtinus's, bays, &c. obſerving to plant the ſhorteſt-growing trees in the front, and the talleſt trees behind, as pines, firs, cedars of Lebanon, &c.

They are alſo formed of ſlopes on the ſide of hills, and covered with turf, and have been eſteemed great ornaments in gardens, but are now generally excluded by perſons of true taſte; for the natural eaſy ſlope of ſuch hills is infinitely more beautiful than the ſtiff angular ſlopes into which theſe Amphitheatres are commonly cut. *Miller's Dict.*

AMY'NTAS, in literature, a beautiful paſtoral comedy compoſed by Taſſo; the model of all dramatic pieces, wherein ſhepherds are actors.

ANA'NAS, the pine-apple, in botany, the name of a genus of plants, whoſe characters are theſe:

It hath a flower conſiſting of one leaf, which is divided into three parts, and is funnel-ſhaped: the embryo's are produced in the tubercles: theſe afterwards become a fleſhy fruit, full of juice: the ſeeds which are lodged in the tubercles are very ſmall, and almoſt kidney-ſhaped.

Tournefort has enumerated three, and Mr. Miller ſix ſpecies of this genus of plants.

Theſe plants are propagated by planting the crowns which grow on the fruit, or the ſuckers which are produced either from the plants, or under the fruit; either of which I have found to be equally good; although, by ſome perſons, the crown is thought preferable to the ſuckers, as ſuppoſing it will produce fruit ſooner than the ſuckers, which is certainly a miſtake; for by conſtant experience I find the ſuckers (if equally ſtrong) will fruit as ſoon, and produce as large fruit as the crowns.

The ſuckers and crowns muſt be laid to dry in a warm place, for four or five days, or more (according to the moiſture of the part which adhered to the old plant or fruit) for, if they are immediately planted, they will rot. The certain rule of judging when they are fit to plant, is by obſerving if the bottom is healed over, and become hard; for, if the ſuckers are drawn off carefully from the old plants, they will have a hard ſkin over the lower part; ſo need not lie ſo long as thoſe which by accident may have been broken. But whenever a crown is taken from the fruit, or the ſuckers from the old plants, they ſhould be immediately diveſted of their bottom-leaves, ſo high as to allow depth for their planting; ſo that they may be thoroughly dry and healed in every part, leſt, when they receive heat and moiſture, they ſhould periſh, which often happens, when this method is not purſued. If theſe ſuckers or crowns are taken off late in the autumn, or during the winter, or early in the ſpring, they ſhould be laid in a dry place in the ſtove, for a fortnight or three weeks before they are planted; but in the ſummer-ſeaſon they will be fit for planting in three or four days.

As to the earth in which theſe ſhould be planted; if you have a rich good kitchen-garden mould, not too heavy, ſo as to detain the moiſture too long, nor over-light and ſandy, it will be very proper for them without any mixture: but, where this is wanting, you ſhould procure ſome freſh earth from a good paſture, which ſhould be mixed with about a third part of rotten neats-dung, or the dung of an old melon or cucumber-bed, which is well conſumed. Theſe ſhould be mixed ſix or eight months at leaſt before they are uſed; but, if it be a year, it will be the better; and ſhould be often turned, that their parts may be the better united, as alſo the clods well broken. This earth ſhould not be ſcreened very fine; for, if you only clear it of the great ſtones, it will be better for the plants than when it is made too fine. You ſhould always avoid mixing any ſand with the earth, unleſs it be extremely ſtiff; and then it will be neceſſary to have it mixed at leaſt ſix months or a year before it is uſed; and it muſt be frequently turned, that the ſand may be incorporated in the earth, ſo as to divide its parts: but you ſhould not put more than a ſixth part of ſand; for too much ſand is very injurious to theſe plants.

In the ſummer-ſeaſon, when the weather is warm, theſe plants muſt be frequently watered; but you ſhould not give them large quantities at a time: you muſt alſo be very careful, that the moiſture is not detained in the pots, by the holes being ſtopped; for that will ſoon deſtroy the plants. If the ſeaſon is warm, they ſhould be watered every other day; but, in a cool ſeaſon, twice a week will be often enough: and, during the ſummer-ſeaſon, you ſhould once a week water them gently all over their leaves; which will waſh the filth off them, and thereby greatly promote the growth of the plants. There are ſome perſons who frequently ſhift theſe plants from pot to pot: but this is by no means to be practiſed by thoſe who propoſe to have large well-flavour'd fruit; for, unleſs the pots be filled with the roots, by the time the plants begin to ſhew their fruit, they commonly produce ſmall fruit, which have generally large crowns on them; ſo that the plants will not require to be new-potted oftener than twice in a ſeaſon: the firſt time ſhould be about the end of April, when the ſuckers and crowns of the former year's fruit (which remained all the winter in thoſe pots in which they were firſt planted) ſhould be ſhifted into larger pots; i. e. thoſe which were in half-penny or three-farthings pots, ſhould be put into penny, or, at moſt, three-half-penny-pots, according

cording to the ſize of the plants; for you muſt be very careful not to over-pot them, nothing being more prejudicial to theſe plants. The ſecond time for ſhifting them is, towards the latter end of Auguſt, or the beginning of September, when you ſhould ſhift thoſe plants which are of a proper ſize for fruiting the following ſpring, into two-penny pots, which are full large enough for any of theſe plants. At each of theſe times of ſhifting the plants, the bark-bed ſhould be ſtirred up, and ſome new bark added, to raiſe the bed up to the height it was at firſt made; and, when the pots are plunged again into the bark-bed, the plants ſhould be watered gently all over their leaves, to waſh off the filth, and to ſettle the earth to the roots of the plants. If the bark-bed be well ſtirred, and a quantity of good freſh bark added to the bed, at this latter ſhifting, it will be of great ſervice to the plants; and they may remain in the tan until the beginning of November, or ſometimes later, according to the mildneſs of the ſeaſon, and will not require any fire before that time. During the winter-ſeaſon theſe plants will not require to be watered oftener than every third or fourth day, according as you find the earth in the pots to dry: nor ſhould you give them too much at each time; for it is much better to give them a little water often, than to over-water them, eſpecially at that ſeaſon.

You muſt obſerve never to ſhift thoſe plants which ſhew their fruit, into other pots; for, if they are removed after the fruit appears, it will ſtop the growth, and thereby cauſe the fruit to be ſmaller, and retard its ripening; ſo that many times it will be October or November before the fruit is ripe: therefore, you ſhould be very careful to keep the plants in a vigorous growing ſtate, from the firſt appearance of the fruit, becauſe upon this depend the goodneſs and ſize of the fruit; for, if they receive a check after this, the fruit is generally ſmall, and ill-taſted.

The method of judging when the fruit is ripe, is by the ſmell, and from obſervation; for, as the ſeveral ſorts differ from each other in the colour of their fruit, that will not be any direction when to cut them; nor ſhould they remain ſo long as to become ſoft to the touch before they are cut; for then they become flat and dead, as they alſo do when they are cut long before they are eaten: therefore, the ſureſt way to have this fruit in perfection, is to cut it the ſame day it is eaten; but it muſt be early in the morning, before the ſun has heated the fruit, obſerving to cut the ſtalk as long to the fruit as poſſible, and lay it in a cool, but dry place, preſerving the ſtalk and crown to it, until it is eaten. *Miller's Dict.*

ANA'TTA, or ANNOTTO, a ſort of red dye brought from the Weſt-Indies. It is made of red flowers, which grow on buſhes, or ſhrubs, ſeven or eight feet high. It is thrown, like indigo, into large tubs, or ciſterns, full of water, with this difference, that nothing but the flower is uſed, the leaves of which are ſtripped off, as is done with regard to roſes. Theſe remain in the water till they are rotten; and when, by much ſtirring, they are reduced into a thick liquid ſubſtance, it is expoſed to the ſun to dry, and afterwards made into rolls, or cakes.

There are none but the Spaniards, who now cultivate this plant and prepare the dye in any quantity, the plantations thereof, which the Engliſh of Jamaica had at St. Angels, being ruined. The Engliſh dyers make more account of this drug than of Indigo; and, accordingly, the merchants of Jamaica, who have it from Porto-Rico, buy it 25 per cent. dearer; for they pay but 3 rials per pound for indigo, and 4 for Anatta. The Europeans who trade in this drug have, at preſent, the greateſt part of it from the bay of Honduras. This commodity ſells extremely, and they who buy it at the firſt hand generally get from 40 to 60 per cent. by it. *Savary's Dict.*

A'NCHOR (*Dict.*)— The parts of an Anchor are, 1, The ring *a* (*Plate* III. *fig.* 9.) to which the cable is faſtened. 2, The beam, or ſhank, *b*, *c*, which is the longeſt part of the anchor. 3, The arm *d e*, which is that which runs into the ground. 4, The flouke, or fluke, by ſome called the palm, which is that broad and peaked part, with its barbs, like the head of an arrow, which faſtens into the ground, as *e f*. 5, The ſtock, a piece of wood faſtened to the beam near the ring, ſerving to guide the fluke, ſo that it may fall right, and fix in the ground, as *g h*.

There are ſeveral kinds of Anchors. 1, The largeſt is called the ſheet-Anchor, and is never uſed but in violent ſtorms, to hinder the ſhip from being drove aſhore. 2, The two bow-Anchors, or bowers, which are leſs, and are uſed for ſhips to ride in a road, or harbour. They are alſo called the firſt and ſecond bower, or beſt and ſmall bower. 3, When a veſſel is to be brought up or down a river by the winds, though the tide be contrary to it, the ſeamen ſet their fore-ſail, foretop-ſail, and mizzen-ſail, and let her drive with the tide. If ſhe comes too near the ſhore, they have a little Anchor ready, which is called the rodger, or redgo-Anchor, with a hawſer faſtened to it from the ſhip; and this they drop in the middle of the current, by which means they wind her head about; after which they take up the Anchor again. 4, The ſtream Anchor, is a ſmall Anchor, made faſt to the ſtream-cable, for a ſhip to ride by in gentle ſtreams, and in fair weather. 5, The grapnel, is an Anchor for a ſmall ſhip, or boat.

Merchants, traders, and others, who fit out ſhips for ſea, cannot be too careful with regard to the goodneſs of Anchors, ſince upon them chiefly depends the preſervation of ſhips and cargoes, and even the lives of all thoſe who are on board.

In order to make Anchors of a good quality, it is ſometimes the practice to conjoin the brittle iron with ſoft and tough iron; and, for this reaſon, the Spaniſh or Swediſh iron ought to be preferred, and united together, the former being ſoft, and the latter brittle.

Aubin, in his Marine Dictionary, obſerves, that the Anchors of a large veſſel are made ſmaller in proportion than thoſe of a ſmall veſſel. The reaſon of which, ſays he, is, that, though the ſea exerts an equal force againſt a large ſhip as againſt a ſmall one, ſuppoſing that they both have an equal extent of wood in the water, which gives room to the water to act equally againſt an equal extent, yet the ſmall veſſel, on account of its lightneſs, has not the ſame ſtrength with the great one, to reſiſt the force of the water, which muſt be ſupplied by the weight of the Anchor.

Method of making ANCHORS.— The ſhank, arms, and flukes, are firſt forged ſeparately; then the hole is made at one end of the ſhank for the ring, which, being alſo previouſly forged, is put into the hole in the ſhank, and the two ends ſhut together. After which the arms are ſhut to the ſhank, one after another, and the Anchor finiſhed. But, that the reader may have an idea of the manner how an Anchor is made, we have given a view of it in *Plate* II. where *a* is the foreman, or maſter Anchor ſmith, holding one end of the ſhank of the Anchor, and guiding it under the hammers, as he would have it ſtruck. *b*, *c*, *d*, *e*, Are hammer-men, ſtriking on the Anchor. *f*, The anvil, on which the part of the Anchor to be wrought is laid. *g*, A door which defends the foreman from the prodigious heat of the fire. *h*, *h*, *h*, *h*, the crane which ſupports the Anchor, and which moves on two gudgeons at *i*, *i*. *k*, An iron collar, which may be moved to any part of the crane, as occaſion requires. *m*, The chain, having a ſwivel at the top to admit of turning the Anchor round, when it is carried from the fire to the anvil, and from the anvil to the fire. *n*, The cradle, in which the ſhank of the Anchor is placed near the center of gravity, that the foreman may be able to move it, as he ſees occaſion. Another man generally ſtands by the cradle to aſſiſt the foreman in moving the Anchor; but we have omitted him in the figure, in order to render the cradle and the manner how the Anchor is placed in it more conſpicuous. *o*, *o*, The forge. *p*, The back of the chimney. *q* 1, *q* 2, Two pair of bellows, which are blown by means of the upright piece *r*, the croſs-piece *s* (called, by workmen, the rocking-ſtaff) and the two tumblers *t*, *u*. The man at *x* takes hold of the rocking-ſtaff *s*, and walks forward and backward, by which means both bellows are alternately elevated, and conſequently the fire continually blown. For, as the rocking-ſtaff is moved to or from the back of the chimney, the two ends of the tumblers *t*, *u*, are alternately raiſed and depreſſed, by means of the chains faſtened to them, at is plain from the figure.

In the poſition repreſented in the plate, the upper board of the bellows *q* 1 is raiſed; for the chain 3, having drawn down the end 4 of the tumbler *t*, by that means has raiſed the end 5, which being faſtened by the chain 6 to the upper part of the bellows *q* 1, muſt be alſo raiſed with it. *w*, Is a man ſtanding on the bellows, to give the wind a greater velocity. He ſteps alternately from one pair of bellows to the other, as they deſcend. When a prodigious blaſt is required, ſeveral men ſtand on the bellows at the ſame time. *y*, Is an inſtrument called a tue-iron. It is put in the fire on the noſes of the bellows, which come through the back of the chimney, and not only defends them from the exceſſive heat, but alſo conveys the wind to different parts of the fire. *z*, Is a tool, called a cant-hook. Its uſe is to take hold of the fluke, when the arm is ſhut to the ſhank.

AN'CLE *luxated*, in ſurgery.— The Ancle is ſubject to be luxated, in jumping, or even in walking; and that in all four directions, either inward or outward, backward or forward. When the Ancle is luxated inward, the bottom of the foot is turned outward; and on the contrary, when it is luxated outward, the bottom of the foot is turned inward, which latter caſe indeed is much more frequent than the others. If it is diſlocated forward, the heel becomes ſhorter, and the foot longer than it ſhould be; and, if backward, the contrary ſigns to theſe will appear. The Ancle however can ſcarce poſſibly be luxated outwards, unleſs the fibula be ſeparated from the tibia, or elſe quite broken, which may happen to the external Ancle; nor is it at all uncommon for a luxation of the Ancle to be attended with very grievous ſymptoms, eſpecially when occaſioned by ſome great external violence; nor can it indeed well happen otherwiſe in this caſe, ſince the diſtortion of the foot muſt neceſſarily overſtrain the adjacent tendons, ligaments, and nerves, and thence excite very violent pains, and other bad ſymptoms; or the veins and arteries may alſo be very eaſily lacerated, which will occaſion

PLATE II. Engraved for the Supplement. Facing Anchor.

Printed for J. Hinton in Newgate Street.

casion a large extravasation of blood about the whole foot, which too often gives rise to a gangrene.

It is however necessary to observe, that the Ancle is not always luxated, after it has been violently strained by leaping or turning the foot on one side; for it sometimes happens, that the Ancle is not dislocated on these occasions, but only the parts are violently contused and strained. The Ancle, when truly luxated, is more or less difficult to be reduced, according to the violence of the force by which the accident was occasioned. The most ready way, however, of reducing a luxation of the Ancle, is, to place the patient upon a bed, seat, or table, letting the leg and foot be extended in opposite directions by two assistants, while the surgeon replaces the bones with his hands and fingers in their proper situation. When the foot is by this means restored to its proper position, it is to be well bathed with oxycrate and salt, and then carefully bound up with a proper bandage. The patient must be enjoined to keep his bed for a considerable time, till the bad symptoms are gone, and the Ancle has recovered its strength so far, as to bear the weight of the body, without any uneasiness or danger. *Heister. Surg.* p. 173.

ANCYLOGLO'SSUM (*Dict.*) ——That operation by which the membrane under the tongue, commonly called the fremulum by physicians, is divided or cut; it is styled untying the tongue. This operation is most generally performed upon infants, and that with two different intentions; first, in very tender infants, when the fore part of their tongue, from the moment of this birth, is so closely joined to the subjacent parts, by means of their membrane, that they cannot move their tongues sufficiently, or thrust them so far out of their mouths as to be able to suck. This operation is also performed on children somewhat farther advanced, when, by this membrane's being too strait or short, they cannot pronounce articularly, at an age when it might be expected of them. For both these reasons, it is absolutely necessary; but it must be remembered, that it is not to be performed promiscuously, and at random, upon all new-born children, as most midwives, women, and even some men, idly imagine. We have reason rather to be assured, that it is scarce necessary in one of a thousand infants; for experience has shewed both myself and a great many more skilful physicians, that this case occurs far less frequent than hair-lips; for, when a child can thrust its tongue without its lips, there is nothing amiss about the fremulum; and it will learn, in process of time, both to suck and speak, unless there be some other defect in the organs necessary for these purposes. On the other hand, if the infant can scarce move its tongue, and cannot thrust it beyond its teeth; or if, in some other respect, this membrane should fetter the tongue, then a skilful incision becomes very proper: but because this operation is not to be rashly performed, lest, as has frequently been the case, the most terrible evils, and sometimes death itself, should ensue, it will not be amiss to direct to the safest and most accurate method of performing it.

The point of the tongue, then, ought to be a little elevated with the left hand, using either a linnen cloth, that it may not slip through the fingers, (see *plate* III. *fig.* 10.) or even with a small fork made for that purpose (*fig.* 11.) then as much of the fremulum, as is necessary for speech and sucking, is to be cut with the common blunt-pointed scissars, or an incision-knife, betwixt the venæ raninæ and the lower salivatory ducts: but this is to be done with a great deal of caution, lest either the salivary ducts, the venæ raninæ, or the nerves of the tongue, should happen to be cut at the same time; for, when they are injured, very terrible consequences ensue. Thus Dionis, in his Surgery, makes mention of an infant, who, by an excessive hæmorrhage, in consequence of the venæ raninæ being cut died very soon after the operation. But if a vein should be unluckily cut, which may very readily happen in a fremulum that is too thick and short, a compress, soaked in vinegar, is to be held a little while under the tongue, till the blood stops; but if, at the first incision, the tongue is not sufficiently untied, a few days, or even a few weeks after as circumstances shall require, the remaining part of the fremulum is very cautiously to be cut with scissars, or an incision-knife: then after the operation is over, the finger dipped in honey of roses, or syrup of violets, is very frequently to be rubbed up and down under the tongue, and the wound is to be anointed with it, lest the cut fremulum should again unite.

From what has been said, it appears that disorders of this kind are not only less frequent, but of more difficult and hazardous cure, than is generally thought. Upon this account, those midwives are miserably mistaken, who, concluding with the ignorant multitude, that no infant is born without this defect, thrust their whole fingers into the infant's mouth, and with their nails destroy the fremulum; for it must necessarily happen, that such a rash and fool-hardy laceration, by the nails, must bring an inflammation of that membrane, convulsions, and often the death of the little patient; for this reason, midwives and foolish women are not only to be cautioned against such practices, but Hildanus is to be carefully consulted; for he (in Cent. 3. Obs. 28.) hath very accurately laid down, not only the nature and cure of the disorder itself, but also the several bad consequences that possibly may, and generally ensue, from performing this operation at an unseasonable time, or in an uncautious manner. But, when the cutting this fremulum is absolutely necessary, it may be done with much more safety, and with much less pain to the patient, by the scissars referred to, than by the long nails of a simple old woman. *Heister's Surgery.*

ANDRA'CHNE, *bastard orpine*, in botany, the name of a genus of plants, of which there is but one species, and called by Tournefort and others telephoides. The characters of this genus are these:

There are male and female flowers on the same plant: the empalement of the male flower is divided into five parts: the flower consists of five leaves, having five small stamina in the center: the female flower hath no leaves, but three styles, which reach upon the pointal; which afterwards becomes a capsule with three cells, filled with small seeds.

A'NDREW (St.) an order of knights in Muscovy, founded by Peter Alexiowitz, emperor of Russia, to recompense the merits of some of his officers, who had distinguished themselves in the war against the Turks, in the year 1698. The badge of this order is a golden medal, on one side of which is represented the cross of St. Andrew, and on the other are wrote these words, Czar Pierre Monarque de tout la Russie. This medal is fastened to a blue ribbon, which is worn across the right shoulder. This order has since been conferred on such noblemen as have distinguished themselves in the war against the Swedes, as also on foreign princes, ministers, or ambassadors. See *plate* III. *fig.* 12.

ANDRO'MEDA, in astronomy, the name of a constellation of the nothern hemisphere, representing a woman chained.

The number of stars in this constellation in Ptolemy's catalogue are 23, in Tycho's 22, in Bayer's 27, and in Mr. Flamsteed's 84.

ANE'MONE (*Dict.*)— A soil, proper for the blowing these flowers to great advantage, may be made as follows:

Take a quantity of fresh untried earth (from a common or some other pasture-land) that is of a light sandy loam, or hazel mould; observing not to take it above ten inches deep below the surface; and, if the turf be taken with it, the better, provided it hath time to rot thoroughly before it is used; mix this with a third part of cow-dung, and lay in an heap, keeping it turned over at least once a month for eight or ten months, the better to mix it, and rot the dung and turf, and to let it have the advantages of the free air: in doing this work, be careful to rake out all great stones, and break the clods (but I would by no means approve of sifting or screening the earth, which I have found very hurtful to many sorts of roots); for, when earth is very fine, upon the first great rains of winter or spring, the smallest particles thereof join closely together, and form one solid mass, so that the roots often perish for want of some small stones to keep the particles asunder, and make way for the tender fibres, to draw nourishment for the support of the root.

The earth should be mixed twelve months before it is used, if possible; but, if you are constrained to use it sooner, you must turn it over the oftener, to mellow and break the clods; and observe to rake out all the parts of the green sward, that are not quite rotten, before you use it, which would be prejudicial to your roots, if suffered to remain. The beginning of September is a proper season to prepare the beds for planting (which, if in a wet soil should be raised with this sort of earth six or eight inches above the surface of the ground, laying at the bottom some of the rakings of your heap to drain off the moisture; but, in a dry soil, three inches above the surface will be sufficient): this soil should be laid at least two feet and an half thick, and in the bottom there should be about four or five inches of rotten neats-dung, or the rotten-dung of an old melon or cucumber-bed, so that you must take out the former soil of the beds to make room for it.

The best season for planting these roots, is about the latter end of September; and, for those of a middle season, any time in October; but observe to perform this work, if possible, at or near the time of some gentle showers; for, if you should plant them when the ground is perfectly dry, and there should no rain fall for three weeks or a month after, the roots will be very apt to grow mouldy upon the crown; and, if they once get this distemper, they seldom come to good after.

In the beginning of April your first-planted roots will begin to flower, which continue for three weeks, or more, according to the heat of the weather, or management in covering them, during the heat of the day, with matts or cloths; then the second-planted sort will come to succeed them, and these will be followed by those planted in the spring, so that you may have these beauties continued for near two months together, or sometimes longer, if the season be favourable.

Towards the middle or latter end of May, the leaves of your first-blown roots will decay; at which time you must take them out of the ground, clearing them from decayed stalks, and washing them, to take the earth clear from the roots; then spread them with a matt in a dry shady place, till they are perfectly dried, when you may put them up in bags and

and hang them out of the reach of mice, or other vermin, which will destroy many of the roots, if they come at them.

Observe also to take up the latter-planted roots, as soon as their leaves decay; for, if they are suffered to remain long after in the ground, and there should fall some showers of rain, they would soon put forth fresh fibres, and make new shoots, when it would be too late to remove them: at the time when you take up the roots, is the proper season for breaking or parting them, which may be done by separating those that you would chuse to make all possible increase from, into as many parts as you can conveniently, provided each of them have a good eye or bud; but those you intend to blow strong, should by no means be parted too small, which greatly weakens their flowering. *Miller's Dict.*

ANE'MOSCOPE.— Under this article in the Dictionary, we have mentioned the Anemoscope invented by Otto Gueric; we shall here give a description of a very curious machine of this kind, invented by the learned Mr. Pickering.

The Anemoscope is a machine four feet and a quarter high, consisting of a broad and weighty pedestal, a pillar fastened into it, and an iron axis, of about half an inch diameter, fastened into the pillar. Upon this axis turns a wooden tube, at the top of which is placed a vane, of the same materials, 21 inches long, consisting of a quadrant, graduated and shod with an iron rim, notched to each degree; and a counterpoise of wood, as in the figure, on the other. Through the center of the quadrant runs an iron pin, upon which are fastened two small round pieces of wood, which serve as moveable radii to describe the degrees upon the quadrant, and as handles to a velum or sail, whose plane is one foot square, made of canvas stretched upon four battens, and painted. On the upper batten, next to the shod rim of the quadrant, is a small spring, which catches at every notch corresponding to each degree, as the wind shall, by pressing against the sail, raise it up; and prevents the falling back of the sail, upon the lessening of the force of the wind. At the bottom of the wooden tube is an iron index, which moves round a circular piece of wood fastened to the top of the pillar on the pedestal, on which are described the thirty-two points of the compass. The figure of this machine may be seen *plate* III. *fig.* 13. where *a* Is the pedestal. *b*, The pillar, in which the iron axis is fitted. *c*, The circle of wood, on which are described the 32 points of the compass. *e*, The wooden tube upon its axis. *f*, The velum. *g*, The graduated quadrant. *h*, The counterpoise of the vane.

Fig. 14. The velum taken off. *a*, The plane of the velum. *b*, The spring. *c*, *c*, The wooden radii. *d*, *d*, The holes through which the pin in the center of the quadrant goes. Its uses are the following.

1. Having a circular motion round the iron axis, and being furnished with a vane at top, and index at the bottom, when once you have fixed the artificial cardinal points, described on the round piece of wood on the pillar, to the same quarters of the heavens, it gives a faithful account of that quarter from which the wind blows.

2. By having a velum or sail elevated by the wind along the arch of the quadrant, to an height proportionable to the power of the column of wind pressing against it, the relative force of the wind, and its comparative power, at any two times of examination, may accurately be taken.

3. By having a spring fitted to the notches of the iron with which the quadrant is shod, the velum is prevented from returning back upon the fall of the wind; and the machine gives the force to the highest blast, since the last time of examination, without the trouble of watching it.

I have carefully examined the dependence that may be had upon the machine, during the late storms in February 1743-4, by comparing the height, to which the wind then forced the velum, with the Deal letter. The 19th of February, Sabbath. 8 a. m. the Anemoscope was at 75: the Deal letter for that day called it a storm. The Saturday following, being the 25th at 8. p m. the machine was at 79: the Deal letter called that a violent storm. The Wednesday following, the last of February it was 84: the Deal letter called that a violent storm. So that it appears, that, in such as the sailors allow to be violent storms, the machine has hitherto answered well, and has had six degrees to spare for a more violent gust, before it comes to an horizontal position.

It is certainly to be depended upon in ordinary weather, the velum being hung so tender, as to feel the gentlest breeze. But, after all, I must freely own, that I fear the exposing this machine to all winds, for a continuance, must soon disorder it; and that irregular blasts and squalls cannot fail in a short time to impair it. It may not therefore be amiss, to prevent this, for gentlemen to take the machine in, in violent weather; and, by taking the tube of the iron axis, to make their observations with the tube, vane, and velum, in their hands; which, as it is very light, and far from cumbersome, is easy to do, as I have often experienced. *Philos. Trans. Numb.* 473.

A'NGEL *(Dict.)* — St. Hilary remarks that the word Angel does not so much denote their nature, as their office, signifying as much as nuncius, a messenger, or person employed to carry orders, or declare one's will. Thus it is St. Paul represents Angels, Heb. i. 14. where he calls them ministring spirits. And for the same reason the name is given in the prophet Malachi to priests. Jesus Christ himself is called, by the Septuagint, the Angel of the mighty council, a name, says Tertullian, which shews his office, not his nature. So the Hebrew word Angel, used in scripture, is also a name of office, signifying legate, envoy, minister. Yet custom has prevailed, and the name Angel is commonly interpreted to shew their nature.

Nothing is more frequent, in scripture, than the missions and apparitions of good and bad Angels: God sends them to declare his will, to correct, teach, reprove, and comfort: God gave the law to Moses, and appeared to the old patriarchs by the mediation of Angels, who represented him and spoke in his name. The existence of Angels is supposed in all religions.

Though the Jews in general believed the existence of Angels, there was a sect among them (the Sadduces) who denied the existence of all spirits whatever, God only excepted: and yet the Samaritans and Caraites, whom the Jews represent as Sadduces, acknowledged such beings. Before the Babylonish captivity the Hebrews seem not to have known the name of any Angel: the Talmudists say they brought them from Babylon: it is true, we find many of them, called by their names in the book of Enoch; but this we know is spurious, and was written after the captivity we are speaking of. Tobit, who is thought to have lived at Nineveh, some time before the captivity, is the first who has called an Angel by his proper name; he mentions Raphael, who conducted Tobias into Media, and Daniel, who lived at Babylon some time after Tobit, has taught us the names Michael and Gabriel. In the New Testament we find only the two latter Angels mentioned by name. It has been questioned, whether the antient Hebrews paid divine homage to Angels or not. The form of benediction, which Jacob used in blessing the sons of Joseph, (the Angel which redeemed me from all evil bless the lads) may seem to imply that they did. The Rabbins in glossing upon this text observe, that the prayers of their ancestors were not directly addressed to Angels, but it was really God they invoked, when they prayed to them; they only go to them as to the king by his ministers, and as one that presents his petition to the first officer of the crown, yet still looks to the king, as the source and spring of his happiness and favour that he has received. But this exposition is refuted by others, who remark that, Jacob, after he had directly applied himself to God, and begged of him both temporal and eternal blessings on his two grand-sons, then addressed himself to the Angel, to obtain of him, that he would keep them from all evil; from whence they conclude, that Jacob addressed his prayers directly to the Angel, to whom he ascribed the power of preserving from evil, whilst he left to God the privilege of bestowing all that was good; and if the prayer of the patriarch was implicitly addressed to God, as the fountain of goodness, yet he certainly prayed explicitly to the Angel. But, notwithstanding this dispute, the best christian expositors deny that this invocation of Jacob implies any thing like a prayer to the Angel. Some indeed conceive, that the Angel in this place is the second person in the trinity; an opinion refuted by others, who more justly say, that Jacob intended no more than a desire that his children might enjoy the angelic protection, by the special favour of God to them; for it is such an expression as that of David to a contrary purpose, Let the Angel of the Lord persecute them, where no one will say he prays to an Angel, though his words are exactly like those of Jacob.

There are divers opinions concerning the time when Angels were created. Some think they were created at the same time as the heavens; and that Moses included them under this name, saying, In the beginning God created the heavens. Others have conjectured, that he inclined to represent them under the name of light, which God created the first day; of this opinion is St. Cyril. Others again have asserted, that they were created before the sensible world, which opinion Job seems to favour, when he says, Where wast thou when I laid the foundation of the earth, — and all the sons of God shouted for joy? The Hebrews think they were created on the second day of the world, and that God consulted with the Angels when he said, Let us make man in our own image. Others are of opinion, that Angels were created on the fifth day. Origen, and other Greek and Latin fathers, think they existed before the world; and Dr. Hyde thinks a very long time before the world. See Basnage's Hist. des Juiffs, lib. 4. cap. 9. The philosophers of the Peripatetic sect believed they were coæval with God, and, consequently, that they existed from all eternity. The Greek fathers of the Christian church were generally inclined to believe they were created before the world. Some few indeed were of different opinions, among whom is Epiphanius.

Though it is an universal opinion, that Angels are of a spiritual, incorporeal nature, yet many of the old fathers, misled by a passage in Genesis, where it is said, that the sons of God (or the Angels) saw the daughters of men, that they were fair, and they took them wives of all which they chose, imagined them to be corporeal and capable of sensible plea-

Printed for J. Hinton in Newgate Street.

pleasures. Other fathers indeed, and those in great number, have asserted Angels to be purely spiritual, and this at present is the common opinion of the schools.

There have been a great many disputes and varieties of fancy, concerning the number, order, nature, and power of Angels; most of which are not to be resolved by scripture or tradition. The author of the books De Hierarchia cœlesti, who wrote about the beginning of the sixth century, is the first who ventures to range the Angels into three hierarchies, and nine orders. The Jews likewise distinguish them into several orders, and set, as it were, a general at the head of them; they call him Metatron, the same with the Christian St. Michael.

As to the office or employment of Angels, some are said to preside over empires, nations, provinces, cities, and particular persons. These latter are stiled guardian Angels. Thus St. Michael is acknowledged to be the protector of the people of Israel; and the Angel Gabriel speaks of the Angel who was protector of Persia, according to the generality of interpreters, when he says that the prince of the kingdom of Persia withstood him one and twenty days. St. John wrote his Revelations to the Angels of the seven Christian churches in Asia minor, whereby he does not mean only the bishops of those churches, but, in the judgment of many of the fathers, the Angels likewise who were appointed for their protection. The learned Dr. Prideaux observes, that the minister of the synagogue, who officiated in offering up the public prayers, being the mouth of the congregation, delegated by them, as their representative, messenger, or Angel, to speak to God in prayer for them, was therefore, in the Hebrew language, called the Angel of the church; and from thence the bishops of the seven churches of Asia are, by a name borrowed from synagogue, called the Angels of those churches. As to guardian Angels, they are very clearly described in the Old Testament. Jacob speaks of the Angel who had been his guide in all his journies, and had delivered him out of all his dangers. The psalmist, in several places, mentions Angels as the protectors of the righteous. In the New Testament, we hear of St. Peter's Angel, who set him at liberty; and Jesus Christ enjoins us not to despise little ones, because their Angels continually behold the face of God. The Jews, and the very Heathens, believed that particular Angels were commissioned to attend us, and had the care of our conduct. Hesiod, the most antient, or, at least, one of the most antient Greek authors, says, that there are good Angels upon earth, sent by Jupiter, for the protection of mankind, and to observe the good or evil, which they practise. Plato says, that every one of us has two dæmons, or two genius's, one inclining us to evil, the other directing us to good; though Apuleius says, that Plato assigned but one dæmon to every man. The antient Christians, as Origen and St. Augustine, ascribe to Angels the office of presenting our prayers to God; and the Christians, in general, agree with the Platonists, that God makes use of the ministry of Angels, to carry his orders, to work miracles, and to foretel future events.

A'NGLING, is an excellent art, which, as it pleads great antiquity, so the knowledge thereof is not without great difficulty to be obtained; but some observations concerning it will not be amiss. And, first, the angler must remember by no means to fish in light and dazzling apparel, but his cloathing must be of a dark sky colour; and, at the places where he uses to angle, he should once in four or five days, or oftener, if for carp or tench, cast in corn boiled soft: he may also cast in garbage, beasts livers, worms chopped in pieces, or grains steeped in blood and dried, which will attract the fish thither: and, in fishing, to keep them together, throw in half a handful of grains of ground malt, which must be done in still water; but in a stream you must cast your grains above your hook, and not about it; for, as they float from the hook, so will they draw the fish after them. If you would bait a stream, get some tin boxes made full of holes, no bigger than just fit for a worm to creep through, which fill therewith; and, having fastened a plummet to sink them, cast them into the stream, with a string fastened thereto, that they may be drawn out at pleasure; by the smallness of the holes, the worms can crawl out but very leisurely, and, as they crawl, the fish will resort about the boxes.

If in a stream you would bait for salmon, trout, umber, or the like, take some blood, and incorporate therewith fine clay, barley and malt, ground, adding some water thereunto; all which make into a paste with ivy gum, then form it into cakes, and cast them into the stream: if you find your bait take no effect in attracting the fish, you may then conclude some pike or perch lurk there to seize their prey, for fear of which the fish dare not venture thereabout; take therefore your troll, made either of brandlings or lob-worms, or you may use gentles or minows, which they will greedily snap at. As for your rod, it must be kept neither too dry nor too moist, lest the former make it brittle, and the latter rotten; and, if it be sultry dry weather, wet your rod a little before you angle, and, having struck a good fish, keep your rod bent, and that will hinder him from running to the end of the line, whereby he will either break his hold or hook. And if you would know what bait the fish loves best, at the time of your fishing, when you have taken one, slit the gill, and take out the stomach, opening it without bruising, and there you will find what he fed on last, and had a fancy to, whereby you may bait your hook accordingly. When you fish, shelter yourself under some bush or tree, so far from the brink of the river, that you can only discern your float; for fish are timorous, and very easy to be affrighted: and you will experimentally find the best way of Angling with a fly is down the river, and not up; neither need you ever make above six trials in a place, either with fly or ground bait, when you angle for trout, for by that time he will either offer or take, or refuse the bait, and not stir at all; but if you would have fish bite eagerly, and without suspicion, you may present them with such baits as they are naturally inclined to, and in such manner as they are accustomed to receive; and, if you use paste for baits, you must add flax or wool, with which mix a little butter to preserve it from washing off the hook: and, lastly, Note,

That the eyes of such fishes as you kill, are most excellent baits on the hook for almost all sorts of fish.

Cautions to be observed in ANGLING, *as to the seasons of the weather, the time of the day and year, &c.*

In Angling you ought so to place yourself, that your shadow do not at any time lie upon the water, if shallow; but in deep waters that is not so necessary to be observed; yet, that you may be exact, you should make use of all the advantages that the place will afford.

In a pond it is best to angle near the ford where the cattle go to drink, and in rivers in those places where such sort of fish as you intend to angle for, usually frequent; as for breams, in the deepest and quietest part of the river; for eels under hangings over banks; for chub, in deep shaded holes; for perch, in scowrs; for roach, in the same places as perch; for trouts, in quick streams, and with a fly upon the stream on the top of the water.

And, if you fish in such places where you can discern the gravelly bottom, then be sure you conceal yourself as much as possible.

In such waters as are pestered with weeds, roots of trees, and such-like, fish lie close and warm, and resort thither in great shoals, and there they will bite freely; but take great care how you cast in the hook, and how you strike a bite, for the least rashness loses hook and line.

And, if the hook happens to be entangled, you should be provided with a ring of lead, about six inches round, fastened to a small pack-thread; this ring you must put over the rod, letting it go into the water, holding fast by the other end of the pack-thread, and work it gently up and down, and it will soon disengage the hook.

It is good Angling in whirlpools, under bridges, at the falls of mills, and in any place where the water is deep and clear, and not disturbed with wind or weather.

The best times are from April to October, for, in cold, stormy, and windy weather, the fish will not bite; and the best times in the day are from three till nine in the morning, and from three in the afternoon till sun-set.

If the wind be easterly, it will be in vain to go to angle; but you may angle well enough if it blow from any other point, provided it do not blow hard; but it is best in a southerly wind, and a close, lowering, warm day, with a gentle wind, and after a sudden shower to disturb the water, at which time they will best rise at the fly, and bite eagerly; and, the cooler the weather is in the hottest months, the better it is.

In winter, all weathers and all times are much a like, only the warmest are the best.

It is very good Angling a little before the fish spawn, for then, their bellies being full, they frequent sandy fords, to rub and loosen their bellies, at which time they will bite freely.

It is also very good Angling in a dull, cloudy day, after a clear, moon-shiny night, for in such nights they are fearful to stir to get food, lying close, so that, being hungry the next day, they will bite boldly and eagerly.

At the opening of sluices and mill-dams, if you go with the course of the water, you can hardly miss of fish that swim up the stream to seek for what food the water brings down with it.

It is best Angling at the ebb, in waters that ebb and flow; but yet the flood is to be preferred, if the tide is not strong. *Sportman's Dict.*

A'NGLO-SA'XON *Language*, that spoken by the Angles or Saxons settled in England. This language is properly the original of our present English, being that spoken by our Saxon ancestors first established in this island. It is now called Anglo-Saxon, to distinguish it from the modern or present English.

A'NIL, in botany, the indigo-plant, the name of a genus of plants, of which there are three species. The characters are: It hath pinnated leaves, which are terminated by a simple lobe at the extremity; the flowers consist of five leaves, of the papilionaceous kind, the uppermost petal being larger than the others, rounded, and lightly furrowed on the side:

the lower petals are ſhort, and terminate in a point: in the middle of the flower is ſituated the ſtyle, which afterwards becomes a jointed pod, containing one cylindrical ſeed in each partition.

Under the article INDIGO in the Dictionary, we have given a ſhort account of the method of making indigo; but as this is an article of great importance in commerce, dying, &c. we ſhall here, from Father Labat, give a full account of the whole proceſs, with the manner of cultivating this plant.

There was formerly a great deal of indigo made in the pariſh of Macauba: there is not a ſtream nor river in it, where one does not meet with indigo-works, that is, backs or vats of ſtone-work, in which the plant that yields the dye is put to digeſt: there are uſually three of theſe vats one above another, in the manner of a caſcade (See *Plate* III. *fig.* 18.) ſo that the ſecond, which is lower than the bottom of the firſt, may receive the liquor contained in the firſt, when the holes, which are made in the bottom of the firſt, are unſtopped; and that the third may in its turn receive what was in the ſecond.

The firſt, largeſt, and higheſt of theſe vats (as *a*) is called the ſteeper or rot; it is uſually made twenty feet long, twelve or fifteen feet wide, and three or four feet deep: the ſecond (as *b*) is called the battery: it is almoſt half as ſmall again as the firſt; and the third (as *c*) which is much leſs than the ſecond, is called the deviling.

The names of the two firſt perfectly agree with their uſes; for the plant is laid to ſteep in the firſt, where it ferments, is macerated, and becomes like rotten dung: after the ſalts and ſubſtance of the leaves and rind are diffuſed in the water by the fermentation, which the heat and ripeneſs of the plant have excited in it. It is in the ſecond that they agitate and beat this water, impregnated and loaded with the ſalts of the plant, till, having collected, reunited, and as it were, coagulated them with one another, they form the particles which form the dye. As for the name of the third, I do not ſee how it agrees with it, unleſs it be becauſe this vat is deeper coloured than the others; for the indigo already formed, remaining in it, conſequently dyes and colours much deeper than the others.

To which I ſhould add, that it is only at St. Domingo that they make uſe of this name. In the windward iſlands they call this laſt vat the ſettler, and this name ſuits it perfectly well; becauſe it is in this that the indigo, begun in the ſteeper, and perfected in the battery, unites, grows into a maſs, ſeparates itſelf from the particles of water which remained in it, leaves them at top, and ſettles at the bottom of the vat, whence it is taken out to be put into little bags, and then into the boxes, as I ſhall mention hereafter.

Nothing ought to be omitted in the building and making theſe vats ſubſtantial: the ſtrength of the fermentation is ſo great, that unleſs the ſtone-work and plaiſter be done very well, and the mortar carefully choſen and wrought, they crack; and a very moderate crack is ſufficient to let out a vat of indigo, and cauſe a conſiderable loſs to the owner.

When this misfortune happens, the following is an eaſy and infallible remedy, which I can anſwer for, having experienced it: take ſome ſea-ſhells, of any kind whatever; pound them without burning them, and ſift them through a fine ſieve. Take an equal quantity of quick-lime, and ſift it; mix theſe together with water enough to make a ſtiff mortar, and, as quick as you can, ſtop the cracks of your vats with it. This mixture incorporates, ſticks, and dries in a moment, and immediately prevents the matter's running out of the vat.

Every-body does, or ſhould know, that indigo is a dye uſed to dye wool, ſilk, cloths, and ſtuffs, blue: the Spaniards call it anilo: the fineſt they make, i. e. in New-Spain, comes from Guatimala; which makes a great many people call it barely guatimala. It is made alſo in the Eaſt-Indies, particularly in the dominions of the great Mogul, the kingdom of Golconda, and other places thereabouts, as Mr. Tavernier relates in his voyages. This ſort is in Europe oftener called India than Indigo or Anil, people taking, for its proper name, the name of the place it was made at.

Indigo is compoſed of the ſalt and ſubſtance of the leaves and rind of a plant of the ſame name; ſo that one may ſay, it is a diſſolution or digeſtion of the plant, cauſed by the fermentation it has excited in the water it was laid to ſteep in. I know ſome writers pretend, that the ſubſtance of the leaves does not produce the indigo, which (as they would have it) is only a viſcous tincture, or colour, which the fermentation of the plant diffuſes in the water; but, before I take their words for it, I deſire they would tell me what becomes of the ſubſtance of the plant; for, when it is taken out of the ſteeper, it is certain, that it has no longer the ſame weight, conſiſtence, nor colour it had before. The leaves which were very plump, and very full of juice, are light, flabby, and withered, and look more like dung than any thing elſe; which makes them frequently give the name of rot to the ſteeper. If then we no longer find in the leaves, and the reſt of the plant, the ſame ſubſtance that was obſervable in it before it was laid in ſteep, is it not moſt natural to believe, that it is the ſame ſubſtance and ſalts, which, being freed from incloſures, and diffuſed in the water, have thickened it, and by their union or coagulation have formed that blue maſs which they call indigo, ſo uſeful in painting and dying.

Method of cultivating the ANIL.——This plant requires a good rich level ſoil, not too dry; it greatly robs and impoveriſhes the ground where it grows, and muſt be alone. There cannot be too much care taken to keep it clean, and to hinder herbs of any kind whatever from growing near it. They weed and cleanſe the ground where they intend to plant the indigo ſeed, five times over. I ſhould think they ſhould call it ſowing; but the term of planting is conſecrated in our iſles, and I do not think I ought for the ſake of a word to fall out with our planters, who deſerve our eſteem upon a thouſand accounts, though they have got an habit of murdering the French language. They ſometimes carry their neatneſs to ſuch a pitch, that they ſweep the piece of ground as they do a room. After that, they make the holes or pits, wherein the ſeeds are to be put: for this purpoſe, the ſlaves, or others, who are to work at it, range themſelves in the ſame line, at the top of the piece of ground; and, going backwards, they make little pits of the breadth of their hoe, of the depth of three or four inches, at about a foot diſtance every way, and as much as poſſible in a ſtraight line. When they are come to the end of the ground, each furniſhes himſelf with a little bag of ſeeds, and, returning that way they came, they put eleven or thirteen ſeeds into each of the holes they have made. This work is the moſt toilſome of any in the manufacture of indigo; for thoſe who plant it, muſt be always ſtooping, without riſing up, till the planting of the whole length of the piece of ground is ended; ſo that, when that is large, which almoſt always happens, they are obliged to remain two hours, and often more, in this poſture.

When they come to the top of the piece, they go back again, and cover the holes they have put the ſeeds in, by thruſting in with their feet the earth they had taken out of them; and ſo the ſeed is covered with about two inches of earth.

Though all ſeaſons are good for the planting of indigo, yet care muſt be taken not to put it in the ground in a dry time: it is true, the ſeed may keep a whole month in the ground, without being ſpoiled: but, when it is planted ſo, one runs the riſk of having it eaten up by vermin, or carried away by the wind, or choaked by the weeds which ſpring up with it; ſo that the prudent planters never run the riſk of planting it dry; i. e. at a time, when they do not probably expect rain in two or three days after the planting is ended: they chuſe therefore, uſually, a moiſt ſeaſon, which promiſes rain; and then they are ſure of ſeeing the plant ſpring up in three or four days after its being planted.

Notwithſtanding all the care that has been taken in clearing the ground, where the ſeeds have been planted, the planter muſt not be careleſs when the indigo is got above-ground; becauſe the goodneſs of the ſoil, joined to the moiſture and warmth of the climate, and the plentiful dews that fall every night, makes a prodigious quantity of weeds ſpring up, which would choak and abſolutely ſpoil the indigo, if extreme care was not taken to weed them up as ſoon as they appear, and to keep the plant extraordinary neat; and very often the weeds are partly the cauſe of the breeding of a kind of caterpillars, which devour all the leaves in a trice.

From the time of the plant's riſing above-ground, to its perfect maturity, is but two months, and then it is fit to cut: if one was to ſtay longer, it would bloſſom; its leaves would grow drier and harder, and conſequently they would yield leſs ſubſtance, and the colour would not be near ſo beautiful.

After this firſt cutting, the new branches and leaves, which the plant produces, may be cut about every ſix weeks, provided the ſeaſon be rainy, and that care be taken not to cut it in a time of drought, becauſe we ſhould then infallibly loſe the plant, or, as they call it there, the choupues, and be obliged to plant again; but, all things being rightly managed, the plant may laſt two years; after which, it muſt be plucked up, and new ones planted.

When the plant is ripe, which is known by the leaves, which grow brittler, and leſs ſupple, they cut it ſome inches from the ground. They uſe for the cutting of it great crooked knives made like ſickles. Some planters make it into bundles like double bottles of hay, that a negro may eaſily carry them to the ſteeper: but moſt people put it into large pieces of coarſe cloth, which they tie by the four corners; and this is more convenient, for the plant is leſs handled and ſqueezed, and the ſmall is carried away as ſafely as the great; and, beſides, the work goes on quicker this way, than in making bottles; and as time is precious every-where, and eſpecially in America, there cannot be too much care taken not to loſe any.

Eighteen or twenty packets of plants, each about the ſize of two bottles of hay, are ſufficient to fill a ſteeper of the aforementioned ſize. When it is filled with water, ſo that it covers the plants, they put pieces of wood on the top, that the plants may not riſe above the water (much as they do upon the grapes that are put into the preſs) and let all ferment.

According as the heat is greater or leſs, or the plant more or leſs ripe, the fermentation is raiſed ſooner or later, ſometimes in six, eight, or ten hours; and sometimes one is obliged to wait eighteen or twenty hours, but very seldom longer. Then the effect of the fermentation visibly appears, the water heats, and boils up on all sides, as the grapes do in the vat: and the water, which at first was clear, insensibly grows thick, and becomes of a blue, inclining to a violet colour. Then, without meddling at all with the plants, they open the cocks which are at the bottom of the steeper, and let all this water, loaded with the salts and substance of the plants, which were freed by the fermentation, run into the battery; and while they throw away, as useless, and almost rotten, the plants that were in the steeper, and clean it, that it may be filled with fresh, they beat the water, which they have let out of the steeper, into the battery.

They formerly used, for this purpose, a battle-door wheel, whose axle was placed on the middle of the vat, and which they turned by two handles, that were at the end of the same axle. Since that, in the room of battle-doors, they have put little bottomless boxes, and afterwards others, whose bottoms were bored full of holes: at present they use a kind of pretty large pails, fastened to strong poles, placed upon chandeliers, by means of which, the negroes violently and continually raise, beat, and stir the water, till the salts and other parts of the substance of the plants are united, and sufficiently, as it were, coagulated to incorporate.

The hitting this minute exactly shews the skill of him who oversees the making of the indigo: for, if he makes them leave off beating a little too soon, the grain, not yet formed, remains dispersed in the water, without sinking and gathering together at the bottom of the vat, and is lost with the water, when they are obliged to let it out; which is a great loss to the owner: or if, when it is formed, they continue to beat, they dissolve it, and the same inconveniency follows. This minute then must be observed, and, when it is found, must leave off beating, and let the matter rest.

To find this minute, they make use of a little silver cup, designed for this use alone: they fill it with this water, while the negroes beat it; and, according as they observe that the fæces sink to the bottom of the cup, or remain dispersed in the water, they cease, or continue beating.

When they have left off beating, they let the matter rest: the fæces sink to the bottom of the vat, and gather together like a kind of mud; and the water, freed from all the salts it was impregnated with, swims above it, and grows clear. Then they open the cocks, which are placed in the battery at different distances from the bottom, and let this water run away; and, when they come to the surface of the fæces, they open the cocks of the bottom, that the fæces may all fall into the deviling or settler. There they let it settle a little while longer, after which they put it into linnen-bags, fifteen or eighteen inches long, made with a point, where it perfectly purges itself of the rest of the water, which remained among its particles. When that is done, they spread it in little boxes, three or four feet long, two feet broad, and about three inches deep, and expose it to the air to dry it perfectly. They observe not to expose it to the sun, because it would starve the colour in drying it; and they take a great deal of care to keep it from the rain, because that would dissolve and utterly spoil it. It sometimes happens, that the caterpillars get among the indigo; and, if they are let alone ever so little a while, they eat all the leaves, and often the very rind and ends of the branches, and kill the stocks; it is but lost time to endeavour to destroy them, or hinder them from ravaging a whole piece, by stopping them with a ditch. The surest way is to cut down the indigo with all speed, let its age be what it will, and to throw both plants and caterpillars pell-mell together into the steeper; they there burst, and part with what they had devoured, and the indigo is not the less beautiful for it. It is true, when the plant is not come to its full maturity, it yields much less: but many experiments have taught us, that the colour it yields is much more beautiful; so that what is lost one way, is gained another. I would not wait for so perfect a ripeness, before I cut the plant. Perhaps all the secret of those, whose indigo is so much extolled beyond ours, lies only in cutting the plant, when it yields the liveliest colour. I have experienced, that in leaving some cochineal-flies upon some Indian figs, which were too ripe, instead of being red, they grew of a filemot colour, like the fruit they fed upon. The same thing might happen in indigo; and what I here propose, is not a groundless doubt, since it is backed by the experiment just now related; which plainly proves, that the same plant, cut at different ages, produces colours of different beauty. I would not venture to give this advice to men wedded to their interest, who value the quantity rather than the quality of their commodity; but I believe I have nothing to fear from our islanders, who are generous and magnificent, sometimes even beyond their abilities: I advise them therefore to make different trials, as to the soil, the season, the age of the plant, the water they steep it in, the point of dissolution, &c. And I am sure, that, with a little time, labour, and patience, they will make indigo that will equal, and even excel, the most boasted indigo of foreign countries. The planters of St. Domingo know, that, in 1701, their coarse sugar was very bad, and was not made without infinite trouble; and at present every-body allows, that by their labour, assiduity, and inquiries, it is grown much more esteemed than that of the windward islands: why may not the same be hoped for in indigo?

Mr. Pomet, author of the general history of drugs, says in his first part, chap. 10, that the Indians of the village of Sarquesse, near Amadabat, use only the leaves of the indigo, and throw away the plant and branches; and that it is from thence the most esteemed indigo comes. I am pretty much of his opinion; for we see, that those who take the pains to strip off the grapes from the branches, before they put them into the vat, and throw away the stalks intirely, make much the best wine; because the stalks always contain an acid, which mixes with the juice of the grape with the treading and pressing them both together; and, for the same reason, the indigo plant must contain a liquid much less perfect in colour than that of the leaves: but one ought to have the leisure and patience of the Indians to undertake such a work, and have work-men as cheap as they are in that country, supposing the fact true, as Mr. Pomet delivers it from the relation of Tavernier.

Though I am a great friend to those experiments which may carry our manufactures to a greater perfection, yet I dare not propose this, because of the expence they must be at, who would try it; and because the profit arising from it would not, perhaps, quit cost: however, I have here given the method of the Indians of Sarquesse, that I may have no reason to reproach myself with having omitted a thing, which may be of some use to my country.

Good indigo ought to be so light, as to swim upon water; the more it sinks, the more it is suspected to be mixed with earth, ashes, or powdered slate. Its colour ought to be a deep blue, inclining to a violet, brilliant, lively, and bright: it ought to be more beautiful within than without, and look shining, and as it were silvered.

If it is too heavy in proportion to its bulk, it ought to be suspected, and its quality examined into; for, as it often bears a considerable price, it is fit that those who buy it, should be acquainted with the frauds that may be committed in it.

The first is the beating the plant too much in the steeper, that the leaves and rind of it may be intirely consumed. It is certain, that the quantity of the matter is very considerably increased by this dissolution; but the indigo is a great deal the less beautiful for it; it is blackish, thick, heavy, and fitter to be thrown away than used.

The second is the mixing ashes, earth, or a certain brown shining sand (which is pretty commonly found in the bays by the sea-side) and especially powdered slate, with the fæces, as they fall into the deviling, and stirring all well together, that it may incorporate, and the fraud not appear; and this fraud is much more easily committed in the powdered indigo, than in that which is in cakes; because it is very difficult for those heterogeneous bodies to unite so well together, as not to make, in many places, as it were beds of a different matter; and then, breaking the piece of indigo, they are easily perceived.

The two following expedients may be made use of, in order to know the goodness or badness of indigo.

The first is to dissolve a bit of it in a glass of water. If it is pure, and well made, it will entirely dissolve; but, if it be adulterated, the foreign matter will sink to the bottom of the glass.

The second is to burn it. The good indigo will burn all away, whereas the ashes, earth, sand, and slate, remain after the true indigo is consumed. *Labat's Travels.*

A'NIMA *Saturni*, the soul of lead, a name given to a preparation of that metal, used by enamellers, for various purposes. The method of making it is this:

Put litharge finely powdered into a glazed earthen vessel, and pour distilled vinegar upon it to the height of four fingers; let it stand till the vinegar has acquired a white or milky colour: pour off this vinegar, and put on fresh, and continue to do so till the vinegar will no longer be coloured by the litharge; then set these vinegars together in open glazed earthen vessels, that the white powder may subside, and the vinegar be poured off clear. This white substance is the Anima saturni. Sometimes this white matter will not precipitate without the addition of water; and sometimes it is necessary to evaporate the liquors; but by that means it is always prepared. *Neri's Art of Glass.*

A'NIMAL *(Dict.)*— An Animal, respect being only had to the body, not the soul, may be defined with Boerhaave to be an organical body, consisting of vessels and juices, and taking in the matter of its nutriment, by a part called a mouth; whence it is conveyed into another called the intestines, into which it has roots implanted, whereby it draws in its nourishment, after the manner of plants.

According to this definition, an Animal is distinguished from a fossile, in that it is an organical body; and from a vegetable by this, that it has its roots within itself, and a plant without itself.

In effect, the intestines of an Animal are, in reality, no more than its earth, or the body it adheres to; into which

which it sends forth its roots, that is, the lacteal vessels, which thence draw the matter of its life and increase.

An Animal is better defined from its mouth than its heart, since we do not know whether the whole tribe have such a part; for as several have sixteen hearts, particularly the silk-worm, and some even sixty: so it is possible others may have none at all.

Nor can any general character of an Animal be taken from the brains, the lungs, or the like, since we know of many quite destitute thereof.

The genuine characteristic, then, of an Animal, is to be free and at large with respect to the subject it derives its nourishment from: for every thing is taken in by the mouth; and the mouth does not adhere to any thing: whereas all plants are connected, in some manner or other, to the body which furnishes them food.

Hence it follows, that a fœtus, while it remains in the mother's womb, is a real plant; as being connected by the funiculus umbilicalis to the placenta, and by the placenta to the uterus, from whence it receives its nutriment.— If it did not derive its food by the said funiculus, but by its mouth, it were an Animal; and, if it drew it by both, a zoophyte, or plant-Animal.

Some have defined Animals from their loco-motion, as being capable of shifting from place to place; and plants, from their sticking fast to the same subject: but, on this principle, oisters, mussels, cockles, &c. are excluded from the class of Animals, inasmuch as they adhere, or grow to rocks, &c. yet it is certain, that those creatures are real Animals, as they have mouths and stomachs to take in their food, and lacteals and mesenteric veins to receive it.— Indeed, mussels seem an exception from the former definition. That anomalous creature breathes, and receives its nourishment, not at the mouth, but by the anus: the part which we account its head, though without either eyes, ears, or tongue, or any other apparatus, save a hole, which we may call its mouth, is an immoveable part; being fastened to one of the shells, so that it cannot seek for food, but the food must come to seek it. This food is water, which, as the shells open, enters in at the anus of the mussel, which opens at the same time; and passing thence into certain canals between the inner surface of the shell, and the outer surface of the Animal, is conveyed thence into its mouth, by a certain motion, which the Animal can produce at pleasure.

We chuse therefore, with Dr. Tyson, to fix the criterion of an Animal in a ductus alimentalis, i. e. a gula, stomach, and intestines: all which make but one continued canal.

But there is no difference absolutely essential and general between animals and vegetables; but nature descends by certain steps and imperceptible gradations, from a more perfect to a less perfect Animal, and from thence to a vegetable. Let us suppose the fresh water polypus to be the last of the Animal and first of the vegetable creation.

After having examined the difference, if we consider the similitude between Animals and vegetables, we shall find it, at first view, very essential and general: you will find in both a common power of producing themselves; such a power implies a greater analogy and similitude in their nature, than appears at first sight; and gives us reason to believe that Animals and vegetables are beings nearly of the same class.

A second similitude between them may be drawn from the unfolding and opening their parts, a property common to both; for vegetables as well as Animals have a power of growing, and, though the manner be different, it is not totally and essentially so, because there are in Animals many different parts, as bones, hair, hoof, horns, &c. the unfolding of which is a true vegetation, and the fœtus, in its first formation, vegetates before it lives.

They have this third resemblance, that some Animals are produced like plants, and by the same means, as, for example, the green lice found on trees, which multiply without copulation, is like increasing plants by sowing their seed; and increasing the polypus, by cutting him in pieces, resembles propagating trees by slips. We may therefore assert on stronger terms, that Animals and vegetables are beings of the same class, and that nature seems to have made a transition from one to the other, by insensible gradations; because it is certain they have many essential and general likenesses, but no difference that can be looked upon as such.

Now, if we compare Animals and vegetables in other respects, as number, magnitude, form, &c. we shall draw new inferences from these considerations.

The number of the species of Animals is much greater than that of plants; for, in the genus of insects only, there is perhaps a great number of species invisible to the naked eye, than there are plants visible upon the face of the earth. Animals resemble each other much less than plants, and in the similarity of plants consists the difficulty of ranging and classing them properly. This gave birth to the art of botany, a more difficult study than zoology; because Animals are much more sensibly different from one another than plants, and are therefore more easy to be distinguished, named, and described. Besides, here is another advantage we have in distinguishing the species of Animals; we ought to look on that as the same species which propagates and preserves itself by the copulation of the male and female of the same species, and consider that as a different species, which by the same means can produce nothing. So that the fox will be a different species from the dog, if nothing proceeds from the copulation of a male and female of these two species; and, even though a creature half dog half fox should proceed from this copulation, yet it would not class the fox properly in the canine species; because this production would be a mule, and nature proceed no farther; whereas, to constitute a species, it is necessary the production should be continued invariable fit for the propagation of its own species, in a word, like other Animals.

In plants we have not the same advantage, for though some pretend to have discovered sexes in plants, and have settled distinctions of male and female from the parts of fecundation, yet this is neither so certain nor apparent in plants as Animals: besides, the production of plants is effected in many cases, where the sex is not concerned, nor the parts of generation necessary; and the notion of sexes in plants is not sufficiently understood, to be a proper method for us, whereby to distinguish plants into their different species.

The number of the species of Animals is therefore greater than that of plants; but it is not the same thing with regard to the number of individuals contained in each species. As, in plants, the number of individuals is much greater in the less than larger species, so, in animals, the species of flies is perhaps a hundred thousand millions of times more numerous than that of the elephant; in like manner there are more herbs than trees. But if we compare the quantity of individuals in plants and Animals, species to species, we shall see, that each species of the plant is more fruitful than each species of the Animal. As for instance: quadrupeds produce but a small number of young, and those at considerable distances of time; trees on the other hand every year produce a great number of their own species.

M. de Buffon objects against the justice of this comparison; and to render it a parallel case, he says, we must first be able to compare the quantity of generative particles in the semen of an Animal with the number of seeds growing on a tree, and then perhaps we should find the generative powers to abound most in Animals. But if, says he, by way of answer, it were possible, by carefully gathering all the acorns of an oak, and sowing them, to raise 100,000 trees, the production of one year, which is by no means impracticable, and, though we took care to help a horse to all the mares he could cover in a season, the produce would be vastly inferior to that of the vegetable. I do not therefore, says M. de Buffon, examine into the quantity of generative particles, first, because in Animals we do not know it; secondly, because the acorn is not a generative principle, but a production as perfect as the fœtus of an Animal, and wants nothing but a proper nudus to display itself.

M. de Buffon mentions the prodigious increase of some kind of insects; the female bee produces thirty or forty thousand; but he declares, that he relates this in general, comparing Animals and vegetables; and that this instance of bees, which is the greatest we know in the Animal world, is yet no proof; for out of this number of thirty or forty thousand, which the mother bee produces, he observes there is but a very small number of females, and about 1500 or 2000 males, the rest being mules, or of no sex, being incapable of generation.

It must be owned that in insects, fishes, and shell fish, there are species which seem to be extremely fruitful; oisters, herrings, lice, &c. are perhaps as numerous as mosses and other common plants. But, if we consider and take a view of the whole, we shall easily discover that the greatest part of the species of Animals are less fruitful of individuals than the species of plants. Farther we may observe, that, by comparing the increase of the species of plants with each other, there is not so wide a difference in the number of individuals, as in the species of Animals; some of which produce a great number, others a very small one, instead of which, the number of productions in plants is always very great, in every species. It follows from what we have said, that the least and lowest species are always the most fruitful in individuals, both in the Animal and vegetable world. In proportion as the species of Animals grow more perfect, we see them reduced to a less number of individuals. Can one imagine it would cost nature more trouble to construct in bodies of a certain figure, as that of quadrupeds, with certain organs for the perfection of sense, than to produce a living creature, and organize it in a manner that appears so difficult to us to conceive? No, it cannot be imagined; to account for this phænomenon we must have recourse to the first order of things, and suppose the production of the larger Animals equal to that of insects. We see, at first sight, that this monstrous species would soon have swallowed up all others, nay, would have devoured even itself, would alone have overspread the face of the whole earth, and that nothing would have been left on the continent but elephants, birds, and insects; in the ocean nothing but whales, and fishes which by the smallness of their size could escape being devoured by the former. An order of things not to be compared with that which exists at present. Thus we see, that the works of providence are regulated by the highest wisdom.

Let

Let us now with M. de Buffon proceed to the compariſon of Animals with vegetables, in point of ſituation, magnitude, and form; the earth is the only place where vegetables can ſubſiſt; the greateſt number riſe above the ſurface of the ground, and are held by roots which penetrate into the earth. Some, as truffels, grow intirely under the ſurface, ſome ſmall number grow under water; but all, to preſerve their exiſtence, muſt be placed in a ſtratum of earth. Animals, on the other hand, are more univerſally diffuſed: ſome inhabit the ſurface, others the bowels of the earth; ſome live at the bottom of the ſea, others in its waters; they are found in the air, the internal parts of plants, in the bodies of men and other Animals, in liquors, nay, even in ſtones.

By the help of the microſcope prodigious diſcoveries have been made of Animals of different ſpecies. But it may ſeem ſomething ſingular, that not above one or two ſpecies of plants have been diſcovered by the application of this inſtrument. The little moſs, produced by mouldineſs, is the only microſcopical plant we have heard of. From this we might be induced to think that nature, which is ſo fruitful in producing animalcula, is very ſparing of her productions in plantulæ or little plants; but we may be led into an error by adopting ſuch an opinion too haſtily, and the error might perhaps take its riſe, from the greater ſimilarity there is between plants than Animals, which renders it more difficult to diſtinguiſh their ſpecies; ſo that this mould which we take for an infinitely ſmall moſs, might be a garden or wood, filled with a vaſt number of plants really very different from each other, and yet that difference imperceptible to our eye.

It is true, if we compare the magnitude of Animals with reſpect to each other and plants in the ſame light, there will appear a great diſparity; for there is a much greater diſproportion between the whale and one of theſe pretended microſcopical Animals, than there is between the talleſt oak and the infinitely minute moſs we have mentioned: and, tho' magnitude be only a relative attribute, yet it is proper to conſider the extreme bounds which nature ſeems to have preſcribed to herſelf. The larger ſpecies in Animals and plants have ſome parity, a vaſt oak and a great whale have ſome correſponding proportion in magnitude; but in the leſſer ſpecies there is no analogy, if it be true that a thouſand microſcopical Animals united are not equal to the microſcopical plant in magnitude.

Farther, the moſt ſenſible and general difference between Animals and vegetables is their formation. That of Animals, though it admits of infinite variety, has no ſimilarity with that of plants, and though the polypus which is propagated in the manner of a plant, may be looked upon as making the continual gradation between the Animal and vegetable, yet we may ſay the figure of any Animal whatever is of ſo different an exterior formation from that of a plant, as to leave no difficulty in diſtinguiſhing one from the other. Animals may indeed perform operations which reſemble plants or flowers; but plants will never produce any thing ſimilar to an Animal. If an ill-grounded prejudice had not ranked the coral among the vegetables, thoſe wonderful inſects that work and produce it had never been miſtaken for flowers. Thus it appears, the errors we are liable to fall into by comparing the formation of Animals with that of vegetables, can only be in a ſmall number of ſubjects which make the gradation between both; and a nicer obſervation will convince us that the Creator has fixed no certain bounds between the Animal and vegetable; that theſe two kinds of organized beings have many common properties, no real difference; that the production of an Animal coſt nature no more trouble than the production of a plant, perhaps leſs; that the production of organized beings in general is nothing extraordinary, and that, in ſhort, the living and animated being, inſtead of being ranked in a degree of præternatural entities, is only actuated by the phyſical property of matter.

After having ſettled one very difficult and important point by the help of M. de Buffon's profound knowledge in metaphyſics, let us proceed to the ſecond, which we owe to M. de Aubenton, his illuſtrious partner, in their natural hiſtory.

Animals, ſays M. d'Aubenton, have the firſt place in the general diviſion of natural hiſtory. All the objects comprehended in this ſcience are diſtributed into three claſſes which they call kingdoms; the firſt is the Animal kingdom: we have put this firſt, becauſe Animals have a nearer connection with us than vegetables, which make the ſecond kingdom, and minerals, having ſtill a more diſtant one, make the third kingdom. In ſome works of natural hiſtory, however, the order is inverted, the mineral kingdom placed firſt, and the animal laſt. Theſe authors were of opinion we ought to begin with contemplating the moſt ſimple objects, ſuch as are minerals, and from thence paſſing through the vegetable world, ſhould gradually proceed to the conſideration of the moſt compounded objects, which are Animals.

The ancients divided Animals into two claſſes; the firſt contains ſuch as have blood, the ſecond thoſe which have none; this diſtinction was made in Ariſtotle's time, and perhaps long before that great philoſopher; and this diſtinction has been generally admitted till of late. Several objections have been raiſed againſt this diſtinction, that all Animals have blood, becauſe all Animals have a fluid, the circulation of which all over the body is neceſſary for a continuance of life, that the eſſence of blood does not conſiſt in its being of a red colour, &c. but theſe objections prove nothing againſt the propriety of the diſtinction we are ſpeaking of: for whether we ſuppoſe all Animals to have a blood or a part only, whether the name of blood may properly be aſſigned to the fluid which circulates in the bodies of ſome, is no part of the queſtion; it is ſufficient to make a diſtinct claſs of Animals, that in theſe the circulating fluid is red, in thoſe not ſo. But there is one objection to this method of claſſing Animals, which admits of no reply. Among the Animals ſaid to have no blood, or, at leaſt, no red blood, ſome are found to have blood, and very red blood too; theſe are earth-worms. This is a fact which ſhews a defect in this method of diſtinction, and yet, perhaps, upon the whole it is the better, and leſs liable to objection than many others.

For a general account of Animals, we ſhall here ſubjoin Mr. Ray's ſcheme.

Animals are either

- Sanguineous, that is, ſuch as have blood, which breathe either by
  - Lungs, having either
    - Two ventricles in their heart, and thoſe either
      - Viviparous.
        - Aquatic, as the whale-kind.
        - Terreſtrial, as quadrupeds.
      - Oviparous, as birds.
    - But one ventricle in the heart, as frogs, tortoiſes, and ſerpents.
  - Gills, as all ſanguineous fiſhes, except the whale-kind.
- Exſanguineous, or without blood, which may be divided into
  - Greater, and thoſe either
    - Naked,
      - Terreſtrial, as naked ſnails,
      - Aquatic, as the poulp, cuttle-fiſh, &c.
    - Covered with a tegument, either
      - Cruſtaceous, as lobſters and crab-fiſh.
      - Teſtaceous, either
        - Univalve, as limpets,
        - Bivalve, as oyſters, muſcles, cockles.
        - Turbinate, as periwinkles, ſnails, &c.
  - Leſſer, as inſects of all ſorts.

Viviparous hairy Animals or quadrupeds, are either

- Hoofed, which are either
  - Whole-footed or hoofed, as the horſe and aſs.
  - Cloven-footed, having the hoof divided into
    - Two principal parts, called biſulca, either
      - Such as chew not the cud, as ſwine.
      - Ruminant, or ſuch as chew the cud, divided into
        - Such as have perpetual and hollow horns.
          - Beef-kind.
          - Sheep-kind.
          - Goat-kind.
        - Such as have ſolid, branched, and deciduous horns, as the deer-kind.
    - Four parts, or quadriſulca, as the rhinoceros and hippopotamus.
- Clawed or digitate, having the foot divided into
  - Two parts, or toes, having two nails, as the camel-kind.
  - Many toes or claws; either
    - Undivided, as the elephant.
    - Divided, which have either
      - Broad nails, and an human ſhape, as apes.
      - Narrower, and more pointed nails, which, in reſpect of their teeth, are divided into ſuch as have
        - Many fore-teeth, or cutters in each jaw;
          - The greater, which have
            - A ſhorter ſnout and rounder head, as the cat-kind.
            - A longer ſnout and head, as the dog-kind.
          - The leſſer, the vermin or weazel-kind.
        - Only two large and remarkable fore-teeth, all which are phytivorous, and are called the hare-kind.

Animals make the principal part of heraldry, both as bearings, and as ſupporters, &c.

It is an eſtabliſhed rule among heralds, that, in blazoning, Animals are always to be interpreted in the beſt ſenſe, that is, according to their moſt noble and generous qualities, and ſo as may redound moſt to the honour of the bearers.

Thus the fox being reputed witty, and withal given to filching for his prey; if this be the charge of an eſcutcheon, we are to ſuppoſe the quality repreſented to be his wit and cunning, not his theft.

Guillim adds, that all ſavage beaſts are figured in their fierceſt action, as a lion erected, his mouth wide open, his claws extended, and in this poſture he is to be rampant.—— A leopard, or wolf, is to be portrayed going, as it were, pedententim; which form of action, ſays Chaſſanæus, fits their natural diſpoſition, and is termed paſſant.

The gentleſt kind are to be ſet forth in their nobleſt and moſt advantageous actions; as a horſe running or vaulting, a greyhound courſing, a deer tripping, a lamb going with a ſmooth and eaſy pace.

Every Animal is to be moving, or looking to the right side of the shield; and it is a general rule that the right foot be placed foremost, because the right side is reckoned the beginning of motion: add, that the upper part is nobler than the lower; so that things, constrained either to look up or down, ought rather to be designed looking upwards.

However, notwithstanding these precepts of Guillim, &c. the other masters of armory, we find by experience, that there are lions passant, couchant, and dormant, as well as rampant, and that most Animals look down and not up. *Guillim's Heraldry.*

Wheel-ANIMAL, a name given by the writers on microscopical discoveries to a species of minute animalcule, which appears in a sort of sheath or case, the end of which it fastens to the roots of water-plants, or whatever else is in its way, *See plate* III. *fig.* 15, 16, 17.

This little creature has two seeming wheels, with a great many teeth or notches coming from its head, and turning round, as it were, upon an axis. This little creature, on the least touch, draws in its wheel into its body, and its body into the sheath; but, as soon as all is quiet, it throws them out, and works them again.

In order to find these animalcules, chuse such roots of duckweed as are long, and proceed from strong old plants, for the young roots seldom afford any; they should not be covered with that rough matter which is frequently found about them, nor any way tending to decay, as they will often be.

In the water found remaining in the leaden pipes, or gutters, on the tops of houses, there are also found great numbers of Wheel-Animals. These are of a different species from the former; and, when the water dries away, they contract their bodies into a globular or oval figure, and are then of a reddish colour, and remain mixed with the dirt, growing together into a lump as hard as clay. This, whenever it is put into water, in half an hour's time, discovers the Animals living again, and as brisk as ever; and they have been found to be living in this manner, after the matter had been kept dry for twenty months.

It should seem from this, that, as the water dries up, their pores become shut in the manner of such Animals as remain torpid for the winter, and that, when they find water come on again from rain, they then unfold themselves, and live and feed as long as it lasts. *Baker on the Microscope.*

A'NKER, a liquid measure, chiefly used at Amsterdam. The Anker is the fourth part of the aem, and contains two stekans; each stekan consists of sixteen mingles, the mingle being equal to the Paris pint.

ANIMA'LCULA (*Dict.*)— Under this term in a philosophical sense are comprehended those animals which are not visible without the help of a microscope; since the invention of this instrument many little animals have been perceived, which had before escaped our notice: we have seen bodies moving in several different liquors, chiefly in the semen of animals, and infusions of the grains of plants. Hartsoeker and Lewenhoeck were the first authors of these discoveries, and have told us these moving bodies were really living creatures; and several others, who have pursued the same study, have found new moving bodies. All have agreed in this opinion, that these bodies were animals; from whence have arose different hypotheses concerning generation, the spermatic Animalcula of the male, and the ova of the female, &c. At last, M. de Buffon has destroyed this false opinion; he has demonstrated by undeniable experiments, in the second volume of his Natural History, that the moving bodies, discovered by the microscope, are not really animals, but moleculæ or little masses of a certain organization, alive, and proper to compose a new body of the same organization with that from whence they were extracted. M. de Buffon has found these moving bodies in the semen of females as well as males: he shews that the moving bodies which he has observed with the microscope in infusions of the seeds of plants, as well as in the semen of animals, are also organized moleculæ of vegetables. M. de Buffon had communicated to Mr. Needham of the Royal Society at London, the observations he had made on the semen of animals, and infusions of the seeds of plants, with his discoveries before the publication of the first volume of his Natural History. I myself, says M. d'Aubenton, with Mr. Needham, was present at the first experiments made in the Royal Gardens, with a microscope Mr. Needham had brought from London with him. It was after having seen the first experiments on infusions of the seed of plants, that Mr Needham entertained a design of pursuing these experiments on vegetables; he communicated this intention to M. de Buffon in my presence, as to the author of a discovery, whose hints he designed to follow. Mr. Needham, in consequence of this resolution, made a number of experiments, and published a work under the title of New Microscopical Observations 1750, and the author has promised to give the public a particular account of all the observations he has made on this head; Mr. Needham has communicated some to me from which I have received great satisfaction.

A number of these Animalcula have been discovered on various substances, as, for example, on a grain of sand pressed through a sieve a little Animal has been found, with a great number of feet, and a back covered with shells; in the liquor of a pustule caused by the itch Animalcula have been found resembling tortoises. See ITCH in the Dictionary.

You may see, in common water some time exposed to the air, a number of little moving bodies of different magnitudes and figures, the generality of which are round or oval. Lewenhoeck says that a thousand millions of those bodies which float in common water, are not so big as an ordinary grain of sand. *Diderot's Encyclop.*

A'NIME (*Dict.*)—The Anime of the shops is of the number of those dry resins which are very improperly called gums, what is called gum Anime being a friable substance, inflammable, and soluble in oil, which are characters of a genuine resin, and such as no gum can possess. We are to observe also, that there is another very frequent error with regard to this drug, which is, that many call it copal, and confound it with another resin, improperly called also a gum, and known by that name. Copal is, indeed, a term used by the Indians in a very large sense, and sometimes, as a generical name for all the scented resins; but with us it is never used so, nor has any good author used it, as a term synonymous with Anime: it is the name of a distinct resin to be treated of in its place.

The Spaniards, according to Hernandez, used the term copal to distinguish all the white, or whitish sweet-scented resins; and the term Anime, which they also made generical, to express all the brown ones: after this, the name Anime became attributed to a peculiar resin, of a sweet scent, and of a brownish yellow colour, brought from the east, or rather from Ethiopia, on the confines of Arabia; and finally, after this, the Portuguese gave it also to certain sweet resins which they found in the Brasils, and esteemed somewhat of the same nature with the Ethiopian Anime.

On this distinction has been founded the name of oriental and that of occidental Anime, long known in the shops, and distinguishing two different resins at this time found there, though neither very frequently.

The oriental or Ethiopian Anime, called by the Portuguese animum and aniimum, and in the shops gum Anime, is a dry and solid resin, brought to us in large cakes or masses, of an irregular figure, and of a very uncertain colour; some of them are greenish, some reddish, some brown, and some of the colour of myrrh; they all agree in this, however, that they are moderately pellucid, of a tolerably compact texture, light and easily powdered, of a fragrant smell, very inflammable, and of a resinous and somewhat bitter taste. This which is the genuine and true Anime is now very rare in the shops. It is brought, as Garcias informs us, only from Ethiopia, but the occidental kind, or resin of the courbaril, is what is universally received in its place. It has been supposed by many, that this Ethiopian or true Anime was known to the ancient Greeks. Some have supposed that Dioscorides meant this resin by the name of myrrha minia, and many arguments have been advanced in favour of the opinion; but the resins themselves are so like one another, and the descriptions the Greeks have left us of them is so short and imperfect, that it is impossible to affirm any thing on this head with any tolerable degree of certainty. We are not yet informed what the tree is that produces the Ethiopian Anime. Herman is of opinion, that it is the same that yields the occidental kind, only growing in a different climate; but this is no more than a conjecture.

The occidental Anime is a whitish, dry, and solid resin, somewhat resembling frankincense in colour. It is often of a fine yellowish white, between that of frankincense and mastich, and in the purest pieces is very clean and transparent; in general, however, it is much inferior to the oriental in these respects. It is moderately heavy, friable, and somewhat oleaginous to the touch. It is extremely fragrant, especially when burnt, and is of a resinous, acrid, and somewhat bitterish taste. It is brought to us from many parts of America, particularly from new Spain and the Brasils. The natives call it jotieacica and jetaicica. Our people from their name of the tree vulgarly call it resin of courbaril.

Whatever might be the case in regard to the Ethiopian Anime, we may be very well assured, that this was not known to the Greeks. The tree which produces it is one of the arbores siliquosæ of Mr. Ray. It is described by Caspar Bauhine under the name of arbor siliquosa ex Virginia lobo fusco scabro, and by Plumier, under that of courbaril bifolia flore pyramidato. It grows to a very great height; its wood is solid, and of a fine grain, of a reddish colour, and very durable, and serves them for many of their better works. The leaves are like those of our bay-tree, but thicker, and they grow constantly two together on every stalk; they are of a shining green, and, if held up to the light, seem to be perforated with innumerable little holes in the manner of the leaves of St. John's-wort. The flowers stand in clusters or tufts towards the tops of the branches; they are of the papilionaceous kind, like those of our vetches, and of a purplish colour: these are succeeded by a kind of pods six inches long, and an inch and a half broad, compressed sideways, and raised into two ridges on the back.

This

This fruit, when ripe, does not open lengthwise into two valves, as the generality of pods of this shape do; it remains intire, and contains in it, among a multitude of irregular fibres, four or five seeds larger than the common pine-kernels, otherwise like them. This tree is common in most parts of America, and the fruit ripens in May and June, when it falls from the trees, and is picked up by the natives, who are fond of the farinaceous substance that is among the fibres within it. The trunk of the tree exsudates the resin here described in very considerable quantities without being wounded for it; the finest lumps of it are white or of a pale yellow, and much resemble amber.

The American Anime, analysed by distillation in a retort, yields first a small quantity of a limpid phlegm of a subacid taste, and of a smell not disagreeable, but much resembling that of oil of Juniper; after this a small quantity also of a reddish liquor more acid than the former, and then of a brown liquor of an empyreumatic smell; after these there comes over a moderate portion of a fine yellow pellucid oil, and then a thick and brown one like butter, in so large a quantity as nearly that of two thirds of the weight of the whole. The remainder in the retort is but in a very small quantity, and, after lixiviation, yields, with the utmost care, only about four grains of a fixed salt, and that of the sal salsus, not the alkaline kind, from the pound.

The natives of America use this resin in fumigations for the head-ach, and for diseases of the breast and lungs. They are also externally dissolved in oil as a liniment, and in spirit of wine as an embrocation for pains in the limbs.

ANIME, in heraldry, is where the eyes, &c. of a rapacious creature, are borne of a different colour from the rest of the creature.

ANNA'LIS *Actio*, in the civil law, signifies an action which may be put in practice any time within the year.

ANNALIS *Clavus*, in antiquity, the nail which the prætor, consul, or dictator, fixed every year in the wall of Jupiter's temple, upon the ides of September, to shew the number of years. But this custom was afterwards changed, and the years were reckoned by the consuls.

ANNA'TES, a tax levied on Christian clergy, and paid to the Pope: it was a year's revenue, or tax upon the revenue of the first year of a vacant benefice, ever since the twelfth century. Some bishops or abbots had, either by customs, or particular privileges, received Annates, or first fruits of the benefices belonging to their patronage or jurisdiction. Thus, in the year 1726, Peter, bishop of Beauvois, gave the canons of the church of St. Quintin the Annates of all the prebends of this cathedral. The court of Rome, which was always incroaching upon the liberties of the church, soon found means to get the Annates into its hands. John XXIII. secured the Annates of all vacant benefices (bishoprics and abbies excepted) for three years. His successors improved the advantage, and took in the bishops and abbots; but the payment of this tax was always grudged, and was warmly contested in the council of Constance, an. 1414. The council of Basil, in 1431, forbad the payment of Annates; and the council of Bourges, in 1438, approved the decree of the synod of Basil; to which we may add its being forbidden by several edicts of the French king's. Matthew Paris, in his History of England, for the year 746, relates that the archbishop of Canterbury, by virtue of a grant or concession of the Pope, received Annates of all the benefices that became vacant in England. Clement V, predecessor of John XXII, was the first, according to Matthew of Westminster, who exacted Annates of all the vacant benefices in the kingdom, for the space of two years; or, according to Walsingham, for three. John XXII. introduced the like in France; yet Polydore Virgil, and some others, take the Annates to be of much older standing, and to have prevailed long before they were paid to the Pope. It is certain, at least, that, from the 12th century, there were bishops and abbots, who, by some peculiar custom or privilege, took Annates of the benefices depending on their diocese or abbey. This burden was laid at first only on such benefices as the Pope himself collated to; and this he did, says Polydore Virgil, before he had such large possessions. Boniface VIII, in the time of Edward I, first started the doctrine of the Pope's universal and absolute dominion in beneficiary matters; but he was vehemently opposed at the reformation. They were taken from the Pope, and vested in the king, or on the crown of England, where they continue to this day, except what alterations have been made since, in relation to small livings.

ANNO'TA. See ANATTA.

ANNU'ITIES. Under this article in the Dictionary, we have shewn the method of finding the value of Annuities; and, under the article *Compound* INTEREST, we have given a short table for computing the value of Annuities on lives; we shall here give a fuller account of that doctrine, according to the observations made by Dr. Halley on the Breslaw bills of mortality.

Breslaw is the capital city of the province of Silesia. It is situated on the eastern bank of the river Oder, near the confines of Germany and Poland, and very nigh the latitude of London. It is very far from the sea, and as much a mediterranean place as can be desired; whence the confluence of strangers is but small, and the manufacture of linen employs chiefly the poor people of the place, as well as of the country round about; whence comes that sort of linen we usually call Silesia linen, which is the chief, if not the only, merchandize of the place. For these reasons the degrees of mortality in the city seem most proper for a standard, and the rather, for that the births do a small matter exceed the funerals: the only thing wanting is the number of the whole people, which in some measure I have endeavoured to supply, says the doctor, by comparison of the mortality of the people of all ages; which is traced out from the curious tables of the births and funerals drawn up monthly by Dr. Newman of that city.

Dr. Halley's Table of observations, exhibiting the probabilities of life.

49	357	56	282	63	212	70	142	77	68	84	20		

M. de Moivre has largely explained the use of the foregoing table, in the following manner:

Suppose that by this table we would know what the probabilities are for a man of 30 to live 1, 2, 3, 4, 5, &c. years. Look for the number 30 in one of the columns of age, and under it you will find 31, 32, 33, &c. and opposite the number 30, in the next adjoining column on the right hand, you find 531, under which are written 523, 515, 507, &c. corresponding in order to the numbers in the column of ages; the meaning whereof, is that, out of 531 persons living of 30 years old, there remain but 523, 515, 507, 499, &c. that attain the respective ages of 31, 32, 33, &c. and who, consequently, from that term of 30, do live 1, 2, 3, 4, &c. years respectively.

In order to compute the value of an Annuity upon a life of a given age, let the quantities A, B, C, D, E, F, &c. represent respectively the person living at the age given, and the subsequent years.

Now it is obvious, that there being A, persons of the age given, and one year after B, persons remaining, the probability which the person of the given age has to continue in life, for one year at least, is represented by the fraction $\frac{B}{A}$, and that the probability which it has to continue in life, for two years at least, is represented by the fraction $\frac{C}{A}$, &c. and that therefore, if money bore no interest, it would be only necessary to multiply those probabilities by the sum to be received

received annually, which is ſuppoſed here to be = 1, and the ſum of the product would expreſs the preſent value of the Annuity. But, as money bears intereſt, let r repreſent the amount of 1 l. with its intereſt at the year's end, and then the preſent values of the ſums to be received would be reſpectively $\frac{1}{r}$, $\frac{1}{rr}$, $\frac{1}{r^3}$, $\frac{1}{r^4}$, &c. and therefore, multiplying theſe ſums by the probabilities of obtaining them, we ſhall have the value of the Annuity expreſſed by the ſeries $\frac{A}{r} + \frac{B}{rr} + \frac{C}{r^3}$ $\frac{D}{r^4} + \frac{E}{r^5} + \frac{F}{r^6} + \frac{G}{r^7} + \frac{H}{r^8}$, &c. which muſt be continued to the end of the tables.

But let us ſuppoſe, that, inſtead of an Annuity upon a life whoſe age is given, there ſhould be the expectation of a ſum, which we will call (1) payable once for all, whenever it happens, that the life ceaſes within a limited time. It is plain that the probability of the life's ceaſing after one year is $\frac{A-B}{A}$, and that the probability of its continuing one year, and dropping the next, will be $\frac{B}{A} \times \frac{B-C}{B}$, or barely $\frac{B-C}{A}$, and that, again, the probability of its continuing two years, and dropping the third, will be $\frac{C-D}{A}$, and ſo on; and that therefore the value of the expectation founded on the contingency of the life's falling within a limited time would be $\frac{A-B}{Ar} + \frac{B-C}{Arr} + \frac{C-D}{Ar^3} + \frac{D-E}{Ar^4} + \frac{E-F}{Ar^5} + \frac{F-G}{Ar^6}$, &c.

Let it now be ſuppoſed, for inſtance, that the party on whoſe life this expectation depends is 10 years of age, and that the age limited, as a condition of obtaining the ſum (1) is 21; hence it is plain, that, the difference between 21 and 10 being 11, we ought to limit ourſelves to 11 terms of the foregoing ſeries, and then, conſulting Dr. Halley's table, we ſhall find the numbers A, B, C, D, E, &c. to be reſpectively 661, 653, 646, 640, 634, 628, &c. and that, therefore A — B, B — C, C — D, D — E, E — F, &c. will reſpectively be 8, 7, 6, 6, 6, &c. and that, conſequently the preſent value of the expectation will be $\frac{8}{661r} + \frac{7}{661rr} + \frac{6}{661r^3} + \frac{6}{661r^4} + \frac{6}{661r^5} + \frac{6}{661r^6} + \frac{6}{661r^7} + \frac{6}{661r^8} + \frac{6}{661r^9} + \frac{6}{661r^{10}} + \frac{6}{661r^{11}}$.

Let it be further ſuppoſed, that this expectation is not given, but ſold to a purchaſer who intends to make 5 per cent of his money, then r ſtands for 1,05, and therefore the ſum, which purchaſers ought in juſtice to pay for their expectations, is the ſum of the numbers here annexed, which is about $\frac{2}{25}$; and therefore if the ſum, called (1) before, ſtands for an eſtate whoſe preſent real value is 20 years purchaſe, the adventurer ought to pay no more for the conſideration of his chance than 1 $\frac{3}{5}$ years purchaſe.

It is not intended here to calculate other intervening chances which might defeat this expectation, ſuch as that of an heir-male, which might live to the age of twenty-one; for, there being not any tables * of obſervations concerning a man's marrying and getting an heir-male between ſixteen and twenty-one, what could be added on that ſubject, would be barely conjectural, which would not be of a-piece with what has been ſaid; however, it is eaſy to conceive, that this muſt conſiderably diminiſh the value of the expectation.

* If any tables of that kind ſhould be calculated, there cannot, perhaps, be a better foundation to proceed on than that of Dr. Arbuthnot, concerning the regularity in the births of both ſexes, publiſhed in the *Philoſophical Tranſactions*, No. 328.

Problem II.

Suppoſing the probabilities of life to decreaſe in arithmetic progreſſion, when conſidered from a term given, to find the value of an Annuity on a life of a given age.

Solution.

Let P repreſent the value of an Annuity certain of 1 l. for as many years as are intercepted between the age given, and the extremity of old age, ſuppoſed at 86, and let that interval of life be called n, then the value of an Annuity upon ſuch a life would be expreſſed by $\frac{1 - \frac{r}{n}P}{r-1}$, ſuppoſing, as before, that r ſtands for the amount of the principal and intereſt of 1 l. in one year.

Thus, ſuppoſing an age of 50, and that intereſt of money be eſtimated at 4 per cent. then n will repreſent 36, and r for 1.04, for which reaſons looking into the tables of 4 per cent. which ſhew the worth of an Annuity certain for 36 years, being 17.9083, this being multiplied by r, that is, by 1,04, the product will be 18.624632; and this being divided by n, that is, by 36, the quotient will be .0.517351. Then this being ſubtracted from unity, and the remainder 0.482649 being divided by $r-1$, that is, by 0.04, the quotient will be found 12.0661, which is very little more than 12 years purchaſe for the value of an Annuity on a life of 50.

But, for the ſake of thoſe who are not ſo well verſed in decimal fractions, it may be proper to expreſs the rule as follows: multiply the Annuity certain as found in the tables by the amount of 100 l. joined with its intereſt for one year, that is, in this caſe, by 104, and let the product be divided by 100; then let the quotient be ſubtracted from 25, which ſhews how many years purchaſe a perpetuity of 100 l. is worth, and the remainder will ſhew how many years purchaſe the Annuity upon the age given is worth in ready money.

Problem III.

Suppoſing a fictitious life, whoſe number of chances to continue yearly are conſtantly equal to a, and the number of chances to fail conſtantly equal to b, ſo that the odds of its continuing, during the ſpace of any one year, be to its failing in that ſame interval of time conſtantly as a to b, to find the value of an Annuity upon ſuch a life.

Solution.

Let 1 be the Annuity, r the amount of 1 l. joined to its intereſt in one year, make $a + b = s$.

It is plain from what has been ſaid already, that the preſent value of the 1ſt year's rent is $\frac{a}{sr}$, of the 2d $\frac{aa}{ssrr}$, of the 3d $\frac{a^3}{s^3r^3}$, &c. which terms conſtituting a geometrical progreſſion, the ſum of them all will be $\frac{a}{rs-a}$; thus, if a repreſented 21, and b 1, then s would repreſent 22; ſuppoſing alſo that $r = 1.05$, then the denominator $rs-a$ would be 23.1—21 or 2.1, and, dividing the numerator 21 by the denominator 2.1, the quotient will be 10, which ſhews that the life would be worth 10 years purchaſe.

Corollary I.

An Annuity upon a fictitious life being given, the probability of its continuing one year is alſo given; for let the value of it be — M, then $\frac{a}{rs-a} = M$, therefore $\frac{a}{s} = \frac{Mr}{M+1}$.

Corollary II.

If a life whoſe value, as reduced from the tables of obſervation, or from the preceding problem, be worth 10 years purchaſe, then ſuch a life is equivalent to a fictitious life, whoſe chances for continuing one year are to the chances of its failing in that year as 21 to 1.

Corollary III.

Wherefore, having calculated a life from the tables of obſervations, or from the ſecond problem, we may transfer the value of that life to that of a fictitious life, and find the number of chances it would have to continue or to fail yearly.

Corollary IV.

And the combination of two or more real lives will be very near the ſame as the combination of ſo many correſponding fictitious lives; and, therefore, an Annuity granted upon ſo many correſponding fictitious lives, and the values of the reverſions granted upon the real lives, will be very near the ſame, as thoſe granted upon the fictitious lives.

Problem IV.

The values of two ſingle fictitious lives being given, to find the value of an Annuity granted for the time of their joint continuance.

Solution.

Let the values be reſpectively M and P, r the rate of intereſt; then the value of an Annuity upon the two joint lives will be expreſſed by $\frac{MPr}{\overline{M+1} \times \overline{P+1} - MPr}$.

Demonſtration.

Let x and y repreſent the reſpective probabilities of the lives continuing one year together, then xy will expreſs the probability of their joint continuance for that year; and x^2y^2 the probability of their joint continuance for two years; and x^3y^3 the probability of their joint continuance for three years, &c. wherefore the value of an Annuity, for all the time, will be expreſſible by the following geometric progreſſion, viz. $\frac{xy}{r} + \frac{x^2y^2}{rr} + \frac{x^3y^3}{r^3} + \frac{x^4y^4}{r^4}$, &c. where the ſum is $\frac{xy}{r-xy}$; but, by the firſt corollary of problem the third, $x = \frac{Mr}{M+1}$, and, for the ſame reaſon, $y = \frac{Pr}{P+1}$, and, therefore, the value of the two joint lives, is $\frac{MPr}{\overline{M+1} \times \overline{P+1} - MPr}$.

Problem V.

The values of two ſingle lives being given, to find the value of an Annuity upon the longeſt of them; that is, to continue ſo long as either of them is in being.

Solution.

Solution.

From the sum of the values of the single lives, subtract the value of the two joint lives found by the foregoing problem, and the remainder will be the value of the Annuity required.

Demonstration.

It will be sufficient to shew what will be the value of the first year, since the values of all the subsequent years are found in the same manner.

Let, therefore, x and y be the respective probabilities of the lives continuing one year together, then $1-x$ and $1-y$ are the respective probabilities of their dropping in that year, and, consequently, the product of $1-x$ by $1-y$, viz. $1-x-y+xy$ is the probability of their both dropping in that year; and, this being subtracted from unity, the remainder $x+y-xy$ will express the probability that either one or the other, or both, out-live the year; which is sufficient for the purchaser of the Annuity to establish his right of receiving the first year's rent, whose present value is, therefore, $\frac{x}{y}+\frac{y}{r}-\frac{xy}{r}$.

And, therefore, one may see at sight, that, the expectation of the other years being founded on the same principle, the value of an Annuity upon the longest of two lives will be the sum of the values of the single lives, wanting the value of the joint lives.

Problem VI.

The value of the three single lives being given, to find the value of an Annuity upon their joint lives.

Solution.

Let x, y, z, respectively, represent the probabilities of the lives continuing one year, then the probabilities of their continuing all three together for one year will be xyz, and the probability of their continuing together for two years is $xxyyzz$, &c. and, therefore, the value of an Annuity upon the three joint lives will be $\frac{xyz}{r}+\frac{x^2y^2z^2}{r^2}+\frac{x^3y^3z^3}{r^3}+\frac{x^4y^4z^4}{r^4}$, &c. which constitutes a geometric progression, whose sum is $\frac{xyz}{r-xyz}$: now in the room of x, y, z, writing their respective values $\frac{M+1}{r}$, $\frac{P+1}{r}$, $\frac{Q+1}{r}$, the sum of the 3 joint lives will be expressed by $\frac{MrPQrr}{\overline{M+1}\times\overline{P+1}\times\overline{Q+1}-MPQrr}$, supposing, as we have done in the preceding problem, that M, P, Q, represent respectively the values of Annuities upon each single life.

Problem VII.

The value of three single lives being given, to find the value of an Annuity upon the longest of them.

Let x, y, z, represent the respective probabilities of the life's continuing one year; then the product of $1-x$ by $1-y$, and of that again by $1-z$, that is, $1-x+xy-y+xz-z+yz-xyz$, will express the probability of their all failing the first year; and, this being subtracted from unity, the remainder will express the probability that either they will all subsist one year, or, at least, that they will not all fail in the year: which being the foundation of receiving the first year's rent, and the other years following the same law, we may draw this conclusion, that, if from the sum of the values of the single lives we subtract the sum of the values of the joint lives taken two and two, and to the remainder add the value of the three joint lives, we shall have the value of the Annuity upon the longest of the three joint lives.

Problem VIII.

To find the value of one life after another.

By the value of one life after another, is meant what a man must pay in present money to purchase the expectation of an Annuity for his life, after the failing of another, with this restriction, that, if the expectant dies before the present possessor, no consideration is to be given to the heirs of the said expectant.

Solution.

Since the expectation of the purchaser is grounded on the failing of the life in possession, and of the continuation of his own life, it follows, that, if we suppose x and y to be the respective probabilities of the lives continuing one year, then $\overline{1-x}\times y$ or $y-xy$ will express the probability of the first life's dropping in the year, and of the second's out-living the year; from whence we may draw this consequence, that, if from the present value of the expectant's life be subtracted the value of the two joint lives, there will remain the value of the expectation.

This may be made plain another way; for, suppose I were the purchaser, I might begin to pay the proprietor of the Annuity the full value of my life, but then I would expect back the value of the two joint lives of the present possessor and myself, since I am to receive nothing, whilst we are both living. To this may be added, that, supposing that the proprietor is to be paid for the longest of the two lives of the present possessor and myself, my share of the purchase ought to be only that part of it which would remain if the life of the present possessor was deducted out of it, which will give the same conclusion as before.

But, if the expectant were to have the reversion absolute for himself and his heirs after the decease of the present possessor, it is plain, that there being nothing interposed between his present circumstances and the possession of the estate, but the life of the present possessor, then, from the value of the perpetuity, ought barely to be subtracted the life of the possessor, and the remainder will be the value of the expectation.

Problem IX.

To find the value of one life after two.

Solution.

From the value of the longest of the three lives, subtract the value of the longest of the two first lives, and there will remain the value of the expectation of the third life.

But, if the expectation be above the absolute reversion, then from the perpetuity subtract the value of the longest of the two first lives, and there will remain the value of the third.

And the same rule may be extended to as many lives as may be assigned. Though these questions may, at first sight, seem to have a great degree of difficulty, yet there is reason to believe that the steps taken, to come at their solution, will easily be followed by those who have a competent skill in algebra, and that the chief method of proceeding therein will be understood by those who are barely acquainted with the elements of that art.

For those, however, who may not be acquainted with this method of reasoning, I shall subjoin what may be more generally intelligible, and, therefore, more generally acceptable. The common method of purchasing Annuities is at a certain number of years purchase; for which reason, the following tables may be useful to shew how long the annuitant must live, to be reimbursed his principal money, with interest, at any given rate.

The table is very plain, as appears by this example: Suppose 11 years purchase is given for an Annuity.

	years	days			
Then, if the Annuitant lives	12	200	he will be reimbursed his principal, with interest, at the rate of	2	per cent per ann.
	13	9		2½	
	13	200		3	
	14	48		3½	
	14	286		4	
	15	190		4½	
	16	134		5	
	18	188		6	
	21	264		7	
	27	201		8	
	53	160		9	

The fractions of the year are made in days, for the greater exactness, though it is common for Annuities to be paid either half-yearly or quarterly.

A table to calculate the value of Annuities upon lives, at 4 l. and 5 l. per cent. Continuance of the lives to reimburse the annuitants their purchase money.

years purchase given for a life.	At 4 per cent.		At 5 per cent.	
	years.	days.	years.	days.
1	1	15	1	19
2	2	46	2	58
3	3	95	3	121

16	26	18	32	360
17	29	19	38	322
18	32	167	47	71

The ingenious Mr. Dodson has defended the above hypothesis of Dr. Halley, in the Philosophical Transactions, Vol. 47. Pag. 333. And also laid down a method for improving the bills of mortality.

ANNUNCIATION, *(Dict.)*— We celebrate the memory of this mystery on the 25th of March; and St. Augustin says, that the church, upon the authority of some old tradition, believed that the Saviour of the world was conceived upon this day. Not only the Greek and Latin churches have chosen the 25th of March, to celebrate this mystery; but likewise the Syrians, Chaldeans and Coptics, do the same. This opinion seems to be founded principally, upon the supposition of Christ's being born upon the 25th of December: as a consequence of this opinion, it was believed that he was conceived upon the 25th of March, because, generally, there are nine months between the birth and conception of children. In the place where the virgin was saluted by the angel, there was a church built. It is certain, this festival was observed before the time of the council of Trullo, in which there is a canon forbidding the celebration of all festivals in Lent, excepting the Lord's day, and the feast of the Annunciation, so that we may date its original from the 7th century. However, among the sermons of St. Augustine, who died in 430, there are two on the Annunciation, viz. the seventeenth and the eighteenth de Sanctis: and in the Greek church we find still earlier testimonies of it. Thus Basil of Seleucia, who died 455, and Proclus, who died 446, and John Chysostom, in 407, and Gregory Thaumaturgus, in 395, have all of them discourses on the Annunciation; some writers indeed question the authenticity of these sermons.

ANO'MALOUS (*Dict.*)—There are Anomalous verbs, or irregular inflexions of words, in all languages.—In the English, all the irregularity in our Anomalous verbs lies in the formation of the preter tense and passive participle; though this only holds of the native Teutonic or Saxon words, and not of the foreign words, borrowed from the Latin, Welch, French, &c.

The principal irregularity arises from the quickness of our pronunciation, whereby we change the consonant *d* into *t*, cutting off the regular ending *ed*.

Thus for mixed, we write mixt or mix'd, for dwelled, dwelt or dwell'd; for snatched, snatcht, &c.— But this is rather of the nature of a contraction than an irregularity; and is complained of by some of our politer writers, as an abuse much to the disadvantage of our language, tending to disfigure it, and turn a tenth part of our smoothest words into clusters of consonants: which is the more inexcusable, in that our want of vowels has been the general complaint of the best writers.

Another irregularity relates to the preter tense and passive participle. - Thus give, if it were regular, or formed according to the rule, would make gived in the preter tense and the passive participle; whereas it makes gave in the preter tense, and given in the passive participle.

ANO'MALY, in grammar, denotes an irregularity in the accidents of a word, whereby it deviates from the common rules or paradigms, whereby other words of the like kind are governed.

ANAMORHOMBOI'DIA *, in natural history, the name of a genus of spars.

* The word is formed from the Greek ἀνώμαλος, irregular, and ῥομβοειδὴς, a rhomboidal figure.

The bodies of this genus are pellucid crystalline spars, of no determinate or regular external form, but all breaking into regular rhomboidal masses; easily fissile, and composed of plates running both horizontally and perpendicularly through the masses, but cleaving more readily and evenly in a horizontal, than in a perpendicular direction: the plates being ever composed of irregular arrangements of rhomboidal concretions.

There are five known species of this genus, all which have, in some degree, the double refraction of the island crystal. *Hill's History of Fossils.*

ANO'NA, in botany, the name of a genus of plants, some species of which Plumier has described under the name guanabanus. The characters of this genus are as follows:

The flower consists of six heart-shaped petals, the inner three of which are smaller than the others; there are scarce any filaments to serve by way of stamina, but the antheræ are very numerous, and seem to adhere to the sides of the germen. The germen is roundish, and stands upon the cup; there are no styles, but several obtuse stigmata. The fruit is an extremely large berry of an oval and rounded figure, containing one cell, and covered with a scaly punctated bark; the seeds are numerous, and of an oblong oval figure, and placed circularly. *Linnæi Gen. Plant.*

ANO'REXY (*Dict.*)—If an Anorexy, or want of appetite, be constant, it is reputed dangerous, in proportion to its increase, rather than its continuance. When it proceeds from viscid humours lodged in the stomach, it is not reputed so dangerous as when from hard drinking, which often ends in an incurable icterus, dropsy, or consumption. If it happen on account of the summer heat, it is not thought dangerous; but, coming upon the palsy, bad. Corpulent bodies are thought better able to bear it, than such as are lean or emaciated. When, from a relaxation of the fibres of the stomach, it is not esteemed dangerous, if taken in time; but, when it proceeds from other distempers, is to be judged of from them. If it continues after those are gone off, it may be looked upon as original. Relishing sauces are here allowable, if not overdosed with unctuous ingredients. All acids are here accounted good. The night-meal should be very easy of digestion, and made an hour or two before bed-time. Riding is thought excellent: the sleep should be moderate, and the air clear. If the patient be plethoric, or the disorders proceed from a stoppage of evacuations, bleeding is good; and in case of sour eructations, pain in the head, sickness at the stomach, dulness, heaviness, or if crapula's, or the use of narcotics, have preceded, an emetic, and afterwards a paregoric, are proper. In the next place, purging, especially if the menses are suppressed, and that with calomel. The tinctura sacra is also good, being taken in the quantity of an ounce at a time. When the indisposition proceeds from any passion, blistering, emetics, the cold-bath, a free air, and diversions are of service, together with proper stomachics. If it comes from a suppression of any evacuations, promote them, and use stomachics. Proceed in the same manner, when this case is a symptom in other distempers. If it was caused by too liberal a use of tea, it should be left off by degrees, and a glass of red wine be drank in its stead, or an infusion of cortex in red wine. And, lastly, let the cold-bath be tried. The chewing of rhubarb is good in most of these cases, especially if they are attended with great costiveness. *Shaw's New Practice of Physic.*

ANT, *formica*, in natural history, an insect famous in natural history, of which we have five species common in England. 1, A small blackish Ant. 2, A small reddish brown Ant. 3, A middle-sized black Ant. 4, A middle-sized reddish Ant; and, 5, The common great hippomyrex, or horse-Ant.

The Ant, examined by the microscope, appears to be a creature of a very singular structure. The head is large, adorned with two pretty horns, each having twelve joints. Its eyes are protuberant and pearled; it has jaws saw-like or indented, with seven little teeth that exactly tally, opening side-ways, and able to gape very wide asunder; by the help whereof it is often seen grasping and transporting bodies of three or four times its own bulk and weight. It is naturally divided into the head, the breast, and the belly or tail: each of these parts joining to the other by a very slender ligament. From the breast-part, three legs come forth on either side. The tail is armed with a sting, which the animal uses only, when provoked: but then a poisonous liquor is conveyed by it into the wound, occasioning pain and swelling. The whole body is cased over with a sort of armour, so hard, as not to be penetrated by a lancet, and thick set with shining whitish bristles. The legs, &c. are also covered with hairs, but much smaller and of a darker colour. *Baker's Microscope made easy.*

The sight of Ants is really very instructive. They are a little people united, like the bees, in a republic governed by its own laws and politics. They have a kind of oblong city, divided into various streets, that terminate at different magazines. Some of the Ants consolidate the earth, and prevent its falling in, by a surface of glue with which they incrust it. Those which we commonly see, amass several splinters of wood, which they draw over the tops of their streets, and use them as rafters to sustain the roof; and across these they lay another rank of splinters, and cover them with a heap of dry rushes, grass, and straw, which they raise with a double slope, to turn the current of the water from their magazines; some of which are appropriated to receive their provisions, and in the others they deposit their eggs, and the worms that proceed from them.

As to their provisions, they take up with every thing eatable, and are indefatigable in bringing home their supplies. You may see one loaded with the kernel of some fruit, another bends under the weight of a dead gnat. Sometimes several of them are at work on the carcase of a May-fly, or some other insect. What cannot be removed they eat on the spot, and carry home all that is capable of being preserved. The whole society is not permitted to make excursions at random: some are detached, as scouts, to get intelligence; and, according to the tidings they bring, all the community are upon the march, either to attack a ripe pear, a cake of sugar, or a jar of sweet-meats; and in order to come to this jar, they leave the garden, and ascend the house; there they find this mine of sugar, this rich Peru of sweets, that opens all its treasures to their view. But their march to it, as well as their return from it, is under some regulation: the whole band is ordered to assemble, and move in the same track; but the injunction is not executed with much severity, and they have liberty to expatiate, when they have an opportunity to spring any game in the country. The green vermin that make an infinite waste among flowers, and cockle the leaves of the peach and pear trees, are surrounded with a glue, or kind of honey, which is sought for by the Ants with great avidity; but they are not sollicitous either for the flesh of these creatures, or for any part of the plant. These are the vermin who are the authors of all that destruction to our trees, which is falsly imputed to the Ants, and draws upon them a very unjust and cruel persecution.

Their next prevailing passion is, to amass a store of corn, or other grain that will keep; and, lest the humidity of the cells should make the corn shoot up, we are told, for a certainty, that they gnaw off the buds which grow at the point of the grain.

I have seen Ants carry, and sometimes push before them, grains of barley and wheat, much larger than themselves; but I never could find out their granary. All the ancients mention

mention it, and Aldrovandus assures us he had seen it. Their labours, as well as their inclinations, may vary according to their species. It is likewise probable that their aurelia's, which are sometimes yellow, have been taken for grains of corn without buds, and swelled by moisture.

The Ants, after they have passed the summer in a constant employment and fatigue, shut themselves up in the winter, and enjoy the fruits of their labour in peace; however, it is very probable, they eat but little in that season, and are either benumbed, or buried in sleep, like a multitude of other insects. And therefore, their industry in storing up provisions is not so much intended to guard against the winter, as to provide, during the harvest, a necessary sustenance for their young. They nourish them, as soon as they leave the egg, with an assiduity that employs the whole nation; and the care of their little progeny is esteemed a matter of importance to all the state.

When the young quit the egg, they are little worms, no longer than common grains of sand, and after they have for some time received their aliment, which is brought to them in common, and distributed in equal proportions, they spin a thread, and wrap themselves up in a white web, and sometimes in one that is yellow; at which period they cease to eat, and become aurelia's. In this state, some people fancy they are the eggs of Ants, when, in reality, they are the nymphs, out of whose ruins the new pismires are to rise. Though the young discontinue their eating, their nurture still proves very fatiguing to their parents. These have generally several apartments, and remove their young, from the nursery, to some other mansion they intend to people. They either raise the aurelia's toward the surface of the earth, or sink them to a distance from it, in proportion as the season is either warm or cold, rainy or dry. They raise them when the weather proves serene, or when a long drought is succeeded by gentle dews; but, at the approach of night and cold, or the appearance of showers, they clasp their beloved charge in their arms, and descend with them to such a depth, that one must then dig above a foot into the earth, before those aurelia's can be discovered.

We might enlarge on many other particulars of their conduct, such as their dispersing themselves over the country, their custom of removing the dead from their habitations, their promptitude in assisting each other to carry their burdens, or invade their enemies. A long description might likewise be given of the small sting they carry in the extremity of their bodies, with a bag of corroding water that causes little tumors. Much might be also said of their wings, that are acquired by the males at a certain age, to facilitate their acquisition of food, and which are refused to the females, that they may be more sedentary, and better devoted to domestic cares. *Spectacle de la Nature.*

In the memoirs of the Royal Academy, there is a curious account of Ants; the writer tells us, that he found a nest of Ants in a box of earth, standing out from a window two stories high; whence they made excursions both upwards, to the top of the house, where some corn lay in a garret, and downwards, into a garden, which the window overlooked. The situation of this nest obliged them to go up or down a great way before they could possibly meet with any thing; but he found, notwithstanding, that none of them ever returned empty, but every one brought a grain of wheat, rye, or oats, a small seed, or even a particle of dry earth, if nothing else could be got. Some travelled to the farther end of the garden, and, with prodigious labour, brought heavy loads from thence. It required four hours, as he learned by frequent observation, to carry a pretty large grain or seed from the middle of the garden to the nest: and he computed therefrom, that an Ant works as hard as a man who should carry a heavy load twelve miles a day.

The pains these Ants took, to carry grains of corn up a wall to the second story, climbing all the way with their heads downward, must be exceeding great. Their weariness was shewn, by their frequent stops at the most convenient places; and some appeared so fatigued and spent they could not reach their journey's end: in which case it was common to see the strongest Ants, which had carried home their load, come down again and help them. Sometimes they were so unfortunate as to fall down with their burdens, when just in sight of home: but, when this happened, they seldom lost their corn, but carried it up again.— He saw one, he says, of the smallest Ants carrying a large grain of wheat with incredible pains. When she came to the box where the nest was, she and her load together tumbled back to the ground. Going down to look for her, he found she had recovered the grain, and was ready to climb up again. The same misfortune befel her three times; but she never let go her hold, nor was discouraged; till at last, her strength failing, she was forced to stop, and another Ant assisted her to carry home her load to the public stock.

How wonderful is the sagacity of these insects! How commendable their care, diligence, and labour! How generous their assistance of one another, for the service of the community! How noble their public virtue, which is never neglected for the sake of private interest! In all these things they deserve our notice and imitation.— A contemplative mind will naturally turn its thoughts from the condition and government of Ant-hills to that of nations; and reflect, that superior beings may possibly consider human kind and all their sollicitudes and toils, pride, vanity, and ambition, with no more regard than we do the concerns of these little creatures.

ANT-HILLS, are little hillocks of earth, which the Ants throw up for their habitation and the breeding of their young. They are a very great mischief to dry pastures, not only by wasting so much land as they cover, but by hindering the scythe in mowing the grass, and yielding a poor hungry food pernicious to cattle.

The manner of destroying them is to cut them into four parts from the top, and then dig into them so deep as to take out the core below, so deep that, when the turf is laid down again, it may lie somewhat lower than the level of the rest of the land, and this will prevent the Ants from returning to the same place, which, otherwise, they would certainly do. The earth that is taken out must be scattered to as great a distance as may be, otherwise they will collect it together and make another hill just by.

The proper time for doing this is winter, and, if the places be left open, the frost and rains of that time of the year will destroy the rest; but in this case care must be taken, that they are covered up early enough in the spring, otherwise they will be less fertile in grass than the other places.

In Hertfordshire they use a particular kind of spade, to this purpose. It is very sharp, and formed at the top into the shape of a crescent, so that the whole edge makes up more than three fourths of a circle; this cuts in every part, and does the business very quickly and effectually; others use the same instruments that they do for mole-hills.

Human dung is a better remedy than all these, as is proved by experiment, for it will kill great numbers of them, and drive all the rest away, if only a small quantity of it be put into their hills.

Some put honey mixed with powder of rats-bane into little boxes pierced full of holes, such as will just admit this creature, and this never fails to destroy them in great numbers; care is to be taken, however, that these holes are not too large, for, if they would admit a bee, those creatures would as surely come in as the Ants, and would not only be destroyed themselves, but might chance to carry this poisoned honey to the hive, and deposit it in the combs among the rest, before they died by it, which would render the whole stock of honey poisonous. A bottle filled half up with any sweet liquor, and hung upon the trees, will destroy great numbers by their getting in, and being drowned in it; but, if they are troublesome to the walks and allies in the pleasure-gardens, the watering these at times will send them away. *Mortimer's Husbandry.*

ANTAPO'CA, in the civil law, implies one's acknowledgment in money paid, by way of rent, interest, or such-like incumbrance. Such an instrument, or Antapocha, the debtor gives upon making payment to the creditor, to serve as a proof of the charge or incumbrance for futurity, and exclude any claim of prescription against the payment of it.

ANTECE'DENT (*Dict.*)—

ANTECEDENT *will*, or *desire*, is that which precedes some other will or desire, or some knowledge or provision.— Thus we say, God by a sincere, but Antecedent desire, wills all men to be saved: that is, this sincere desire of God precedes, and does not suppose, the knowledge of their faith and repentance.

By the way it must be noted, that the term Antecedent is only applied to God in respect of the order of nature, not of an order of succession; for that God, by reason of his infinite perfections, sees and foresees at the same time: after the same manner he also wills, and not successively, one thing after another.— Yet does not this hinder, but that God may will one thing on occasion of another, or have such a desire on occasion of such a provision; which divines call the order of nature, in contradistinction to that of time.

ANTECE'SSORS, in the art of war, is an appellation given to a party of horse, dispatched before the agmen or body of an army, partly by way of intelligence, and partly to chuse a proper place for encamping on, as well as the most convenient roads for the soldiery to travel in. *Aquin. Lex. Milit.*

ANTECESSO'RES, in the antient military art, parties sent before to mark out a camp, procure provision, or even reconnoitre the enemy. *Aquin. Lex. Milit.*

ANTEJUSTINIA'NEAN, an appellation sometimes given to the antient Roman law, as it stood before the time of the emperor Justinian.

A'NTEDATE, a falsified date, a date set down before the true one. Antedates are of a very dangerous consequence in matters of trade.

To ANTEDATE, in commerce, is to set down a false date, to date, from a day prior to that on which the business is transacted, the note, or bill, drawn, or letters written, &c.

In France it was formerly the ill custom to leave blank orders on the back of bills of exchange; that is to say, to endorse them by writing only one's name, so that they could easily

be

be Antedated, which might occasion very great abuses, especially from those who happened to break: for they who fell under that misfortune, and had bills of exchange drawn at two usances, or payable in the payment of Lyons, which were to order, in blank, might Antedate the order, and make them thus be received under borrowed names, or give them in payment to such of their creditors as they wanted to favour, to the prejudice of others; by which means those bills could not be demanded to be added to the bankrupt's effects, because, the date of their order seeming to be prior to the time of the failure, it could not be urged that they were negotiated within the time wherein the person became a bankrupt.

The regulation for commerce in France, made in the year 1673, has provided, that it is not now so easy to Antedate orders on the back of bills of exchange: for, in the 22d article of Tit. V, it is ordered, that the signature, or name signed, on the back of bills of exchange, shall serve only as an endorsement, and not as an order, unless it be dated, and contain the name of the person who should have paid the value in money, merchandize, or otherwise: and, by the 26th article of the same title, it is ordered, that whoever Antedates orders, shall be punished as guilty of forgery.

ANTEDILU'VIAN *Philosophy*, or the state of philosophy before the flood. Some who have traced philosophy back, to its origin, do not stop at the first man, who was formed in the image and likeness of God; but, as if the earth were unworthy to give birth to such a science, soar to the skies, and seek it among angels, where they shew it us brilliant in a glare of brightness. This opinion seems founded on what the scripture says of the nature and wisdom of angels. It is natural to think, that, being of a nature very much superior to our's, they must consequently have a better knowledge of things, and be better philosophers than men. Some learned men have carried things farther yet; in order to prove that angels excelled in natural knowledge, they have asserted that God made use of their service in the creation of the world, and in the formation of the different animals that inhabit it. This opinion it is easy to see flows from the doctrines of the Pythagorean and Platonic philosophy. Pythagoras and Plato, puzzled at the infinite space between God and man, thought proper to fill up the interval with genii or angels, but, as M. Fontenelle judiciously observes in his Hist. des Oracles, with what shall we fill the infinite space between God and these genii or angels; for the distance between God and any creature whatever is infinite? Now, if the action of God must traverse an infinite vacuum, if I may be permitted the expression, to descend to angels, it might have descended to men as they are removed only some degrees lower, which bears no proportion to the distance of angels from the first cause. When God speaks to man by the means of an angel, it is not because, as Plato has asserted, angels are necessary for such a communication; no, God employs them for reasons that philosophy never will find out, and can be perfectly known only by himself.

Plato imagined spirits to form a scale of beings, so that, by ascending from a less perfect to a more perfect Being, we might at last arrive at a creature inferior to the Deity, only by some degrees of perfection: but, as it is certain, all beings are infinitely imperfect, compared to him, because they are infinitely removed from him, the different degrees of perfection which are between them, disappear, when we compare them with God; what raises them one above another, does by no means bring them near to him. Thus, without any higher aid than human reason supplies, it is plain, there is no occasion for spirits, or any intermediate beings between God and us, to render our approaches towards the divine Being more proportional.

But if good angels, ministers of the will of God, and his messengers to men, are excellent in the philosophical sciences, why should we refuse this power and capacity to the fallen angels? Their fall did not change the excellency of their nature, nor perfection of their knowledge. One may see a proof of this in astrology and augury. The devil who tempted our first parents, owed his victory over them to artful and subtle reasonings. None have been so weak as to advance, that the fallen angels have revealed to men whom they had commerce with, and had inchanted, several secrets, as the nature of metals, the virtues of herbs, magic, and the art of reading men's destinies in the skies, except some fathers of the church, whose heads were infatuated with the dreams of the Platonic philosophy.

It will be needless to shew the weakness and absurdity of their arguments, who assert that angels or dæmons are philosophers, and great philosophers too: let us leave this philosophy to these invisible philosophers, and come to that which is more suitable to the nature of man, and within our own sphere.

Was Adam, the first man, a philosopher? This several make no doubt of. Hornius, in short, tells us, that, in in his opinion, Adam, before his fall, was not only perfect in all knowledge, but also retained some vestigia or traces of this perfection after his fall. The remembrance of what he had lost, being always in his mind, kindled in his heart a passionate desire of recovering the knowledge sin had robbed him of, and dissipating the darkness which had thrown a veil over it. To satisfy this thirst of knowledge, he dedicated his whole life to the contemplation of nature, and, carrying science to the highest pitch, left most of his discoveries to his children; because he lived long enough to communicate them. Such are the reasonings of Dr. Hornius, to which we might add what the Jewish rabbins have wrote, if their fables merited our attention. But Hornius offers some farther arguments, to prove Adam a philosopher, and even of the first rank. Had he not been a naturalist, says Hornius, could he have given the animals names so expressive of their nature? Eusebius has brought a proof of Adam's logic. As to the mathematics, he must have certainly understood them, or he could never have made cloaths out of the skins of wild beasts, have built him an house, observed the motions of the stars, and regulated the year by the course of the sun. But the highest of all these convincing arguments, brought in favour of Adam's philosophy, is this, that he wrote books, that these books contained all the sublime sciences which he had made himself master of with incredible labour. It is true, indeed, these books are apocryphal, or lost; but that signifies nothing; because tradition has preserved the titles of the authentic books whereof he was the real author.

Nothing is more easy than to refute all these arguments; first, if we speak of Adam's wisdom before the fall, it has no relation to philosophy in the sense we accept it; for that wisdom consisted in the knowledge of God and himself, but, particularly, in that practical knowledge which might lead him to the happiness for which he was created. It is true, Adam possessed this kind of wisdom, but what connection has this with a philosophy which admiration and curiosity, the daughters of ignorance, produce, which is not acquired without the toil of reflection, nor brought to perfection without the conflict of different opinions? The wisdom with which Adam was created, was that divine wisdom which is the fruit of grace, which God pours forth even on the weakest minds. This is, no doubt, a true philosophy, but it is very different from that philosophy which the rational mind first conceived, and all ages have concurred to produce and carry to its present maturity. If Adam, in his state of innocence, had no philosophy, what will become of that they attribute to him after his fall, which was but a faint glimmering of what he had before? Would they persuade us that Adam, whose sin continually followed him, and who could think on nothing but the means of reconciling himself to God, and resisting the evils that surrounded him, had a mind sufficiently at ease to apply himself to the barren speculations of vain philosophy? He gave names to animals; but does this prove him well acquainted with their nature and properties? He reasoned with Eve, our common mother, and his children; from thence shall we conclude he understood the art of logic? By such reasoning as this we may make every man a logician. He built himself a poor cottage, governed his family prudently, instructed them in their duty, taught them religious worship; but are these sufficient reasons to prove Adam an architect, a politician, and divine? How can any one maintain Adam to have been the first inventor of letters, when it is evident, that, mankind, long after the flood, made use of hieroglyphics, the most imperfect of all kinds of writing, to convey their ideas to each other; and that this was the first attempt made of the kind. The wonders of nature are exposed to our view in the most glaring light, a long time before we have reason, opportunity, or penetration enough to enquire into them. If we came into the world with the same degree of reason with which we go to a playhouse the first time, struck, on the sudden drawing of the curtain, with the magnificence of the scenes and decorations of the play, we could not possibly forbear admiring its beauty, and examining its structure; but who is surprized at what he has seen for a course of fifty years? Among men, the wants of some take up all their time to supply their necessities, they have none to apply themselves to metaphysical speculations; the rising sun calls them to their labour, and the finest night that ever shone on the bespangled sky, speaks no language to them, or only says this, 'Go, weary labourer, " to rest." Many, of more leisure, either have not had opportunity to interrogate nature, or wanted capacity to understand her answers. The philosophical genius, whose sagacity, shaking off the yoke of custom, first gazed with admiration on the prodigies of nature which surrounded him, descended into himself, asked himself questions, and gave himself answers concerning all the objects which he saw, must have been a long time in suspence, might even have died without having credited his own opinions, says the author of the essay on Merit and Virtue, page 92.

If Adam had no philosophy, there can be no inconsistence in denying it to his children Abel and Cain: no body but Hornius has discovered that Cain was the founder of a set of philosophers. A man would scarce think Cain had sown the first seeds of the Epicurean doctrine, and been an atheist. The reason Hornius brings to prove this is very singular: Cain, says he, was a philosopher, but a wicked and atheistical philosopher; because he loved pleasures and diversion, and

and his children have but too well followed the lessons he gave them of voluptuousness. If every man must necessarily be an Epicurean philosopher who listens to the blandishments of pleasure, and takes refuge in atheism for impunity of the crimes he commits, the garden of Epicurus would not be large enough to contain so great a number of philosophers. As to what he says about the city Cain built, and the tools he made use of in tilling the earth, these by no means prove him a philosopher; for what necessity and experience made men discover, in this early age of the creation, required no precepts of philosophy; necessity and experience only taught them. Besides, it may be supposed God taught the first man agriculture, and other arts, and he instructed his children in them.

Jealous Cain having murthered his brother Abel, God revived Abel in the person of Seth. The sacred traditions which concerned religion, were, therefore, preserved in this family. The espousers of the Antediluvian philosophy, not contented with asserting Seth was a great philosopher, would persuade us he was also a great Astronomer. Josephus, speaking mightily in praise of the learning which the Children of Seth had acquired before the deluge, relates, that they erected two columns, one of brick, the other of stone; that they spared no pains nor cost to build them in the strongest manner, in order to resist the conflagration and the flood, the world was threatened with; and on these they inscribed their learning, and all the discoveries they had made. Josephus adds, that the column built of brick remained even to his time. I know not whether we ought to lay any great stress on this passage. Hyperboles and exaggerations cost Josephus little, when the point is to aggrandize his own nation. The main scope of this historian is to shew the superiority of the Jews over the Gentiles in arts and sciences; this probably may have given birth to the fiction of two columns being built by the children of Seth. What probability is there that such a column could have resisted the devastations of the deluge? Besides, can it be imagined that Moses, who has mentioned the arts invented by the children of Cain, as music, metallurgy, the art of working in iron and brass, &c. should be silent about the great knowledge Seth had acquired in astronomy, in writing of which they pretend him the inventor, that nothing should have been said in his writings concerning the names he gave to the constellations, and the division he made of the year into months and weeks?

We are not to imagine Jubal and Tubal-Cain were great philosophers, one for having invented music, the other for having possessed the secret of working in iron and brass: these two men, perhaps, only carried to a greater perfection what others had found out before them. But, supposing them to have been the inventors of these arts, does it follow as a necessary conclusion they must have been philosophers? Every one knows that many of the arts most useful to society owe their invention to chance; it is the part of philosophy to reason on the genius she discovers in them after they are found out. It is a blessing chance has prevented our wants, and left philosophy almost nothing to do. Thus you see there is no philosophy either in the branch of Cain or Seth. We find honest laborious men, before the flood, who applied themselves to agriculture, preserved their primitive traditions, tended their flocks, and retained a true knowledge of God, but were no philosophers; wherefore it is in vain to seek the origin and rise of philosophy in the time preceding the flood.

ANTEDILUVIAN *World.* — Dr. Burnet and Dr. Woodward differ very widely about the Antediluvian world; the former imagines its face and appearance to have been smooth, equable, and in all respects different from what we now find it to be.

The latter, on the contrary, endeavours to prove, that the face of the terraqueous globe, before the deluge, was the same as it is now, viz. unequal, distinguished into mountains and dales, and having, likewise, a sea, lakes, and rivers; that this sea was salt as ours is; was subject to tides, and possessed nearly the same space and extent that it now does, and that the Antediluvian world was stocked with animals, vegetables, metals, minerals, &c. that it had the same position, in respect of the sun, which ours now hath, its axis not being parallel, but inclined, as at present, to the place of the ecliptic; consequently, that there were then the same succession of weather, and the same vicissitudes of seasons, as now.

A'NTELOPE, *gazella*, in zoology, the name of an animal of the goat kind, of which there are three known species.

1. The gazella Africana strepsicheros Plinii. This is the species we usually see under the name of the Antelope; it is called the addace in Africa, and is the dorcas Lybica of Ælian. Its horns are slender and erect; they are black, transversly radiated, and twisted into the appearance of spiral lines; though these are, in reality, so many annular circles, they are towards the middle bent a little outwards, and thence they turn in again, so that they, in some measure, represent the antient lyre.

2. The gazella Indica, or Indian Antelope, with very long straight horns, which are annulated only in that part near the head. The horns of this creature are sometimes three feet long, and are perfectly smooth and glossy, except near the head and back. The creature is of the size of our common deer, and is of a greyish colour; its tail is a foot long, and has longer hairs on it than those of the rest of the body. The horns of this species are very common in the musæum's of the curious. This creature seems to be the animal which produces the bezoar stone so much valued in medicine.

3. The African kind, which has flat horns annulated to the very top, and crooked near the middle; this has been seen alive, sometimes, in England. It was much smaller than our deer, and of a sandy colour; its belly white, and its sides, where the white and sand-colour meet, of a dusky appearance. Its horns grow out of the middle of the forehead near the eyes, and are very long, sharpening at the ends, and all the way marked with transverse striæ or furrows, and a little bent upwards. Its ears are large, and its legs very slender.

ANTEPENU'LTIMA, in grammar, is either taken substantively or adjectively, to agree with a syllable understood. Words of many syllables have the two last thus distinguished, the ultima or last, the penultima or last but one; which is a contraction of pene almost, and ultima the last. The syllable preceding the penultima is called the Antepenultima, Ante, before, being added to penultima: thus, in the word amaveram, ram is the ultima, or last syllable, ve, the penultima, and ma the Antepenultima.

In Greek, the acute-accent is placed over the last syllable, as Θεὸς, God; over the penultima, as λόγος, discourse; over the Antepenultima, as ἄνθρωπος, man; but it is never carried farther back.

In Latin, if accents be made to direct the reader in his pronunciation, if the penultima be short, the accent must be placed over the Antepenultima, though that be short also, as *dóminus*, a lord.

ANTEPREDI'CAMENTS, *antepradicamenta*, in logic, certain previous matters, requisite to a more easy and clear apprehension of the doctrine of predicaments or categories.

Such are definitions of common terms, as equivocals, univocals, &c.

They are thus called, because treated by Aristotle, before the predicaments, that the thread of the discourse might not afterwards be interrupted.

ANTHESTE'RIA *, in antiquity, was a festival celebrated by the Athenians in honour of Bacchus.

* Some think it takes its name from the month Anthesterion, on which it was celebrated: others, as Apollodorus, quoted by Aristophanes, imagine, it was not the name of any particular feast, but that all the feasts of Bacchus were called Anthesteria; but the most natural derivation of the word Anthesteria is from ἄνθος, a flower, because they then offered garlands of flowers to Bacchus.

The Anthesteria lasted three days, the eleventh, twelfth, and thirteenth days of the month, each of which days had a name suited to its proper office. The first day of the feast, or eleventh of the month, was called πιθοίγια, that is, opening of the vessels, in regard on this day they opened the vessels and tasted the wine.—The second day of the feast, or twelfth of the month, they called χόες, congius, the name of a measure, containing the weight of about ten pounds: on this day they drank the wine prepared the evening before. The third day of the feast, or thirteenth day of the month, they called χύτροι, kettles: on this day they boiled all sorts of pulse in kettles, which, however, they were not allowed to touch, because they were offered to the god Mercury. At these festivals the servants had the same liberty as at the Roman feriata. *Meursii Græca Saturnalia.*

ANTHOLO'GIA, in polite literature, signifies a collection of Greek epigrams.

Meleager, a native of Gadara, a city of Syria, who lived in the reign of Seleucus, the last king of that realm, made the first collection of Greek epigrams, which he called Anthologia, because, as he had the brighest and most florid epigrams of forty-six antient poets, he considered his collection as a nosegay, and denominated each of those poets after some flower, Anytus the lilly, Sappho the rose, &c. After him Philip of Thessalonica made a second collection, in the time of the emperor Augustus, out of only fourteen poets. Agathias made a third, about five hundred years after, in the reign of the emperor Justinian. Planudes, a monk of Constantinople, who lived in the year 1380, made the fourth and last, which he divided into seven books, in each of which the epigrams are disposed, in an alphabetical order, according to their subjects. This is the Anthologia that have reached our hands. He retrenched abundance of obscene epigrams, for which some of the learned are not a little angry with him.

There are a great many epigrams in this collection, that abound with wit and sense, but more of a different character. *Rollin.*

ANTHO'CEROS, in botany, the name of a genus of mosses. The name was given by Micheli, and the generical character established, in that it has a monopetalous flower, which is corniculated and divided into two carinated parts,

 the

the division running to the center, where there stands a dusty stamen or filament; this, he says, is barren, and arises from the tubular cup of the flower; the fruits being, sometimes, on the same plants with these flowers, and sometimes on others, and being of a radiated form, each of the several rays containing two, three, or four seeds.

Dillenius, however, observes, that what this author calls the monopetalous flower of the Anthoceros, is properly the capsule, containing a fine dust, which is like that of the capsules of all other mosses, and is, by him, supposed to be the farina or male part of the fructification; the filament in the middle of this capsule is surrounded with yellow dust, and the whole capsule, viewed by the microscope, appears of the nature of the common unicapsular and bivalve seed-vessels of the larger plants, as the pods of mustard, and the like. And this author further observes, that he could not accurately perceive the seed-vessels described by Micheli.

There are only five known species of this genus.

1. The common Anthoceros, with smaller and more divided leaves; this grows most frequently in damp shady places.

2. The Anthoceros, with larger and less divided leaves, the heads, in this kind, standing on very short pedicles; it is found in many parts of Germany. 3. The narrow-leaved Anthoceros with a short flower; this is found in Italy by waysides. 4. The five-cut leaved Anthoceros; the leaves of this are of a purple green; it grows on clayey ground. 5. The mushroom-headed moss, or small leafless moss, with thick bivalve heads; this is frequent in Muscovy. *Dillen. Hist. Musc.*

A'NTHRAX, in the natural history of the antients, was a word used by the most early writers, for the substance we now call pit-coal and lithanthrax. Theophrastus plainly tells us, that the substance strictly and properly called Anthrax (for they also knew a gem by the same name used in a metaphorical sense) was an earthy fossil substance, which was broken in pieces to be used, and kindled well, and burnt almost like wood-coals, and was used by the smiths.

ANTHROME'TRICA *Machina*, a name given by Sanctorius to his weighing chair, contrived for measuring the quantity of insensible perspiration.

ANTHROPOGRA'PHIA *, a description of man; more particularly, of the structure of his body, and the parts thereof.

* The word is formed from the Greek ἄνθρωπος, a man, and γράφω, to describe.

ANTHROPO'LOGY, is particularly used in theology for a way of speaking of God, after the manner of men; but by attributing human parts to him, as eyes, hands, ears, anger, joy, &c.

We have frequent instances of Anthropology in holy scripture, by which we are only to understand the effect, or the thing which God does, as if he had hands, &c.

ANTHROPO'PATHY, a figure, expression or discourse, whereby some passion is attributed to God, which properly belongs only to man.

Anthropopathy is frequently used promiscuously with anthropology; yet, in strictness, they ought to be distinguished as the genus from the species.— Anthropology may be understood of any thing human attributed to God: but Anthropopathy, only of human affections, passions, sensations, &c.

ANTHROPOPHA'GIA, the act of eating human flesh. Some authors trace the original of this barbarous custom as high as the deluge, attributing it to the giants. It is pretended that the land of Canaan itself was inhabited by giants, who were naturally so fierce and cruel, that they ordinarily fed on human flesh. Some historians, particularly Pliny. lib. 4. cap. 12, say, the Scythians and Sauromatans practised this horrid custom: the same author also says, there were Anthropophagi in Ethiopia: and Juvenal mentions the barbarity of certain people of Egypt, who, after the manner of tygers, devoured human bodies. Titus Livy says, that Hannibal obliged his soldiers to eat human flesh, to make them more fierce and intrepid in battle. In the southern parts of Africa, and in some parts of America, this horrid practice still obtains. Vespusius relates, that he has seen the men and women naked eat indifferently each other's flesh; the children fed greedily upon their father's dead body, and gloried in having eat a great number of men.

ANTHOSPE'RMUM, in botany, the amber-tree. The characters of this genus are:

It is male and female in different plants, and some are hermaphrodite: the empalement is divided into four parts; the flower is of one leaf; there are two pointals, which are accompanied by four stamina: the flower sits upon the ovarium.

We have but one sort of this plant in the English gardens at present, viz.

Anthospermum mas. Lin. The male Anthospermum.

It has been long known, in the curious gardens, under the title of frutex Africanus, ambram spirans, or amber-tree; by some ambergrease, from the scent of this plant being supposed to be like that of ambergrease.

This is preserved in most curious gardens, which have collections of tender plants. It is easily propagated by planting cuttings, during any of the summer months, in a border of light earth; which will take root in six weeks time, provided they are watered and shaded, as the season may require; or, if these cuttings are planted in pots, and plunged into a very moderate hot-bed, they will take root sooner, and there will be a great certainty of their growing: then they should be taken up, with a ball of earth to their roots, and planted into pots filled with light sandy earth, and may be exposed to the open air until October; at which time they should be removed into the conservatory, where they should be placed as far as possible from being over-hung with other plants: and, during the winter-season, they must be refreshed with water, but should not have too much given them each time. You may let them have as much air as the weather will permit; for, if they are kept too close, they will be subject to grow mouldy, and generally decay soon after; so that, if the green-house is damp, it will be difficult to preserve these plants through the winter. *Miller's Gardener's Dict.*

ANTICA'RDIUM, in anatomy, &c. that hollow part under the breast, just against the heart, commonly called the pit of the stomach: called also scrobiculus cordis.

ANTICHRE'SIS, in the civil law, a covenant or convention, whereby a person, borrowing money of another, engages or makes over his lands or goods to the creditor, with the use and occupation thereof, for the interest of the money lent. This covenant was allowed of by the Romans, among whom usury was prohibited: it was afterwards called mortgage, to distinguish it from a simple engagement, where the fruits of the ground were not alienated, which was called vif gage.

ANTICHTHO'NES, is used, in antient writers, to denote the inhabitants of contrary hemispheres.

In which sense Antichthones differ from antœci and antipodes. The ancients considered the earth, as divided by the equator into two hemispheres, the northern and southern; and all those who inhabited one of these hemispheres were reputed Antichthones to those of the other.

A'NTI-CHRIST (*Dict.*)— As to the time when Anti-Christ will make his appearance, it is far from being agreed on. We know, in general, that he will precede the second coming of Christ. But all those who have attempted to fix the year of his appearance have only discovered their ignorance and rashness. There have been impostors ever since St. Paul's time, who have terrified believers, by persuading them that the day of the Lord was at hand. St. Paul warns the Thessalonians against any deceit of this kind. The heretics of that time were true signs of Anti-Christ, but this still shews that the Christians of that time expected the coming of the Messiah.

The same opinions and dispositions are observable in the generality of the fathers of the first ages. The churches of Vienna and Lyons in Gaul, seeing the violence of the persecution, which was set a-foot by Marcus Aurelius, believed they then beheld the preludes to the persecution of Anti-Christ. Judas Syrus, in the reign of the emperor Severus, asserted that Anti-Christ would soon appear, because the persecution was then carrying on with great heat against the church. Tertullian, who lived about the same time, and St. Cyprian, who flourished soon after, believed the coming of Anti-Christ was very near. St. Hilary was of opinion, that the progress of Arianism was a forerunner of Anti-Christ. St. Basil the great, St. Ambrose, St. Jerom, St. Martin, St. Crysostom, and Gregory the great were of opinion, that the end of the world was at hand, and that the coming of Anti-Christ would not be far off.

After the tenth age, which concluded the sixth millenary, according to their opinion, who reckoned the birth of Jesus Christ to have happened in the year of the world 4500; people began to get the better of that apprehension, they had been under, of the appearance of Anti-Christ, and conclusion of the world, which was to be, according to the tradition of the ancients, after the duration of 6000 years. They then began to build larger churches and edifices. St. Jerom's translation of the scriptures, which allowed the world to have existed not above 4000 years before Jesus Christ, contributed likewise to persuade men that the last period of the world, and the coming of Anti-Christ, were not so near. Notwithstanding this, it did not hinder some from attempting once more to fix the year of Anti-Christ's appearance. The council of Florence, assembled in 1105, condemned Fluentius, bishop of that city, for maintaining that Anti-Christ was then already born; Abbot Joachim, who lived in the twelfth age, pretended that Anti-Christ was to appear in the 60th year of his time. Arnaud de Villeneuve said, he would come, in 1326: Peter Daille, in 1789: Cardinal de Cusa, in 1730: John Picus, of Mirandola, in 1994: Jerom Cardan, in 1800: and Vincent Ferrier, who lived in the 15th century, wrote to Pope Benedict XIII, that Anti-Christ would appear in a very short time; and that an holy hermit had informed him, nine years before, that this enemy of God was born. The event has already confuted the generality of these predictions; and we may safely venture to affirm, that the rest are no better grounded, nor at all more certain, than the preceding ones.

Our

Our Saviour, in his gospel, describes the times that shall precede his coming, as times of war, famine, and rebellion; and says, that all this is but the beginning of sorrows. Then the just shall be given up into the hands of the wicked, and put to death by them; many good men shall be offended, and the abomination of desolation shall be seen in the holy places. The calamities which will then happen, will be also so extreme, that, if they were not to be shortened, no one would be saved: but, for the elect's sake, they will be shortened. Then shall arise false Christs, and false prophets, and shall shew great signs and wonders, insomuch that (if it were possible) they would deceive the very elect. After all this, the son of man shall appear in the brightness of his majesty.

There is likewise a difference among authors, as to the manner of the birth of Anti-Christ. Some say, he will be begot by a devil upon some very corrupt woman: others tell us, that Anti-Christ will be a devil incarnate, and not a man; that, as Jesus Christ was born of a pure virgin, Anti-Christ will pretend to the same: but, whereas the son of God assumed real flesh, Anti-Christ will take only the phantom and appearance of flesh. But St. Crysostom, Theodoret, Theophylact, and some others, with more reason, imagine that Anti-Christ will be a real man, and an agent of the devil in exercising all his cruelty and malice against the faithful. There was a tradition received among the ancients, that he should be born of a Jewish family, and proceed from the tribe of Dan. In which sense these words of Jeremiah are explained, the snorting of his horses are heard from Dan: The whole land trembled at the sound of the neighing of his strong ones; for they are come, and have drowned the land and all that is in it. The most ancient commentators upon the Revelations, such as Aretas, Bede, Primasius, Rupert, Hiacino, and many others, are of opinion, that St. John's omission of the name of Dan, in his enumeration of the tribes of Israel, proceeds from the knowledge he had, that Anti-Christ should be born of this tribe.

As to the dominion, or kingdom of Anti-Christ, as it is supposed that he will be born in Babylonia, it is said that he will there lay the foundation of his empire, and that the Jews will be the first to declare for him, acknowledge his dominion, and enjoy the principal employments in his government. He will begin with attacking the Roman empire, which will then be divided among ten kings, according to the prophecy of Daniel. After he has subdued Egypt, Ethiopia, and Lybia, he will conquer Jerusalem, and there fix the seat of his empire. Then, finding himself master of the eastern and western empires, he will apply himself to the destruction of Christ's kingdom. Some of the ancients believe he will be seated in the churches of Christians, and there receive the adoration of great numbers of apostates from the Christian faith.

The scripture does not particularly tell us what the duration of Anti-Christ's kingdom will be; but, in several places, it seems to allow three years and an half for the continuance of his persecutions; at least three years and an half for the persecutions of those who were looked upon as figures of Anti-Christ.

The righteous, under the persecution of Anti-Christ, will retire to the mount of Olives, where they will soon be attacked by this enemy of God. Then will they cry unto the Lord, and he will send Jesus Christ to deliver them. He will descend from heaven, attended by his angels, and preceded by by a flame, which nothing will be able to extinguish. The angels will make such a slaughter of the Anti-Christ, that their blood shall flow like a torrent in the valley. Anti-Christ himself will come to the top of mount Olivet, where he will be put to death in his own tent, and upon his own throne, without receiving the least assistance from any one.

The Mussulmen, as well as the Jews and Christians, expect an Anti-Christ. The Mussulmen call him Daggial, or Deggial, from a name which signifies properly an impostor, or a lyar; and they hold that their prophet Mahomet taught one of his disciples, whose name was Tamini al Dari, every thing relating to Anti-Christ; and upon the faith of this man they tell us, that Anti-Christ must come at the end of the world, that he will make his entry into Jerusalem like Jesus Christ, who, as they will have it, is not yet dead, but will come, at his second advent, to encounter him, and that, after having conquered him, he will then die.

A'NTIC, in sculpture and painting, denotes a fantastical composure of figures of different natures, sexes, &c. as men, beasts, birds, flowers, fishes, and even things merely imaginary, or which have no existence in the nature of things. *Build. Dict.*

ANTIHE'CTICUM *Poterii (Dict.)*— This medicine is prepared in the following manner:

Take equal quantities of tin and martial regulus of antimony, melt them in a large crucible; then put to them, by little and little, three times the quantity of nitre; after the detonation and noise is over, wash the whole with warm water, till no saltness remain.

This is accounted a forcing penetrating medicine, insomuch as to make way through the minutest passages, and search even the nervous cells; whence, in all disorders of that original, it is reckoned very effectual. In those heavinesses of the head, giddiness, and dimness of sight, whence proceed apoplexies and epilepsies, it does great service. And, in all affections and foulnesses of the viscera of the lower belly, it is reckoned inferior to nothing in cleansing away and discharging their impurities. Thus it obtains in the jaundice, dropsies, and all kinds of cachexies. It is likewise esteemed of great service, even in obstinate venereal cases, in clearing the blood from all impressions of contagion, and cleansing the glands from those corrosive recrements, which such distempers frequently lodge upon them, and occasion blotches and ulcerous deformities. In short, there is hardly a preparation, in the chymical pharmacy, of greater efficacy in most chronic distempers; but it is not often met with in prescription, although constantly kept in the shops. The dose is from six grains to a scruple in grown persons; for it is seldom given to children, their tender vessels not well bearing the force of such medicines. *Quincy's Dispensatory.*]

ANTIME'RIA, in grammar, a figure whereby one part of speech is used for another. e. gr. velle suum cuique est, for voluntas sua cuique est; also, populus late rex, for populus late regnans.

Antimerica, in a more restrained sense, is a figure whereby the noun is repeated instead of the pronoun. *Ludovic. Hebraism.*

The Antimeria is frequent in the Hebrew, and is sometimes retained in our version of the Old Testament accordingly. Thus in *Gen.* cap. iv. Hear my voice, ye wives of Lamech, for my wives. *Gen.* c. iv. 23.

ANTIMETA'BOLE *, ἀντιμεταβολὴ, in rhetoric, a figure which set two things in opposition to each other.

* The word is Greek, compounded of ἀντὶ, against, and μεταβολὴ, from, μεταβάλλω, to shift or transfer.

This figure is twice exemplified in an apophthegm of Musonius; which, on account of its excellence, is called aureum monitum, the golden maxim or precept. This apophthegm, translated into English, is as follows:

Allowing the performance of an honourable action to be attended with labour, the labour, is soon over, but the honour immortal; whereas, should even pleasure wait on the commission of what is dishonourable, the pleasure is soon gone, but the dishonour eternal.

A'NTIMONY, *antimonium (Dict.)*—A considerable heavy semi-metal, naturally running into masses composed of an infinite number of striæ or filaments. It is softer than any other of the bodies of this class; it breaks easily with a small blow, and is very readily reducible to powder, by only rubbing it in a mortar. It has not the least degree of ductility, but it is naturally very bright and glossy, and not much susceptible of rust. It is not at all sonorous in itself, yet, like tin, which has not that quality in itself, it is capable of heightening it in other metallic bodies that are possessed of it. It is easily fused by fire; a small degree of heat answers this purpose: it flows the thinnest of all the known mineral bodies, and, when urged by a violent fire, proves totally volatile. It bubbles up in the manner of lead, when the degree of fire is a little greater than what is barely necessary to melt it. It is not only volatile in itself, but it renders all other substances volatile by mixture, gold alone excepted. It leaves this metal infusion clearer and purer than it can be made by any other means, but carries off every thing else in vapour with it. Antimony very easily runs into a glass, like that of lead, which is of the same use with the glass of lead in the vitrifying earth and stones; but is even preferable to it, as it attenuates them more, and in a strong fire carries them off with it in vapour. It would therefore be very useful in the fusion of ores, by the vitrifying and separating the stony matter, but that it carries the metal itself also, except that be gold, away with it. This glass is very easily prepared by only fusing Antimony with a mineral substance, commonly known by the name of calk, and very frequent in our leadmines: a lump of this, the bigness of a walnut, thrown into a pound of Antimony in fusion, vitrifies it almost instantly, and receives no visible change itself in the operation.

The glass, produced by this process, is of a dusky brownish red, and semi-pellucid; wherever calk is to be had, there is no way so ready as, by this means, to make the glass of Antimony: where it is not at hand, it is easily vitrified alone, by calcining it in coarse powder to a grey mass, stirring it that it may not run into lumps, and then putting this calx into a crucible in a strong fire: the Antimony is thus converted into a glass, like that of the former process, but of a clearer red.

Where bodies very difficult of vitrification are mixed among the matters to be putrified by Antimony, as is the case in the more refractory ores of many kinds, the Antimony is apt to evaporate away before it has done its office: this however is easily prevented by only throwing a little piece of suet or tallow into the matter, which keeps it from flying off a long time. The regulus of Antimony mixes very readily with the several metals; most freely of all with iron, and, next to that, with copper. It consists of a large quantity of of a true fossil sulphur, and a matter very much resembling the nature of the metals, and which, if art could arrive at any method of rendering it ductile under the hammer, would be a true metal. Mr. Boyle tells us, he knew a secret process, by which a true fluid mercury might be obtained from it; and others, since his time, have pretended the same thing, but we have never seen any of them do it. It would therefore have been a great satisfaction if Mr. Boyle had given us the process. It renders all metals brittle with which it is mixed; and, upon the whole, there seems great reason, from its effects on these bodies compared with those of arsenic, to believe that it is very nearly allied to that poisonous mineral, though it do not exert the same fatal power in the body. The whole difference between the two substances seems to be, that the arsenic is fixed in Antimony by a vitrifying earth.

The ores of Antimony are very numerous and very various in their form, colour, and figure. It is pretended by many, that Antimony is often found pure, in its perfect state in the earth; and the cabinets of collectors hold so many substances under the name of native Antimony, that it should seem almost absurd to deny the existence of such a fossil. I can only observe, that, of all the specimens I have seen preserved as native Antimony, I never met with one that would bear the test, and prove truly such: and, to silence the clamour that such a harsh assertion may raise among the gentlemen who are robbed by it of some of the greatest glories of their cabinets, I may add, that many of the very finest of these substances preserved under this pompous name, and resembling the wrought Antimony in their grey colour and striated texture, are specimens of manganese.

Antimony is found reduced to the state of ore by sulphur and other extraneous matter, and, as these are blended with it in greater or lesser quantities, it has more or less of the external appearance of wrought Antimony, and is from this external appearance arranged by collectors in the class of native Antimony, or of Antimony-ores.

The most usual ore of Antimony is a hard and ponderous substance of a bluish grey colour, not striated as common Antimony, but composed of a number of small irregular granules, which appear very bright and sparkling, wherever the mass is fresh broken. This ore has much the appearance of a bright piece of cast iron, where fresh broken.

Other ores of Antimony, in which there is less extraneous matter, are formed of broader and flatter granules; these more nearly resemble wrought Antimony, but are more brittle: these are very bright, of a paler grey than the granules of the last mentioned kind, and the ores composed of them are more beautiful and more valued.

When there is yet less of the extraneous matter, and that is almost pure sulphur, the ores approach infinitely more than either of these to the appearance of wrought Antimony. They are composed of multitudes of fine and slender filaments, of a bright and glittering steel colour; these are laid more or less closely together in the several specimens, and are much broader and coarser in some than in others. These are properly enough called striated Antimony-ores; but, the generality of people who collect minerals loving sounding names, they are generally found in the cabinets, under the title of native Antimony.

These are the forms, in which Antimony appears in those ores in which it is most pure; but, besides these, there are others very frequently met with, in which this semi-metal is mixed with silver, and with iron; these give it a very different appearance. In England we also have Antimony mixed with lead in the same ore, a thing scarce known in any other part of the world; and some of our Cornish Antimony-ore contains also a small portion of tin. The German ores of Antimony, are frequently found of a fine silvery white, or a fine gold-like yellow: these colours are owing to the admixture of the white or yellow marcasites with them, and, though very splendid as to the appearance, they are far from being the most valuable of Antimony-ores for working.

Antimony-ore is very frequently blended with crystalline or sparry matter; sometimes it is perfectly covered with a fine yellow sulphur, and sometimes with a mixture of these and other substances together.

Antimony-ore is found in great abundance in many parts of the world. The German mines abound with it. There is a great deal of it in France and Italy. In Hungary, particularly about Presburg, there is a great deal of very rich ore found. The first Antimony of France is that of Poictou; and in England, where we have no small quantity, that of Endellion in Cornwall is the best; but this must be well purified from the lead the ore also contains before it is fit for use.

The Hungarian Antimony-ore is much of it of the naturally striated kind; this was called the male Antimony by the Romans. The broad-grained, or that formed of large and shining granules, which the Romans called the female, is frequent in Saxony. Some of the striated Hungarian Antimony-ores are variegated with yellowish or orange-coloured spots. These pieces are frequently found in the gold mines, and supposed to contain sulphur of gold. The chymists call this kind antimonium solare, and are very full of an opinion, that vast matters may be done with it in the great work of the transmutation of metals.

The Antimony-ore is never brought into the shops, or at least it never ought to be. What we see there has been all melted from its state of ore, and is in cakes of the figure of the vessels it has been cast in, all throughout composed of the same sort of striæ or filaments as the finer ores, resembling so many bright needles, disposed in fasciæ or bubbles throughout the mass.

It should be chosen very bright, tender, and friable; composed of long and broad striæ of the palest colour, and the most glittering that can be found; and the tops of the cakes, which are of an irregular or spongy texture, and blacker colour, ought to be thrown away. The sulphur that Antimony contains is not separated in that fusion in which it passes in the reducing it from its ore. We have the most evident instances of it in the calcination of it afterwards, in which operation we are offended with a smell, wholly like that of common brimstone; and, if it be performed in a dark place, we even see it burn away in thin blue flames.

Antimony, thrown into a crucible with nitre, deflagrates in the very same manner that common sulphur does under the same circumstances; and, if crude Antimony be distilled with corrosive sublimate, a cinnabar is prepared, called cinnabar of Antimony. This owes it origin solely to the mercury in the sublimate united with the sulphur in the Antimony. In fine, the sulphur may be separated from Antimony, in its proper form, by boiling crude Antimony in common water, after it has been run with a mixture of quicklime or pot-ash, and then adding vinegar or some other acid to the solution made of the sulphur of it, by the water and alkaline salts; for a plain sulphur is precipitated from it in this manner.

The glass of Antimony only loses its semi-metalline form by the sulphur's having been driven off from the Antimony in calcination; and if it be fused in the fire, and any sulphureous and inflammable matter be added to it, it instantly becomes Antimony again. Nay, this sulphur abounds so much in the common melted Antimony, that an acid, plainly of the kind of that of common sulphur or vitriol, for they are the same, may be produced from it.

The proper solvent of Antimony, in its reguline state, is aqua regia.

Antimony is more easily separated out of its ores than almost any others of the metalline substance. It needs no flux-powders, and the utmost caution necessary is to keep off in a great measure the communication with the external air, and to keep the fire moderate, that part of it does not burn away or go off in vapour. The method of separating it is no more than this: bore three or four holes in the bottom of a crucible, and, filling it half full of broken Antimony-ore, set it in another crucible, and cover it with a tile; lute all the junctures with some Windsor loam or any common lute, and set these vessels, thus joined, on the hearth. Place some stones or bricks round them at six inches distance every way, and fill up the intermediate space with ashes up to the rim of the lower crucible; then put burning charcoal about the upper crucible, and blow it till it be red-hot; keep it so a quarter of an hour, and then let all cool. The melted Antimony will be found in a striated mass in the lower vessel.

Antimony has had various names among the writers of the several ages, and chymists have added to these a number of fantastical ones, expressive either plainly or metaphorically of its qualities. We generally call it antimonium or stibium. The Greeks called it stimmi, and sometimes alabastrum. And, in the writings of Hippocrates in particular, it seems to stand under the name of tetragonon. Pliny calls it lapis spumæ candidæ nitentisque non tamen translucentis, and the Arabians antimad or atemed. The chymists, from its power of destroying other metals, call it lupus vorax, the voracious wolf, and saturnus, from the name of the god who was said to eat his own children. They have also called it plumbum sapientum, the lead of the wise men, from its performing the office of lead only more perfectly in the purifying of gold; and some of them magnesia saturnina. They also call it lavacrum solis.

The character they denote it by is this ♁, a circle, denoting the body to be gold, to which a cross is added, to shew it very corrosive at top.

Antimony is not only given in substance, but a great many preparations of it are in common use in medicine; they are either emetic, cathartic, diaphoretic, or sudorific. Crude Antimony, in powder, is found of great benefit in dissolving viscidities in the fluids; it gives relief in cutaneous diseases, and, as some very confidently assert, in convulsions and epilepsies. Externally, in ointments, it is much commended for drying up ulcers, and for curing the itch, and other diseases of the skin, and in plaisters for resolving of tumors. With the antients it was in frequent use among the cosmetics, being the most esteemed substance for tinging the eye-brows black. This practice is even as old as the Old Testament, for we find Jezebel, and others of the Israelitish women, censured cenfured for this ufe of it: the Greeks gave it two new names on this account, calling it gyraicon and platyophthalmon, from its making the eye-brows appear broader than they naturally are.

Diofcorides, and the older Greeks, feem to have been but imperfectly acquainted with its virtues internally; they tell us it was aftringent and cooling, but that it was apt to obftruct the paffages. They ufed it frequently in collyriums for the eyes, when they meant to dry up redundant humours, and alfo in old ulcers. They calcined it, in order to prepare it for ufe, and made it into paftils with the milk of a woman's breaft; thefe were ufually of a fquare form, and hence the name of tetragonon feems to have been given it by Hippocrates. The Greeks do not feem to have known any thing of it in any other intentions than thefe.

Its virtues, as a purge, became known in the twelfth century, at which time Bafil Valentine publifhed his book, entitled Currus Antimonii Triumphalis, in which he extols it as a remedy for almoft all difeafes. In the fifteenth century, Paracelfus brought it yet more into ufe. It was even after this, however, a difputed point a long time among the phyficians, whether Antimony were a falutary or a poifonous medicine. At prefent we are, however, very well fatisfied of its falutary effects, and know of two very different qualities in it, according to the different form it is given in, a purge and a diaphoretic. All the preparations of Antimony operate either by ftool or vomit, or by infenfible perfpiration or fweat. There appears no reafon in the world for people's ever having been afraid of giving the crude Antimony internally; we daily fee it taken in large dofes, a drachm or more at a time, and that for a long continuance, without any bad fymptom, or even the leaft naufea, unlefs, by accident, the acid of the ftomach fhould be ftrong enough to prove a menftruum to it. *Hill's Hift. Mat. Med.*

Golden fulphur of ANTIMONY, *fulphur auratum antimonii*—Boil the fcoriæ of Antimony, till they are all diffolved; into the inodorous liquor drop vinegar, and there will inftantly arife a moft noifome, ftercoraceous fmell, and the liquor, which before was thin, will become very thick. Drop in more vinegar, ftir the mixture about, and proceed in this manner, till nothing more will precipitate. Let the veffel ftand quiet, and a precipitate will gradually fubfide to the bottom, which will be reduced to a much lefs compafs than one would expect. Pour off the liquor that fwims at top; wafh the precipitate with water, till it is abfolutely infipid; dry it gently, and keep it under the title of fulphur auratum antimonii.

Remarks.

The fulphur of Antimony, mixed with an alcali, makes the fcoriæ of Antimony. Thefe, boiled in water, make a fulphureous lixivium; and from this, by the acid, the fulphur is precipitated. This has a mild emetic quality. If this is rubbed upon filver, it makes it of the colour of gold, and hence it is called auratum. *Boerhaave.*

Glafs of ANTIMONY, *vitrum antimonii.*—Take of powdered Antimony one pound, calcine it with a gentle fire in an unglazed earthen veffel, continually ftirring it with an iron fpatula till the fumes ceafe, and the Antimony is reduced to a grey powder; melt this powder with an intenfe fire, and pour the fufed matter on a heated plate of copper.

Diaphoretic ANTIMONY, *antimonium diaphoreticum*, called, alfo, *fweet Antimony.*—Take any quantity of calcined Antimony. Reduce it to a fine powder, pour hot water upon it, and ftir them about with a ftick, by which means the fixing nitre, that adheres to it, will be diffolved. Let the white calx fubfide, pour off the faline liquor, put on more water, and thus render the calx perfectly fweet, fo that there fhall be no nitre fenfibly adhering to it; and then dry it, and it will be white, infipid, and heavy, and is the thing you want.

Remarks.

This is called diaphoretic, but it is an inert, noxious calx, without any thing active in it, as far as one can judge by its effects, and wants every thing valuable it had before. It acts only in a fenfible manner, when it is mixed with half as much of a purgative; for then it truly quickens its operation, as appears by undoubted experiments in the pulvis Cornachini: But, otherwife, I diffuade the ufe of it. How furprifingly are the colours changed in the Antimony, by fimply varying the proportion of the nitre in the calcination? And what a furprifing alteration do we find in the ftrength? *Boerhaave's Chem.*

Kermes mineral, or *pulvis Carthufianorum.*— Take of Antimony four pounds, rain-water three pounds, and boil them for two hours. Then the boiling decoction is to be paffed through cap-paper, and fet in a quiet place for twenty-four hours, till a yellowifh or faffron-coloured powder finks to the bottom of the veffel, the liquor remaining clear. This liquor being poured off by inclination, the powder is to be firft wafhed by the frequent affufions of warm water, till it is deprived of all its falts; and then about four ounces of fpirit of wine burnt upon it, and afterwards dried, and kept for ufe.

This powder is looked upon as a kind of panacea, or univerfal remedy. It fometimes excites vomiting, efpecially when it meets with an acid in the ftomach, and is fometimes cathartic, diaphoretic, and fudorific, according as it is determined, by the difpofition of the patient, to act upon any one humour more than other. It is given from one to four grains, or, fometimes, when it is defigned only to attenuate and divide any vifcidities in the fluids, in the quantity of half a grain, repeated every three, four, or fix hours. In acute fevers, where there is a great crudity and fpiffitude of the humour, it is given in fmall dofes with fuccefs. It changes the crude and ferous evacuations by ftool, into a more bilious confiftence, by attenuating the vifcid bile, and fo difpofing it to pafs off by ftool. It is often given with fuccefs in the beginning of the fmall-pox and meafles, when they are apprehended to be of a bad kind, in fmall dofes mixed with bezoartic powders, or abforbents, fuch as crabs-eyes, red coral, pearl, egg-fhells, crabs-claws, and the like; for thus it excites a fpitting and diaphorefis, removes anxieties, corrects the lympha and coagulated ferum, and raifes fuch an effervefcence in the blood as tends to purify it. Glauber confirms thefe virtues by the examples of feven children in the fmall-pox. Frederic Hoffman commends the ufe of this powder in ftubborn autumnal agues, becaufe it powerfully opens obftructions, particularly of the liver, by which thefe fevers are produced, efpecially when taken in the quantity of a grain, mixed with detergent anti-febrile falts; fuch as the falt of wormwood, the febrifugous falt of Sylvius, vitriolated tartar, and the like.

It is, however, to be carefully obferved, that this powder is not to be given till the quantity of blood has been leffened, and all the fluids fufficiently diluted and attenuated; for, as by the ufe of it the blood is fuddenly rarefied, and put into a kind of effervefcence; if the veffels are before full, they muft be ftill more diftended, by the increafed heat and motion of the blood and other fluids, and hurtful congeftions may be formed in the vifcera. It ought, therefore, never to be given, till the dangers from a plethora are taken off, and till the humours have been rendered fluid by great quantities of diluents often repeated.

The lixivium in which Antimony has been boiled, paffed through cap-paper, is recommended by fome in fcabs, and other difeafes of the fkin. *Geoffrey.*

Vitrum ANTIMONII *ceratum.*—Take a glafs of Antimony in powder, one ounce; bees-wax, one drachm: melt the wax in an iron ladle; then add the powder; fet them on a flow fire without flame, for the fpace of half an hour, continually ftirring them with a fpatula; then take it from the fire, pour it upon a piece of clean white paper, powder it, and keep it for ufe. After it has been about twenty minutes in the fire, it begins to change the colour; and, in ten more, comes pretty near the colour of fnuff: by that colour I know it is fufficiently prepared, without attending to the degree of heat, or fpace of time.

Of all the preparations of glafs of Antimony this, which is given by Dr. Pringle in the Edinburgh medical effays, is doubtlefs the moft perfect; for it is infinitely fuperior to the chylifta of Hartman. This chylifta is nothing more than a glafs of Antimony well pounded, and opened by acids, and then digefted in fpirit of wine impregnated with maftic; which never can cover the particles of this glafs with coats of equal impenetrability with thofe formed by wax bituminized by burning.

This medicine fucceeds equally in bloody-fluxes, diarrhœa's, fimple loofneffes, quartan agues, even the moft obftinate, and in certain cafes of the fluor albus.

It muft be given with caution, beginning with a very fmall dofe, as one, two, or three grains, efpecially when it has been levigated again after its calcination: and thus it may be fafely given to children, and even to pregnant women.

In giving it to robuft perfons, I always began by a fmall dofe, as four or five grains, which I gradually increafed to eighteen, according to the effects produced by lefs confiderable dofes. By gradually increafing the dofe of this medicine, I have given as far as twenty-four grains at a time, which had no other effect, but to procure two or three moderate ftools the next day: but in this cafe it would be imprudent to continue its ufe, without interruption; becaufe, as it paffes flowly, the dofe may poffibly unite with the firft, at the time that it begins to operate; and thefe two dofes thus joined might caufe a fuperpurgation, which is always to be dreaded.

I fhould never have ventured to give this medicine to pregnant women, if chance had not convinced me, that it is not more dangerous for them than for others, when given with caution. For, among feveral women whom I have cured of bloody-fluxes with this medicine, there were fome that were actually with child, and did not know it themfelves, at the time of their taking it. They were all cured, and no accident happened to any of them.

When the patient has been purged too violently by one of the firft dofes of this medicine, which are always fmall, it is a proof of the weaknefs of the patient; and then I give it to him but every fecond or third day. The diftance of time obferved between the dofes of this medicine makes it operate lefs brifkly, and more equally.

When the vitrum Antimonii ceratum vomits, the patient is to drink warm water at every motion.

When the dyfenteric flux is attended with fharp pains in the abdomen, with heat and tenfion, the vitrum Antimonii is not to be given, till the pains are removed by emollient clysters, and other proper remedies.

I have not observed any difference in the effects of this medicine, whether the patient had, or had not, been bled or purged; whether the disease were recent, or of long standing; whether in fine it were attended with a fever, or not. They were all cured equally well, agreeable to what is said in the Edinburgh observation.

The vitrum Antimonii ceratum is a good febrifuge. Three or four days use of this medicine generally suffices for removing the fever accompanying diarrhœa's, loosenesses, &c. But, in order to its having this effect, it must either purge or vomit the patient; otherwise it cures the looseness, but the fever continues, and requires a very long use of the medicine to cure it. When it operates in a sensible manner, it generally gives the patient an appetite, when he is near being cured: but the weakness of his stomach does not allow his giving way to it, without running great risks.

When this remedy operates a cure without producing any visible effects, it would be dangerous to increase the dose till it causes evacuations; for, unless the patient be of a strong constitution, you endanger the bringing on a hypercatharsis. Moreover I have observed, that the fineness of the powder has a great influence on the manner of its operation. That, which is very fine, is much more active, than that which is somewhat less so: for example, a grain of the vitrum Antimonii ceratum reduced to a very fine powder will have more force and action, than two grains of the same glass reduced to a powder somewhat less fine. Wherefore I always preferred the first sort, as productive of more certain effects, and less incommoding the stomach.

The vegetable acids develope and increase the emetic quality of this medicine to such a degree, that you would always put the patient's life, who takes it, in great danger, if you did not absolutely forbid him the use of acid fruits, and aliments that are liable to turn sour, as milk, wine, &c.

In obstinate quartan intermittents, which had resisted the most powerful febrifuges, I have given this medicine on the two days of intermission, omitting it the day of the paroxysm; and continuing it thus, and increasing the dose very gradually, the paroxysms grew considerably weaker; and generally the fourth did not return. The patients, whom I cured in this manner near a year ago, have never had the least return of the fever.

Excepting in the cases of fevers, all the patients, who used the vitrum Antimonii ceratum, drank habitually of a ptisan made with rice, oatmeal or hartshorn. These ptisans prevent the pains of the stomach, which this medicine sometimes occasions. *Geoffroy.* See *Philos. Transact.* Vol. 47. p. 273.

ANTIO'CHIAN *Epocha*, a method of computing time from the proclamation of liberty granted the city of Antioch about the time of the battle of Pharsalia. *Strauch. Brev. Chronol.* l. 4. c. 34.

It is disputed among chronologers, whether the Antiochian epocha commences in the spring or the autumn before the battle of Pharsalia. The chronicle of Alexandria fixes it to the former; Scaliger and Calvisius to the latter. In the first year of the epocha began the first indiction; so that the Antiochian years being divided by fifteen, the remainder shews the true character of the cycle of indiction.

ANTI'PATHY is used, in painting, for an opposition between the qualities of colours. *Du Piles Conversat. sur la Connois. de la Paint.*

This Antipathy is chiefly observed between colours, which endeavour, as it were, to predominate over each other, and which, by their mixture, destroy each other, e. gr. ultramarine and vermilion. This does not obtain the clair obscure; for though there be nothing more opposite to each other than black and white, as the one represents light, and the other darkness; yet they each preserve themselves in the mixture, and form together a grey, which partakes of both.

ANTIPERISTA'LTIC *(Dict.)*—The cause of the Antiperistaltic motion is usually assigned to be a stoppage of some of the intestines, but chiefly of the ilium.

The mechanism whereby it is effected, differs in nothing from that which produces the peristaltic motion, except in the determination of the motion, which in iliac cases prevents the fæces from proceeding on to the anus; so that the motion is peristaltic from the stomach to the place of obstruction; but when the fecal matters are arrived there, they give rise to an Antiperistaltic motion, by occasioning a great influx of spirits into the fleshy fibres adjoining; these, being contracted, of course will compress, and propel the contents and chylous matters towards that side where there is the least resistance, which will be upwards, since an insurmountable obstacle is supposed downwards: consequently they must rise to the fibres next above, which, being contracted in their turn, will raise them a step further, till, by degrees, they have reached the pylorus, whose valve, being forced, admits them into the cavity of the stomach, from whence they continue their ascent to the mouth.

Some late ingenious authors have overturned the whole Antiperistaltic system, and shewn this motion imaginary, as well as unnecessary, for accounting for these disorders. Mess. Chirac and Du Verny have endeavoured to prove this, in respect to vomiting; and M. Haguenot, and after him M. St. Andre, in the iliac passion.

ANTIPERI'STASIS *(Dict.)* — Antiperistasis is usually defined "the opposition of a contrary quality, whereby the "quality it opposes becomes heightened, or intended: or "the action whereby a body, attacked by another, collects "itself, and becomes stronger by such opposition: or an in"tention of the activity of one quality, caused by the oppo"sition of another."

Thus cold, say the school-philosophers, on many occasions, exalts the degree of heat, as dryness that of moisture.

Thus it is, that quick-lime is set on fire by the affusion of cold water: so water becomes warmer in winter than summer, by Antiperistasis: and to the same cause it is owing, that thunder and lightning are excited in the middle region of the air, which is continually cold.

This Antiperistasis is a principle of great use and extent in the Peripatetic philosophy. "It is necessary," according to the authors of that class, "that cold and heat be both of them "endued with a self-invigorating power, which each may "exert, when surrounded by its contrary; and thereby pre"vent their mutual destruction. Thus it is supposed, that, "in summer, the cold, expelled from the earth and water by "by the sun's scorching beams, retires to the middle region "of the air, and there defends itself against the heat of the "superior and inferior air. And thus, also, in summer, "when the air about us is sultry hot, we find that cellars and "vaults have the opposite quality: so in winter, when the "external air freezes the lakes and rivers, the internal air, in "the same vaults and cellars, becomes the sanctuary of heat; "and water, fresh drawn out of deep wells and springs, in a "cold season, not only feels warm, but manifestly smokes."

Mr. Boyle has canvassed this doctrine thoroughly, in his history of cold.—It is certain, that a priori, or considering the reason of the thing, abstracted from the experiments alledged to prove an Antiperistasis, it appears highly absurd; since, according to the course of nature, one contrary ought to destroy, not to strengthen another: besides, that it is an axiom, that natural causes act as much as they can; which, as to inanimate creatures, must be allowed physically demonstrative, in regard these act not by choice, but by a necessary impulse.

It is commonly, indeed, alledged, as a proof of a power nature has given bodies of flying their contraries, that drops of water, falling on a table, collect into little globules, to avoid the contrary quality of the table, and keep themselves from being swallowed up by the dry wood: but this we can account for on more intelligible principles, viz. the power of attraction and repulsion. As to the Antiperistasis of cold and heat, the Peripatetics talk of those qualities being surrounded by their opposites, as if each of them had an understanding and foresight, that in case it did not gather up its spirits, and guard against its antagonists, it must infallibly perish; which is to transform physical agents into moral ones.

In effect, not only reason, but experiment also, concludes against the notion of an Antiperistasis; the leading argument, urged in the behalf of it, is, the heating of quick-lime in cold water; now, who can sufficiently admire at the laziness and credulity of mankind, who have so long and so generally acquiesced in what they might so easily have found to be false? For if, instead of cold water, the lime be quenched with hot water, the ebullition will, oftentimes, be far greater than if the liquor were cold.

Again, in freezing a bason to a joint-stool, with a mixture of snow and salt, by the fire-side, it is pretended, that the fire so intends the cold, as to enable it to congeal the water that stagnated upon the surface of the stool, betwixt that and the bottom of the vessel. But how little need there is of an Antiperistasis in this experiment appears from hence, that Mr. Boyle has purposely made it with good success, in a place where there neither was, nor ever probably had been a fire.

The patrons of an Antiperistasis usually plead that aphoristical saying of Hippocrates, "the viscera are hottest in winter," in behalf of their own opinion: but the only proof of such greater heat is, that men then have a greater appetite; so that the aphorism supposes digestion to be made in the stomach by heat, which is easily refuted.

Another argument, urged in favour of an Antiperistasis, is borrowed from the production of hail, which is presumed to be generated in summer only, not in winter; and, according to the schools, is made in the lowest region of the air, by the cold of the falling drops of rain being so highly intended by the warmth they meet with in the air near the earth, as to congeal into a solid form.

As to refreshing coldness which subterraneous places afford in summer, it may be denied that they are then really colder than in winter; though, if the contrary were allowed, it would not necessarily infer an Antiperistasis.—It is certain, the smoking of waters, drawn from deep places in frosty weather, do not necessarily infer such water to be warmer than at other times when it does not smoke; since that effect may proceed, not from the greater warmth of the water, but from the greater coldness of the air. For a man's breath in summer, or in mild winter weather, becomes very visible;

sible; the cold ambient air suddenly condensing the fuliginous steams discharged by the lungs, which, in warm weather, are readily diffused, in imperceptible particles, through the air.

ANTIPHRASIS.—Sanctius defines Antiphrasis to be a form of irony, whereby we say a thing, by denying what we ought rather to affirm it to be; Antiphrasis est ironiæ quædam forma, cum dicimus negando id quod debuit affirmari.—As when we say, it did not displease me, or, he is no fool; meaning, I was pleased with it, or, he is a man of sense.—On this principle, the Antiphrasis ought to be ranked among the figures of sentences, and not among those of words.

It is a common error to make Antiphrasis consist in single words; as when we say, that the parcæ are thus called by Antiphrasis, because they spare nobody, parcæ, quia nemini parcunt.—St. Jerom, in his epistle to Riparius against Vigilantius, says he ought rather to be called Dormitantius per Antiphrasin, than Vigilantius, because he opposed the Christians holding wakes at the tombs of the martyrs.

Sanctius holds it improper to call these Antiphrases; by reason, phrasis is not applicable to a single word, but signifies orationem, aut loquendi modum.

ANTIPHTHISICA *, in pharmacy, a remedy against a consumption.

* The word is formed from the Greek ἀντὶ, against, and φθίσις a phthisis, or consumption.

Tinctura ANTIPHTHISICA, a tincture against a consumption; which is prepared as follows:

Take of saccharum saturni, and vitriol of iron, each an ounce; French brandy, a pint; and, without heat, draw a tincture. *Edinburgh Disp.*

Quincy, in his English Dispensatory, gives it thus:

Take salt of steel, and saccharum saturni, each four ounces; put them into a matrass with two pints of good French brandy. Twenty hours digestion will make a beautiful tincture.

This is by some accounted a specific in hectic fevers; and it is not an unlikely medicine in such cases, because it will astringe and draw up the fibres, whereby their tone will be rendered more rigid, and the pores and secretory passages streightened, so that the juices and nourishment itself will not so soon run off by those ways. It will also procure a firmer texture to the blood itself, which, in those diseases, is almost fused and broken. This is also good in many hysterical affections.

ANTOFLE *of cloves*; thus they call cloves which remain by chance upon the clove-trees, after the cloves are gathered. The fruit, thus left upon the tree, continues to grow, and becomes an inch thick. The Dutch call them the matrix, or womb, of cloves, or mother-cloves. They are pretty much used in physic, but the apothecaries often put common cloves instead of them, though the virtues and smell of both are very different.

ANTIPODES (*Dict.*)—The Antipodes have nearly the same degree of heat and cold, days and nights of equal length, but in opposite seasons. It is noon to one, when midnight to the other; and the longest day with the one, when shortest with the other.

We have said the Antipodes have nearly the same degree of heat and cold, not absolutely the same of necessity. Because, first, there are many accidents to modify the action of the solar heat, so that people, situated in the same climate, have not the same temperature of air. This may in general be accounted for by the interposition of mountains, the nearness or distance of the sea, the winds, &c. Secondly, the sun is not throughout the whole year at the same distance from the earth; it is sensibly at a greater distance in the month of June, than in January; from whence it follows, that, consideratis considerandis, our summer in England is not so hot as that of our Antipodes, and our winter less cold. Nay, ice is found, in the seas of the southern hemisphere, at a much less distance from the equator, than in those of the northern hemisphere.

The horizon of the one place being 90 degrees distant from the zenith of the other, it follows, that the Antipodes have the same horizon; it follows also, that, when the sun rises to the one, he sets to the other.

Plato is esteemed the first who thought it possible that the Antipodes subsisted, and is looked upon as the inventor of the word. As this philosopher apprehended the earth to be spherical, he had only one step to make, to conclude the existence of the Antipodes.

The ancients, in general, treated this opinion with the highest contempt; never being able to conceive how men and trees could subsist suspended in air with their feet upwards; for so they apprehended they must be in the other hemisphere.

They never reflected that these terms, upwards, downwards, are merely relative, and signify only nearer to, or farther from the center of the earth, the common center to which all heavy bodies gravitate; and that, therefore, our Antipodes have not their feet upwards and heads downwards any more than ourselves; because they, like us, have their feet nearer the center of the earth, and their heads farther from it. To have the head downwards, and feet upwards, is to place the body in a direction of gravity, tending from the feet to the head; but this cannot be supposed with regard to the Antipodes; for they, like us, tend towards the center of the earth, in a direction from head to foot.

If credit may be given to Aventinus, Boniface, archbishop of Mentz and legate of pope Zachary, in the eighth century, declared one Virgil, a bishop in that age, a heretic, for having dared to maintain there were Antipodes.

As some people make use of this transaction, to turn the infallibility of the church into contempt, an anonymous author has called in question the truth of the fact in the memoirs de Trevoux.

The only authority, says this anonymous author, on which the truth of this fact can be supported, as tradition has transmitted it to us, is a letter of pope Zachary to archbishop Boniface: "If it be proved, says pope Zachary, in this letter, that Virgil maintains there is another world and other men under the earth, another sun, and another moon; call a council, condemn him, excommunicate him, after having degraded him from the priesthood, &c." This author asserts, that this order of pope Zachary was never carried into execution, and that Bonifice and Virgil lived afterwards in a very good understanding with each other; and that Virgil was even canonized by this very pope.

But the anonymous author goes yet farther: Admitting, says he, this story for a matter of fact, the pope cannot be accused of having acted contrary to truth and justice. For, says he, the notions they entertained of the Antipodes, were very different from our's. "Mathematical demonstrations gave rise to philosophical conjectures. Philosophical conjectures supposed the sea formed two great circles round the earth, which divided it into four parts; that the vast extent of the ocean and excessive heat of the torrid zone cut off all communication between those parts; so that it was impossible the inhabitants should be of the same species, or proceed from the same origin as ourselves. Thus much only, says this author, was understood, at that time, about the Antipodes. In this manner the anonymous author endeavours to justify pope Zachary; but the arguments he urges seem by no means conclusive. For pope Zachary's letter contains these words: "If Virgil maintains that there is another world and other men under this earth, condemn him." The pope therefore admitted of no Antipodes, and looked upon it as an heresy to assert any such thing. It is true, he adds these words, another sun, another moon. But, 1st, whoever asserts the existence of Antipodes, may very well advance they have another sun: What is more common than this expression, 'the sun in Ethiopia and England is not the same? Does this import any thing more, than that the action of the sun is different? That the moon of March and September are different, &c. so these words, another sun, another moon, might, both according to Virgil and the pope's letter, have a very simple, true, and obvious meaning. These words, "another sun under our earth," no more signify two suns than these words "Another world under our earth," signify another earth under our's.

It is indeed more than probable all Virgil meant was, that there were Antipodes; because, by allowing the earth a spherical form, and admitting the existence of the Antipodes, it is a necessary consequence they should have the same sun as we, to give them day, while it is night with us.

The anonymous author, in the following part of his dissertation, suppresses these words "under our earth," and pretends that pope Zachary did not deny the Antipodes, but only that there were other men, another sun, another moon. 2dly, on a supposition Virgil had maintained the real existence of another sun and moon for the Antipodes, in this he had only committed a gross error in natural philosophy, but seems not in my opinion to fall justly under the censure of heresy; and, in case the pope had a mind to condemn it as such, he ought to have distinguished between the pretended heresy, and the truth which Virgil asserted with regard to the existence of Antipodes, and not have jumbled together, in the same phrase, these words "other men under our earth, another sun and another moon."

What are we therefore to infer from what the anonymous apologist for pope Zachary advances, with regard to the general opinion concerning the existence of Antipodes, but that the pope fell into and followed a vulgar error, and on that score condemned poor Virgil as an heretic, for having maintained a truth in opposition to a received opinion? In fact, the good understanding, whether true or pretended, in which Boniface and Virgil lived afterwards, does not prove that pope Zachary was infallible, in condemning Virgil for an heretic, about the Antipodes; and, if Virgil recanted, so much the worse for him.

In the whole course of this argument we admit every thing for fact which the anonymous author relates; but at the same time are sensible it is the more generally received opinion, that the pope actually condemned Virgil for maintaining the existence of Antipodes; and perhaps this is the truth; but the question is of too little importance to be enquired into, whether it be a matter of fact or no.

It is surprizing, that the anonymous author of the apology did not hit on a shorter and wiser method, by passing over this

this whole affair, and ſhewing, that this miſtake of pope Zachary's in natural philoſophy is no argument againſt it. We maintain the earth's motion; the holy writings in general ſeem to attribute this motion to the ſun; becauſe, in matters where points of faith are not concerned, the ſcripture conforms to the common methods of expreſſion. So that, though the pope might be deceived in a queſtion of coſmology or natural philoſophy, we can by no means conclude from thence, that the church and general councils that repreſent it, were guilty of errors in matters of faith; this reply is very ſufficient, and we wonder how it eſcaped the anonymous author.

As to the ſentiments of the primitive Chriſtians, with regard to Antipodes; ſome, rather than admit the concluſions of the philoſophers, abſolutely denied the whole, even the demonſtrations of the geometricians relating to the ſphericity of the earth: which is Lactantius's way, Inſtit. lib. 3. c. 24. Others only called in queſtion the conjectures of the philoſophers: which is St. Auguſtine's method, de Civit. Dei, lib. 14. c. 9. After putting the queſtion, whether there ever were nations of Cyclops, or Pigmies, or of people whoſe feet ſtood outward, &c. he comes to the point of Antipodes, and aſks, "whether the lower part of our earth be inhabited by Antipodes?" He made no doubt of the earth's being round, nor of there being a part diametrically oppoſite to our's; but only diſputes its being really inhabited. And the conſiderations he ſuggeſts for that purpoſe are juſt enough: as, that they who aſſerted Antipodes, had no hiſtory for it; that the lower part of the earth may be covered with water; and that to place Antipodes there, of a different origin from us (as muſt have been the opinion of the ancients, ſince they thought it impoſſible to go from our world to their's;) is to contradict ſcripture, which teaches, that the whole race deſcended from one man. Such are the ſentiments of that father.

It may be added, that the Chriſtian fathers were not the only perſons who diſputed the truth of Antipodes. Lucretius had done it before them, at the end of his firſt book, v. 10. 63, &c. See alſo Plutarch, lib. de facie in orbe lunæ; and Pliny, who refutes the opinion, *lib.* 2. c. 65.

We have conſidered the Antipodes here, as being placed diametrically oppoſite on the terreſtrial globe, ſo that a perpendicular or vertical line being drawn through any place whatever, and which, conſequently, paſſes through the zenith of that place, the oppoſite part on the ſurface of the globe, which this vertical line continued would cut, is the ſituation of the Antipodes to that place; this depends on a ſuppoſition of the earth's being a perfect ſphere; for if the earth be not a perfect ſphere, but is an oblate or prolate ſpheroid, there are no reciprocal Antipodes. That is, for inſtance, if a line be drawn through the zenith of London, and center of that city which is in the northern hemiſphere, this line would cut the ſouthern hemiſphere in a point which will be diametrically oppoſite to London, but London then will not be the Antipodes to this place: thus the reciprocal equality of ſituation, latitude, day and night, in the oppoſite hemiſpheres at ſix months diſtance, and all that we are uſed to include in the idea of Antipodes, as inſeparable from it, is no longer ſo; and muſt alter, in proportion as the figure of the earth deviates from a true ſphere. A little attention will convince us of this.

What we have advanced is founded on this poſition, that the ſphere, or, to render the theory more ſimple, the circle, is the only regular figure, which all diametrical lines drawn through the center cut at right-angles. Therefore, in every figure terminated by another kind of curve, to inſtance in the ellipſis, the perpendicular drawn to one of its foci or to its tangent, except the two axes which correſpond to the polar line, or a diameter drawn at the equator, will not paſs through the center, nor cut the oppoſite part of the ellipſis at right-angles; therefore the nadir of Paris or London is not the zenith of their reſpective Antipodes. So if, in the center of London or Paris, a perpendicular column were erected, and another in their reſpective Antipodes, it would not make the ſame right-line, but would form an angle more or leſs acute, in proportion as the ellipſis departed more or leſs from a circle; and, conſequently, the latitude, days, nights, ſeaſons, &c. would alter in the ſame proportion. Places ſituated under either pole, or on the equator, are excepted for the reaſon we have before ſuggeſted; becauſe, in the former caſe, it is one of the axes of the ellipſis that joins both foci, and in the latter it is always a circle, the other axis of which is the diameter of the ellipſis: the ſpheroid, however oblate or prolate, being always ſuppoſed to reſult from the revolution of the elliptical meridian round the axis of the world. See *Hiſt. Acad.* 1741.

ANTIPTOSIS *, a figure in grammar, by which, as it is commonly ſaid, one caſe is put for another.

* The word is derived from ἀντὶ, for, inſtead of, and πτῶσις, caſe.

Examples, produced of this kind of figure by the grammarians, are numerous; from Virgil, *Æneid.* V. verſe 451. It clamor cœlo, inſtead of ad cœlum. Terence, in the prologue to the Andria, ſays, Populo ut placerent quas feciſſet fabulas, inſtead of fabulæ, &c. But Sanctius, Voſſius, Perizonius, and other grammarians, who have attended to the rationale of grammar, though it muſt be owned the number is ſmall, have branded this figure in rhetoric with the name of an abſurdity, and juſtly too; becauſe admitting it into uſe would overturn ſyntax, and render the regimen of verbs unworthy attention; a ſcholar might juſtify his error, in this point, to a maſter, by an Antiptoſis, ſays Sanctius, lib. 4. cap. 13. "Figura hæc Latinos canones excedere videtur, nihil imperitius, quod figmentum ſi eſſet verum, fruſtra quæreremus quem caſum verba regerent." "This figure ſeems to leap over all grammar rules, for, if this be admitted, the government of verbs needs not be attended to." Under the word CONSTRUCTION we ſhall endeavour to ſhew what figures ought to be admitted.

The ſame thought may be expreſſed in a different manner, but we muſt always have regard to propriety of language; thus we meet with urbs Roma, the city Rome, by appoſition, on account of the identity, where urbs is uſed adjectively, and muſt be explained urbs quæ eſt Roma, the city which is Rome. In Cicero we find this paſſage, urbs Romæ in oppido Antiochiæ; in Virgil, Butroti aſcendimus urbem; in both theſe paſſages urbs repreſents the ſpecies, the names Roma and Butrotum the particular city.

In theſe different methods of expreſſion, if we meet with any thing which the grammarians ſolve by an Antiptoſis, we ought firſt to enquire whether the copyiſt has not committed ſome blunder in the text, and afterwards, without having recourſe to ſo irrational a figure, ſee if the expreſſion be of ſufficient authority, and whether we can reconcile it to propriety of language, and always give the preference to that which is uſed by the beſt authors.

But to explain this, and ſhew the abſurdity of the figure Antiptoſis in the examples already quoted, which will account for all others of the ſame kind. With regard to it clamor cœlo, the verb is put acquiſitively; and, therefore, cœlo in the dative caſe, inſtead of ad cœlum, which is an elegant and natural ſyntax. In the paſſage cited from the prologue to Terence's Andria, "Populo ut placerent quas feciſſet fabulas," we muſt conſider the relative qui, quæ, quod, to have ſome antecedent, and baniſhing ſo abſurd a figure as the Antiptoſis, ſolve it by the ellipſis to be ſupplied in this manner, ut fabulæ, quas fabulas feciſſet, placerent populo.

ANTIQUE, a term moſt in uſe among architects, ſculptors, and painters: they make uſe of it to expreſs pieces of architecture, ſculpture, or painting, executed, in the ages when thoſe arts were carried to the higheſt perfection, by men of the fineſt genius in Greece and Rome; that is, from the age of Alexander the Great to the reign of the emperor Phocas, about, the year of our Lord 600, when Italy was over-run by the Goths and Vandals.

Antique in this ſenſe is oppos'd to modern; thus we ſay an Antique edifice, buſto, baſſo relievo, or manner; an Antique model; and of a ſtatue, that it is in an Antique taſte.

We have ſeveral Antique pieces of ſculpture left, as the Laocoon and Venus in poſſeſſion of the family of Medicis, the Apollo and Hercules of the houſe of Farneſe, &c.

Antique paintings are more ſcarce; we have only the wedding of Aldobrandinus, ſome little figures of the pyramid of Ceſtius, a Venus which is the palladium of Rome, and ſome ſmall pieces in freſco, preſerved out of the ruins of the baths of Titus and Heraclius.

Some ſculptors have counterfeited Antiques ſo nicely as to impoſe on the judgment of the public; witneſs the famous ſtory of Michael Angelo's Cupid, which we have related in the preface to the Dictionary.

Antique is ſometimes diſtinguiſhed from ancient, which means a leſs degree of antiquity, a time when the art was not in its higheſt perfection. Some writers uſe a compound word antiquo-modern in ſpeaking of old Gothic churches and other buildings, which they would not confound with thoſe of the Greeks and Romans.

ANTIQUITY, *antiquitas*; we make uſe of this term to denote paſt ages.

In this ſenſe we ſay, the heroes of Antiquity, traces or veſtigia of Antiquity, monuments of Antiquity.

We make uſe of the ſame word, to expreſs what is left us of the ruins, monuments, remains, &c. of the ancients.

In this ſenſe we ſay a maſter-piece of Antiquity; a fine piece of Antiquity; Italy, France, and England are full of Antiquities.

Antiquity is taken alſo for the ancientneſs of any thing, or the time it has ſubſiſted.

In this ſenſe we ſay, the Antiquity of a kingdom, a cuſtom, or any thing of the like nature. Moſt nations pretend to a greater Antiquity than they can prove. We may ſay, that the preſent time is the age of the world, and that, in thoſe times which we call ancient, the world was only in its infancy.

We read in Plato, that Solon learned from an Egyptian, that the Antiquity of the Athenians was 9000 years, of the Saides 8000. Pomponius goes farther back ſtill, following the traces of Herodotus; reckons 330 kings before Amaſis, and ſo concludes the world to be above 13000 years old. Diodorus Siculus reckons an interval of 23000 years, between the firſt king of Egypt and the expedition of Alexander the

the Great. Diogenes Laertius leaves all other writers behind him in the Antiquity of his chronology, and doubles this number of 23000 years. When Alexander went into Egypt, the priests pretended to prove to him by their sacred histories (in which mention was made of the Persian empire which he had just conquered, and the Macedonian empire, which was his birth-right) that they were both 8000 years old. Yet it is demonstrable from the best authors, historians, and chronologists, that the Persian empire, at that time, was of no more Antiquity than 300, nor the Macedonian of more than 500 years.

We need not be surprized that the Egyptians and Assyrians fell into such ridiculous errors in point of chronology, for the Egyptians compute the reigns of their first kings at 4000 years, the Assyrians at 1200 only.

The Chaldeans asserted, in the time of Alexander the Great, that they had made observations of the celestial motions 470000 years, and taken the horoscopes of children born in this prodigious interval of time. But Callisthenes, having been appointed by Aristotle to enquire into these observations they pretended to produce, found they could actually go backwards no farther than 1900 years before Alexander. This is a fact acknowledged by Porphyry, who certainly had never any intention to give authority to the books of Moses.

The study of Antiquity is to a certain degree absolutely necessary, since there are in all authors a great many expressions, allusions, and comparisons, which cannot be understood without it; and it is scarce possible, without it, to make one single step in the perusal of history, without being puzzled with difficulties, which a very slight knowledge of Antiquity would frequently resolve. Let any one but lightly run over the first book of Livy, which, with the origin of the Roman people, contains that of the greatest part of their laws and customs, and he will soon be sensible how useful and serviceable this study is.

This science, however, like all others, if carried too far, has its rocks and dangers. There is a kind of obscure and ill-managed learning, which is employed only upon questions equally vain and frivolous, which seeks only what is most abstruse and uncommon in every subject, being almost wholly confined to the discovery of such things as are absolutely superfluous, and which it is often better to be ignorant of, than acquainted with. Seneca often complains of this bad taste, which taking rise among the Greeks, was got among the Romans, and began to seize upon that nation. He observes, that there is, in point of study, as in every thing else, a vicious excess and intemperance; that it is no less blameable to collect, at a large expence, an heap of useless knowledge, than of superfluous furniture; that this sort of learning is calculated to make men impertinent, foolishly possessed with a notion of their own merit, and at the bottom really ignorant. In applying one's-self to history or Antiquities, we should not carry our enquiries too far, but be guided in this point by prudence and discretion: with this precaution, the study of Antiquity cannot be recommended too much, as it makes a part of learning which is not only suitable to their character, but absolutely necessary for all such persons as are designed by their station to study and teach the belles lettres.

Thus, though Antiquities, and, consequently, the study and reading of antient authors, are things much recommended, yet must we by no means put such an implicit faith in whatever they deliver, if repugnant to reason, or even common-sense or observations, as never to scruple giving up our belief of them, strenuously adhering to all they assert, never contradicting, examining, or refuting their doctrines, &c. Yet has this prevailing humour of extolling every thing that is antique, and passing slightly over the merit of our contemporaries, ever been a grievance, that men of a free and unprejudiced thought have complained of through all ages.

The immoderate respect and adherence to Antiquity is, says Dr. Brown, a general cause of error, and a mortal enemy to knowledge. That which has done the greatest execution upon truth, has been a peremptory adhesion to authority and Antiquity, more especially, the establishing of our belief upon the dictates of it. For most men of the present age so superstitiously look on ages past, that the authorities of the one exceed the reasons of the other; whose persons, indeed, being far removed from our times, their works, which seldom, with us, pass uncontrouled, either by contemporaries, or immediate successors, are now out of the distance of envy; and, the farther removed from present times, are conceived to approach the nearer unto truth itself. But hereby we manifestly delude ourselves, and widely walk out of the track of truth. For men, by these means, impose a thraldom on their times, which the ingenuity of no age shall endure, or, indeed, the presumption of any did ever yet enjoin. Thus Hippocrates, about 2000 years ago, conceived it no injustice, either to examine or refute the doctrines of his predecessors; Galen the like, and Aristotle most of any: yet did not any of these conceive themselves infallible, nor give their opinions as positive verities; but when they either delivered their own inventions, or rejected other men's opinions, they proceeded with judgment and ingenuity; establishing their judgments not only with great solidity, but submitting them also to the correction of future discoveries.

In criticism many pretenders insinuate, that all that is good is borrowed from Antiquity. This is very common in the mouths of pedants, and, perhaps, in their hearts too; but is often urged by men of no great learning, for reasons very obvious. Now, nature being still the same, it is impossible for any in modern life to paint her otherwise than the antients have done; if, for example, one was to describe the general's horse at the battle of Blenheim, as fancy represented such a noble beast, and that description should resemble what Virgil hath drawn from the horse of his hero, it would be almost as ill-natured to urge the description from Virgil, as to reproach the duke of Marlborough for fighting only like Æneas. All that the most exquisite judgment can perform, is, out of the great variety of circumstances wherein natural objects may be considered, to select the most beautiful, and to place images in such views and lights, as will affect the fancy after the most delightful manner. But, over and above a just painting of nature, a learned reader will find a new beauty superadded in an happy imitation of some famous antient, as it revives in his mind the pleasures he took in his first reading such an author. Such copyings as these give that kind of a double delight, when we look upon children of a beautiful couple; where the eye is not more charmed with the symmetry of the parts, than the mind by observing the resemblance transmitted from parents to their offspring, and the mingled features of the father and mother. The phrases of holy writ, and allusions to several passages in the inspired writings, though not produced as proofs of doctrines, add majesty and authority to the noblest discourses of the pulpit. In like manner an imitation of the air of Homer and Virgil raises the dignity of modern poetry, and makes it appear stately and venerable. However, if the antients excel the moderns in any thing, it is only in acuteness of wit and elegance of language, in their poetry and oratory. As for painting and sculpture, music and architecture, some of the moderns certainly equal, if not excel, the best of them, not in theory only, but, also, the practice of those arts: neither do we give place to them in politics or morality; but, in natural history and experimental philosophy, we far excel them. In the purely mathematical sciences abstracted from matter, as geometry and arithmetic, we may certainly vie with them: but, in astronomy, geography, and chronology, we excel them much. No wonder they should out-strip us in those arts which are conversant in polishing and adorning their language, because they bestowed all their time and pains in cultivating them, and had but one, and that their native tongue, to mind. But those arts are by wise men censured as far inferior to the study of things; and to be wholly occupied about them is to fall in love with a picture, and neglect life: and oratory, which is the best of these arts, is but a kind of voluptuary one, like cookery, which sophisticates meat, and cheats the palate, spoiling wholesome viands, and helping unwholesome.—— *Brown's Vulgar Errors. Rollin's Belles Lettres. Ray's Letters.*

ANTIRRHINUM (ἀντίῤῥινον, of ἀντὶ, against, and ῥὶν, the nostrils, as though it represented a nose: it is also called cynocephalus, of κύων, a dog, and κεφαλή, an head; because its fruit resembles the head of a dog) *snap-dragon*, or *calf's snout*, a genus of plants whose characters are:

It is a plant with an anomalous flower, consisting of one leaf, which is divided, as it were, into two lips; the upper of which is cut into two parts, and the under into three parts: out of the flower-cup arises the pointal, fastened like a nail in the hinder part of the flower; which afterwards turns to a fruit resembling a calf's-head, which is divided in the middle by a partition into two cells, in which are contained many small seeds. Botanists enumerate twelve species of this plant.

All the sorts of snap-dragon are pretty ornaments in a garden, and, requiring a very little culture, are rendered more acceptable. They are all hardy plants, and will resist the cold of our winters extremely well, especially if they are planted on a dry, gravelly, or sandy soil; for, when they are planted in a rich moist soil, they will grow very luxuriant for a while, but are very subject to rot in autumn or winter, and are much more susceptible of cold, than when they are in a dry, hungry, rocky soil: they will grow in the joints of old walls, where they may be placed so as to make some abject part of the garden agreeable; for they will continue in flower for several months; and, if the seeds are permitted to shed, there will be a continual supply of young plants, without any trouble.

Where-ever those plants are designed to grow upon walls, or on a rocky barren soil, the seeds should be sown the beginning of March, where they are designed to remain (for if the plants are first raised in a better soil, and afterwards transplanted into those places, they seldom succeed well). When the plants are come up, they will require no other culture but to keep them clear from weeds; and, where they come up too thick, to pull some of them out, so as to give them room to grow. In July these sorts will begin to flower, and will continue flowering till the frost prevents them.

These plants which grow on walls, will be strong, and have woody stems, which will continue two or three years or more. *Miller's Gard. Dict.*

ANTISI'GMA, among the ancient grammarians, signifies one of the notes or sentences affixed to those verses whose order was to be changed.

ANTI'STROPHE, in the ancient drama, implied the stanza repeated by the chorus to the audience on the left-hand; the word being derived from ἀντὶ, against, and στρέφω, to turn. Thus the strophe signifies that stanza or those verses which the chorus sing, turning themselves towards the spectators on the right hand; the Antistrophe means the same stanza sung by the chorus turning themselves towards the audience on the left. In rhetoric, the Antistrophe or epistrophe signify repartee, as, for example, if, after having said the man of such a master, we add, and the master of such a man, this last phrase is an Antistrophe, or expression in reply to the first; a famous passage in St. Paul is expressed in this figure of rhetoric. Hebræi sunt, et ego; Israelitæ sunt, et ego; semen Abrahæ sunt, et ego; 2. Cor. chap. xi. verse 22.

This is also a term used in antient lyric poetry among the Greeks; the Antistrophe made one of the three parts of their ode, the other two were called the strophe and epode. The strophe and Antistrophe always contained an equal number of verses, and those too of the same measure, which could consequently be sung to the same music: but the epode was composed in verses of a different measure, either longer or shorter. The Antistrophe was a kind of answer or relative echo both to the strophe and the epode; the Greeks called these three united a περίοδος, and is the same thing that we should call a song of three stanza's.

ANTITHETA'RIUS, in law, signifies a man who endeavours to discharge himself of the fact of which he is accused, by recriminating and charging the accuser with the same fact. This word is mentioned in the title of a chapter in the laws of Canutus, cap. 47. *Jacob's Law. Dict.*

A'NTITYPE, a Greek word, properly signifying a type or figure. In this sense St. Paul uses the word, Heb. ix. ver. 24, where he says, that Jesus is not entered into the holy of holies made with hands, which was the type of the true: instead of the word type, we read, in the Greek of St. Paul, Antitype, which Messieurs Port-Poyal and Amelot have translated type or figure. Thus, according to the true import of the word, it signifies a type, which answers to another type, or rather that which is in the place of a type.

Tower of ANTO'NIA, in antiquity, the most magnificent monument which Herod the Great ever built; he gave it that name in memory of Anthony his friend: it was built on the hill of Jerusalem, formerly called Barri. The front of it was built entirely of white marble, and defended by a wall of three cubits high; the distance from this wall to the tower was forty cubits; within it were contrived halls, apartments, and baths. At equal distances were four other towers, three of which were fifty cubits high; and the fourth, which took up the southern and eastern angles, was of seventy cubits. These towers had galleries communicating with the temple-stairs, from whence the Roman soldiers used to observe the people on festival days, to see that they did not form any dangerous enterprize.

ANTONIA'NA *Aqua*, in the materia medica, the name of a medicinal water of Germany, remarkably pleasant to the taste, and of service in many cases as a medicine.

This water, if mixed with any acid liquor, raises a considerable effervescence, and when mixed with Rhenish wine and sugar, which is a common way of drinking it, it makes a great hissing and bubbling, and becomes turbid and milky. If powder of galls be added to it, it suffers no change but remains limpid and colourless, whence it is plain that it contains no iron, nor vitriol; syrup of vitriol mixed with it turns the whole green, whence it is plain that it contains an alkali; and, if oil of tartar be added to it, it becomes turbid and milky, and precipitates a white sediment, whence it appears that there is either common salt or a calcarious earth in it. If it be exposed some time in the air in an open vessel, it, like all the other mineral waters, loses its pungent taste and pellucidity, becoming turbid and vapid. A quart of it evaporated with a very gentle heat leaves two scruples of a dry sediment, which, being separated by another solution, is found to be one half an alkaline salt, and the other a calcarious earth. Oil of vitriol mixed with the salt produces a great effervescence, and a penetrating scent arises, like that produced by the mixture of oil of vitriol and common salt. Hence it appears that these waters contain a small portion of an alkaline salt, a larger portion of sea salt, and a yet larger of a calcarious earth, and with these a very considerable quantity of a subtile and penetrating mineral spirit.

It is a very temperate water, not too strongly operating either by stool or urine; and hence it is a very proper drink for persons in chronic and many acute diseases, either alone, or mixed with wine, to supply the place of malt liquor, which is proper but in very few illnesses. A long use of it alone may also prove of considerable service in hypochondriac cases. *Hoffman's Oper.*

ANU'BIS, a God of the antient Egyptians, represented by a statue having a dog's head, and in one hand a caduceus, and in the other a lyre. Moreri has given us various conjectures with regard to the origin and odd figure of this deity. Cynopolis was built in honour of him, where they kept a number of dogs which they stiled sacred.

Both Christians and heathens have made themselves merry at the expence of poor Anubis. Apuleius and Jamblichus have spoken very indecently about the consanguinity of Isis and Anubis. Eusebius calls him the Egyptian Mercury, and with very good reason; for there is very great probability that the Grecian Mercury and Egyptian Anubis were the same god.

The Romans who were extremely polite in admitting the gods of nations they conquered, permitted him priests, but these priests came to a terrible end; they suffered themselves to be bribed by a young nobleman of Rome called Mundus, who had conceived a passion for Paulina; this lady unhappily frequented the temple of Anubis, and the priests corrupted by Mundus persuaded her, the God Anubis had fallen in love with her. This flattering Paulina's vanity, she came to the temple at night, and found something more agreeable than a god with a dog's head. Mundus could not keep the secret, but spoke of the adventure of the temple, in such a manner as made it easy to guess Mundus had played the part of Anubis. She complained to her husband, and to the emperor Tiberius, who resented it very highly. The priests were crucified, the statue of the lady and Anubis thrown into the Tiber, and the temple demolished. The great men of Rome diverted themselves a long time with this metamorphosis into the god Anubis, and Volusius a Roman senator, escaped the proscription of the triumvirate under this disguise.

A'NVIL (*Dict.*)— The face or uppermost surface of the Anvil must be very flat and smooth, without flaws; and so hard that a file will not touch it. At one end is sometimes a pike, bickern or beak-iron, for the rounding of hollow work. The whole is usually mounted on a firm wooden block.

Forged Anvils are better than those of cast-work. Locksmiths have also a smaller kind of Anvil called a stake, which is moveable and placed ordinarily on their work-bench. Its use is for setting small cold work straight, or to cut or punch on with the cold chissel, or cold punch. *Moxon's Mech. Exerc.* p. 3.

ANNUNCIA'DA, a society founded at Rome in the year 1640, by cardinal John Turrecremata, for the marrying poor maids. It is now grown so very rich, that it gives fortunes of 60 Roman crowns to above 400 maids for their portion, with a suit of white serge, and a florin for slippers every Lady-day. The popes have so great a regard for this charitable foundation, that they make a cavalcade, attended with the cardinals, &c. to distribute the tickets for these 60 crowns, &c. for those who are to receive them. If any of these maids are desirous to be nuns, they have each of them 120 crowns, and are distinguished by a chaplet of flowers on their head.

AORA'SIA *, in antiquity, the invisibility, of the gods.

* The word is Greek, ἀορασία, and derived from α privative, and ὁράω, to see.

The opinion of the ancients, with regard to the appearance of the gods to men, was, that they never shewed themselves face to face, but were known from their backs, as they withdrew. Whence it followed, according to them, that every being they had time to look at in the face, was not a deity. Neptune assumed the form of Calchas to speak to the two Ajaxes, but they knew him not till he turned his back to leave them; and discovered the god by his majestic step, as he went from them. Venus appeared to Æneas in the character of a huntress, but her son knew her not till she departed from him; her divinity was betrayed, if I may use the word, by her radiant head, her flowing robe, and her majestic pace.

AORI'STUS *, ἀόριστος, in the Greek grammar, an indefinite or indeterminate kind of tense which sometimes expresses the present, sometimes the future, but oftenest the past time.

* The word is compounded of α priv. and ὁρίζω, to bound or limit.

Critics are divided as to the proper and primary import of the Greek Aoristus. Some take them for mere variations of the præterperfect tense, introduced only for copiousness, without any peculiar signification; but it is certain the ancient grammarians of that nation allowed a difference between the Aorist and præter tenses. According to them, the præterperfect tense expresses a thing just now, or lately compleated; whereas the Aorist denotes it past, but indeterminately whether it were lately or long ago. This distinction, however, is rejected by Gretzer, who produces instances among the ancients, where the two are used indifferently. Ursinus also allows this promiscuous use, but looks deeper into the origin and reason of the Aorist. According to this writer, an Aorist is then properly used ἀορίστως, as an Aorist, when it does not denote any certain or definite time, but, in reality, comprehends all times. That this is the primitive use of the Aorist, he shews by a great number of instances. This appears

appears a peculiarity in the Greek tongue, unknown in any other language, to have a tense merely indefinite, yet comprehending all the other tenses.

The Greeks usually distinguish two Aorists. Some, however, will not allow any second Aorist, maintaining that what grammarians call the second Aorist, is the same tense with the first, only under a little difference of termination. *Bibl. Anc. & Mod.*

AO'RTA, (*Dict.*)— The Aorta is subject to many disorders; the following cases will give some light into the nature of others, which it is necessary to know, in order to distinguish them, and make a proper prognostic; for they are always incurable.

Mr. Littre, having opened the body of a woman who died suddenly in the street, and who had, till the very moment of her death, been vigorous, sound, besides other things, the coats which form the trunk of the Aorta ossified in several places, and its interior part full of ulcers and fungous excrescences, but yet without any inflammation: the sigmoid valves were likewise become hard and callous.

This state of the Aorta, besides other concurring causes, may have contributed very considerably to the sudden death of this patient; for the arteries are all along in their course furnished with fleshy fibres, which, by their action and spring, continue to the blood that momentum or impulse, which it at first received from the heart; for it is plain, that the contractile force of the heart, considering its weakness, could not, without this continued impulse, throw the blood so far, and that too in canals so winding and so small; but it is in a particular manner impossible, that, without this impulse of the arteries, the contraction of the heart should propel the blood with such a degree of force, as to make it enter the imperceptible orifices of the distant veins. Thus the arteries, and all their ramifications, are, as it were, so many continued hearts, seconding and promoting the action of the chief and principal one. Now it is plain, that in this woman the ossification and consumption of a part of the substance of the trunk of the Aorta must have absolutely taken away its spring, and, consequently, deprived the heart of that assistance, without which it could not carry on the circulation of the blood.

Mr. Merry says, that, having opened a man that died suddenly, he found his Aorta so dilated, that it had begun to separate itself from the base of the heart, in which case, the circulation of the blood must have necessarily had an immediate stop put to it. *Hist. de l'Acad.* 1710.

Mr. Morand the younger, upon opening the body of a merchant in Paris, who died suddenly, after having been some time subject to palpitations of the heart, was not surprised to find polypous concretions formed in the Aorta, and in the branches of the pulmonary arteries and veins; but was astonished with some other uncommon circumstances; for, on the left side of the heart, one of the two valvulæ mitrales of the pulmonary sack was transformed into a kind of cystis, the bottom of which lay towards the sack itself, and the mouth towards the ventricle of the heart. This cystis was the valve itself, dilated to such a degree as to be able to contain one's thumb, thickened, and having small bones in several parts of it; the sigmoid valves of the Aorta, in like manner, being considerably thickened, and in each of them, in several places, small bones, very solid, irregularly ranged, and rising like so many rocks. Nor is it easy to conceive, that, of the blood, which flowed from the pulmonary sack to enter the left ventricle, some part must remain in this cystis, preternaturally formed; and that the other part could not, without a great deal of difficulty, make its way through the Aorta, the valves of which, being thickened and ossified, did not become flat, as they ought to have done, in order to perform their functions duly. *Hist. de l'Acad.* 1729.

AOVA'RA, in natural history, a fruit as large as a hen's egg, which grows with many others in a cluster, inclosed in a great pod, fastened to a species of very high and prickly palm-tree, which grows in the East-Indies and Africa.

When the pod is ripe, it bursts, and there appears a cluster of fruit, which, being ripe, are fleshy, and of a golden yellow colour: the Indians eat them; the flesh incloses a stone very hard and bony, as large as a peach-stone, having at its superficies three holes at the side, and two lesser near each other. The bark of the stone is two lines thick; it contains a fine white kernel, which, being chewed, at first hath an agreeable taste; but, at the end, it becomes of a sharp taste, which approaches that of some sorts of cheese. They extract from the kernel a sort of palm-oil.

The kernel of Aovara is astringent, and good to stop a looseness, being eaten. *Lemery des Drogues.*

APA'NAGE, Appenage, Appanage, Apannage, or Apennage, in the French laws, the fortune of a king's younger son: or a settled portion of lands, &c. assigned for the subsistance of the cadets, or younger sons of a sovereign prince.

Some will have the Apanages, at their first institution, to have been only pensions, or annual payments of a certain sum of money.—The younger sons of England have no certain Apanages, as in France; but only what the good pleasure of the king bestows upon them.

Even in France, during the first and second race of kings, the right of primogeniture, and Apanages, were unknown; but the domains were divided pretty equally among all the children.

Great inconveniences arising hence, it was at length found proper to put off the younger born with counties, duchies, or other districts, on condition of their paying homage and fealty for the same, and of their reverting, in defect of heirs-male, to the crown.

This has happened accordingly to the first and second branch of the dukes of Burgundy.— The duchy of Orleans is the Apanage of the second son of France.

APARI'NE, *cleavers*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf and is bell-fashioned, very wide, and open at the mouth, and divided into several segments; the cup becomes a fruit, which is dry, covered with a very thin skin, and composed of two round bodies, which contain an umbilicated seed. The leaves of this plant are rough and hairy, and stand in rundles round the stalk.

Aparine, in the Linnæan system of botany, makes a distinct genus of plants; the characters of which are these: the calyx is an extremely small perianthium, placed on the germen, and divided by four notches at its end. The flower consists of one single petal which forms no tube, but is placed flat, and divided into four segments; the stamina are four pointed filaments shorter than the flower. The antheræ are simple; the germen of the pistillum is double, and situated below the receptacle; the style is slender, somewhat bifid at the end, and of the same length with the stamina; the stigmata are headed. The fruit is composed of two roundish dry bodies, growing together, and armed with hooked hairs which make them rough and rigid, and stick to things; the seeds are single, roundish, umbilicated, and large. *Linnæi Genera Plantarum.*

APATU'RIA *, in antiquity, a solemn feast celebrated by the Athenians in honour of Bacchus.

* The word is generally derived from the Greek ἀπάτη, fraud.

It is said to have been instituted in memory of a fraudulent victory, obtained by Melanthus king of Athens, over Xanthus, king of Bœotia, in a single combat, which they agreed upon, to put an end to a debate between them relating to the frontiers of their countries.—Hence Budæus calls it *festum deceptionis*, the feast of deceit.

Other authors give a different etymology of this feast, from what we have now related; they tell us, that the young Athenians were not admitted into the tribes on the third day of the Apaturia, till their fathers had first swore that they were their own children; and that till that time they were supposed, in some measure, to be without fathers, ἀπάτορες, whence the feast, say they, took its name.

Xenophon, on the other hand, informs us, that the relations and friends met on this occasion, and joined with the fathers of the young people who were to be received into the tribes; and that from this assembly the feast took its name: that, in ἀπατούρια, the α, far from, being a privative, is a conjunction, and signifies the same thing with ὁμοῦ, together.

This feast lasted four days: the first day, those of the same tribe made merry together; and this they called δορπία. The second day, which they called ἀνάῤῥυσις, they sacrificed to Jupiter and Minerva. The third day, which they called κουρεῶτις, such of their young men and maids as were of age, were admitted into their tribes. The fourth day they called ἐπίβδα.

APHA'CHA, in botany, the name of a genus of plants, the characters of which are these: the flower is of the papilionaceous kind, and its pistil, which arises from the cup, finally becomes a pod which contains roundish seeds. To this it is to be added, that there are only two leaves at every joint of the stalk, and that the tendrils grow from the alæ of these leaves.

There is only one known species of Aphacha, which is the yellow vetching, called, by some, the bind-weed-leaved vetch. *Tournef. Inst.*

APHA'NIS, in the Linnæan system of botany, the name of a genus of plants, the characters of which are these: the cup is a tubular perianthium remaining till the seeds are ripe; it consists of one leaf divided at the extremity into eight segments, which are extremely small, and alternately different in size. There are no petals; the stamina are four erect, pointed, and very small filaments, inserted on the rim of the cup; the antheræ are roundish. The pistillum has two germina of an oval figure, and two styles of the same length with the stamina, inserted on the basis of the germina; the stigmata are headed. The cup supplies the place of a fruit, shutting together at its mouth, and containing two oval, pointed, compressed seeds, of the length of the styles. *Linnæi Genera Plantarum.*

APHE'A, in mythology, a goddess worshipped by the Cretans and people of Ægina.

Aphea, before she was made a deity, went by the name of Britomartis in Crete; her passion for hunting attached her

to

to the train of Diana, and dedicated her virginity to the goddeſs; to avoid the purſuit of Minos, who was deſperately in love with her, ſhe threw herſelf into the ſea, and was taken up in the nets of ſome fiſhermen. Diana rewarded her virtue with the honours of immortality. Britomartis afterwards appeared to the people of Ægina, who paid adoration to her under the name of Aphea.

APHE'LION, *(Dict.)*— The celebrated Dr. Halley has given us the following geometrical method of finding the Aphelia of the planets.

The annual motion of the earth through the ecliptic occaſions an optical inequality in the motions of the other planets, which is well known to aſtronomers that embrace the Copernican ſyſtem, by the name of the parallax of the orbit. And this inequality, which without much labour is derived from obſervations, I lay down as the ſtrongeſt foundation of the following method. In which, beſides obſervations, nothing elſe is ſuppoſed, than that the orbits of the planets are ellipſes, and that the ſun is placed in the common focus of all the orbits; and laſtly, that the periodical times of them all are ſo well known, that no error can be perceived at leaſt in two or three revolutions. Theſe things being granted, firſt I muſt begin with the motion of the earth, which is neceſſarily required to account for the motions of the other planets.

Let S be the ſun, A B C D E *(plate* IV, *fig.* 12.) the orbit of the earth, P, the planet Mars, which for many reaſons is chiefly to be preferred for this purpoſe. And firſt let the true time and place be obſerved, when Mars is oppoſite to the ſun; for then the ſun and earth coincide in the ſame right-line with Mars; or, if he has latitude (which almoſt always happens) with that point where a perpendicular from Mars falls upon the plain of the ecliptic. Thus, in the ſcheme S, A, and P are in a right-line. Again, after 687 days Mars returns to the ſame point P, where he was oppoſed to the ſun in the former obſervation: but, as the earth does not return to A till after 730½ days, in B it regards the ſun in the line S B, but Mars, in the line B P; and, the longitude of the ſun and Mars being obſerved, all the angles of the triangle P B S are given, and, PS being ſuppoſed 100000, in the ſame parts the length of the line S B is found. In like manner, after another period of Mars, the earth being in C, the line SC is found, and ſo likewiſe the lines S D, S E, S F; and the differences of the obſerved places of the ſun are the angles at the ſun A S B, B S C, C S D, D S E. Thus we come at laſt to this geometrical problem, three lines being given both in length and poſition, meeting in one of the focus's of an ellipſis, to find the length of the tranſverſe diameter, and the diſtance of the foci. The reſolution of this problem may be extended alſo to the other planets, if, after the theory of the earth's motion is known, we find out (according to the method propoſed by the right reverend the biſhop of Saliſbury, in his geometrical aſtronomy, lib. 2. part 2. cap. 5.) three diſtances of any planet from the ſun with its poſitions. Now, becauſe the biſhop ſuppoſes the planet ſo to move in its orbit, that in equal lines it compleats equal angles at the other focus of the ellipſis, and upon this ſuppoſition builds his calculations; it will not be improper to ſhew how the ſame thing may be done without that ſuppoſition, which obſervation obliges us to reject.

Let S be the ſun, A L B K *(fig.* 2.) the earth's orbit, P, the planet, or the point in the plain of the ecliptic, marked out by the perpendicular from the planet; A B, the line of the earth's apſides. Firſt let the longitude and latitude of the planet be obſerved, and alſo the ſun's longitude from the earth, in K; and after a period of the ſame planet, the earth being in L, let two poſitions of the planet and the ſun be again obſerved as before. Now from the obſerved longitudes of the ſun and the earth's Aphelion are given the angles A S K, A S L, and conſequently the ſides S K, S L. Now, in the triangle K S L, are given the ſides K S, L S, and the angle K S L; required the ſide K L, and the angles S K L, S L K. Then in the triangle K L P are given K L, K P L, the difference of the obſerved longitudes of the planet, and P K L the difference of the angles S K L laſt found, and of S K P the planet's elongation from the ſun in the firſt obſervation; required L P. Then in the triangle L S P are given the ſides L S, L P, and the angle P L S, the planet's elongation from the ſun in the ſecond obſervation; required the ſide S P and the angle L S P; which being found, it is, as S P to L P, ſo is the tangent of the latitude obſerved at L to the tangent of inclination or latitude to the ſun; and, as the co-ſine of inclination to radius, ſo is S P, the curtated diſtance, to the true diſtance of the planet from the ſun. So at laſt we have found the deſired poſition and longitude. It remains to ſhew, how from three given diſtances from the ſun, with the intercepted angles, to find the middle diſtance excentricity of the ellipſis.

Let S be the ſun, and S A, S B, S C, *(fig.* 3.) three diſtances in due poſition, and drawing A B, B C, let A B be the diſtance of the foci in an hyperbola, and S A — S B = E H be the tranſverſe diameter. Theſe things being premiſed, let the hyperbolical line be deſcribed, whoſe internal focus is at the point A, and the extremity of the longer line S A. In like manner let B, C, be the foci of another hyperbola, whoſe diameter is S B — S C = K L; from which let the hyperbolical line be deſcribed, having its internal focus at the point B. I ſay theſe two hyperbola's thus deſcribed will interſect one another in the point F, which is one of the foci of the ellipſis required; and drawing the line F A, F B, or F C, either S A + F A, S B + F B, or S C + F C, will be equal to the tranſverſe diameter, and S F is the diſtance of the foci. Theſe being ſuppoſed, the deſcription of the ellipſis will be very eaſy. But, whereas the reaſon of this conſtruction may not be obvious to every one, it will not be improper to give ſome illuſtration of it. I ſay therefore, that, from the moſt known property of the ellipſis, it is S B + F B = S A + F A, and tranſpoſing the parts of the equation F B — F A = S A — S B, ſo that, though we did not know F B and F A, yet their difference is equal to S A — S B, that is, to E H. And ſince it is from the nature of the hyperbola, that it has any two lines from their foci to any point in the curve, conſtantly differing by the quantity of the tranſverſe diameter; it is plain that the point F is ſomewhere in the curve of the hyperbola, whoſe tranſverſe diameter is equal to S A — S B, and its foci A and B. In a like manner it may be demonſtrated, that the point F is in an hyperbola, whoſe diameter is S B — S C, and its foci B and C. Therefore it muſt neceſſarily be in the interſection of theſe two hyperbola's, which, as they interſect one another in one point only, plainly ſhew where the other focus of the ellipſis required muſt be.

Now, that the ſame thing may be performed analytically, ſuppoſe it done, and let F B = a, S a — S B = F B — F A = b, A B = c, S B — S C = F C — F B — d, B C = f, and let the ſine of the angle A B C = S, and the coſine of the ſame = s.

Then $c : b :: 2a - b : \frac{2ab - bb}{c}$; and $\frac{2ab - bb + cc}{2c}$ = B D, by 36. *Eucl.* III.

And $f : d :: 2a + d : \frac{2ad + dd}{f}$, and $\frac{ff - 2ad - dd}{2f}$ = B G, by the ſame. Now, to abbreviate the calculation, make $\frac{cc - bb}{2c} = g$, and $\frac{b}{c} = h$; alſo make $\frac{ff - dd}{2f} = k$, and $\frac{d}{f} = l$. Then B D = $g + ha$, and B G = $k - la$.

And becauſe in every {Obtuſe-angled / Acute-angled} Triangle the ſquare of the baſe is equal to the {Sum / Difference} of the ſquares of the ſides, and of the double rectangle of the ſides into the coſine of the contained angle; it will be $gg + 2gha + hhaa + kk - 2kla + llaa + 2gks - 2glsa + 2khsa - 2hlsaa$ is equal to the ſquare of D G. But D G is equal to the ſine of the angle D F G or D B G drawn into F B or a (for F B D G is a quadrilaterum inſcribed in the circle whoſe diameter is F B) therefore S S $aa = gg + 2gha + hhaa + kk - 2kla + llaa + 2gks - 2glsa + 2khsa - 2hlsaa$: which equation is eaſily reſolved, ſince it does not exceed an affected quadratic, and is always compoſed of thoſe ſquares and rectangles. Yet the ſigns + and —, becauſe of the different conſtitution of the three lines, muſt be applied to the rectangles with good caution. *Philoſ. Tranſ. Numb.* 128.

Kepler places the Aphelion of Saturn, for the year 1700, in 28°. 3′. 44″. of Sagittarius: De la Hire, in 29°. 14′. 41″.— The Aphelion of Jupiter in 8°. 10′. 40″. of Libra: De la Hire, in 10°. 17′. 14″.— The Aphelion of Mars in 0°. 51′. 29″. of Virgo: De la Hire, in 0°. 35′. 25″.— The Aphelion of the earth in 8°. 25′. 30.″ of Cancer.— The Aphelion of Venus in 3°. 24′, 27″. of Aquarius: De la Hire, in 6°. 56′. 10.″— And the Aphelion of Mercury in 15°. 44′. 29″. of Sagittarius: De la Hire, in 13°. 3′. 40″.

The annual motion, according to Kepler, of the Aphelion of Saturn is 1′. 10″. of Jupiter 47″. of Mars 1′. 7″.— Of Venus 1′. 18″. and of Mercury 1′. 45″. According to De la Hire, that of Saturn is 1′. 22″. of Jupiter 1′. 34″. of Mars 1′. 7″. of Venus 1′. 26″. and of Mercury 1′. 39″.

APHO'NIA *(Dict.)*—a loſs of ſpeech.

The learned Frederic Hoffman has given a very accurate account of this diſeaſe, and the method of cure.

By the word ſpeech we commonly underſtand ſuch an emiſſion of articulate ſounds, as is capable of conveying the ideas of a man's mind to his neighbour; whereas the voice is not, properly ſpeaking, an articulate ſound, but a certain diverſified illuſion and repercuſſion of the air thrown with a kind of force through the aſpera arteria, the larynx, and its fiſſure called the glottis, to the cavity of the mouth and jaws. Thus, though ſpeech and voice are different things, yet the former cannot ſubſiſt without the latter: for, when the organs neceſſary for emitting ſounds, eſpecially the aſpera arteria, and its head the larynx, with their reſpective cartilages, muſcles, and nerves, or the roof of the mouth, are vitiated, the power of forming ſounds, and, conſequently, the faculty of of speech, is destroyed. Now, Galen long ago proved by reiterated experiments, that when one of the recurrent nerves which are formed by the par vagum and the nervus accessorius, and reach to the larynx, and, according to Winslow, to the tongue itself, is cut, the animal becomes only capable as it were of an half and unfinished pronunciation; and, when both are cut, it loses at once the power of uttering sounds, and the faculty of speech; or, in other words, becomes intirely dumb.

This incapacity of emitting sounds, and consequent loss of speech, a case which frequently happens in hysteric suffocations, is by physicians called Aphonia. But I take the word Aphonia in a more restrained sense, and confine it to the incapacity of speaking or emitting articulate sounds, which depends on some fault of the tongue; in which case sounds may be uttered, but the faulty tongue cannot articulate them right, and seems, as it were, to be silenced by its own fruitless struggles. There is an affinity betwixt this distemper and that hesitation in speaking, which we commonly call stammering; in which case indeed articulate sounds are formed, but not distinctly enough expressed, because the tongue is too slow, as it were, and incapable to cloath the ideas with language, with the same celerity with which they are excited in the mind.

Now, since in an Aphony the tongue is principally in fault, and since we consider it as the seat of the disorder, it will not not be improper to take such a view of its structure as we think necessary, to answer our present purpose. The tongue then is a muscle of all others perhaps the most moveable, by reason of its longitudinal, transverse, perpendicular, acuminated, angular, and other variously disposed fibres; and by means of the mylo, stylo, hyo, and genioglossi muscles, as well as those ascribed to the os hyoides, it can move itself most nimbly and expeditiously in all possible directions. These muscles now mentioned derive their vis motrix, or moving power, from the third branch, called the lower maxillary branch, of the fifth pair of nerves, which is almost totally employed in producing motion; just as the ninth pair seems to be destined for the purposes of taste.

If by the volubility of the tongue, and its capacity of moving in all directions, sounds formed by the assistance of the larynx are modified into certain letters, speech is produced; but, the more difficult the motion of the tongue is, the more difficult speech must consequently be; and when its mobility ceases, the facility of speech is destroyed with it, though sounds at the same time may be clearly enough uttered.

Since the motion of any given part is either diminished or destroyed by the diminution or interception of the nervous fluid, which should flow into its nerves; and since the nerves, destined for the motion of the tongue, arise principally from the fifth pair; it plainly appears, that the seat of an Aphony is to be sought for in the said pair, and that the influx of the nervous fluid into that nerve, being more or less diminished, is to be assigned as its immediate cause. In this opinion we shall be confirmed, if we carefully dissect human subjects, who during their lives were aphonous. Thus Bonetus (in Sepulchr. Anat. lib. 1. sect. 22. obs. 7.) affirms, that in a man, whose melancholy degenerated into madness, and who remained aphonous to his very death, he found the brain very dry, and the origin of the nerves in the same state, but much smaller than ordinary, the tongue in the mean time remaining unaffected; and (obs. 20.) he quotes a case, from Riverius, of a stammering person, in whose brain about the lingual nerves a cystis was found with a hole in it, from which a serum always drivelled.

Whatever therefore tends to hinder the influx of the nervous fluid into the nerves destined to the motion of the tongue, that very thing contributes proportionably to the bringing on an Aphony. Hence a palsy of the tongue, which is either antecedent or subsequent to hemiplectic or apoplectic disorders, deserves our most attentive consideration. This disorder sometimes happens in old men, and in languid or much weakened constitutions. If it appears alone, it is generally the unwelcome omen of an approaching hemiplexy or apoplexy; but if it succeed these disorders, and is complicated with a weakness of memory, and a sluggish heaviness of the mental powers, it threatens the return of the former distemper. In this case the tongue is generally tumid, flaccid, half numbed, less susceptible of motion than in its natural state, and its taste impaired; and in an hemiplegia is vitiated and faulty only in one side.

That Aphony is like to terminate more happily, which proceeds from a stagnation, or secession of serous humours compressing the nerves of the fifth pair, which run to the tongue; but it is no less afflicting to the patient, and proves sufficiently obstinate against the means of cure. Aphonies of this kind happen after the striking-in of serous pustules and efflorescences, especially in moist and rainy seasons.

There also arises an Aphony from too great a congestion of blood in the fauces and tongue; but this species of the disorder generally uses to quit the patient immediately, upon lessening the quantity of humours. An instance of this degree of disorder's being cured, by a subsequent hæmorrhage from the nose, may be seen in the *Acta Academ. Natur. Curios.*

An Aphony proceeding from worms lodged in the cavities of the stomach and intestines deserves our consideration, because it occurs pretty frequently. This species of the disease seizes the patient suddenly, but ceases to rage when the worms, its remote and secondary cause, are dislodged.

The cure.—The first intention of cure, in an Aphony, is to remove the causes compressing the lingual nerves, and thereby hindering the influx of the nervous fluid into them. The second is to strengthen them, and corroborate the weakened parts: but, as these causes differ widely from one another, so he that will take the trouble of thinking, must plainly perceive, that they call for proportionably different methods of treatment; and it is no hard matter for any one to see, that an Aphony, produced by a cause that lies latent and remote in the cavity of the cranium, must with incredible difficulty admit of a cure.

That species of Aphony therefore which proceeds from a true palsy of the tongue, calls for a discussion and evacuation of the serum, which compresses the nerves and brain: the cure is therefore to be attempted by venesection, pretty sharp clysters, diuretics, sternutatories, &c. but especially nervous and balsamic medicines are to take place, and be applied even externally to the tongue itself. For this purpose the following are recommended:

Strong waters of lily of the valley, cowslips, rosemary, mother of thyme, of ants, essence of amber, and of Peruvian balsam, oil of cinnamon, and of clove-gilliflowers, and a few drops of my balsamum vitæ, taken in sugar, and kept under the tongue. Internally also the same balsamum vitæ, mixed with three parts of the vinous spirit of sal ammoniac, and two parts of the acid tincture of antimony, may be taken with great success, twice or thrice a day; and the dose may be thirty drops. Neither will it be improper to apply a gentle vesicatory to the nape of the neck.—The reader will find the method of making the balsamum vitæ, under the article BALSAMUM *Vitæ*.

If suppressions of sweat, or a stop put to the usual excretion in case of a catarrh, have contributed to the disorder, nothing can be used with greater advantage and efficacy, than diaphoretics and diuretics, duly and skilfully prescribed; for, immediately upon the diaphoresis being restored, the faculty of speech returns. Infusions to be drank by way of tea, a mild regimen, succinated spirit of harts-horn, acid tincture of antimony, and essence of amber, especially if they be mixed with balsam of Peru, or my balsamum vitæ, are also most sovereign and efficacious remedies in this case.

An Aphony sometimes seizes the patient under a mercurial salivation, that is, when the serous and salival humours flow to the tongue and fauces in too great a quantity. In this case, the intention of cure consists in making a derivation and evacuation of those humours from the head. This end is most effectually answered by diaphoretic decoctions drank warm; by laxatives, and especially by cephalic pills of a pretty sharp and stimulating quality, a proper regimen in the mean time being entered into, and carefully persisted in.

In an Aphony which remains after the shocks of an hemiplexy or apoplexy, and has all the appearances of being sufficiently obstinate, I have observed remarkable effects, produced by applying to the nape of the neck plaisters prepared of turpentine or pitch, and the gums caranna and mastich; for other remedies, how rich and generous soever, generally come short of expectation, and disappoint our hopes in this case.

If an Aphony proceeds from too great a congestion of blood in the head, the whole cure consists almost in letting blood in proper places, and in due quantities. The quantity taken from the patient must be large, and drawn, just as circumstances require, either from the arm, the feet, or sometimes the veins under the tongue. Cupping and scarification are also proper. The feet must also be washed, in order to procure a derivation of the humours to the inferior parts. Nitrous antispasmodic medicines are also to be used internally, because, in cases of this nature, the spasms of the lower parts are generally complicated with some other disorders: for this reason, temperating powders, mixed with nitre and cinnabar, or my anodyne liquor, mixed with essence of castor, are highly serviceable in this case. See *Anodyne* LIQUOR.

Though bleeding is a circumstance of great importance and efficacy in the present case, yet it is not to be used indiscriminately and at random; for in old men, languid constitutions, and patients of phlegmatic habits, or those whose strength is exhausted, it does more harm than good; and, if drawn in a larger quantity than is sufficient to answer the end, is so far from guarding against it, that it even excites and brings it on. Phlebotomy then should rather take place where the pulse is quick and large, and the face red and turgid with blood. And even in this case it is not to be used, till the strictures of the lower parts are relaxed, and mitigated by previous clysters, frictions, and bathing of the feet. Plethoric people before bleeding should carefully abstain both from the internal and external use of the hotter, more ſpirituous, and nervous medicines; becauſe they ſtimulate the humours more, and hurry on their congeſtion to the fauces.

If ſpaſmodic conſtrictions of the fauces and tongue have produced an Aphony, as happens in hyſteric and hypochondriac paroxyſms, which are attended with difficulty of deglutition, external paregorics are of more ſervice than in ternal medicines. For this purpoſe a little caſtor, or nutmeg, or theriaca, or ſage, may be held under the tongue; or a few drops of the balſamum vitæ, mixed with ſome anodyne liquor, may be poured upon the tongue. Beſides, bathing the feet, carminative clyſters, emollient fomentations and baths, are highly ſerviceable in this caſe.

Laſtly, that Aphony which is produced by worms lodged in the cavities of the inteſtines and ſtomach, is eaſily cured by anthelminthic medicines, and ſuch as relax and mitigate the ſtrictures of the inteſtines; for, when theſe are at an end, the power of ſpeaking returns, but is again frequently loſt, till the worms, the remote cauſe of the diſorder, are diſlodged: For this reaſon, when the ſpaſms are gone, the phyſician is to endeavour, by proper remedies, to diſlodge theſe troubleſome animals, as effectually as he poſſibly can. *Hoffman.*

APHRA'CTÆ, in antiquity.— The gallies of the ancients which were open without any deck, and had only one bank of oars, were diſtinguiſhed by this appellation from the cataphractæ which had decks.

The Aphractæ had only at the ſtem and ſtern a little floor of planks, which they mounted to fight on; but this method of building was not general.

It alſo appears from hiſtory ſome veſſels were called Aphractæ, which were cloſe and had a deck with one of theſe raiſed floors at their ſtern which they called roſtra. Livy, ſpeaking of Octavius, ſays, that when he ſailed from Sicily with thirty men of war and two hundred ſtore-ſhips, he had not good weather all the voyage, for, when he was juſt arrived in ſight of the African coaſt with a fair wind, on a ſudden he was retarded by a calm; after which the wind changed, and a ſtorm riſing diſperſed his fleet, and he had great difficulty to keep his naves roſtratæ from ſinking by the help of his oars. Here he calls thoſe naves roſtratæ, which he had before called naves longæ, men of war. He ſays, beſides, that open boats were built with roſtra at their ſtern; from whence it follows, that the difference between the Aphractæ and cataphractæ conſiſted principally in this, that the Aphractæ were open boats, the cataphractæ decked veſſels; for the roſtrum was common to both.

APHRODI'SIA, in antiquity, feſtivals in honour of the goddeſs 'Αφροδίτη, or Venus. There were ſeveral of theſe Aphrodiſia, obſerved in divers parts of Greece; the moſt remarkable was that at Cyprus, firſt inſtituted by Cinyras, out of whoſe family certain prieſts of Venus were elected, and for that reaſon named κινυράδαι. At this ſolemnity ſeveral myſterious rights were practiſed: all who were initiated to them offered a piece of money to Venus as an harlot, and received, as a token of the goddeſs's favour, a meaſure of ſalt, and a φαλλὸς; the former, becauſe ſalt is a concretion of ſea water, to which Venus was thought to owe her birth; the latter, becauſe ſhe was the goddeſs of wantonneſs. *Pott. Archæol. Græc.*

APHRODI'TE *, a name of Venus.

* The word is Greek, and derived from ἀφρὸς, foam; becauſe, according to the poets, Venus ſprung from the foam of the ſea.

APHRODI'TES, in natural hiſtory, a name given by ſome authors to the fineſt ſpecies of amethyſt.

The ancients had a way of diſtinguiſhing what they allowed to be gems, into ſeveral kinds, according to their degrees of colour: theſe they called ſo many ſpecies, and gave to each its peculiar name. This has been the occaſion of no little confuſion among the writers on theſe ſubjects, by ſeemingly enlarging the number of the gems. The pæderos and gemma Veneris of the antients are the ſame ſtone with this, though many have applied theſe names to the opal.

A'PHTHÆ *(Dict.)* Aphthæ, or ſmall ulcers, are frequent in acute diſeaſes, attended with inflammations of ſome of the viſcera. Theſe are ſmall, round, ſuperficial ulcers, on the inſide of the mouth; which, upon an accurate examination, appear to be exulcerations of the extremities of the excretory ducts of thoſe glands which ſeparate the ſalivary humour, and convey it to the mouth: now, when this fluid is, by any cauſe, rendered too thick and viſcid, it ſtops up the extremities of theſe canals, which, upon this, exulcerate.

Every part, therefore, into which ſuch excretory ducts diſcharge themſelves in a natural ſtate, are ſubject to Aphthæ; as the lips, gums, internal parts of the cheeks, tongue, palate, fauces, tonſils, uvula, throat, ſtomach, and ſmall inteſtines.

It is ſaid, that the large inteſtines, though rarely, are infeſted with theſe ſmall exulcerations; and that they are propagated through the whole inteſtinal tube.

The northern people, who inhabit marſhy places, are moſt ſubject to Aphthæ in a hot and rainy ſeaſon; and infants and old people are, in general, moſt affected with them. But in countries which are warm or mountainous, or where the air is habitually ſerene and dry, they are ſcarcely, if ever, known.

Aphthæ, in the mouth, are uſually preceded by a continual putrid fever; or an intermittent, degenerated into a continual fever, which began with a diarrhœa or dyſentery; a conſiderable and perpetual nauſea, vomiting, loſs of appetite, and great anxieties about the præcordia, frequently returning; by great weakneſs, or any conſiderable evacuation of the humours; by ſtupor and heavineſs; by unequal, but perpetual, and not very violent drowſineſs; and by perpetual complaints of a ſenſation of heavineſs and pain about the ſtomach: and it is remarkable, that thoſe preceded by great evacuations of the humours are very dangerous.

Sometimes, in the beginning, a ſolitary puſtule will appear in different parts of the mouth; as upon the tongue, in the angles of the lips, in the fauces, or elſewhere, without any certainty as to the part on which they are firſt viſible; and theſe are generally of a mild nature. But, ſometimes, they appear firſt at the lower part of the fauces, and a white thick cruſt, ſhining like new bacon, which adheres firmly to the parts, and aſcends ſlowly, ſeems, as it were, to proceed from the œſophagus: theſe are uſually a very bad ſort, and generally fatal. But the worſt ſort, and of which the patient very ſeldom recovers, are thoſe which cover the whole mouth, as far as the extremities of the lips, with a hard, firm, thick, and tenacious kind of cruſt. The two laſt ſpecies ſhould ſeem to have their origin in the ſtomach, and thence to aſcend into the mouth.

The malignancy of Aphthæ may be eſtimated by their colour. Thus thoſe which are white and pellucid, and almoſt of the colour of pearls, are the leaſt malignant; thoſe which are white, but opaque, by reaſon of their thickneſs, are more ſo; but not ſo bad as thoſe which are brown, yellow, or livid: the black are, of all others, the worſt.

When theſe Apthæ, or apthoſe cruſts, have adhered ſome time to the parts affected, they begin to ſeparate, and be looſened from the ſubjacent part, and to fall off, ſo that all the affected parts are, by degrees, and ſucceſſively, freed from them: but this ſeparation is effected in ſome kinds ſooner, in others later. And hence, alſo, we may judge of the degrees of malignity; for, the ſooner the ſeparation happens, the leſs is the danger.

Sometimes theſe, when fallen off, are immediately ſucceeded by freſh Aphthæ; but ſometimes this ſucceſſion happens more ſlowly, and ſometimes not at all: ſometimes, alſo, the ſucceeding Aphthæ are as thick, or more ſo, than the firſt; and hence, alſo, the danger may be eſtimated; for the ſooner they are renewed, and the thicker, the greater is the malignity.

From conſidering what has been premiſed, we may readily form an idea of the ſeat, nature, cauſe, and ſymptoms of the Aphthæ, and of their different ſorts; and hence, alſo, their effects may be underſtood.

Thus, if ſuch an aphthoſe cruſt, as is above deſcribed, covers the whole ſuperficies of the parts mentioned, all ſenſation, which ſhould be communicated to the nerves, is intercepted, and the patient loſes his taſte. Beſides this, the egreſs of the fluids, by theſe obſtructed emiſſaries, is utterly prevented; the conſequences of which are, a drineſs of the parts, a dilatation of the ſubjacent veſſels, a putrefaction of the fluids ſtagnating under the aphthoſe cruſt, and an inflammation of the parts themſelves in which they ſtagnate.

Hence, alſo, the orifices of the abſorbent veſſels are obſtructed in ſuch a manner, that no freſh chyle, fluids, or medicines, can enter them; and this produces all thoſe diſorders which may proceed from a deficiency of nouriſhment, and, in the end, death.

When theſe cruſts fall off, there is an increaſed flux of humours from the mouths of the diſtended veſſels now opened; hence a large diſcharge of ſaliva, or a diarrhœa, which are good ſymptoms, if the aphthoſe cruſts are not renewed; but bad, if they are.

Upon the falling off of the cruſts, a great pain ſucceeds of the parts underneath, which are now inflamed and expoſed: theſe often diſcharge blood, whence bloody ſaliva, and a bloody dyſentery.

If what has been ſaid is applied to the ſtomach, the excretory ducts of the liver, pancreas, and of the other glands which open into the inteſtines, we may form an idea of an infinite number of diſorders ariſing from this diſtemper; inſomuch that a farther detail of the prognoſtics will be ſuperfluous.

If theſe ulcerous cruſts are very ſlow of ſeparation, thick, broad, and compact, the ſubjacent fleſh, being, as it were, ſuffocated, inflames, ſuppurates, or even mortifies; the conſequences of which are malignant ulcers, which ſometimes affect the os palati, and its perioſteum: hence we may judge of their effects in the ſtomach and inteſtines.

The cure.— 1ſt, The impulſe of the vital fluids, upon the parts affected, is to be gently excited, and ſo conducted, that, by a proper ſupply of fluids, the ulcerous cruſts may be looſened, ſeparated, and fall off: this is effected by drinking great quantities of warm, diluting, reſolving, and abſterging liquids.

liquids. And becaufe, in fome bad cafes, the orifices of the lacteals are fo obturated, as not eafily to admit the liquids thus taken; fomentations, vapours, and baths, are of fingular ufe. The very beft aliment is bread boiled in water, and then mixed with wine and honey.

Take, of fweet almonds blanched, two ounces; of piftachio-nut kernels, one ounce; of the four greater and leffer cold feeds bruifed, each three drachms; of excorticated oats, three ounces: boil thefe in a fufficient quantity of water, that two pints of liquor may at laft remain in a clofe veffel for an hour; and then add, of liquorice root, an ounce, and let them boil together a little: then let the boiled ingredients be thoroughly bruifed in the decoction, and of this let the patient drink frequently; and with this let him wafh his mouth: Or,

Take, of the roots of carrots, fkirrets, china, farfaparilla, and turneps, each four ounces; of whole barley, an ounce: let thefe ingredients be well bruifed, and boiled in water; and, to thirty ounces of the expreffed liquor, add, of fyrup of marfh-mallows, an ounce. Let this be ufed as the preceding.

Take, of the roots of turneps unpared, a fufficient quantity; let them be grated or rafped, and let the juice be preffed out; and, whilft it is boiling, let it be defpumated; then, to fixteen ounces of this juice, add the yolks of two eggs, and of fyrup of violets two ounces. Let the patient take half an ounce every half hour.

The moft proper aliments, befides thofe mentioned before, are decoctions of the farinaceous vegetables.

2dly, The cruft muft be difpofed to feparate foon and eafily; which is effected by fomentations, gargarifms, and clyfters: thefe muft confift of warm, relaxing, emollient, and deterging liquors, which moiften the parts by adhering to them a fufficient time, and which refift putrefaction. Thus,

Take, of the leaves of mallows, brank-urfine, marfh-mallows, pellitory of the wall, mullein, mercury, lady's-mantle, each two ounces; of the roots of marfh-mallows, one ounce; of the roots of turneps, ten ounces: to three pints of the decoction, made with water and expreffed, add the yolks of four eggs, and honey of rofes two ounces. With this let the mouth be perpetually wafhed or gargled.

Make a cataplafm of the refiduum, to be applied externally to the region of the fauces.

Let clyfters, alfo, of this decoction, be adminiftered.

3dly, As foon as the cruft is fallen off, it will be proper to ufe anodyne and demulcent remedies, and fuch as contribute to ftrengthen the relaxed parts. Thus,

Take, of fyrup of white poppies, two ounces; of cream, two ounces; the yolks of two eggs; of rofe-water, two ounces: let a little of this be held continually in the mouth. Or,

Take of the jelly of harts-horn, or of flefh, made very thick, and cut into flices, a fufficient quantity: let one of thefe flices be perpetually diffolving on the tongue, and fo gradually fwallowed.

Thefe two medicines act agreeably upon the excoriated parts, and the following contributes to ftrengthen them.

Take, of the decoction of the frefh leaves of agrimony, feven ounces; of honey of rofes, an ounce: let this be applied perpetually to the afflicted parts.

4thly, As foon as the fever is abated, a fediment appears in the urine, and the pulfe begins to be free, corroborating medicines are to be directed. Thus,

Take, of the root of the fharp-pointed dock, one ounce; of the Peruvian bark, and that of tamarifk, each fix drachms; of the leaves of agrimony, one handful: boil thefe ingredients in a fufficient quantity of water, and to a pint and an half of the decoction add, of the fyrup of kermes, an ounce. Of this let the patient take half an ounce every hour. This corroborates the relaxed veffels of the inteftines. *James's Dict.*

APHYLLA'NTHES, in botany, the name of a genus of plants, the characters of which are thefe: the flower is of the liliaceous kind, and is compofed of fix petals which arife from the center of a fquamofe and fome degree tubular cup; the piftil arifes alfo from the cup, and finally becomes a trigonal turbinated fruit, which, when ripe, burfts into three parts or cells, which contain roundifh feeds. *Tournef. Inft.* p. 657.

There is only one known fpecies of this plant, which is the Montpelier Aphyllanthes, called by fome the blue Montpelier pink.

A'PIARY (*Dict.*) — Methods of making an Apiary. When there are but few bees, it is ufual to fet them in any corner of the garden, or court; and fometimes in clofes adjoining to the houfe; though fome, for want of room without doors, have fet them in lofts or upper rooms; but this is not fo proper for them. If a perfon intends to have a confiderable ftore of bees, a fquare plat muft be made by itfelf, proportioned to the number of bees intended to be kept, not quite a fquare, but rather lower extended from eaft to weft, but fo contrived that they may have as much of the morning and evening fun as poffible. The Apiary fhould be fecurely defended from high winds on either fide, either naturally by hills, trees, &c. or artificially by houfes, barns, walls, &c. It ought alfo to be well fenced from cattle, efpecially hogs, and from all forts of fowl, their dung being very prejudicial to them; neither fhould there be any ill fmells, nor any poultry kept near the place.—The Apiary fhould be furnifhed with ftools or benches, of wood or ftone; but the firft is beft, ftone being hot in fummer, and cold in winter: thefe are placed at different heights, but about twelve inches is a good height; they fhould be fet a little fhelving, that the rain may run off; they fhould alfo be two or three inches wider than the hives fet upon them, and at leaft five feet diftant from the other.

To have a compleat Apiary, for every ftock of bees intended to be kept, make a cot or houfe about two feet fquare, and two and a half high, fet on four legs about ten inches above ground, covered over with boards or tiles to keep off the rain, the back or north fide being clofed up, and the fides facing the eaft and weft, to have doors with latches and hafps to them; the fore or fouth fide to have a falling door to cover one half thereof, which is to be raifed up at pleafure, and in fummer-time ferves for a pent-houfe, not only to keep off the beating rain from the hives, but to defend them from the extreme heat of the fun, which at noon-day is apt to melt the honey. The other lower half fhould have two fmall doors to open to either hand, which will ferve to defend the doors or holes of the hives from injurious winds: all the doors may be faftened in winter, when the weather is too cold, or in fummer, when it is too hot for the bees; only making a little open fquare at the bottom of the little doors juft againft the bee-hole, that the bees may have fome liberty to fly abroad, after the doors have been fhut: by means of the fide doors, efpecially if the weft door be made to open to the right hand, a perfon may fit fafe, and fee the feveral workings of the bees in glafs hives, if any fuch are ufed; if not, at thefe places he may order, view, and obferve them better than when they ftand on naked ftools, and with lefs offence to the bees, and more fecurity to himfelf.

In the winter feafon, if the Apiary ftand cold, good fweet ftraw may be ftuffed within the doors about the hives to keep them warm; but extremity of cold does not hurt bees fo much in the winter as wet, from which thefe cafes beft preferve them; or as light, and the warm beams of the fun, at fuch time when there is no provifion abroad for them, againft which this houfe or cot is the beft prefervative; for, when the doors are fhut, though the fun fhine, yet they are infenfible of it, the hives ftanding fix or eight inches within the doors; whereas, after the common way of benches or ftools, the fun cafts rays to their very doors, which warmth and light together draw them out, at the expence of their provifions and lives together, as is evident from frequent experience, the mildeft and cleareft winters ftarving and deftroying moft bees; when, on the contrary, the coldeft and moft frozen beft fecure them.

A'PIOS, the knobbed-rooted Viginian liquorice vetch, in botany, a genus of plants, whofe characters are: it has a climbing ftalk; the leaves grow almoft oppofite, and faftened, as it were, to the mid-rib; the root is tuberous.

There is, at prefent, but one fpecies of this plant known to us, which is, *Apios Americana Cornuti*; the American Apios of Cornutus.

This plant hath large knobbed roots, which part as they grow old, by which means the plant is increafed; for it rarely produces ripe feeds with us: it is hardy, and will endure the cold in the open ground, if planted in a dry foil; but is fubject to rot with too much wet in winter: it dies to the root every autumn, and rifes again the fucceeding fpring, and will twift itfelf round a pole, and grow to the height of eight or ten feet, and produce, in July, fine fprigs of flowers: it hath alfo been planted near arbours, where it hath covered them very well towards the latter end of fummer, but is cut down with the firft cold of autumn: and in fevere frofts the roots are often deftroyed, where they are not well covered with litter or tanners bark; for want of this precaution, moft of the roots of this plant were deftroyed in the hard winter, 1739-40. *Miller's Gard. Dict.*

A'PIS, a famous deity among the Egyptians, reprefented by an ox with certain external marks. Into this animal, according to the Egyptians, the foul of the great Ofiris retired and withdrew itfelf from the world. He gave this creature the preference, becaufe the ox is the fymbol of agriculture, the perfection of which this prince had very much at heart.

The ox, Apis, muft have a ftar in the forehead, that is, a fquare white mark, the figure of an eagle on his back, a knot under his tongue in the form of a beetle, the hair of his tail double, and a crefcent on his right flank; and the cow that bore him muft have conceived by a clap of thunder.

As it is difficult to apprehend nature fhould produce an animal with all thefe marks, requifite for an Apis, we muft fuppofe that the priefts took care, by impreffing the neceffary marks on young calves, to be provided always with one.

And if it happened at any time an Apis could not immediately be found, and they were obliged to put it off for some time, it was, certainly, because they were very careful not to be thought guilty of the imposition. But this artifice seems needless; people, on these occasions, voluntarily shut their eyes. When they had found the Apis, before they carried him to Memphis, they fed him forty days in a city on the Nile. Women only were permitted to see and wait upon him, and these were obliged to present themselves before the divine ox in an undress. After these forty days, they put him on board a superb vessel, and brought him down the Nile to Memphis, where the priests received him with all imaginable pomp; they were attended by numbers of people, and children were happy who could smell his breath, because they imagined it inspired them with the gift of prophecy.

On his arrival at Memphis, they conducted him to the temple of Osiris, wherein were two magnificent stalls; one of which was built by Psammeticus, supported by statues, after the manner of the colossus, twelve cubits high; here he continued almost always shut up, being hardly ever seen but by strangers, to whom he was shewn in a little meadow joining to the temple. If they at any time led him about the city, he was attended by officers to keep off the croud, and accompanied by young children who sung his praises.

According to the sacred books among the Egyptians, the god Apis had a certain appointed time to live; near the expiration of which, the priests brought him forth, and led him to the banks of the Nile with great pomp and solemnity, and drowned him in that river. He was afterwards embalmed, and his obsequies celebrated in so expensive a manner, that the charge generally ruined the person to whom the care of his funeral was committed. Under Ptolemæus Lagus, they borrowed fifty talents to celebrate the funeral of Apis. The people, at the death of Apis and his embalming, lamented as if they had lost Osiris, and the mourning continued till the priests thought proper to shew them another Apis to succeed him. At the sight of their new god they rejoiced, as if their prince had risen from the dead; and the festival on this occasion lasted seven days.

Cambyses, king of Persia, on his return from Ethiopia, found the Egyptians celebrating their festival on account of the appearance of their god Apis; and, imagining they made rejoicings at the ill success of his expedition, commanded the pretended god to be brought before him, whom he slew with his sword, buffeted the priests, and ordered his soldiers to destroy all they should find celebrating this festival.

The Egyptians consulted Apis as an oracle; if he took what was offered him to eat readily, it was looked on for a good omen; his refusal, on the contrary, was accounted a presage of ill fortune. Pliny, an author of no mean reputation for sagacity and judgment, observes that Apis would not eat what Germanicus offered him, and that this prince died soon after. Surely, he could not be of opinion there was any connection between these two events. It was the same with regard to the two stalls they had built him, his continuing in one foreboded happiness to Egypt; his removal into the other, the contrary. Those who went to consult this god, laid their mouth close to his ear, and their hands upon their own, keeping them stopped till they were without the walls of the temple, and then took the first thing they heard for the answer of the god.

APO'CALYPSE (*Dict.*)— This book, according to Irenæus, was written about the year 96 of Christ, in the island of Patmos, whither St. John had been banished by the emperor Domitian. But Sir Isaac Newton, with very good reason, places the writing this book earlier, viz. in the time of Nero, Some attribute this book to the arch-heretic Cerinthus: but the ancients unanimously ascribed it to John, the son of Zebedee, and brother of James. This book has not, at all times, been esteemed canonical. There were many churches in Greece, as St. Jerom informs us, which did not receive it; neither is it in the catalogue of canonical books prepared by the council of Laodicea, nor in that of St. Cyril of Jerusalem: But Justin, Irenæus, Origen, Cyprian, Clemens of Alexandria, Tertullian, and all the fathers of the fourth, fifth, and the following centuries, quote the Revelations as a book then acknowledged to be canonical. The Alogians, Marcionites, Cerdonians, and even Luther himself, rejected this book: but the Protestants have forsaken Luther in this particular; and Beza has strongly maintained against his objections, that the Apocalypse is authentic and canonical.

The Apocalypse consists of twenty-two chapters. The three first are an instruction to the bishops of the seven churches of Asia Minor. The fifteen following chapters contain the persecutions, which the church was to suffer from the Jews, Heretics, and Roman emperors. Next, St. John prophesies of the vengeance of God, which he will exercise against those persecutors, against the Roman empire, and the city of Rome, which he describes under the name of Babylon, the great whore, seated upon seven hills. In the last place, the 19th, 20th, 21st, and 22d chapters describe the triumph of the church over its enemies, the marriage of the Lamb, and the happiness of the church triumphant.

'It is a part of this prophecy (says Sir Isaac Newton) that it should not be understood before the last age of the world; and therefore it makes for the credit of the prophecy, that it is not yet understood.— The folly of interpreters has been to foretel times and things by this prophecy, as if God designed to make them prophets. By this rashness they have not only exposed themselves, but brought the prophecy also into contempt. The design of God was much otherwise: he gave this and the prophecies of the Old Testament, not to gratify men's curiosities, by enabling them to foreknow things, but that, after they were fulfilled, they might be interpreted by the event, and his own providence, not the interpreters, be then manifested thereby to the world.— There is already so much of the prophecy fulfilled, that as many as will take pains in this study, may see sufficient instances of God's providence.— Amongst the interpreters of the last age, there is scarce one of note, who has not made some discovery worth knowing; and thence I gather, that God is above opening these mysteries.

The Apocalypse of John is written in the same style and language with the prophecies of Daniel, and hath the same relation to them, which they have to one another; so that all of them together make but one consistent prophecy, pointing out the various revolutions that should happen, both to the church, and to the state, and, at length, the final destruction and downfal of the Roman empire. *Newton on Prophecies.*

APO'CRYPHA *, or *apocryphal books*, such books as are not admitted into the canon of scripture, being either not acknowledged as divine, or rejected as heretical and spurious.

* The word is Greek ἀπόκρυφα, which is derived from ἀπὸ and κρύπτω, which signifies to hide or conceal.

When the Jews published their sacred books, they only gave the appellations of canonical and divine to such as they then made public; and such as were still retained in their archives they called Apocryphal, for no other reason, but because they were not public; so that they might be really sacred and divine, though not promulged as such.

Thus, in respect of the Bible, all books were called Apocryphal, which were not inserted in the Jewish canon of scripture.—Vossius observes, that, with regard to the sacred books, none are to be accounted Apocryphal, except such as have neither been admitted into the synagogue, nor the church, so as to be added to the canon, and read in public.

The Protestants do not only reckon those books to be Apocryphal which are esteemed such in the church of Rome, as the prayer of Manasseh king of Judah, the third and fourth books of Maccabees, the third and fourth book of Esdras, St Barnabas's epistle, the book of Hermas, the addition at the end of Job, and the 151st psalm.

But also Tobit, Judith, Esther, the book of Wisdom, Jesus the son of Sirach, Baruch the prophet, the song of the three children, the history of Susanna, the history of Bell and the dragon, and the first and second book of Maccabees.

It is not pretended that these books were received by the Jews, or so much as known to them. None of the writers of the New Testament cite or mention them: neither Philo nor Josephus speak of them. The Christian church was for some Ages an utter stranger to these books. Origen, Athanasius, Hilary, Cyril of Jerusalem, and all the orthodox writers, who have given catalogues of the canonical books of scripture, unanimously concur in rejecting these out of the canon. And for the New Testament they are divided in their opinions, whether the epistle to the Hebrews, the epistle of St. James, and the second epistle of St. Peter, the second and third epistles of St. John, the epistle of St. Jude, and the Revelations, are to be acknowledged as canonical or not.

The Protestants acknowledge such books of scripture only to be canonical as were so esteemed to be in the first ages of the church; such as are cited by the earliest writers among Christians, as of divine authority; and after the most diligent enquiry were received, and so judged to be by the council of Laodicea. The several epistles above mentioned and the book of Revelations, whatever the sentiments of some particular persons are, or may have been of them, are allowed by all the reformed churches to be parts of the canon of the New Testament.

APOCY'NUM, *dogs-bane*, in botany, a genus of plants, whose characters are: the leaves are produced opposite, by pairs, upon the branches: the flower consists of one leaf, which is cut into several segments: from its flower-cup arises the pointal, which is fixed like a nail in the back part of the flower, and is afterwards changed into a fruit, which is, for the most part, composed of two capsules, or pods, which open from the base to the top, inclosing many seeds, which have a long pappous down adhering to them: to this may be added, that the whole plant abounds with a milky juice.

There are several sorts of this plant cultivated in the curious gardens of plants, some of which are very beautiful, and deserve a place in every good garden. *Miller's Gard. Dictionary.*

APOLLINA'RIAN *Games*, *Apollinares ludi*, in antiquity, games at Rome, celebrated yearly in honour of Apollo, on the fifth day of July, under the direction of the prætor, in the circus maximus.

The occasion was a kind of oracle delivered by the prophet Marcus after the fatal battle at Cannæ, declaring, that to expel the enemy, and cure the people of an infectious disease, which then prevailed, sacred games were to be annually performed in honour of Apollo. The prætor to have the direction of them, and the decemviri to offer sacrifices after the Grecian rite. *See Livy*, *l.* 25. *c.* 12.

APOLLO'NIA, Ἀπολλωνία, in antiquity, feasts sacred to Apollo at Egialea.

The occasion of their institution is thus related: Apollo, after his victory over Python, went to Egialea, accompanied with his sister Diana; but, being frighted thence, fled into Crete. After this the Egialians were infected with an epidemical distemper, and, being advised by the prophets to appease the two offended deities, sent seven boys, and as many virgins, to intreat them to return; Apollo and Diana accepted their piety, and came with them to the citadel of Egialea, in memory of which a temple was dedicated to Pitho the goddess of persuasion; and it became a custom to appoint chosen boys and virgins to make a solemn procession, in shew, as if they designed to bring back Apollo and Diana; which solemnity was continued till Pausanias's time. *Pott. Archæol Græc.*

APO'MYOS *Deus*, in the mythology of the ancients, a name under which Jupiter was worshipped at Elis, and both Hercules and Jupiter at the Olympic games.

APO'PHTHEGM, a wise, short, and pithy saying.

A'POPLEXY *(Dict.)*— It has been the general opinion of physicians, that an Apoplexy is caused by an extravasation of the fluids, or the fulness of the vessels. But the learned M. le Cat, by curing a surprizing hydrocele in the head, has shewn that this opinion is ill founded; for the patient, notwithstanding the prodigious quantity of water, which continually pressed on the brain, had not the least symptom of an Apoplexy.

"How can one then believe, says this author, that the Apoplexy is caused by the extravasation of the liquids, or by the fulness of the vessels, after having seen a brain filled with water, and distended so vastly as this was, without any one apoplectic symptom? Verduc, who in his pathology proposes an objection similar to this against his own system, endeavours to solve it, but has not succeeded. The objection remains victorious.

Nevertheless, when the brain of a person dead of an Apoplexy is opened, and extravasated blood is found in it, his death is imputed to this extravasation alone, and the Apoplexy is pronounced sanguineous. This has happened on the death of M. de Frequienne, president of our parliament. On opening him I found about a tea-spoon full of blood extravasated within the medulla oblongata, between the third and fourth ventricle, at the beginning of the latter. Could so small a quantity of blood press on the principles of the nerves so as totally to intercept the course of the spirits? No, certainly; for this would be mistaking the effect for the cause. This extravasated blood was but an accident owing to the convulsive motions of the dura mater, and of the vessels of the whole basis of the scull, seized with the apoplectic disorder, which most commonly is nothing else but the matter of the gout or rheumatism fixing on this source of the nerves. Now this general attack, which swells and distends the dura mater throughout this whole basis, makes the blood stagnate in the vessels, some of the weakest of which burst, and at the same time closes all the canals of the nerves, and consequently kills the patient. Unless a person would chuse to say, that these broken canals were those, which concurred in the substance of the brain to the formation of the spirits, that give motion to the heart: which opinion is not free from difficulties; since it is well known, that this organ receives the influences of several nerves at a time, all which ought to bear their part in this accident, which, after all, is but the rupture of a simple capillary vessel.

The drift of these reflections is to engage practitioners to have somewhat less confidence in their theories, and, for example, not to make a poor apoplectic patient die under the lancet; a thing, which I have seen several times, from the notion which they hold, that it is the over-great quantity of blood, that kills: for, besides that this false opinion is fatal to this patient in particular, it will still be so to all future apoplectics, if the prejudice in favour of this theory be such as to prevent seeking the true causes, and the real remedies of the Apoplexy." *Philosophical Transactions, vol.* 47, *pag.* 271.

APOSTA'GMA, in natural history, the juice which flows from the grapes, before they are trodden or pressed.

APO'STLE *(Dict.)*— The Apostles of our Saviour were the first and most distinguished of his disciples; he invested them with an authority superior to that of others, filled them with the Holy Spirit, trusted them particularly with his mysteries, and chose them, out of all those that followed him, to raise the edifice of his church upon them. Jesus Christ, after his resurrection, sent them into all the parts of the world, with commission to preach and baptize in the name of the Father, and of the Son, and of the Holy Ghost, and with power to work miracles and cures of all kinds.

The Apostles continued to exercise their ministry in Palestine near twelve years, our blessed Saviour having commanded them not to depart from Jerusalem, and the parts adjacent, till twelve years after his ascension. According to Apollonius and Clemens Alexandrinus, they resolved to disperse, and apply themselves to the full execution of the commission Christ had given them, to go teach and baptize all nations; and, having settled the general affairs and concerns of the church, they betook themselves to the several provinces of the Gentile world, preaching the gospel to every nation under heaven. Many believe, that before their departure they composed the creed, called the Apostles creed, and those canons called the Apostles canons; but most learned men are satisfied that they are both the composure of later times, though the former is acknowledged to be the summary of the Apostles doctrine. It is generally affirmed by the ancients, that the Apostles agreed among themselves, what parts of the world they should take; and this, according to some, was done by lot, though not without the guidance and direction of the Holy Ghost. According to this division, St. Peter went into Pontus, Galatia, and those other provinces of the lesser Asia. St. Andrew had those vast northern countries of Scythia and Scydiana to his portion: though afterwards he is supposed to return towards Greece, and to have founded the bishopric of Byzantium. St. John's portion was partly the same with St. Peter's, namely, the lesser Asia: though, it is believed he did not immediately enter upon his charge, but stayed some years in Jerusalem, till after the blessed Virgin's death. St. Philip had the upper Asia appointed him, with some parts of Scythia and Colchis. Arabia Felix was allotted to St. Bartholomew, into which parts he carried the gospel of St. Matthew. St. Matthew himself preached in the Asiatic Ethiopia, by Chaldea, Persia, and Parthia: but Parthia was more particularly allotted to St. Thomas, who also preached to the Hyrcanians, Bactrians, and Indians. St. James the less, being bishop of Jerusalem, continued principally in that city. As for St. James the great, we have no certain account what became of him immediately after our Saviour's ascension. St. Jerom tells us, that he preached to the dispersed Jews, by which, he probably means the Jewish converts, dispersed after the death of Stephen. And we may conclude, that since the Apostles, after our Lord's ascension, staid several years together at Jerusalem, or in the bounds of Judea; and since St. James lived so short a while; it is utterly improbable that he went either to Spain, Portugal, Britain, or Ireland, to plant christianity; however, some Spanish and other monastic writers affirm it; but, there being no account of this earlier than the middle age of the church, it is safest to confine his ministry to Judea, and the parts thereabouts. St Simon had for his portion Egypt, Cyrene, Lybia, and Mauritania. St Jude had Syria and Mesopotamia; and St. Matthias, Cappadocia and Colchis. Of all their travels and actions we have but a very short and imperfect account. Had we the writings of Papias, bishop of Hierapolis, and, according to Irenæus, scholar to John; the commentaries of Hegisippus, Clemens Alexandrinus's institution, Africanus's chronology, and other writers about that time, mentioned by the ancients; we might expect a much more perfect and authentic account. Dr. Cave among the moderns, in his Antiquitates Apostolicæ, gives the best account we have seen of the Apostles travels, the success of their ministry, the places and countries to which they went, the churches they planted, and their acts and martyrdoms. There are no authors extant, who wrote an history of the church near the apostolic times; the first ecclesiastic historian that now remains being Eusebius, who wrote in the 4th century.

In order to qualify the Apostles for the arduous task of converting the world to the Christian religion, they immediately received the doctrine they taught from the mouth of Christ himself. They were infallibly secured from errors, in delivering the principles of christianity, and to this end had the spirit of truth promised to them, who should guide them into all truth. Hence there was an exact harmony among them in all their doctrines: these twelve stars all shone with the same light, conveyed to them by the sun of righteousness. They had been eye-witnesses of all the material passages of our Saviour's life, and reported nothing but what they had seen with their own eyes, and of the truth whereof they were as competent judges as the most antient philosopher in the world: they were miraculously enabled to speak the languages of the several nations to whom they were to preach, and were endowed with the power of working miracles, such as healing diseases, casting out devils, foretelling things to come, and raising the dead, in confirmation of the doctrine they taught; gifts which were unnecessary, and therefore ceased in future ages of the church, when christianity came to be established by the civil power.

APOSTLE, was an appellation given the ordinary travelling ministers of the church.

APOSTLE, was also a title given to those sent by the churches to carry their alms to the poor of other churches. This usage they borrowed from the synagogues, who called those, whom they sent on this message, by the same name.

APOSTLE, in the Greek liturgy, is particularly used for a book containing the epistles of St. Paul, printed in the order wherein they are to be read in churches, through the course of the year.

APOSTLE, is also used, among the Jews, for a kind of officer, anciently sent into the several parts and provinces in their jurisdiction, by way of visitor, or commissary; to see that the laws were duly observed, and to receive the monies collected for the reparation of the temple, and the tribute payable to the Romans.

These Apostles were a degree below the officers of the synagogue called patriarchs, and received their commissions from them.

APOSTO'LIC, or APOSTOLICAL, something that relates to the apostles, or descends from them. Thus we say, the apostolical age, apostolical doctrine, apostolical character, constitutions, traditions, &c. The Romanists calls their church the catholic and Apostolic church; and thus appropriated a title to Rome, which anciently was held in common with it by several other churches.

Apostolic, in the primitive church, was an appellation given to all such churches as were founded by the apostles; and even to the bishops of those churches, as being the reputed successors of the apostle. These were confined to four, viz. Rome, Alexandria, Antioch, and Jerusalem.

In after-times, other churches assumed the same quality, on account, principally, of the conformity of their doctrine with that of the churches which were apostolical by foundation, and because all bishops held themselves successors of the apostles, or acted in their dioceses with the authority of apostles.

The first time the term apostolical is attributed to bishops, as such, is in a letter of Clovis to the council of Orleans, held in 511; though that king does not here expressly denominate them apostolical, but (apostolica sede dignissimi) highly worthy of the Apostolic see. In 581 Guntram calls the bishops met at the council of Manson apostolical pontiffs, apostolici pontifices.

In progress of time, the bishop of Rome growing in power above the rest; and the three patriarchates of Alexandria, Antioch, and Jerusalem falling into the hands of the Saracens, the title apostolical became restrained to the Pope, and his church alone. Though some of the Popes, as St. Gregory the great, not contented to hold the title by this tenure, began, at length, to insist, that it belonged to them by another and peculiar right, as being the successors of St. Peter.

APO'THECARY (*Dict.*)— This is a very genteel business, and has been in great vogue of late years, there being, as has been computed, upwards of 1000 in and about London. There are, in this profession, various degrees, as to employ and extent.

Some do little else but make up medicines, according to the prescription of the dispensatory (compiled by the order of the college of physicians, for their direction) and those of particular physicians, besides visiting their patients.

Others not only prepare almost all kinds of medicines, as well galenical as chemical, but likewise deal in drugs; with all which they supply their brethren in trade, and so become a sort of wholesale dealers, as well as Apothecaries.

Others, again, practise surgery, manmidwifery, and, many times, even officiate as physicians, especially in the country, and often become men of very large practice, and eminent in their way. There is another branch, also, many of them fall into, which is that of curing lunatics, &c.

A youth intended for this profession should be a pretty good scholar, and have a tolerable knowledge in the Latin tongue at least, that he may be the better able, in due time, to read some of the best authors who have wrote upon the subjects of botany, pharmacy, anatomy, and medicine; though it must be owned there are, at present, almost innumerable helps in our mother-tongue.

In London, they are one of the city companies, and were first incorporated with the grocers in the year 1606, in the reign of king James I, but not alone till 1617.

They have a hall, where there are two fine elaboratories, out of which all the surgeons chests are supplied with medicines for the use of the British navy.

In the year 1712, the 10th of queen Anne, an act passed for reviving and continuing several acts therein mentioned, one whereof was for exempting the Apothecaries from serving the offices of constables and scavengers, and other parish and ward-offices, and from serving upon juries: which act was made perpetual in the 9th year of king George the First.

The Apothecaries in England are obliged to make up their medicines according to the formula's prescribed in the dispensatory of the college of physicians, and are under an obligation to have the medicines there enumerated always ready in their shops; and their shops are liable to be visited by the censors of the college, who have it in their power to destroy such medicines as they judge not to be good.

The Apothecaries of Paris make but one corporation with the merchants-grocers, which is the second of the six corporations of merchants.

By a regulation of the 15th of October, 1631, all the Apothecaries of Paris are prohibited to give any medicine to patients, unless by the order, and with the advice of a regular-bred physician, or of a person approved by the faculty; nor are they to make up any prescription, given, or drawn up, by any person stiling himself an empiric physician, or operator.

Among the good regulations made in Denmark, that which the Apothecaries are obliged to observe, is reckoned one of the best: for no person can have leave to follow that profession, unless he be approved of by the college of physicians, and confirmed by the king himself. There are but two Apothecaries allowed for the city of Copenhagen, and but one in every other considerable town. The magistrates, attended by the doctors of physic, visit their shops and drugs twice or thrice a year, and those drugs that are either stale or bad are seized, and publickly thrown upon a dung-hill without the city; and this is a stain upon the character of such Apothecary, that is scarce ever wiped off. The price of all drugs is fixed, so that one may, without fear of being imposed upon, send even a child for any drug to an Apothecary's shop, where nothing is sold but what is good, and at a reasonable price. All drugs are sold for ready money, and yet the Apothecaries are obliged to register in a book what they sell, to whom, and by what physician's prescription. So that there seldom happens any accident by poison, either accidentally, or with design: and, if any such thing happens, it is easily found out, and quickly punished. Present state of Denmark (in French) by Des Roche, 1730, tom. 9. p. 431.

APOTHEO'SIS (*Dict.*)— It was one of the doctrines of Pythagoras, which he had borrowed from the Chaldees, that virtuous persons, after their death, were raised into the order of the gods.

And hence the ancients deified all the inventors of things useful to mankind, and who had done any important service to the common-wealth.— Tiberius proposed to the Roman senate the Apotheosis of Jesus Christ, as is related by Eusebius, Tertullian, and St. Chrysostom. Juvenal, rallying the frequent Apotheoses, introduces poor Atlas, complaining that he was ready to sink under the prodigious burden of so many new gods as were almost every day added to the heavens.

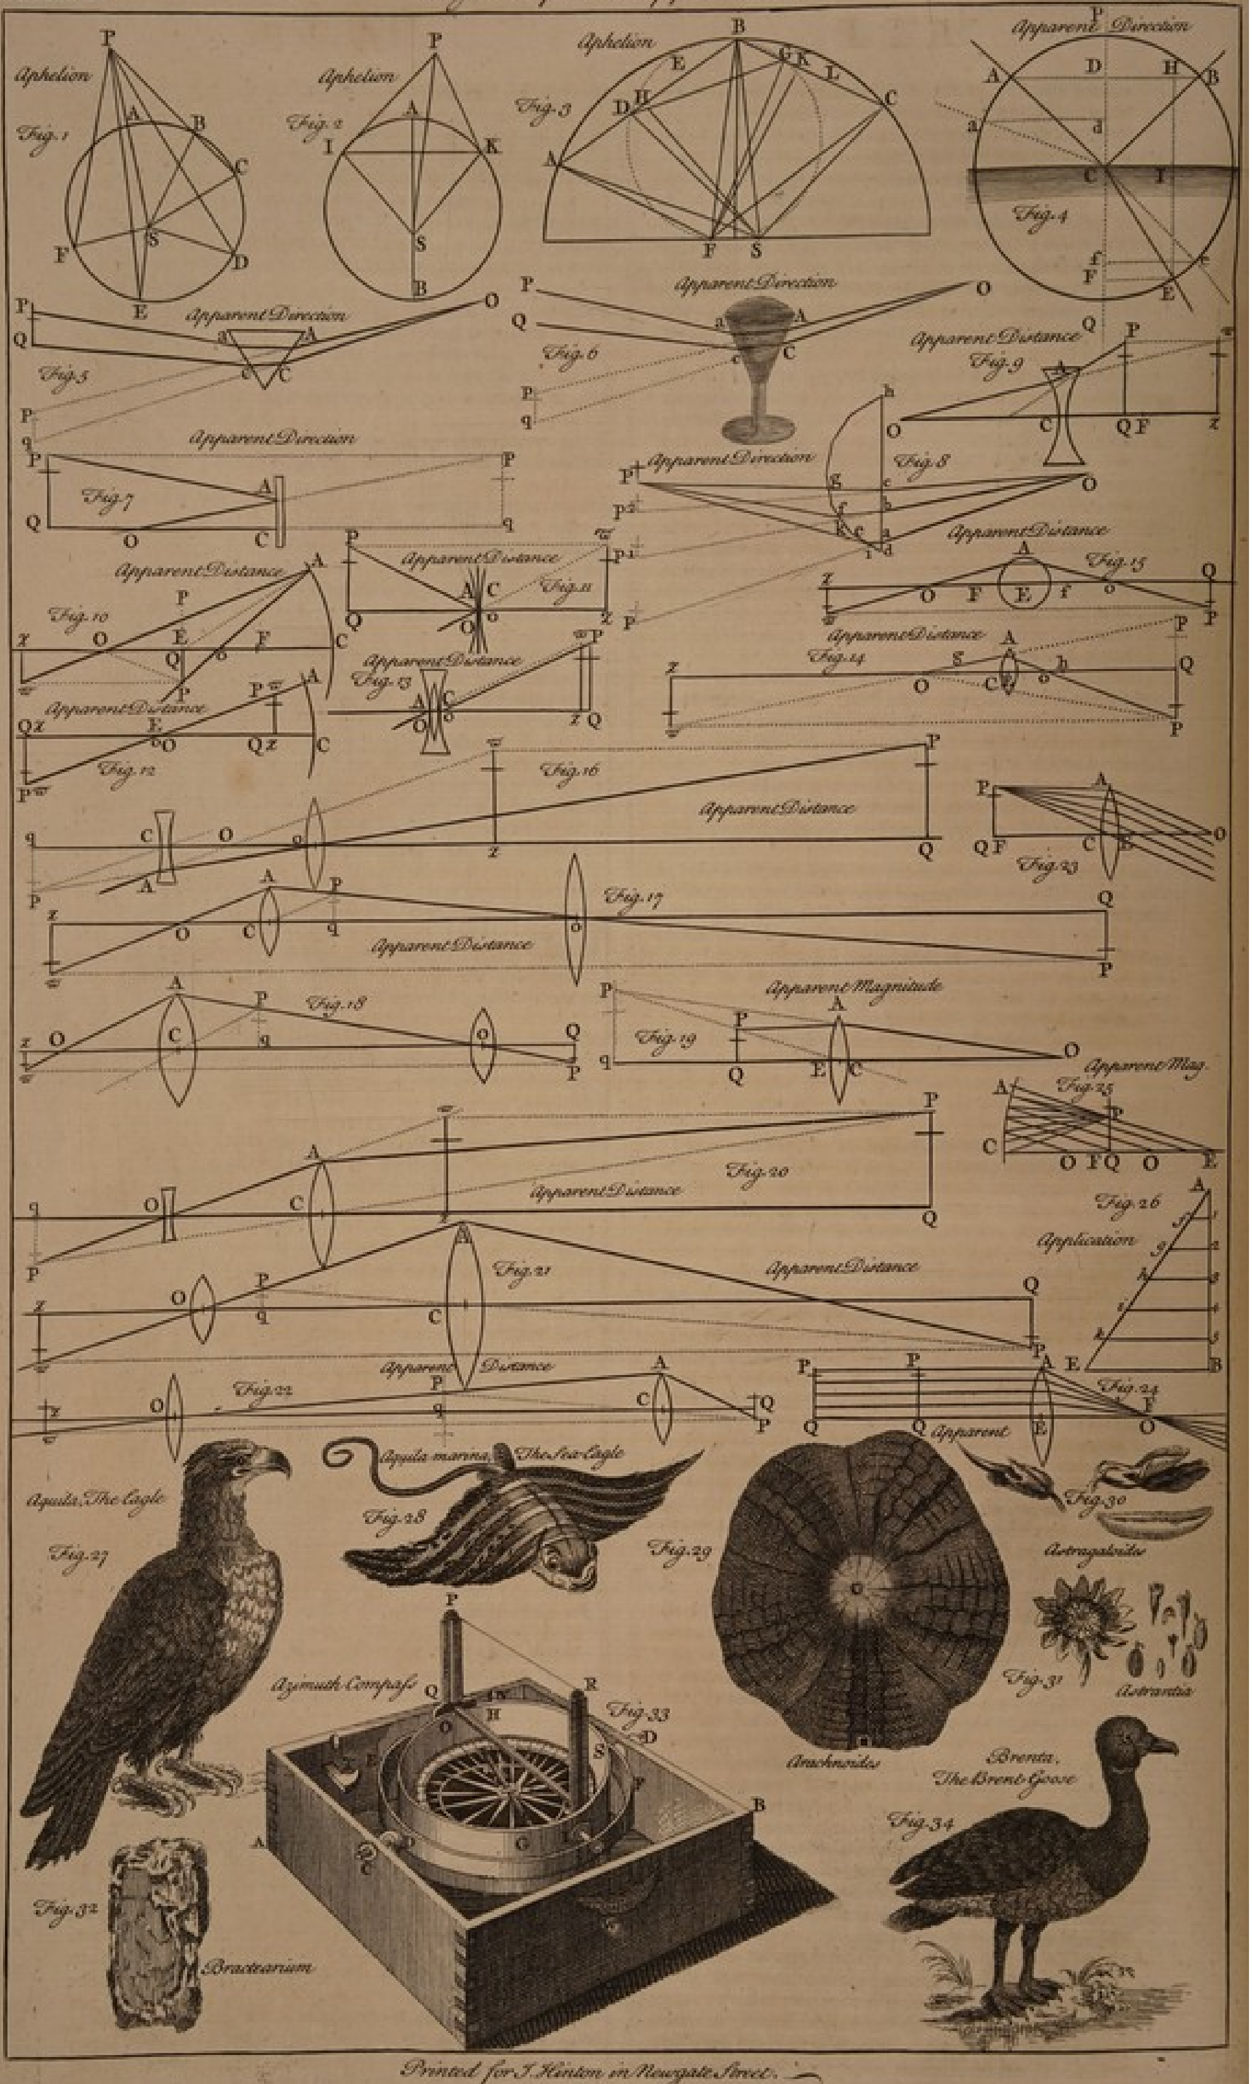
Seneca ridicules the Apotheosis of Claudius with admirable humour.— Herodian, lib. 4, in speaking of the Apotheosis of Severus, gives us a very curious description of the ceremonies used in the Apotheosis of the Roman emperors.— After the body of the deceased emperor, says he, had been burnt with the usual solemnities, they placed an image of wax, perfectly like him, but of a sickly aspect, on a large bed of ivory, covered with cloth of gold, in the vestibule of the palace. The greatest part of the day, the senate sat ranged on the left side of the bed, dressed in robes of mourning; the ladies of the first rank sitting on the right side, in plain and white robes, without any ornaments.— This lasted for seven days successively, during which, the physicians came from time to time to visit the sick, always making their report that he grew worse; till at length they published it, that he was dead.

This done, the young senators and Roman knights took the bed of state upon their shoulders, carrying it through the via sacra, to the old forum, where the magistrates were used to divest themselves of their offices. There they set it down between two kind of amphitheatres, in the one whereof were the youth, and in the other the maidens of the first families in Rome, singing hymns set to solemn airs, in praise of the deceased. These hymns ended, the bed was carried out of the city into the Campus Martius, in the middle of which place, was erected a kind of square pavilion, the inside whereof was full of combustible matters, and the outside hung with cloth of gold, and adorned with figures of ivory, and various paintings.

Over this edifice were several others, like the first in form and decoration, but less; always diminishing and growing slenderer towards the top.— On the second of these was placed the bed of state, and a great quantity of aromatic perfumes; and odoriferous fruits and herbs were thrown all around: after which, the knights made a procession or cavalcade in solemn measures around the pile; several chariots also run round it, those who conducted them being clad in purple robes, and bearing the images of the greatest Roman emperors and generals.

This ceremony ended, the new emperor came to the catafalco or pile, with a torch in his hand; and at the same time fire was set to it, on all sides; the spices and other combustibles kindling all at once.

While this was doing, they let fly, from the top of the building, an eagle, which, mounting into the air with a fire-brand, carried



Printed for J. Hinton in Newgate Street.

carried the soul of the dead emperor along with it into heaven, as the Romans believed; and thenceforward he was ranked among the gods.—It is for this reason, that the medals, wherein Apotheoses are represented, have usually an altar with fire upon it; or, however, an eagle taking its flight into the air, and sometimes two eagles.

A'PPANAGE. See the article APANAGE.

APPA'RENT *Directions of visible Points*, in optics.—Any small object or point of an object, seen by refracted or reflected rays, appears somewhere in the direction of that line, which the visual ray describes after its last refraction or reflection in falling upon the eye.

By experiments made to prove the laws of reflection and refraction, the pin at B (*plate* IV. *fig.* 4.) seen by a ray reflected from the water, appears somewhere in the line A C produced, which the visual ray B C A describes after reflection at C, when it advances to the eye. And as the whole line C E appears lifted up by the refraction at the water, as if it had been a continuation of the line A C straight on; so, if a straight oar be in part immersed obliquely in the water, it appears crooked, as if the part immersed was broken at the surface, and lifted higher. For this part of the oar is seen in the direction of rays which are bent downwards by refraction, at their emergence from the water, and, consequently, advance to the eye, as if they came from a place in the water which is higher than the real place of the oar. In like manner any point P (*fig.* 5, 6, 7.) of an object seen by the ray P A O twice refracted, either by passing through the edge of a prism, or of a concave or convex lens, or through the sides of a globe or decanter, or of a drinking-glass filled with any transparent liquor; or seen by a ray P A O reflected from a plane or spherical looking-glass; appears to the eye at O, somewhere in the direction of the last refracted or reflected ray A O. Lastly, an object P (*fig.* 8.) viewed by the eye at O, through a multiplying-glass, appears at one view in as many different places, *p*, *p* 1, *p* 2, situated in as many different directions O A, O B, O C of the last refracted rays produced, as the glass has different surfaces, D E, E F, F G, differently inclined to the opposite surface D H. For these surfaces, like so many different prisms, give the visual rays P I A O, P K B O, P G C O, so many different bendings at I and A, K and B, G and C, and make them fall upon the eye at O, in as many different directions A O, B O, C O. And in all these instances when the refracting or reflecting surfaces of the water or glasses are shaken by the wind, or otherwise, the objects seen by reflection or refraction appear to shake and tremble; because the last directions of the visual rays are shaken and varied by those motions.

Now, the reason why an object or point of an object appears always in the direction of the last refracted or reflected ray, is, because the place of its picture upon the retina is the same as it would be if the object was really removed from its proper place into the direction of that ray, and was seen by direct rays. And having no sensation of the previous reflections or refractions of the rays at the glasses, but only of their action upon a certain place of the retina, we form the same judgment of the place of the object as we used to do in the more common cases of direct vision. How we know and judge of the place and position of an object by the place and inverted position of its picture upon the retina, will be shewn under the article EYE; whence it will appear to be entirely the effect of experience.

It is manifest from what has been said, that any point P of an object P Q, seen by refractions or reflections, appears somewhere in the line *p* O, drawn from the corresponding point *p* of its last image to the eye at any place O; because all the rays which flowed from P, do after the last refraction or reflection flow from or towards the corresponding point *p* of the last image. The reason why I say the last image will be mentioned under APPARENT *Magnitude*.

It is also manifested why an object seen by refracted or reflected rays appears sometimes upright and sometimes inverted. For when the refracted or reflected rays A O, C O, have the same situation with respect to each other, as two rays that come directly from the same points of the object to the eye, these points will appear in the same situation with respect to each other in both cases. But, if the rays that come from these points shall have crossed each other before they arrive at the eye, they will then have a contrary situation to that of two rays coming directly from the same points to the eye; and, consequently, these two points will appear in the glass in a contrary situation. And one may add that, in the former case, the picture upon the retina of the eye will have the same position, though not the same magnitude, as if the glass was removed, and will have a contrary position in the latter case. *Smith's Optics.*

APPARENT *Distance (Dict.)*—The Apparent distance of an object, perceived by sight, is an idea of a real distance usually measured by feeling, as by the motion of the body in walking, or otherwise; and is suggested to the mind by the Apparent magnitude of the object in view, if seen alone (as a bird in the air, or as an object in a telescope or microscope;) but if it be seen with other objects, as it usually happens, its distance is suggested both by its own apparent magnitude, and by the apparent magnitudes of other adjoining objects obliquely extended between the eye and the object in view; as the surface of the ground, rivers, walks, high-ways, hedges and ditches, or the houses in a street, or the walls and ceiling of a room, or the sky over head. For what is the Apparent magnitude or Apparent extension of an object, but the Apparent distance of its extremities from one another? And what is the Apparent distance between two objects in any situation, or between one object and the spectator himself, but the Apparent extension of intermediate objects? And since they are seldom seen alone, excepting through glasses, it cannot be doubted, but we estimate their distances from one another, and from ourselves, by our ideas of the magnitudes of those intermediate objects: and every one knows that surveyors, gunners, travellers, and all sorts of artificers, who are conversant in measuring distances, are able to make a truer estimate of distance by the eye, than others that have not had so much experience. Sometimes, indeed, without attending to those oblique surfaces, we are sensible of the approach of a body by the increase of its own Apparent magnitude, and on the contrary; and, sometimes, we are also sensible of it when the body is at rest, provided it be known and familiar to us. For bodies are distinguished into sorts chiefly by their shapes and colours, and we reckon them small or great, not with comparison with bodies of another sort, but with one another; and having found by experience, that certain quantities of Apparent magnitudes of a known body are constantly attended by certain quantities of distance, the sensation of the magnitude of the body immediately excites the usual idea of its distance: which is also evident in oblique surfaces, as well as those that are perpendicular to the eye: for the ideas of variable distances must either mediately or immediately be excited in the mind by variable sensations, caused by some certain variations in the pictures upon the retina. But, while the distance of the object varies, nothing is varied in its picture, excepting its magnitude; its figure, colour, brightness, and distinctness, receive no sensible variation in most cases: and, for one idea to excite another, every one knows it is sufficient that they have been constantly observed to go together; as in languages, and a thousand things besides. Lastly, I have found by abundance of experiments made with glasses of all sorts, that, while the Apparent magnitude of an object increases by moving the glass, eye, or object, it always appears to approach and to recede, while its Apparent magnitude decreases, excepting a particular case or two to be mentioned hereafter. And these experiments seem to me to put the question beyond dispute. For in looking through a glass with one eye only, and on a single object, when nothing is perceived in the space interposed, how it is possible for different Apparent magnitudes of the object to suggest the ideas of different quantities of that invisible space, according to a certain rule to be mentioned hereafter, if those ideas had not usually gone together, before we looked into the glasses? I find, also, that by altering the degrees of Apparent brightness and distinctness of an object, either by looking through little holes made with a pin, or through lenses of different figures put close to my eye, or through both at once put close together and to my eye, that neither the Apparent magnitude, nor Apparent distance, is sensibly altered thereby. The reason is, we have had no experience in such confused vision with the naked eye, and, therefore, though different degrees of confusion and distinctness in glasses are plainly perceived, yet, like the words of an unknown language, their signification of distance, or of any thing else, is entirely unknown. The same may be said of the degrees of brightness and obscurity. By day-light objects appear equally bright at all moderate distances from the eye, and we retain much the same ideas of their distances in the night, when we see them more obscurely. The permanent colours, and shades of bodies, serve chiefly to distinguish their Apparent shapes; and their colours and shapes are manifest distinctions of their various sorts, but, being permanent, they are no distinctions of their Apparent distances from the eye. When the eye is fixed, and a fixed line is extended from it, the divergency of rays, from different points of that line, is neither distinguished, nor so much as perceived by sense, by persons that see distinctly. It is a rational deduction from sense, which informs us that rays diverge from the points of an object; which the majority of mankind are entirely ignorant of: and the ancient philosophers, who thought that something like rays proceeded from the eye to the object, could distinguish distances as well as we. Therefore, the divergency of rays from points at different distances is not the medium which introduces the ideas of distances into the mind. Sometimes, indeed, there are degrees of its distinctness and confusion consequent upon it, but their relation to distance, as I said before, is not perceived. Besides this, in vision with glasses, we have ideas of as many different degrees of distance conveyed to us, as well when the rays come converging towards points behind the eye, as when they diverge from points before it,

as

as will be shewn hereafter. The divergency of rays from the place of an object is, therefore, no cause of its appearing in that place. It is also matter of fact, in painting and perspective, that our sensible ideas of the places of the objects in the picture are quite different from our rational ideas of the places from whence the rays diverge: and the difference in these ideas is caused by the different Apparent magnitudes of the known objects represented in the picture. It is also evident, that our sensible ideas of the places of the remote parts of a long walk or gallery, and of the clouds over head, and of all celestial bodies, are quite different from the rational ideas of the places from whence the rays diverge, as will appear more fully hereafter. Neither is distance suggested to the mind by the magnitudes of the angles in a triangle made by the optic axes, and the interval between the eyes. For these angles are all varied by turning the head sideways while we look at the object, till at last we see it at the same distance with one eye as with both: which shews, also, that the faint and confused appearance of collateral objects does not alter our ideas of their distances. Nor is distance suggested by feeling the turn of the eyes in widening or contracting the interval between pupils, when we direct them to different places. For the place of the object is generally perceived by a side-view, before we direct our eyes to view it more distinctly. From what has been said, it appears to me, that the ideas of distance are suggested to the mind by the ideas of the magnitudes of objects.

Hence it follows, that an object, seen by refraction or reflection, appears at the same distance from the eye, as it usually does from the naked eye, when it appears of the same magnitude as in the glasses. To determine this distance in all cases, I conceive a ray A O (*plate* IV. *fig.* 9, 10.) to go from the eye at O, and after its last reflection or refraction to belong to the focus ε, in the common axis O C Q of all the surfaces, and to meet an object P Q in P, placed perpendicular to O Q; and that a line P ϖ is drawn parallel to the axis O Q till it meets the ray O A, produced, in ϖ. Then, supposing the object P Q to be removed to the place ϖ κ, and there to be viewed by the naked eye; since it appears under the same angle ϖ O κ or A O C as it appeared under in the glasses, when it was at P Q, it will also appear of the same magnitude, and, consequently, at the same distance from the eye in both cases. Therefore, if, when the object is placed at ϖ κ, its Apparent distance from the naked eye be represented by its real distance O κ, the same O κ will also represent its Apparent distance in the glasses when it was at P Q. I shall, therefore, call O κ the Apparent distance of the object P Q, and ϖ κ the Apparent object.

When the point P and the ray O A, by which it is seen, are on contrary sides of the axis O Q, the point ϖ and the line ϖ κ will be behind the eye, and, therefore, must be viewed by the naked eye inverted and turned about. But, if you had rather ϖ κ should always be before the eye, in this case invert the object P Q, and then slide it along the axis; and its extremity P will touch the visual ray O A, produced, at the same distance from the eye as before; because the opposite angles A O C, ϖ O κ, are equal.

Hence, while the eye, object, or glasses are in motion, the Apparent distance of the object will be increased in the same proportion as its Apparent magnitude decreases; and, on the contrary. For the same Apparent distance of the same object, seen at ϖ κ by the naked eye, varies in the proportion of the same Apparent magnitude.

Hence, also, the Apparent distance, O κ, of an object, P Q, seen in glasses, is to its Apparent distance, O Q, seen by the naked eye, as its Apparent magnitude to the naked eye to its Apparent magnitude in the glasses. For conceiving a line O P, which is omitted in the figures for the sake of simplicity; since P Q and ϖ κ are equal, the former distance, O κ, is to the latter O Q, as the latter angle P O Q to the former ϖ O κ.

The ratio of the Apparent and true magnitudes being determined in most cases in the next article, their Apparent distances are also determined by this rule. But, because this subject of Apparent distance has hitherto been handled but very imperfectly by all optic writers, it may not be unacceptable to some readers to see it pursued a little farther. I will, therefore, deduce all the cases of Apparent distance immediately from the definition of it, without the help of those former demonstrations.

The Apparent and true distances (*fig.* 11, 12, 13.) O κ and O Q will be equal, first, when the object touches any thin lens or any single surface; for then the points P, A, ϖ, will coincide. Secondly, when the eye touches any thin lens or reflecting surface. For, when the points O, A, C, coincide at a lens, the visual ray will pass through the middle of it very nearly; and, consequently, its incident and emergent parts produced will be nearly parallel and coincident, and so the points P, ϖ, will nearly coincide; and when the points O, A, C, coincide at a reflecting surface, the incident and reflected rays produced will make equal angles with the perpendicular Q C κ, and so the triangles P C Q, ϖ C κ, will be equal. Thirdly, when the eye is at the center of a reflecting concave; then the incident and reflected rays, and, consequently, ϖ κ and P Q will coincide. Fourthly, when a ray (*fig.* 10, 14, 15.) P O, coming directly to the eye, makes an angle P O Q equal to A O C or ϖ O κ; for then the triangles P O Q, ϖ O κ, are equal. This happens in a reflecting concave, when the object is very near its center; for producing the object P Q till it cuts the reflected ray in *p*, since the angles P O Q, ϖ O κ, or *p* O Q, are supposed to be equal, the lines P Q, *p* Q, will also be equal, and, consequently, a line Q A will nearly bisect the angle P A *p*, when A is very near to C, as a line drawn from the center E will do, and so the points Q, E, are almost coincident.

The Apparent distance of an object seen in a telescope, or a microscope, is to its Apparent distance perceived by the naked eye, as its Apparent magnitude to the naked eye to its Apparent magnitude in the telescope or microscope; for conceiving (*fig.* 20, 21, 22.) A C to be the object-glass, and the eye to be close to the eye-glass at O, the visual ray A O will go in a manner straight through it; and so the Apparent magnitude, and Apparent distance of the object, will continue the same as when there was no eye-glass: and since, when the vision is distinct, the rays in every pencil come parallel through the eye-glass, the Apparent magnitude, and, consequently, the Apparent distance, will still continue the same as before, while the eye is drawn back.

Consequently, the Apparent distance in a telescope is to the Apparent distance perceived by the naked eye, as the focal distance of the eye-glass to the focal distance of the object-glass, by the 120th and 141st articles; which may thus be demonstrated, independently of the 120th article: let *p q* be the image of a remote object terminated by the line P C *p*, so that *q* C and *q* O may be the focal distances of the object-glass and eye-glass; then supposing the object viewed by the naked eye at C, since the angles ϖ O κ, P C Q, have equal subtenses ϖ κ and P Q, the Apparent distance, O κ, in the telescope, is to the Apparent distance, C Q, to the naked eye at C, as the latter angle P C Q to the former ϖ O κ, or as the opposite angle *p* O *q*, or, since *p q* subtends them both, as the latter focal distance *q* O to the former *q* C.

The same proportion may be proved when (*fig.* 16, 17, 18.) A C represents the eye-glass of a telescope or microscope, and the object-glass is placed at ε, the conjugate focus to O. For let *p q* be the image of the remote object P Q terminated by the line P ε A, and when *q* ε and *q* C are the focal distances of the glasses at ε and C, the ray A O will be parallel to *p* C. Now the Apparent distance O κ is to the Apparent distance ε Q, perceived by the naked eye at ε, as the latter angle P ε Q to the former ϖ O κ, or as the opposite angle *p* ε *q* to the opposite angle A O C, or its equal *p* C *q*, or as the latter distance *q* C to the former *q* ε.

An object seen in any glass will appear behind it, or at it, or before it, according as (*fig.* 9, 10.) ϖ κ or P Q, the real magnitude of the object, is bigger, equal, or less, than A C, the part of the glass in which it appears. For since ϖ κ and A C do both subtend the same, or equal angles, at the eye, O ϖ will be bigger, equal, or less, than O C, according as ϖ κ or P Q is bigger, equal, or less, than A C.

Hence it follows, that an object always appears behind any surface or glass which cannot make rays go parallel that diverged from the eye; for then P Q or ϖ κ will always be greater than A C.

The rule is true in a globe, or in any number of surfaces, taking A for the concourse of the incident and emergent parts of the visual ray produced, and a perpendicular A C upon the axis, instead of the aperture of a single glass. *Smith's Optics.*

APPARENT *Magnitude* (*Dict.*) — The Apparent magnitude of an object P Q (*plate* IV. *fig.* 8.) seen by refracted or reflected rays, either upright or inverted, is a quantity of visible extension, measured by the angle A O C, which the two rays, A O, C O, that came from its extremities, P, Q, do make, after their last refraction or reflection, in falling on the eye. Or, in other words, the object appears greater or smaller, in proportion as that angle A O C is greater or smaller; because its extremities appear in the directions of the last refracted or reflected rays O A, O C; and, also, because its picture upon the retina is greater or smaller, in proportion as these rays constitute a greater or smaller angle at the eye.

Therefore, the Apparent magnitude of an object PQ (*fig.* 19.) is also measured by the angle *p* O *q*, which its last image *p q* subtends at the eye. For the lines A O, *p*O, are but one line continued, and so are CO, *q* O; and, therefore, the angles A O C, *p* O *q*, are the same when the image lies before the eye, and are equal when it lies behind it.

Hence, the Apparent magnitude of an object increases and decreases, in proportion as the eye approaches to, or recedes from, its last image (just as if it was a real object) placed either before or behind the eye; for, when the image is fixed, the angle *p* O *q*, when small, increases in the same proportion as O *q* decreases, and on the contrary.

Hence, if the last image be removed to an infinite distance, that is, if the object be placed in the principal focus of a lens, sphere, or concave looking-glass, its Apparent magnitude to the eye, at any place whatever, will be invariably the same; and

and equal to its Apparent magnitude seen by the naked eye, supposing it put into the place of the center of the sphere, lens, or reflecting concave. For since all the rays of any one pencil are parallel to its axis P E (*fig.* 23.) the angle C O A, which measures the Apparent magnitude at any point O, is every where equal to the angle Q E P at the center E.

The Apparent magnitude of the object will also be invariable wherever it be placed (*fig.* 24.) when the eye is fixed at the principal focus of any glass which makes parallel rays converge to the eye. For, conceiving them to flow back again from the eye to the object, they will fall upon the same points of the object from whence they came, while it is moved in any place along the axis of the glass: and no other rays but these can return from the same points of the object to the eye, in that place: therefore, the several parts of the object will always be seen under the same angles, and, consequently, will appear of the same magnitudes.

The Apparent magnitude of an object seen by reflected or refracted rays being measured by the angle which its last image subtends at the eye, and its Apparent magnitude to the naked eye in any place being measured by the angle which the object itself subtends at the eye in that place, it follows that the former Apparent magnitude is to the latter, as the former angle to the latter angle. For the measures of things and the things measured by them are proportionable.

Consequently, the Apparent magnitude of an object, seen in a glass, will be equal to its Apparent magnitude to the naked eye in the same place, if the glass was removed. First, when the object touches any thin lens or any single surface. For the image is then equal to the object, and coincides with it. Secondly, when the eye touches any thin lens or any reflecting surface. For then the ray P A O will pass from the object to the eye, through the middle of the lens very nearly, and, therefore, being almost straight, will make nearly the same angle with the axis as an unrefracted ray would do: and, when the point of incidence, A (*fig.* 25.) coincides with C at any reflecting surface, the incident and reflected rays P A, A O, produced, will also make equal angles with the axis or perpendicular Q C; and so the object will appear under the same angle as it would do to the naked eye turned about. Thirdly, when the eye is at the center of a reflecting concave, for then the incident and reflected rays, P A, A O, will coincide with the direct ray P E, and, consequently, will make the same angles with the axis. Fourthly, when the object is at the center of the reflecting concave; for then the reflected image is also at the center, and is equal to the object. Fifthly, when a ray, coming directly from P to O, would make an angle with the axis equal to the angle A O C, which the refracted or reflected ray P A O makes with it on the other side.

These cases being excepted, the Apparent magnitude of an object, seen through a concave lens, is always less than the true; and when it is seen uprightly through a convex lens, or a globe, it is greater than the true; for the ray P A O, coming from the extremity of the object to the eye, is bent by the concave lens from its axis, and therefore makes a less angle with it at the eye, than a ray coming directly from that extremity to the eye. But the same ray is bent by the convex lens towards its axis, and therefore makes a greater angle at the eye than the direct ray: and the Apparent magnitudes are measured by these angles.

What has hitherto been demonstrated concerning the Apparent magnitude of an object P Q, will continue in force, if you suppose the object P Q to be an image formed by another glass, or other glasses; for the rays diverge from either of them in the same manner, and for this reason I have always called *p q* the last image of the object.

The place of the eye at O (*fig.* 19.) being given, to determine what part of an object is visible in a given portion or aperture A C of any refracting or reflecting glass, draw A O to the edge of the aperture and produce it till it cuts the image in *p*, and through the center of the glass draw *p* E cutting the object in P; and P Q will be the part in view in the aperture A C. For the whole pencil of rays flowing from P will belong to *p* after refraction or reflexion, and, consequently, some one of those rays will advance to the eye in the line A O drawn through *p*. If the image be at an infinite distance, all the rays that belonged to *p* will be parallel to the axis of the pencil; therefore P Q is now determined by drawing E P parallel to O A. In a plane looking-glass, *p* P must be drawn from *p* parallel to *p* Q, or perpendicular to the glass, to cut off the part P Q visible in the aperture A C. For this glass may be considered as having a center at an infinite distance from it.

Hence, if the glass and object be fixed, the part in view in a given aperture will decrease perpetually while the eye recedes from the glass, unless the image be behind the eye. For then it will decrease only till the eye arrives at the image, and, after the eye has passed by the image, it will increase perpetually. The reason is, because the object and image, being fixed in their places, do both increase or both decrease together, being both terminated by two lines P *p*, Q *q*, that meet or cross in E the center of the glass.

Therefore the part in view is greatest when the eye is close to the glass, and least when close to the image; and, in this latter case, it appears infinitely magnified. For, conceiving the distance O *q* infinitely diminished, the parts *p q*, P Q, cut off by the lines A O *p*, *p* E P, will both be infinitely diminished; but the magnitude of the angle at O, subtended by *p q* or by A C, continues finite, while the angle subtended by P Q at O is infinitely diminished: and so the disproportion between these angles, that is, between the Apparent and true magnitudes of the particle P Q, is infinitely great. It appears also infinitely confused, when the pupil is open, for the reason given under the article EYE.

APPARENT *Place* (*Dict.*) — Opticians are divided in their opinions with regard to the Apparent place of an object, seen by a mirrour, or through a glass. It was thought in general, till lately, that the object appeared in that point where the reflected or broken ray, passing through the center, met the perpendicular drawn from the object on the surface of the mirrour or glass. This principle father Taquet has applied, in his Catoptrics, to explain the phænomena of convex and concave mirrours; M. Mairan, in a memoir read before the Academy of Sciences at Paris, published in the year 1740, proceeded on the same principle to find the apparent curve of the bottom of a basin full of water. But father Taquet himself acknowledges, at the end of his Catoptrics, that this principle is not universal, and is contradicted by experiments. With regard to M. Mairan, he rather lays it down as a principle of geometry than optics, and owns that Sir Isaac Newton, Dr. Barrow, and other authors, of the first reputation, never entirely admitted it. They, to determine the Apparent place of the object, imagine first, that the object throws, on the surface of the glass or mirrour, two rays infinitely near each other, which, after suffering one or more refractions or reflexions, pass to the eye. These broken or reflected rays, being continued, meet in one point, and, consequently, enter the eye as if they came from this point; from whence it follows, according to Newton and Barrow, that the Apparent place of the object is the point of concourse of these reflected or broken rays, which passes on to the eye, and is easy to determine by the laws of geometry. Dr. Barrow produces an experiment which seems unanswerable, by which he demonstrates that a plumb line sunk in water forms a curve; whence it follows that the Apparent place of an object, seen by refraction, is not in the point where the refracted ray cuts the perpendicular drawn from the object to the refracting surface. But we must own also, that Dr. Barrow, at the end of his Optical Lectures, mentions an experiment that seems to contradict the foregoing principle. He adds that this experiment contradicts Taquet's principle, as well as his own. He is however of opinion that a particular case which does not conform to this principle, ought to be looked upon only as a trifling exception against a general rule. With regard to Sir Isaac Newton, though he follows the principle of Dr. Barrow about determining the Apparent place of the image, yet he looks on this problem as one of the greatest difficulties in all optics; his words are these: *Puncti illius accurata determinatio problema solutu difficillimum præbebit, nisi hypothesi alicui saltem verisimili, si non accurate veræ, nitatur assertio. Opt. Schol. Prop.* VIII. *p.* 80.

APPA'RITORS.— Among the Romans, Apparitors were the same with serjeants or tip-staffs among us; or rather Apparitor was a general term, and comprized under it all the ministers and attendants of the judges and magistrates, appointed to receive and execute their orders. And hence, they say, the name was derived, viz. from apparere, to be present, or in waiting.

Under the general name of Apparitores the ancients comprehended the scribæ, accensi, interpretes, præcones, viatores, lictores, statores, and even carnifices or hangmen.

They were usually chosen out of the freed-men of the magistrates; and their condition was held in such contempt, that, as a mark of ignominy, the senate appointed a city that had revolted from them, to furnish them with Apparitors.

There were also a kind of Apparitors of cohorts, called cohortales, or conditionales, as being attached to a cohort, and doomed to that condition. The Apparitors of the prætors, prætoriani, were those who attended the prætors, or governors of provinces; and who, on their master's birth-day, were always changed and preferred to better posts. Add, that the pontifices had also their Apparitors, as appears from an inscription of an ancient marble in the Via Appia.

APPEA'L, of wrong imprisonment, is used by Bracton for an action of wrong or false imprisonment.

Appeal is more particularly used for a private accusation of a murderer, by one who had interest in the murdered party; or of any felon by one of his accomplices in the fact.

If an appeal of murder or felony be used by any common person against a peer, he shall be tried by commoners, and not by his peers.

The person who brings an Appeal, is called the appellant; and the person appealed to, the appellee.

APPEA'RANCE, the exterior surface of a thing; or that which first strikes the sense, or the imagination.

The Academics maintain, that the sensible qualities of bodies are only appearances; and the like doctrine is held by some later philosophers.

APPEARANCE, in perspective, is the representation or projection of a figure, body, or the like object, upon the perspective plane.

The Appearance of an objective right-line is always a right-line. The appearance of an opake body and a luminary given, we can find the Appearance of the shadow.

A'PPLE, denotes a well known fruit, of a roundish figure, of considerable use both as a food, a remedy, and likewise yielding cyder.

The Apple is composed of four distinct parts, viz. the peel, the parenchyma, the branchery, and the core.

The peel or skin is only a dilatation of the outermost skin or rind of the bark of the branch on which it grew.

The parenchyma or pulp, as tender and delicious as it is found, is only a dilatation, or, as Dr. Grew calls it, a swelth, or superbience of the inner part of the bark of the branch.

This appears not only from the visible continuation of the bark from the one through the pedicle or stalk to the other, but also from the structure common to both, as being both composed of bladders; with this only difference, that whereas, in the bark, the vesiculæ are spherical, and very small, scarce exceeding one sixteenth part of an inch in diameter; in the pulp they are oblong, and very large, generally measuring one third of an inch in length. But all uniformly stretched out by the arching of the vessels from the core towards the circumference of the Apple.

The branchery or vessels are only ramifications of the woody part of the branch sent throughout all the parts of the parenchyma, the greater branches being made to communicate with each other by inosculations of the less. The main branches are usually twenty; ten of them distributed through the parenchyma, most of which inarch themselves towards the cork or stool of the flower; the other ten, running from the stalk in a directer line, at last meet the former at the cork, and are there inosculated with them. To these branches the coats of the kernels are fastened. Most of the branches were originally extended beyond the fruit, and inserted into the flower for the due growth thereof; but when the fruit afterwards grew to a head, and thus intercepted the aliment before sent to the flower, this latter being starved and falling off, the service of the said branches became wholly appropriated to the fruit, fifteen to the pulp, and five to the seed. The Apple core is originally from the pith of the branch; the sap of which, finding room enough in the parenchyma, through which to diffuse itself, quits the pith, which by this means hardens into a core.

All the sorts of Apples are propagated by grafting or budding, upon the stocks of the same kind; for they will not take upon any other sort of fruit-tree. In the nurseries there are three sorts of stocks generally used, to graft Apples upon: the first are called free-stocks: these are raised from the kernels of all sorts of Apples, indifferently; and these are also termed crab-stocks; for all those trees which are produced from the seeds, before they are grafted, are termed crabs without any distinction: but, as I before observed, I should always prefer such stocks as are raised from the kernels of crabs where they are pressed from verjuice: and I find several of the old writers on this subject of the same mind. Mr. Austin, who wrote an hundred years ago, says, the stock which he accounts best for Apple-grafts, is the crab; which is better than sweeter Apple-trees to graft on, because they are usually free from canker, and will become very large trees; and, I conceive, will last longer than stocks of sweeter Apples, and will make fruits more strong and hardy to endure frosts: and it is very certain, that, by frequently grafting some sorts of Apples upon free-stocks, the fruits have been rendered less firm and poignant, and of shorter duration.

The second sort of stock is the Dutch creeper: these are designed to stint the growth of the trees, and keep them within compass for dwarfs or espaliers.

The third sort is the paradise-Apple, which is a very low shrub; so only proper for trees which are kept in pots, by way of curiosity; for these do not continue long.

Some persons have made use of codlin-stocks for grafting of Apples, in order to stint their growth: but, as these are commonly propagated by suckers, I would by no means advise the use of them; nor would I chuse to raise the codlin-trees from suckers, but rather graft them upon crab-stocks; which will cause the fruit to be finer, last longer, and have a sharper flavour: and these trees will last much longer sound, and never put out suckers, as the codlins always do; which, if not constantly taken off, will weaken the trees, and cause them to canker; and it is not only from the root, but from the knots of their stems, there are generally a great number of strong shoots produced, which fill the trees with useless shoots, and render them unsightly, and the fruit small and crumpled.

The method of raising stocks from the kernels of crabs or Apples is, to procure them where they are pressed for verjuice or cyder; and, after they are cleared of the pulp, they may be sown upon a bed of light earth, covering them over about half an inch thick with the same light earth: these may be sown in November or December, where the ground is dry; but, in wet ground, it will be better to defer it till February: but then the seeds should be preserved in dry sand, and kept out of the reach of vermin; for, if mice or rats can get to them, they will devour the seeds: there should also be care taken of the seeds, when they are sown, to protect them from these vermin, by setting of traps to take them, &c. In the spring, when the plants begin to appear, they must be carefully weeded; and, if the season should prove dry, it will be of great service to water them two or three times a week; and, during the summer, they must be constantly kept clear from weeds; which, if suffered to grow, will soon over-top the plants, and spoil their growth: if these thrive well, they will be fit to transplant into the nursery the October following; at which time the ground should be carefully digged, and cleansed from the roots of all bad weeds: then the stocks should be planted in rows three feet asunder, and the plants one foot distance in the rows, closing the earth pretty fast to their roots: when the stocks are transplanted out of the seed-bed, the first autumn after sowing, they need not be headed; but, where they are inclined to shoot downward, the tap-root must be shortened, in order to force out horizontal roots: if the ground is pretty good in which these stocks are planted, and the weeds constantly cleared away, the stocks will make great progress; so that those which are intended for dwarfs, may be grafted the spring twelve-month after they are planted out of the seed-beds: but those which are designed for standards will require two years more growth, before they will be fit to graft; by which time they will be upwards of six feet high.

The other necessary work to be observed in the culture of these trees, while they remain in the nursery, being exhibited under the article of NURSERY, I shall not repeat in this place.

I shall next treat of the manner of planting such of these trees, as are designed for espaliers in the kitchen garden; where, if there is an extent of ground, it will be proper to plant, not only such sorts as are for the use of the table, but also a quantity of trees to supply the kitchen: but, where the kitchen garden is small, the latter must be supplied from standard-trees, either from the orchard, or wherever they are planted: but as many of these kitchen Apples are large, and hang late in the autumn upon the trees, they will be much more exposed to the strong winds, on standard-trees, than on espaliers; whereby many of the fruit will be blown down before they are ripe, and others bruised, so as to prevent their keeping: therefore, where it can be done, I should always prefer the planting them in espaliers.

The distance I should chuse to allow these trees, should not be less than twenty-five feet, for such sorts as are of moderate growth (if upon crab or free-stocks) but the larger growing sorts should not be allowed less room than thirty or thirty-five feet, which will be found full near enough, if the ground is good, and the trees properly trained: for the branches of these trees should not be shortened, but trained at their full length, so that in a few years they will be found to meet. Indeed, at the first planting, the distance will appear so great, to those persons who have not observed the vigorous growth of these trees, that they will suppose they never extend their branches so far, as to cover the espalier; but if these persons will but observe the growth of standard-trees of the same kinds, and see how wide their branches are extended on every side, they may be soon convinced, that, as these espalier-trees are allowed to spread but on two sides, so they will of course make more progress, as the whole nourishment of the root will be employed in these side-branches, than where there is a greater number of branches on every side of the tree, which are to be supplied with the same nourishment.

The next thing to be observed, is the making choice of such fruits as grow nearly alike, to plant in the same espalier. This is of great consequence, because of the distance which they are to be placed; otherwise those sorts which make the largest shoots, may be allowed less room to spread, than those of the smaller growth: beside, when all the trees in one espalier are nearly equal in growth, they will have a better appearance, than when some are tall, and others short.

If these Apples are grafted upon crab-stocks, I would willingly place them at the following distance from each other; especially where the soil is good; viz. the largest-growing trees at forty feet, the middle-growing at thirty feet, and the small-growing at twenty feet; which, from constant experience, I find to be full near enough: for in many places, where I have planted these trees at twenty-four feet distance, the trees have shot so, as that in seven years their branches have met, and in ſome places, where every other tree have been taken up, the branches have almoſt joined in ſeven years after: therefore it will be much the better way to plant theſe trees at a proper diſtance at firſt; and between theſe to plant ſome dwarf cherries, currans, or other ſorts of fruit, to bear for a few years; which may be cut away when the apple-trees have extended their branches to them: for, when the apple-trees are planted nearer together, few perſons care to cut down the trees, when they are fruitful; ſo that they are obliged to uſe the knife, ſaw, and chiſſel, more than is proper for the future good of the trees; and many times, where perſons are inclinable to take away part of their trees, the diſtances will be often ſo irregular (where there was not this conſideration in planting) as to render the eſpalier unſightly.

When the trees are upon the Dutch dwarf-ſtock, the diſtance ſhould be for the larger growing-trees twenty feet, for thoſe of middle growth ſixteen, and the ſmaller twelve feet; which will be found full near, where the trees thrive well.

The next is the choice of the trees, which ſhould not be more than two years growth from the graft; but thoſe of one year ſhould be preferred: be careful that their ſtocks are young, ſound, and ſmooth, free from canker, and which have not been cut down in the nurſery: when they are taken up, all the ſmall fibres ſhould be intirely cut off from the roots, which, if left on, will turn mouldy and decay, and ſo will obſtruct the new fibres in their growth: the extreme parts of the roots muſt be ſhortened, and all bruiſed or broken roots cut off; and if there are any miſplaced roots, which croſs each other, they ſhould alſo be cut away. As to the pruning of the head of theſe trees, there need be nothing more done, than to cut off any branches which are ſo ſituated as that they cannot be trained to the line of the eſpalier: in the planting, there muſt be care taken not to place their roots too deep in the ground, eſpecially, if the ſoil is moiſt; but rather raiſe them on a little hill, which will be neceſſary to allow for the raiſing of the borders afterwards. The beſt ſeaſon for planting theſe trees (in all ſoils that are not very moiſt) is, from October, to the middle or latter end of November, according as the ſeaſon continues mild; but, as ſoon as the leaves fall, they may be removed with great ſafety. After the trees are planted, it will be proper to place down a ſtake to each tree, to which the branches ſhould be faſtened, to prevent the winds from ſhaking or looſening their roots, which will deſtroy the young fibres, for, when theſe trees are planted pretty early in the autumn, they will ſoon puſh out a great number of new fibres; which, being very tender, are ſoon broken; ſo the trees are greatly injured thereby. If the winter ſhould prove ſevere, it will be proper to lay ſome rotten dung, tanners-bark, or ſome ſort of mulch, about their roots, to prevent the froſt from penetrating the ground, which might damage theſe tender fibres: but I would not adviſe the laying this mulch before the froſt begins; for if it is laid over the roots, ſoon after the trees are planted (as is often practiſed) it will prevent the moiſture's entering the ground, and do much harm to the trees.

The following ſpring, before the trees begin to puſh, there ſhould be two or three ſhort ſtakes put down on each ſide of the tree, to which the branches ſhould be faſtened down as horizontally as poſſible, never cutting them down, as is by ſome practiſed; for there will be no danger of their putting out branches enough to furniſh the eſpalier, if the trees are once well eſtabliſhed in their new quarters.

In the pruning of theſe trees, the chief point is, never to ſhorten any of the branches, unleſs there is an abſolute want of ſhoots to fill the ſpaces of the eſpalier: for, where the knife is much uſed, it only multiplies uſeleſs ſhoots, and prevents their fruiting; ſo that the beſt method to manage theſe trees is, to go over them three or four times in the growing ſeaſon, and rub off all ſuch ſhoots as are irregularly produced; and train the others down to the ſtakes, in the poſition they are to remain: if this be carefully performed in ſummer, there will be little left to do in the winter; and by bending of their ſhoots from time to time, as they are produced, there will be no occaſion to uſe force, to bring them down, nor any danger of breaking their branches. The diſtance which theſe branches ſhould be trained from each other, for the largeſt ſorts ſhould be about ſeven inches, and for the ſmaller four or five. If theſe plain inſtructions are followed, it will ſave much unneceſſary labour of pruning; and the trees will, at all times, make an handſome appearance: whereas, when they are ſuffered to grow rude in ſummer, there will be much greater difficulty to bring down their ſhoots, eſpecially, if they are grown ſtubborn. All theſe ſorts of Apples produce their fruit upon curſons or ſpurs, ſo that theſe ſhould never be cut off; for they will continue fruitful a great number of years. *Miller's Gard. Dict.*

APPLICATION *of one ſcience to another*, is a term generally made uſe of to convey the idea of the uſe we make of applying the principles and truths which belong to one ſcience, to complete and advance another.

In general, it may be ſaid that there is no art or ſcience which has not ſome connection with another; many articles, in this work, furniſh matter enough to prove this.

APPLICATION *of algebra to geometry*.—Algebra being the calculation of magnitude, in general, and the analyſis the uſe of algebra to diſcover unknown quantities; it was natural, after having diſcovered algebra and the analyſis, to think of applying theſe two ſciences to geometry; becauſe the line, the ſurface, and the ſolid, objects of geometry, are commenſurable magnitudes, and, conſequently, bear a proportion to each other: however, till Deſcartes, nobody ever thought on it; though algebra had made a great progreſs, eſpecially under the hand of Vieta. It is in Deſcartes's geometry that we firſt find the Application of algebra to it, as well as ſome excellent methods to carry algebra itſelf to perfection. This great genius has, by theſe means, done immortal ſervice to the mathematics, and given a key to the moſt important diſcoveries we can ever hope to make in this ſcience.

He firſt taught us to expreſs the nature of curves by equations, to reſolve geometrical problems by theſe curves: in ſhort, often to demonſtrate theorems of geometry by the help of algebraical calculation, when it would be too laborious to demonſtrate them any other way; at leaſt by making uſe of the common methods. Under the articles CONSTRUCTION, EQUATION, and CURVE, *in the Dictionary, and Supplement*, may be ſeen in what this Application of algebra to geometry conſiſts. We know not whether the antients had any help like this in their ſtudies; if they had not, we cannot help wondering they continued ſo long in the dark. We have a treatiſe of Archimedes on ſpiral lines, and his own demonſtrations; but it is hard to know, whether theſe demonſtrations exactly ſhew the method by which he arrived at a diſcovery of the property of ſpiral lines; or, whether, after having made the diſcovery by ſome private method, which he kept to himſelf, had a mind to conceal it, by puzzling demonſtrations. But, if he, indeed, followed no other method than that contained in theſe demonſtrations, it is amazing he did not loſe himſelf, and it is impoſſible to give a greater proof of the depth and ſtrength of his genius. Bouillaud confeſſes he never underſtood the demonſtrations of Archimedes; and Vieta has unjuſtly charged them with abſurdity.

But, be this as it may, theſe ſame demonſtrations which gave Bouillaud and Vieta ſo much trouble, and, perhaps, coſt Archimedes as much, may, at preſent, be rendered extremely eaſy, by the Application of algebra to geometry. The ſame may be ſaid of all the geometrical works of the antients: for ſcarce any man can read and underſtand them eaſily, without knowing how to apply algebra to their demonſtrations.

Sir Iſaac Newton, however, who knew, better than any other man, all the advantages of analytical algebra in geometry, complains, in many places of his works, that reading the antient geometricians is ſhamefully neglected.

In ſhort, the method made uſe of by the antients who applied themſelves to geometry, is looked upon to be more difficult, than that of analytical algebra; and on this principally Sir Iſaac Newton's complaints are grounded; apprehending, by the too frequent uſe of algebra, geometry, which is ſo remarkably difficult in its demonſtrations, might be loſt, or leſs cultivated, ſomething ſo much more eaſy being ſubſtituted in its room. I apprehend, this great man recommends reading the antient geometricians, becauſe their demonſtrations exerciſe the mind ſo much more, accuſtom it to greater application, enlarge its views, and form it to a degree of patience and perſeverance, neceſſary for making new diſcoveries. But we muſt be careful not to run into the oppoſite extreme; for, by applying cloſe to the method of the antients, there is no likelihood, that even the fineſt genius will make ſo great diſcoveries in geometry, or, at leaſt, ſo many, as he might by the help of algebra. As to the ſuperiority given to demonſtrations after the manner of the antients, becauſe they are more difficult, I am in great doubt whether the plea be well founded. On opening Sir Iſaac Newton's Principia, I ſee every thing therein demonſtrated after the manner of the antients; but at the ſame time I perceive very plainly, that Sir Iſaac found out his theorems by other methods than thoſe whereby he demonſtrates them, and that his demonſtrations are nothing more than analytical calculations, which he has diſguiſed by ſubſtituting the name of lines to the algebraical ſymbols. If it be objected that the demonſtrations of Sir Iſaac are difficult, which is true, why ſhould not transferring theſe demonſtrations into the language of algebra be difficult alſo? Let us call a line A B, or expreſs it in algebra by the letter *a*, what difference can ariſe from this, as to the certainty of the demonſtration? In truth, this laſt method has this particular in it, that, when we have expreſſed all the lines in algebraical characters, we may perform many operations, without thinking either on the lines or figure; by which advantage, the mind is relaxed; and, as its ſtrongeſt attention is required to ſolve ſome problems, analytical algebra ſpares it as much as poſſible. It is ſufficient to know, that the principles of calculation are right; the hand works, as it were, mechanically, and exhibits the theorem or problem ſought; which, without theſe methods, we ſhould never have obtained, but by a great deal of trouble. The algebraiſt will have no more to do, to give his ſolution

or

or demonstration the difficulty they pretend it wants, than to turn it into the stile of the ancients, as Sir Isaac has done his.

Admitting the too frequent use of algebra may render the mind remiss, yet it must be owned, that it is absolutely necessary in a great number of our enquiries; but I am very much in doubt whether the use of algebra renders mathematical demonstrations less difficult or not. We may look on the method of the ancients as a fatiguing, rocky, rough road, into which the geometrician leads his reader; the algebraist placed in a more elevated point of view sees, if I may use the expression, all the road, at one cast of his eye; explores every path; can conduct others into them, or keep them there, as long as he pleases.

Besides, there are some cases wherein algebra, instead of shortening demonstrations, renders them more tedious; of this number, among others, is that of comparing angles; on which several problems and theorems depend.

These angles are not to be expressed in algebra, but by their sines; these sines are often complicated, which makes their constructions and expressions difficult. Great geometricians must decide which is preferable, the method of the ancients or algebraical solutions; it is extremely difficult to give general rules with any exactness in this point.

APPLICATION *of Geometry to Algebra*. Though the Application of algebra to geometry be much more common and useful than that of geometry to algebra, yet, on some occasions, the latter takes place. As we represent geometrical lines by letters, we may, sometimes, represent numerical quantities expressed by letters in algebra, by lines in geometry; and from this sometimes results a greater facility of demonstration, in certain theorems, and an easier solution of some problems. To give a plain example, suppose we would find the square of $a + b$; it is easy to demonstrate by algebraic calculation, that this square contains the square of a plus that of b plus twice the product of a by b. But we can demonstrate this proposition geometrically too. In order to this, we need only make a square whose base and perpendicular must be divided each into two parts, one of which we will call A, the other B; afterwards drawing parallel lines through the points of division on the sides of the square, we shall divide it into four superficies, one of which will be the square of a, another that of b, and the two others will be each a rectangle formed by a and b, from whence it follows, that the square of the binomial $a + b$ contains the square of each of the two parts, plus twice the product of the first by the second. This plain example may serve to shew how geometry may be applied to algebra, that is to say, how we may sometimes make use of geometry to demonstrate theorems in algebra.

The Application of geometry to algebra is not so necessary in the example we have just mentioned, as in several others too complicated for us to make an exact enumeration of. We shall therefore only observe, that the consideration of curves of the parabolic kind, and of the course of these curves with regard to their axis, is often useful to demonstrate several theorems relating to equations and their roots with more ease. We may even sometimes apply geometry to arithmetic, that is, make use of geometry to demonstrate some certain theorems in arithmetic more easily, without any particular analysis in a general manner; as for example, let it be required to prove that a series of odd numbers 1, 3, 5, 7, 9, &c. added, shall successively give a series of squares 1, 4, 9, 16, 25, &c.

To this end make a rectangle triangle (*plate* IV. *fig*. 26.) of which let one side be horizontal and the other vertical (we mention the terms horizontal and vertical to fix the imagination) divide the vertical side A B into as many equal parts as you please, and through the points of division 1, 2, 3, 4, &c. draw the parallels 1 f, 2 g, &c. to B E, you will at first have the little triangle A 1 f; then the trapezium 1 f g 2, three times as big as the triangle; then a third trapezium 2 g h 3, 5 times as big as the triangle; so that the spaces determined by these parallels 1 f, 2 g, &c. will be represented by the following numbers 1, 3, 5, 7, &c. beginning this arithmetical progression from the triangle A 1 f.

Now the sums of these spaces will be the triangles A 1 f, A 2 g, A 3 h, &c. which are as the squares of the sides A 1, A 2, A 3, that is to say, as 1, 4, 9, &c. then the sum of the odd numbers gives the sum of the square numbers. This proposition may indeed be demonstrated algebraically, but the preceding demonstration may satisfy those who are ignorant of algebra.

APPLICATION *of Geometry and Algebra to Mechanics*. This is founded on the same principles as the Application of algebra to geometry. It consists chiefly in representing the curves which bodies describe in their motion by equations, in determining the equation between the spaces which bodies generate (when acted upon by any powers whatever) and the time they take to pass through these spaces, &c. We cannot indeed compare two things of a different nature together, such as space and time; but we may compare the proportion of time with the parts of space passed over. Time in its nature flows uniformly, and mechanics imply the same uniformity.

Further, without knowing time in itself and having any exact measure of it, we cannot represent it more clearly, with respect to its parts, than by the parts of an infinite right-line. Now the proportion between the parts of such a line, and that of the parts of space passed through by a body, moved in whatever manner, may always be expressed by an equation. Let us suppose a curve, the abscissæ of which represent the portions of time past since the beginning of the motion, the corresponding ordinates denoting the spaces passed through during these portions of time. The equation of this curve will express, not only the proportion of the time to the space, but, if we may speak so, the proportion of the proportion that the parts of time have to their unity, to that which the parts of space, passed through, have to their's; for the equation of a curve may be considered either as expressing the proportion of the ordinates to the abscissa, or as the equation between the proportion that the ordinates have to their unity, and that which the corresponding abscissa have to their's.

It is evident then, that by the bare Application of geometry and calculation we may account for the general properties of motion, varied by any law whatever, without the help of any other principle. In the article ACCELERATED *Motion*, in the Dictionary, may be seen an example of geometry applied to mechanism; the time of the descent of a gravitating body is there represented by the perpendicular of a triangle, the velocity by the base, and the spaces passed through by the area of the parts of the triangle.

APPLICATION *of Geometry and Astronomy to Geography*. This consists in three things. 1, In determining the figure of this globe we inhabit. 2, In finding, by their longitude and latitude, the situation of places. 3, In determining the situation of places near each other. Astronomy and geometry are of great use in navigation.

APPLICATION *of Geometry and Algebra to Physics*. This we owe to Sir Isaac Newton, as we may owe the Application of algebra to geometry to Des Cartes, and it is founded on the same principles. The properties of bodies in general have between each other certain proportions, which we may compare with each other, more or less distinguishable; and these we can discover by geometry or algebra. On this are founded all the physico-mathematical sciences. One single observation or experiment often demonstrates a whole science. As for example: the bare knowledge of this, that the angle of incidence is equal to the angle of reflexion, which is known to be true, contains the whole science of catoptrics. This principle of being once admitted, catoptrics becomes a science purely geometrical, because it is reduced to comparing angles with given lines of position. The thing is the same in many other cases. By the help of geometry and algebra, we can in general determine the power of one effect, which depends on another better known. This science, therefore, is almost always necessary to compare and examine the facts experiments discover to us. It must be owned however, that every subject of physics is not equally capable of the Application of geometry. Several experiments admit of no calculation at all; such are those of the magnet, electricity, and many others; in these cases we must forbear applying it. Geometricians, however, are apt to run into this fault, by advancing hypotheses on experiments, and proceeding to calculation according to these hypotheses; but these calculations ought no farther to be regarded, than as the hypotheses on which they are supported, are conformable to nature; and, therefore, observations ought to confirm them, which unfortunately sometimes does not happen. Besides, supposing the hypotheses true, they are not always sufficient. If there be in an effect a great number of circumstances owing to several causes, which act all together, and we content ourselves with considering some of these causes only, which, being more simple, can be calculated more easily; we may gain a partial effect of these causes; but it will be very different from the total effect, which would result from uniting all the causes.

APPLICATION *of a Geometrical Method in Metaphysics*.—Geometry has been sometimes abused in physics by applying the calculation of the properties of bodies to arbitrary hypotheses. A geometrical method has also been misapplied in sciences, which in their own nature submit to no calculation, I mean the method only, not the science. Several metaphysical writers, who have published certain truths, have yet, copying after the manner of geometricians, ridiculously enough, swelled their page with the pompous words axiom, theorem, corollary, &c.

The authors of these works certainly imagined that these words, by some secret charm, composed the essence of a demonstration; and that by writing at the end of a proposition, that it might be demonstrated, they should make that demonstrable which was not really so. Geometry does not owe its certainty to this method, but to the evidence and simplicity of its object: and though a treatise on geometry, when divested of its ordinary terms, may be very good; yet, a treatise on metaphysics may be often very bad, by the

the affectation of following a geometrical method. We ought even to distrust this class of writers, for the generality of their pretended demonstrations are only founded upon an abuse of words.

Those who have considered these things, know how common and easy the abuse of words is, especially in metaphysical subjects. It is in this particular the school-men have excelled pity; and it is they made no better use of their sagacity.

APPLICATION *of metaphysics to geometry.* Metaphysics are sometimes misapplied in geometry, as well as geometry in metaphysics. Geometry, like all other sciences, has a kind of metaphysics proper to itself, which is certain and incontestable; because the geometrical propositions, which result from it, afford an evidence, which demands our assent. But, as mathematical certainty arises from the simplicity of its object, its metaphysics too must be extremely simple and clear; must always be capable of being reduced to perfect ideas, without any obscurity. In short, how can the consequences of any thing be certain and evident, if the principles are not so? Yet some authors have thought themselves able to introduce into geometry a kind of metaphysics, often obscure, and, what is still worse, have affected to demonstrate, metaphysically, truths which have been already established on other principles; this surely was the way to render those truths doubtful, if they could possibly be so. The new geometry has principally occasioned this false method. By considering parts infinitely small as real quantities, and admitting some of these to be greater and some less, they have acknowledged an infinity of small particles of different classes; and looked on them as real somethings, instead of endeavouring to reduce these suppositions and calculations to simple ideas.

Another abuse of metaphysics in geometry consists in confining metaphysics to geometrical demonstrations. Admitting even the metaphysical principles we set out upon to be certain and evident, there are scarce any geometrical theorems that can be accurately demonstrated by their help alone; they almost always require lines and calculations: this manner of demonstration is very material, because it is in short the only sure and certain method; since with our pens, not metaphysical reasonings, we can make combinations and certain calculations.

This latter kind of metaphysics, which we have been speaking of, is however good to a certain degree, provided we do not confine ourselves too much: it makes us carefully examine the principia of discoveries; it furnishes us with lights; it points out to us the road; but we are not sure of being right, if we may be allowed the expression, without the staff of calculation, to point out the proper objects which we before saw confusedly.

One would think great geometricians ought always to be excellent metaphysicians; at least in the objects of their science. This is not, however, always the case. Some geometricians are like people who possess a sense of seeing, contrary to that of feeling; this proves yet more how necessary calculation is in geometrical truths. One may venture to affirm that the geometrician, who is a bad metaphysician in the objects he applies himself to, will, in others, be intolerable: though geometry, whose object is the mensuration of body and matter, may in some cases be applied to thought.

APPLICATION *of one thing to another*, is a term made use of to denote the service the first is of to understand or bring the second to perfection. Thus the Application of the cycloid to pendulums signifies the use made of the cycloid to bring pendulums to perfection.

APPORTIO'NMENT, APPORCIONMENT, or APPORTIONAMENTUM, in law, a dividing of a rent into two parts or portions, according as the land, whence it issues, is divided among two or more proprietors.

Thus if a man, having a rent-service issuing out of land, purchase a part of the land; the rent shall be apportioned, according to the value of the land. So if a man let lands for years, reserving rent, and a stranger after recover part of the lands, the rent shall be apportioned.

But a rent-charge cannot be apportioned, nor things that are intire; as if one hold land by service, to pay to his lord yearly at such a feast a horse or a rose; there, if the lord purchase part of the land, this service is totally extinct; because such things cannot be divided without hurt to the whole. But if part of the land, out of which a rent charge issues, descends to the grantee of the rent, this shall be apportioned. A man purchases part of the land where he hath common appendant, the common shall be apportioned: of common appurtenant it is otherwise; and, if by the act of the party, the common is extinct. Common appendant and appurtenant may be apportioned on alienation of part of the land to which it is appendant or appurtenant. Conditions generally are intire, and cannot be apportioned by the act of the party; a contract may not be divided or apportioned, so as to subject a man to two actions.

APPRA'ISER, one who rates, or sets, a value upon goods, &c. He must be a skilful and honest person. It is not a business of itself, but generally performed by brokers of household furniture, to which set of men the word was formerly, and I believe still is, chiefly applied; yet now also upholsterers, and other brokers, are employed, or even any person or persons who are supposed to be skilled in the commodities they are to appraise, or set a value on.

They are employed in cases of death, executions brought in upon goods, of stock to be turned over from one person to another, or divided between copartners; and have the name of sworn Appraisers, from their taking an oath to do justice between party and party.

They sometimes appraise jointly, each party agreeing to have the same Appraiser, or Appraisers; sometimes in opposition, each party chusing one, or more, of a side; and sometimes by commission, or deputation, of trustees, masters in chancery, &c.

Their manner is, each one for himself, to take an inventory of every article, and mark its value with his own private characters. When they have gone through the whole, they give their estimates in a gross sum, very rarely of particulars. When they value against one another, if they happen to differ much, they reconsider, and at length most commonly bring it to an average; and, in some cases, they are obliged to take the goods at their own valuation, if the parties shall think proper to relinquish them.

At Bourdeaux they call Appraisers (appreciateurs in French) those clerks of the custom-house and of city duties, who appraise and rate the merchandizes which are imported or exported, in order to regulate upon what footing the duties of importation or exportation ought to be paid.

The custom-house at Bourdeaux is called the convoy, and the office of the city duties is called comptablie. The city duties are such as were granted by the French king to certain cities, either to pay their debts, or for their particular occasions.

The office of those Appraisers consists in the following particulars:

1. They are obliged to keep a register, or memorandum-book, marked and numbered by the director of the office, and to transcribe and enter into it all the declarations which are delivered from day to day at the office for the receiving the city duties, without augmenting or diminishing any thing in them but by the express order of their superiors.

2. To deliver carefully as many receipts, or bills of entry, as there are articles in each declaration.

3. The merchandizes being entered, and carried into the said custom-house, according to the order of those receipts, or bills of entries, the Appraisers are obliged to open and visit them, when the merchant requires it, in order to know the quantity and quality of them; which being found to agree both with the declarations and bills of entries, the Appraisers make a true estimate, or evaluation, of each merchandize in particular, according to the market-price of them.

4. They must enter into their register their estimate both of the weight and of the quality and quantity of the merchandize, as they found them by their search, or visit. And, as to those merchandizes which are weighed in the custom-house, the Appraisers expedite them upon the report of the warehouse-keeper.

5. They are obliged, after appraising the merchandizes, to deliver a second receipt, or bill of entry, which serves the merchants to clear their merchandizes, either at the custom-house, if any duty be owing there; or at the office of the city duties; as also what may be due for brokerage.

6. They ought to write the said bills of entry upon the register of importations by sea; and, if there be grocery, they must also register them in the register of receipts designed for that purpose, that the merchants may pay the duties owing for them at the custom-house, according to the printed tariff. And, with regard to the merchandizes that come from the western isles, the said Appraisers are obliged to register them all indiscriminately, in a particular register, as well as in the register of importations by sea, with their appraised price, except sugars, which are not registered in the registers of importations by sea, nor in that of the city duties, but only in a particular register kept by the receiver of the custom-house, as well as that of the western isles.

7. As for those merchandizes which are not carried to the custom-house, as deal-boards, and other timber coming by sea, the said Appraisers expedite them upon the report, and after the examination, of the searchers of outward-bound ships. And, with regard to tar, gum, pitch, train-oil, herrings, pilchards, &c. they expedite them according to the bill of lading: and, as for green or dried fish, the Appraisers expedite it according to the report of the clerks who were present at the unloading and landing of it.

8. At the end of every quarter they draw up an alphabetical list of all the merchandizes imported by sea, that have been cleared at the custom-house.

9. Finally, with regard to the merchandizes that come by land, the Appraisers have several things to observe, viz. as to those that come from the inland country by the boats of Thoulouse, Agen, and other places, they follow the same rules

rules and methods with regard to those that come by sea, except that they do not deliver bills of entries for those merchandizes, which is done by the clerks of the office of the city duties, after receiving the declarations.

As for those that come by the stage-coaches, by carriers, by waggons, or other carriages, they clear them upon the certificates, or acquits, given by the clerks of the custom-house offices through which they passed. *Postlethwait's Dict. of Commerce.*

APPRE'NTICESHIP, the time during which apprentices are obliged to continue with the merchants or tradesmen with whom they are bound. Their indentures ought to be recorded in the register of the company, or body, to which their masters belong; and their time does not begin but from the day on which the indenture is registered. No one, in France, can be admitted a tradesman, unless he produces his indenture, and the certificates of his Apprenticeship. *Art.* 3. *of tit.* 1. *of the ordonnance of the year* 1673.

The French give the name of apprentisse to a maiden, or woman, who binds herself for a time with a mistress, before a notary-public, in order to learn her art, or trade, almost after the same manner as apprentice-boys.

And with us it is enacted, by *stat.* 8. *Ann. cap.* 9. *sect.* 32, that there shall be paid the duty of six-pence for every pound, of every sum of 50 l. or under, and twelve-pence for every twenty shillings of every sum more than 50 l. which for five years shall be paid, or agreed for, in the putting out any clerk, apprentice, or servant, to learn any profession, trade, or employment; and proportionably for greater or lesser sums, to be paid by the master or mistress.

The full sum given, or agreed to be given, with an apprentice, &c. shall be written in words, at length, in the indenture, &c. which must bear date on the day it was executed, upon pain that every master or mistress, offending in these particulars, shall, for every offence, forfeit double the sum given, or agreed to be given; one moiety to the crown, the other, with costs, to him who will sue within one year after the time limited for such clerk, or apprentice, to serve his master, &c. is expired. *Sect.* 33.

All indentures, &c. of Apprenticeships, which shall be executed in any other part of Great-Britain, shall, within two months after they are executed, be brought either to the head office, or to some collector of the stamp-duties; and the duty shall be paid; and, in case the payment be made to the receiver-general, the indenture shall be stamped; and, in case the payment be made to a collector, he shall indorse in words, at length, a receipt of the money paid to him, and subscribe his name. *Sect.* 37.

Every indenture so endorsed, if it is executed within 50 miles of London, shall, within three months after date, if executed at a greater distance, then within six months after date, be brought to the said head office where (the same beino produced with a receipt endorsed) it shall be stamped. *Sect.* 38.

Indentures wherein the full sum agreed on shall not be inserted, or the duties not paid, or not stamped, or tendered to be stamped, shall be void, and the clerk, or apprentice, shall have no privilege of freedom, or using his trade.

Money given to put out apprentices, either by parishes or public charities, shall not pay any duty. *Sect.* 39.

Forging the stamps, or any receipt for monies payable by this act, is felony, without benefit of clergy. *Sect.* 41.

No indenture, &c. shall be admitted in evidence in any suit to be brought by the parties thereunto, unless he, for whom it shall be given in evidence, first makes oath, that, to the best of his knowledge, the sum therein mentioned was all that was paid, &c. on behalf of the apprentice, for the benefit of the master, &c. *Sect.* 43.

Where any thing shall be given to a master, not being money, the duty shall be paid for the full value thereof. *Sect.* 45.

APPREHE'NSION, in metaphysics, an operation of the mind, which makes it perceive an object.

The soul according to Father Malbranche is capable of apprehension three different ways, the intellectual faculty, the imagination, and the senses. It perceives spiritual and universal things, simple ideas, and, in general, all its thoughts that arise from reflection on itself, purely from the intellectual faculty. Material things too it perceives this way, as extension with all its properties; for there is nothing, but the pure intellectual faculty can conceive a perfect circle or square, a figure of a thousand sides, and many things of a like nature. This kind of apprehension is called pure or intellectual apprehension, because it is not necessary the mind should form images in the brain, to represent all these things to itself. It perceives by imagination material beings, though absent, as if present, by forming images of them in the brain. It is in this manner we imagine all kinds of figures: these perceptions may be called imaginations; because the soul represents these objects to itself, by forming images of them in the brain; and, because we cannot form images of spiritual substances, it consequently follows, the soul cannot imagine them. In short, the soul only perceives grosser objects by the senses, which by being present make an impression on the external organs, which impression is communicated to the brain; and these perceptions are called sensations.

When Father Malbranche says, corporeal substances are represented by the imagination, and spiritual by the understanding or intellectual faculty; does he understand himself? In either case is it not equally a thought of the mind; and is it not equally employed whether it think on a mountain, which is a corporeal object, or an intelligence, which is a spiritual being? It may be answered, the operation of the mind, that acts by virtue of the impressions made in the brain by corporeal objects, is imagination, and that the operation of the mind, independent of these impressions, is purely the intellectual faculty. When the Cartesians speak of these traces in the brain, are they in earnest? With what kind of microscope have they discovered these traces in the brain which form the imagination? Admitting they had discovered them, how can they tell, whether the mind may not have occasion for them, in all her operations, even the most spiritual?

To speak more justly, let us say, the faculty of thinking is always the same, always equally spiritual, on whatever object it is employed. They by no means prove its spirituality more by one object than another; no more by what they call the intellectual faculty, than by the imagination. Do not angels think on corporeal as well as spiritual objects? Should we therefore distinguish in them the imagination from the pure intellectual faculty? Have they more occasion for traces on the brain in either case? With us it is the same: as soon as the mind thinks, it thinks absolutely, with an essential spirituality, as real, as that of purer spirits; call it which you will, imagination or intellectual faculty.

But, when a body presents itself to the mind, is it not said we form an ideal shape of it? This term in use among the ancient philosophers is nothing to the present purpose, or barely signifies the internal object of the mind, when it thinks on a body. Besides, this internal object is equally spiritual, whether it thinks on material or immaterial substances; because in either case it stands in need of the senses. We conclude, therefore, that the essential difference some are fond of establishing between the pure intellectual faculty and the imagination, is nothing more than a chimerical distinction.

APPROA'CHING, in fowling, a term used to express such devices as are contrived for the getting within shot of shy birds.

It is principally used in marshy low places. The best method of Approaching is by the means of three hoops tied together at proper distances, according to the height of the man that is to use it, and having boughs of trees tied all round it, with cords to hang it over his shoulders; a man, getting into this, conceals himself, and approaches by degrees toward his game in the form of a moving bush.

Geese, ducks, and teal, quit the waters in the evening and pass the night in the fields, but at the approach of morning they return to the water again, and even when on the water, they will retire to great distances, on the approach even of a horse or cow, so that the business of the stalking horse is of little use; but this device of Approaching by the moving bush succeeds tolerably well with them. *Dict. Rust.*

APPRO'XIMATION (*Dict.*)—Under this article in the Dictionary we have given the method of approximating the roots of equations by their limits; we shall here add the method of approximating by converging series.

If there be only two letters, x and a, in the proposed equation, suppose a equal to an unit, and find the root of the numeral equation that arises from the substitution, See APPROXIMATION in the dictionary. Multiply these roots by a, and the products will give the roots of the proposed equation.

Thus the roots of the equation $x^2 - 16x + 55 = 0$ are found to be 5 and 11. And therefore the roots of the equation $x^2 - 16ax + 55a^2 = 0$, will be $5a$ and $11a$. The roots of the equation $x^3 + a^2x - 2a^3 = 0$ are found by enquiring what are the roots of the numeral equation $x^3 + x - 2 = 0$, and, since one of these is 1, it follows that one of the roots of the proposed equation is a; the other two are imaginary.

If the equation to be resolved involves more than two letters, as $x^3 + a^2x - 2a^3 + ayx - y^3 = 0$, then the value of x may be exhibited in a series, having its terms composed of the powers of a and y, with their respective co-efficients; which will "converge the sooner the less y is in respect of a, if the terms are continually multiplied by the powers of y, and divided by those of a." Or, "will converge the sooner the greater y is in respect of a, if the terms be continually multiplied by the powers of a, and divided by those of y." Since, when y is very little in respect of a, the terms y, $\frac{y^2}{a}$, $\frac{y^3}{a^2}$, $\frac{y^4}{a^3}$, $\frac{y^5}{a^4}$, &c. decrease very quickly, If y vanish in respect of a, the second term will vanish in respect of the first, since $\frac{y^2}{a} : y :: y : a$. And after the same manner $\frac{y^3}{a^2}$ vanishes in respect of the term immediately preceding it.

But, when y is vastly great in respect of a, then a is vastly great in reſpect of $\frac{a^3}{y}$, and $\frac{a^3}{y}$ in reſpect of $\frac{a^3}{y^2}$; ſo that the terms a, $\frac{a^2}{y}$, $\frac{a}{y^2}$, $\frac{a^4}{y^3}$, $\frac{a^5}{y^4}$, &c. in this caſe decreaſe very ſwiftly. In either caſe, the ſeries converge ſwiftly that conſiſt of ſuch terms; and a few of the firſt terms will give a near value of the root required.

If a ſeries for x is required from the propoſed equation that ſhall converge the ſooner the leſs y is in reſpect of a; to find the firſt term of this ſeries, we ſhall ſuppoſe y to vaniſh, and extracting the root of the equation $x^3 + a^2x - 2a^3 = 0$, conſiſting of the remaining parts of the equation that do not vaniſh with y, we find, that $x = a$; which is the true value of x when y vaniſhes, but is only near its value when y does not vaniſh, but only is very little. To get a value ſtill nearer the true value of x, ſuppoſe the difference of a from the true value to be p, or that $x = a + p$. And, ſubſtituting $a + p$ in the given equation for x, you will find

$$\left.\begin{aligned} x^3 &= a^3 + 3a^2p + 3ap^2 + p^3 \\ +a^2x &= a^3 + a^2p \\ -2a^3 &= -2a^3 \\ +ayx &= a^2y + apy \\ -y^3 &= -y^3 \end{aligned}\right\} = 0$$

$$\left.\begin{aligned} = 4a^2p + 3ap^2 + p^3 \\ a^2y + apy - y^3 \end{aligned}\right\} = 0.$$

But ſince, by ſuppoſition, y and p are very little in reſpect of a, it follows that the terms $4a^2p$, a^2y, where y and p are ſeparately of the leaſt dimenſions, are vaſtly great in reſpect of the reſt; ſo that, in determining a near value of p, the reſt may be neglected: and from $4a^2p + a^2y = 0$, we find $p = -\frac{1}{4}y$. So that $x = a + p = a - \frac{1}{4}y$, nearly. Then to find a nearer value of p, and conſequently of x, ſuppoſe $p = -\frac{1}{4}y + q$, and ſubſtituting this value for it in the laſt equation, you will find

$$\left.\begin{aligned} p^3 &= -\tfrac{1}{64}y^3 + \tfrac{3}{16}y^2q - \tfrac{3}{4}yq^2 + q^3 \\ 3ap^2 &= \tfrac{3}{16}ay^2 - \tfrac{3}{2}ayq + 3aq^2 \\ 4a^2p &= -a^2y + 4a^2q \\ ayp &= -\tfrac{1}{4}ay^2 + ayq \\ a^2y &= a^2y \\ -y^3 &= -y^3 \end{aligned}\right\} = 0 =$$

$$\left.\begin{aligned} = -\tfrac{65}{64}y^3 + \tfrac{3}{16}y^2q - \tfrac{3}{4}yq^2 + q^3 \\ -\tfrac{1}{16}ay^2 - \tfrac{1}{2}ayq + 3aq^2 \\ +4a^2q \end{aligned}\right\} = 0.$$

And ſince, by the ſuppoſition, q is very little in reſpect of p, which is nearly $= -\frac{1}{4}y$, therefore q will be very little in reſpect of y; and, conſequently, all the terms of the laſt equation will be very little in reſpect of theſe two, viz. $-\frac{1}{16}ay^2 + 4a^2q$, where y and q are of leaſt dimenſions ſeparately; particularly the term $-\frac{1}{2}ayq$ is little in reſpect of $4a^2q$, becauſe y is very little in reſpect of a; and it is little in reſpect of $-\frac{1}{16}ay^2$, becauſe q is little in reſpect of y.

Neglect therefore the other terms, and ſuppoſing $-\frac{1}{16}ay^2 + 4a^2q = 0$, you will have $q = \frac{1}{64} \times \frac{y^2}{a}$; ſo that $x = a - \frac{1}{4}y + \frac{1}{64} \times \frac{y^2}{a}$. And by proceeding in the ſame manner you will find $x = a - \frac{y}{4} + \frac{y^2}{64a} - \frac{131y^3}{512a^2} + \frac{509y^4}{16384a^3}$, &c.

When it is required to find a ſeries for x that ſhall converge ſooner, the greater y is in reſpect of any quantity a, you need only ſuppoſe a to be very little in reſpect of y, and proceed by the ſame reaſoning as in the laſt example of the ſuppoſition of y being very little.

Thus, to find a value for x in the equation $x^3 - a^2x + ayx - y^3 = 0$, that ſhall converge the ſooner the greater y is in reſpect of a. Suppoſe a to vaniſh, and the remaining terms will give $x^3 - y^3 = 0$, or $x = y$. So that, when y is vaſtly great, it appears that $x = y$ nearly.

But, to have the value of x more accurately, put $x = y + p$, then

$$\left.\begin{aligned} x^3 &= y^3 + 3y^2p + 3yp^2 + p^3 \\ -a^2x &= -a^2y - a^2p \\ +ayx &= ay^2 + ayp \\ -y^3 &= -y^3 \end{aligned}\right\} = 0 =$$

$$\begin{aligned} = +3y^2p + 3yp^2 + p^3 - a^2y - a^2p \\ + ay^2 + ayp. \end{aligned}$$

Where the terms $3y^2p + ay^2$ become vaſtly greater than the reſt, y being vaſtly greater than a or p; and conſequently $p = -\frac{1}{3}a$ nearly.

Again, by ſuppoſing $p = -\frac{1}{3}a + q$, you will transform the laſt equation into

$$\left.\begin{aligned} -\tfrac{1}{27}a^3 + 3y^2q + 3yq^2 + q^3 \\ -a^2y - ayq - aq^2 \\ -\tfrac{1}{3}a^2q \end{aligned}\right\} =$$

where the two terms $3qy^2 - a^2y$ muſt be vaſtly greater than any of the reſt, a being vaſtly leſs than y, and q vaſtly leſs than a, by the ſuppoſition; ſo that $3qy^2 - a^2y = 0$, and $q = \frac{a^2}{3y}$ nearly. By proceeding in this manner, you may correct the value of y and find that $x = y - \frac{1}{3}a + \frac{a^2}{3y} + \frac{a^3}{81y^2} - \frac{8a^4}{243y^3}$, &c. which ſeries converges the ſooner the greater y is ſuppoſed to be taken in reſpect of a.

In the ſolution of the firſt example thoſe terms were always compared in order to determine p, q, r, &c. in which y and thoſe quantities p, q, r, &c. were ſeparately of feweſt dimenſions. But, in the ſecond example, thoſe terms were compared in which a and the quantities p, q, r, &c. were of the leaſt dimenſions ſeparately. And theſe always are the proper terms to be compared together, becauſe they become vaſtly greater than the reſt, in the reſpective hypotheſis.

In general; to determine the firſt, or any term in the ſeries, ſuch terms of the equation are to be aſſumed together only, as will be found to become vaſtly greater than the other terms; that is, which gave a value of x, which, ſubſtituted for it in all the terms of the equation, ſhall raiſe the dimenſions of the other terms all above, or all below, the dimenſions of the aſſumed terms, according as y is ſuppoſed to be vaſtly little, or vaſtly great in reſpect of a.

Thus, to determine the firſt term of a converging ſeries, expreſſing the value of x in the laſt equation $x^3 - a^2x + ayx - y^3 = 0$, the terms ayx and $-y^3$ are not to be compared together, for they would give $x = \frac{y^2}{a}$, which ſubſtituted for x, the equation becomes $\frac{y^6}{a^3} - ay^2 + y^3 - y^3 = 0$, where the firſt term is of more dimenſions than the aſſumed terms $ayx - y^3$: and the ſecond of fewer; ſo that the two firſt terms cannot be neglected in reſpect of the two laſt, neither when y is very great nor very little, compared with a. Nor are the terms x^3, ayx, fit to be compared together in order to obtain the firſt term of a ſeries for x, for the like reaſon.

But x^3 may be compared with $-a^2x$, as alſo $-a^2x$ with $-y^3$, for that end. Theſe two give the firſt terms of a ſeries that converges the ſooner the leſs y is; as $x^3 = y^3$ gives the firſt term of a ſeries that converges the ſooner the greater y is.

The comparing x^3 with $-a^2x$ gives theſe two ſeries,

$$x = a - \tfrac{1}{2}y - \frac{y^2}{8a} + \frac{7y^3}{16a^2} - \frac{59y^4}{128a^3}, \text{ \&c.}$$

$$x = -a + \tfrac{1}{2}y + \frac{y^2}{8a} + \frac{9y^3}{16a^2} + \frac{69y^4}{128a^3}, \text{ \&c.}$$

The comparing $-a^2x$ with $-y^3$ gives

$$x = -\frac{y^3}{a^2} - \frac{y^4}{a^3} - \frac{y^5}{a^4} - \frac{y^6}{a^5} -, \text{ \&c.}$$

And theſe ſeries give three values of x, when y is very little; the laſt of which is itſelf alſo very little in that caſe, as it appears indeed from the equation, that, when y vaniſhes, the three values of x become $+a$, $-a$, and 0, becauſe, when y vaniſhes, the equation becomes $x^3 - a^2x = 0$, whoſe roots are a, $-a$, 0.

A'PRICOCK. See ARMENIACA.

A'PSIS (*Dict.*)— Some mechanic philoſophers conſider the motion of a plant from one Apſis to the other, as vibrations of a pendulum: for example, the motion of the moon from her perigee to her apogee, and from her apogee to her perigee; and apply the laws of vibration to this motion; from whence they infer, that theſe oſcillations of the heavenly bodies will ceaſe on the reſtoration of the equilibrium, which will one day return.

Others are of opinion there is ſomething not mechanical in this motion; they aſk why was the equilibrium deſtroyed; and why have theſe vibrations taken place? Why is not the equilibrium reſtored; and why continue theſe vibrations to interrupt it? See *Memoires de Trev. April* 1730, *p.* 709 *& ſeq.*

Theſe queſtions they look on as unanſwerable; which only proves they were ſtrangers to the Newtonian philoſophy. See *Newton's Principia, lib.* 1. *ſect.* 9. *Herman. Phoron. lib.* 1. *cap.* 4.

Among the authors who have compared theſe vibrations to that of a pendulum, one of the moſt celebrated is Bernouilli, late profeſſor of mathematics at Baſe, in a piece intitled, 'New Thoughts on the Carteſian Syſtem, with the Manner 'of reducing the Orbits and Aphelia of the Planets from it.' This carried the prize at the Royal Academy of Sciences at Paris in the year 1730. In it he endeavours to explain, how it might happen, even in the ſyſtem of vortices, that a planet muſt not neceſſarily be always at the ſame diſtance from the ſun, but alternately approach nearer to it, or recede farther from it. But in natural philoſophy it is not ſufficient to give a plauſible explication of a particular phænomenon. The hypotheſis we lay down for explaining this phænomenon, muſt be conſiſtent with itſelf, and what depends on it. Now, if we examine the explanation given by Bernouilli, it will appear difficult to conceive how he can ſhew it poſſible a plant ſhould deſcribe an ellipſis round the ſun, and the ſun poſſeſs one focus of that ellipſis; and yet the area of the diſtances, deſcribed round the ſun, be proportionable to the time

time of its revolution, as deduced from obſervations. See, on this ſubject, a Memoir of Monſieur Bouguer, Member of the Academy, publiſhed in 1731, on the curvilinear Motion of Bodies in the Mediums wherein they move.

If the line of the greateſt diſtance of a planet, and that of the leaſt diſtance, be not ſituated in a right line, but form an angle more or leſs than 180 degrees, it is called the motion of the line of the Apſides, or the motion of the Apſides. And, if the angle be leſs than 180 degrees, we ſay the motion of the Apſides is contrary to the order of the ſigns: on the contrary, if the angle be more than 180, we ſay it is according to the order of the ſigns. As to a method of determining the poſition of the Apſides, ſeveral ways have been made uſe of. The antients, who thought the planets deſcribed perfect circles, of which the ſun was not the center, made uſe of a method to determine the Apſides, explained by Keil in his Aſtronomical Inſtitutions. Since it has been diſcovered that the planets deſcribe ellipſes, of which the ſun poſſeſſes one of the foci, new methods have been diſcovered to determine the ſituation of the Apſides in their orbits. Halley has propoſed one which requires only the time of the revolution of the planet to be given. Seth Ward has laid down another, which ſuppoſes three different obſervations of the planet to be made in any three different parts of its orbit; but this is founded on an hypotheſis not exactly true, and the celebrated Mr. Euler has publiſhed a far better method in the 7th vol. of the Memoirs of the Academy of Peterſburgh; all theſe different methods, except the laſt, may be ſeen in Keil's Aſtronomy. See Halley's method under APHELION.

Sir Iſaac Newton has given a curious method for determining the motion of the Apſides in his Principia, by ſuppoſing the orbit deſcribed by the planet to be little different from a circle, as almoſt all the planetary orbits are. This great philoſopher has ſhewn, that if the ſun were fixed, and all the planets gravitated towards him in an inverſe ratio of the ſquare of their diſtances, there would be no motion of the Apſides; that is, the lines of the greater and leſſer diſtance would be exactly 180 degrees diſtant from each other; and, conſequently, form a right line. The reaſon, therefore, why the two points of the Apſides are not always exactly in a right line with the ſun, is, becauſe the reciprocal tendence of the planets towards each other, and their gravitation towards the ſun, is not exactly in an inverſe ratio to the ſquare of their diſtances. Sir Iſaac gives a very nice method of determining the motions of the Apſides, by ſuppoſing we knew the force added to the gravitation of the planet towards the ſun, and that this additional force always has its direction towards the ſun.

APUI', or APPUI, in the manage, q. d. reſt or ſtay upon the hand, the reciprocal effort between the horſe's mouth and the bridle-hand; or the ſenſe of the action of the bridle on the hand of the horſeman.

A juſt Appui of the hand, is the nice bearing up or ſtay of the bridle; ſo that the horſe, being awed by the ſenſibility and tenderneſs of the mouth, dares not reſt too much upon the bit-mouth, nor check or beat upon the hand to withſtand it.

A dull, obtuſe Appui, is when a horſe has a good mouth, but his tongue ſo thick, that the bit cannot work, or bear upon the bars; the tongue not being ſo ſenſible as the bars: though the like effect is ſometimes owing to the thickneſs of his lips. A horſe is ſaid to have no Appui, when he dreads the bit-mouth, is too apprehenſive of the hand, and cannot bear the bit. He is ſaid to have too much Appui, when he reſts or throws himſelf too much, too hardily upon the bit. Horſes, deſigned for the army, ought to have a full Appui upon the hand.

A'PUS, in aſtronomy, a conſtellation in the ſouthern hemiſphere placed near the pole, between the triangulum auſtrale and the chameleon, ſuppoſed to repreſent the bird of paradiſe. *Keil, Aſtron. laſt.*

The Apus is ſuppoſed one of thoſe birds called apodes, as having no feet.

There are four ſtars of the ſixth, three of the fifth, and four of the fourth magnitude, in the conſtellation Apus.

Dr. Halley, in 1677, obſerved the longitude and latitude of the ſtars in Apus, which Hevelius, in his Prodromus, reduced, with ſome alteration, to the year 1700.

P. Noel has alſo given the places of theſe ſtars, with their right aſcenſions and declinations for the year 1687: but his obſervations differ widely from thoſe of Dr. Halley. Hevelius has repreſented the figure of Apus, and its ſtars, in his Firmamentum Sobieſcianum, according to Halley's account; Noel has done the like, according to his own account. Wolfius, with what juſtice we ſhall not pretend to ſay, gives the preference to this laſt.

APU'TTASY, in botany, a name given by the people of Guinea to a tree, a decoction of which is in great uſe among them for waſhing the mouth to cure the ſcurvy in the gums, and preſerve the teeth; the leaves of this tree ſtand very irregularly; ſometimes in pairs, ſometimes alternately, and ſometimes at ſmaller, ſometimes at greater diſtances from one another. They have ſcarce any pedicle; they are broad at the baſe, and narrow at the point; ſmooth and gloſſy above, and whitiſh and ſomewhat hoary underneath; eſpecially the large ribs, which, being obſerved againſt the light, are clouded; the largeſt leaves are two inches and a half long and about one inch broad; the tree is large and ſpreading. *Phil. Tranſ.* Nº. 232.

A'QUA-FO'RTIS *(Dict.)*—The diſtillation of Aqua-fortis is as follows, viz.

Put vitriol into an earthen or iron pot: if you make a fire under it, the vitriol begins to melt and ſmoak; by increaſing the fire gradually, it thickens, and aſſumes an aſh colour. Let it be ſtirred with a twig before it becomes ſolid, till it be perfectly dry; but let it be taken as yet boiling out of the pot, for, if it grows cold therein, it will ſtick ſo faſt that you will hardly be able to get it out. Pound to a ſubtile powder three pounds weight of this calcined vitriol, and mix them well with four pounds of nitre well dried, and pulverized very fine. Put theſe together in a cucurbit, or retort, or an iron pot, and then put it in a furnace.

At firſt, let the fire be made not much greater than is neceſſary to boil water. When the recipient grows warm, continue the ſame degree of fire, till all the phlegm is expelled, which you will know from the diminution of the heat of the recipient: increaſe the fire gradually, till you ſee a few yellow vapours ariſe. Keep up the ſame fire for an hour or two, and make it ſo ſtrong as to warm the veſſels moderately. Continue this for ſome hours, and, letting the veſſels cool, pour the liquor, now emitting reddiſh fumes, out of the recipient into a glaſs veſſel, having a glaſs ſtopple: this liquor thus prepared is your Aqua-fortis.

Remarks.

1. In this operation you muſt always proportion the duration of the degrees of your fire to the quantity of the matter to be diſtilled.

2. For ſecurity's ſake, you muſt leave, in the cloſure of the recipient and veſſel that contains the matter to be diſtilled, a hole, which may be ſtopped and opened with a wooden peg: for, if you happen to exceed the juſt degree of fire, eſpecially in the beginning of the operation, the firſt and more ſubtile ſpirits, which are very elaſtic, come forth; the opening, therefore, of the hole may give them a paſſage, leſt the veſſels ſhould burſt, which would be very dangerous.

3. The better your nitre is refined, the better will the Aqua-fortis be. Avoid carefully the mixture of ſea-ſalt therewith, for the reaſon we ſhall give, when we treat of Aqua-regia.

4. There are many other ingredients uſed in the making of Aqua-fortis, ſuch as burnt allum, ſand, and the like; the reaſon whereof is, to hinder the ſpecies, which may happen not to be ſufficiently calcined, from fuming, and from breaking the veſſel with great violence. But, when theſe ſpecies are duly calcined and dried, theſe additions are quite needleſs; and, indeed, by overſwelling the maſs to be diſtilled, require veſſels of a ſize proportionable.

5. There are many other needleſs and noxious ingredients uſed by ſome in making Aqua-fortis. Theſe are blood-ſtones, unſlaked lime, plume allum, &c. all which ſhould be avoided, they making a much worſe, as well as a more expenſive Aqua-fortis. Water thus made, therefore, ſhould never be uſed in docimaſtical operations, before it has been accurately tried; for, Aqua-fortis being tainted with theſe heterogeneous matters, the major part of it conſumes away, and becomes frequently ſo fixed, that the ſtrongeſt fire is hardly able to take off any of it. Nothing ſhould be uſed beſides calcined vitriol, intimately mixed with nitre, there being no need of any thing elſe.

6. However, bole, clay, and brick-duſt expel Aqua-fortis out of nitre, which then is called the ſpiritus nitri; but you muſt add four times as much of theſe, in proportion to the nitre: conſequently, this method, requiring larger veſſels and more fire, cannot be ſo profitable, as without theſe ingredients.

7. As the extracted ſpirits of nitre are with difficulty condenſated into drops, eſpecially in ſultry weather, it will be proper, by reaſon of the calcined ingredients, to pour into the recipient one quarter part of pure water, or rather of the phlegm, extracted out of the Aqua-fortis; by which means the ſpirits will be much eaſier received.

The beſt Aqua-fortis is often tinged with a greeniſh colour, which happens if, Aqua-fortis having been expoſed ſome days to the air, and loſt its red fuming ſpirit, there be mixed with it ſome freſh ſtrong Aqua-fortis ſtill emitting its fumes, or if Aqua-fortis be diluted with water. As this colour may, however, proceed from copper diſſolved in it, to be certain that it does not, a little is to be poured into a cucurbit, and as much of ſome alcaline liquor to be added to it as will ſaturate the acid. Then, if there be ever ſo little copper in it, the colour becomes a deep blue, and there is a cloudy precipitation made, becauſe the nitre has been regenerated by this proceſs, and does not diſſolve copper, ſo much as Aqua-fortis does: but, if there be no copper in the Aqua-fortis, the colour diſappears.

The nice aſſayer, after having carefully proved this Aqua-fortis, muſt concentrate it to a certain degree; for, if too weak, it often retards the ſolution, and ſometimes does not even

even affect the silver; but this concentration is only to be in a certain degree; for, if carried too far, and the Aqua-fortis made too strong by it, it vanishes into fumes, which rush violently out of the receiver, or vessel the solutions are made in, though sufficiently high, and carries away a part of the silver with it in vapours; and if there is any thing of gold in the silver, it will be corroded into a fine dust, which it proves very difficult afterwards to collect together. *Cramer's Art of Assaying.*

When Aqua-fortis is too weak, it is to be put into a deep cucurbit, and the watery part is to be drawn from it, by a gentle fire, till yellow fumes begin to arise. To find out whether it be too strong, the following method is to be used: melt together one part of gold, and four parts of silver; of this make a flat plate, which cut into three or more parts; roll up up each part, that it may be conveniently put into the neck of a cucurbit: when rolled up, and gently heated at the fire, put it into a cucurbit, pour upon it three times its weight of Aqua-fortis, and set it into a gentle heat: if the silver be eroded from the gold, and the gold retain the same figure of a piece of plate rolled up, and there appear no reddish dust at the bottom of the vessel, then the Aqua-fortis has its proper degree of strength: but, if the dissolution has been made with so much violence, that the gold was eroded, or the plate almost broken, then the Aqua-fortis was too strong. It must then be diluted with a tenth, or an eighth part, of Aqua-fortis phlegm; or, if that is not at hand, with the same quantity of common water. This done, the trial is to be repeated, by the dissolution of a like plate rolled up; and this several times over, till the silver be dissolved, without the least diminution of the gold. By this the assayer is assured of a due degree of strength in his menstruum, for all the purposes he requires it for. *Cramer's Art of Assaying.*

AQUA MARINA, *(Dict.)*— This precious stone, is of a colour compounded of green and blue, nearly resembling that of sea-water, from whence the name.

It seems very probable that the ancients knew it under the name of the beryl-stone; for Pliny observed that the most beautiful beryls were those that imitated the colour of sea-water; he likewise distinguishes several sorts of beryls, which bear no resemblance with our Aqua marina; as the chrysoberyls, which were of a golden colour. Whatever the ancients called the Aqua-marina, we are now to endeavour to find out a sure means to distinguish this precious stone from all others. The colour being a mixture of green and blue, we cannot confound it either with green or blue stones as the emeralds and the saphires: for if we suppose the emerald of a pure green without any tincture of blue, and the saphire blue as indigo, and free from any tincture of green, we may easily discover that all stones, compounded of a green and blue, can neither be emeralds nor saphires. This mixture of an emerald-colour with that of a saphire, that is, of green and blue, describes so well the Aqua marina, that it seems impossible to be mistaken. Not but that there are some of these stones, where the green is more predominant than the blue; as well as others, where the blue is more powerful than the green. These stones are very different from each other, with respect to their hardness. The oriental are reckoned the hardest, and bear the finest polish; and, consequently, are more beautiful, more scarce, and dearer than the occidental.

The most beautiful Aqua marina's come from the East-Indies; and it is said that some of them are found on the borders of the Euphrates and at the foot of Mount Taurus. The occidental ones come from Bohemia, Germany, Sicily, the Isle of Elba, &c. And it has been affirmed that some of them have been found on the sea-shore.

AQUA-*Regia* *(Dict.)*—This menstruum is made in the following manner:

Take one pound of common salt: melt it in a clean crucible, or iron ladle: pour it out into an iron mortar; and when cold, break into little bits of the size of pease. Put these into a retort, and pour upon them twice their weight of good Aqua-fortis. Set the retort in a sand-furnace; lute on a recipient, and apply a gradual fire, till no more liquor drops from the nose of the retort.

An Aqua-regia may likewise be made, by mixing one part of spirit of salt with three of Aqua-fortis; or by dissolving the same quantity of sal armoniac in it: but this should be done slowly, and by degrees; otherwise great quantity of offensive fumes will arise.

Aqua-regia dissolves perfectly iron, copper, tin, gold, mercury, regulus of antimony, bismuth, and zink. It even dissolves lead more than spirit of salt does; however, it becomes somewhat troubled in the operation. If it has its requisite degree of strength, it does not dissolve silver: but if you have put in the mixture a quantity of sal-armoniac, or of marine salt, or of spirit of common salt, not sufficient, it then corrodes silver, nay, it even dissolves it in part, this Aqua-regia being imperfect.

The reason is then self-evident, why, in the separation of silver and gold by Aqua-regia, it is better to use a quantity of spirit of salt, or of marine salt, or of sal-armoniac, exceeding, than one short of the right measure. Nor is it less evident thence, why an exact separation of silver and gold is better effected with Aqua-fortis than with Aqua-regia; as the former never corrodes gold, whereas the latter corrodes silver frequently.

AQUIFO'LIUM, *the holly-tree*, in botany, a genus of trees, whose characters are:

The leaves are set about the edges with long sharp stiff prickles: the berries are small, round, and, for the most part, of a red colour, containing four triangular striated seeds in each.

Botanical authors enumerate thirty-three species of this tree. These trees were formerly in much greater request than at present, and there was scarcely a small garden of any worth, but was filled with these trees, which were clipped either into pyramids, balls, or some other figures; but as this was crouding a garden too much with one sort of plant, and the fashion of clipping greens going off, they are now almost wholly neglected: such are the changes in men's tempers and fancies, that what is one year esteemed, is the next despised.

The manner of raising the common hollies, is, by sowing the berries, which, if sown as soon as ripe, will lie two years in the ground, that is, until the spring-twelvemonth after; you may therefore mix the berries with dry sand, and put them in a large garden-pot, burying it in the ground till next August or September; and take them out, and sow them on a bed of common earth, covering the seeds about a quarter of an inch with light mould, and the spring following the plants will appear above-ground: but as this is a tedious method, and the young plants making but small progress for the two or three first years, I would rather advise the purchasing of young stocks, of about three or four years growth, of some nursery-men, who raise them for sale, and these will be fit to bud or graft the second year after they are planted; or you may purchase such young plants, of several kinds, as have been budded or grafted two years, which are generally sold very reasonably in the nurseries; than to hazard the budding them yourself, especially if you are not sure of being provided with cuttings very near you.

Hollies are also planted for hedges, and have been by some very much esteemed for that purpose; but the leaves being very large, when these hedges are clipped, they are generally cut in pieces, and appear very ragged; otherwise they make a very durable strong hedge, and very proper for an outside fence of a green-garden.

The great variety of variegated hollies, which were so much cultivated in the nurseries some years ago, and were sold for large prices, are now almost entirely neglected, few persons caring to plant them in their gardens; nor indeed are they so beautiful as the common green holly, which is also much more hardy than the variegated sorts, which in severe winters are often greatly injured, and sometimes killed, by frost.

The Dahoon holly is a native of Carolina, from whence the plants have been procured. This sort hath smooth shining-green leaves, which are a little indented on their edges; the leaves are as large as those of the bay-tree, and its having a beautiful green renders it one of the best kinds of ever-green trees: the berries are produced in large clusters close to the branches, which are of a bright red colour, and make a fine appearance when they are ripe. *Miller's Gardener's Dictionary.*

A'QUILA, *the eagle*; the general characters of these birds are, that they are birds of prey, flying about in the day-light, not like the owl kind in the night, very large in size, extremely bold and fierce, and have beaks growing crooked, immediately from their insertion at the head. The eagle differs from the hawk in size, and from the vulture in the crookedness of his whole beak. *Willoughby's Ornithol.* See *Plate* IV. *fig.* 27.

AQUILA *marina*, the sea-eagle, in ichthyology, the name of a species of cartilaginous flat-fish, of the pastinachia marina kind. It is generally found small, but sometimes grows to a very large size. Its head is large for a fish of this genus, and somewhat resembles a toad's in shape; its eyes are large and prominent: its mouth is placed in the under part of the head, and is large, and furnished with strong teeth. It sides are broad and thin, and represent the expanded wings of an eagle, whence it had its name. *Salvian de Aquat.* See *Plate* IV. *fig.* 28.

AQUILE'GIA, in botany. See COLUMBINE.

ARABE'SQUE, or ARABESK, something done after the manner of the Arabians.

A'RABIC, *Arabicus*, something that relates to Arabia, or the Arabs.

ARABIC, or ARABIC *Tongue*, is a branch or dialect of the Hebrew.

Father Angelo de St. Joseph speaks much of the beauty and copiousness of the Arabic. He assures us it has no less than a thousand names for a sword; five hundred for a lion; two hundred for a serpent; and eighty for honey.

ARABIC *Figures* *(Dict.)*— The origin of these characters, has been a subject of dispute in the republic of letters.

The learned are generally of opinion, that the Arabic figures were first taught us by the Saracens, who borrowed them from the Indians. Scaliger was so satisfied of their novelty, that he immediately pronounced a silver medallion, he was consulted about, modern, upon his seeing of the numeral figures 2 3 4, 2 3 5, on it. The common opinion is, that Planudes, who lived towards the close of the thirteenth century, was the first Christian who made use of them. Father Mabillon even assures us, in his work de Re Diplomatica, that he has not found them any where earlier than the fourteenth century.

Yet Dr. Wallis insists on their being of a much older standing; and concludes they must have been used in England, at least as long ago as the time of Hermannus Contractus, who lived about the year 1050; if not in ordinary affairs, yet at least in mathematical ones, and particularly astronomical tables. *Vid. Wall. Algebr.*

The same author gives us an instance of their antiquity in England, from a mantle-tree of a chimney in the parsonage house of Helmdon in Northamptonshire, wherein is the following inscription in basso relievo, M°. 133, being the date of the year 1133. *Philos. Transact.* N°. 255.

Mr. Luffkin furnishes a yet earlier instance of their use, in the window of a house, part of which is a Roman wall, near the market-place in Colchester; where between two carved lions stands an escutcheon, containing the figures 1090. *Philos. Transact.* N°. 255.

Mr. Huet is even of opinion, that these characters were not borrowed from the Arabs, but from the Greeks; and that they were originally no other than the Greek letters, which we all know that people made use of to express their numbers by.

ARA'BIAN *Philosophy*, or *the state of philosophy among the ancient* ARABIANS. Authors of great antiquity inform us, that the ancient Arabians applied themselves very much to philosophy, and distinguished themselves by a peculiar and superior sagacity: but all they say on this head seems very uncertain. Indeed, after Islamim, learning and the study of philosophy were greatly esteemed among this people; but this has no place in history till we come to the philosophy of the middle age; and, consequently, proves nothing with regard to the philosophy of the ancient inhabitants of Arabia Felix.

Some men of letters have asserted, that the ancient Arabs applied themselves to philosophical speculations; and to maintain their opinion, raise imaginary systems which they attribute to them, and draw in the religion of the Sabeans to their aid, which they pretend to have been the offspring of philosophy. But all they advance in favour of this opinion, is founded on assertions and conjectures; and what are these where proof and testimony are wanting? They are even forced to acknowledge, that the Greeks were of another opinion, looking on them as a most barbarous and ignorant people without the least tincture of learning. If credit may be given to Abulfaragius, the Arabian writers themselves confess, that before Islamim they were sunk into the deepest ignorance. But these reasons do not seem strong enough to those on the other side of the question, to induce them to retract their opinion of the philosophy they attribute to the ancient Arabs. The contempt the Greeks express for this nation, say they, proves the pride of the Greeks, not the barbarianism of the Arabians. But what authority can they produce, or what writers can they quote, in favour of their opinion concerning the philosophy of the ancient Arabians? They agree with Abulfaragius, that there are none; this opinion therefore stands on a very weak foundation. Joseph Peter Ludewig has signalized himself most in this dispute, and seems to have had the honour of the ancient Arabians very much at heart. He sets out in this manner: "Pythagoras, says he, as Porphyry relates, in his travels to improve his learning, did the Arabians the honour of a visit; staid some time among them, and learned of their philosophers divination by the chirping and flight of birds; an art in which they excelled. Moses himself, instructed in all the learning of the Egyptians, chose Arabia for a retreat in his exile, preferable to other countries. Can one imagine the great legislator of the Hebrews would have chose this retreat, if the people had been barbarous, stupid, and ignorant? Besides, their origin leaves no room to doubt of the improvement of their mind: they boast of their lineage from Abraham, whom no one can deny to have been a great philosopher. By what strange accident is that spark of philosophic spirit extinguished which they inherited from their common father Abraham? But what appears yet a stronger argument, is this, that the holy writings, to give a more exalted idea of Solomon's wisdom, place it in opposition to the wisdom of the wise men of the East; which is certainly Arabia. From this same Arabia came the queen of Sheba to admire the wisdom of the philosopher, invested with a diadem; this has been the constant opinion of all men of erudition. It is easy to prove that the Magi who came out of the East to worship our Saviour, were Arabians. In short, Abulfaragius is obliged to agree, that, before the time of Islamim, to whom the revival of learning in that country is owing, they were perfect masters of their own language, good poets, excellent orators, and able astronomers. Is not this enough to give them a right to the title of philosophers"? No, it may be replied, the Arabians might have polished their language, have succeeded in composition, have been skilful in the solution of riddles, and interpretation of dreams; nay, though it be admitted they had some knowledge of the courses of the stars, it will not follow they were philosophers; for all these arts, if they merit the name, tend more to increase and encourage superstition, than to discover truth, or divest the soul of the passions which enslave it. As to what concerns Pythagoras, nothing is more uncertain, than whether he travelled into the East or no: but, admitting he did, what are we to conclude, but that he learned from the Arabians all those superstitions and extravagant notions he was so extremely fond of. It is needless to quote Moses here; if this great man went into that country, and settled there, by marrying one of Jethro's daughters; it certainly was not with a design of studying and incouraging them in their foolish curiosity in philosophical systems. Providence permitted this retreat of Moses among the Arabians, to carry among them the knowledge of the true God, and his religion. The philosophy of Abraham, from whom they boast their descent, by no means proves their having cultivated this science. Abraham might have been their primogenitor, and a great philosopher; but their philosophy is no necessary consequence of this. If they lost the thread of those most valuable truths they had learned from Abraham; if their religion degenerated into gross idolatry; why might not their philosophy, admitting Abraham to have taught it them, have been lost also, in course of time? Besides, it is not certain that these people descended from Abraham. This is a traditionary tale, that seems to have taken birth with Mahometanism. The Arabians, like the Mahometans, to give the sanction of authority to their errors, have pretended to deduce their origin from the father of the faithful. Another thing that overturns Ludewig's hypothesis, is, that Abraham's philosophy is a mere device of the Jews, who would fain persuade us that the origin of all arts and sciences is to be found among them. What they say in support of the queen of Sheba's coming to visit Solomon on the fame of his wisdom, or of the wise men who came out of the East to Jerusalem, will prove nothing more than has been advanced before. Let it be granted this queen was born in Arabia; is it proved she was of the sect of the Sabians? No one will pretend to deny her to have been the most expert and sagacious woman of her time, and that she frequently puzzled all the kings of the East with her wise questions; because the sacred writings has given this account of her. But what has this to do with the philosophy of the Arabians? We acknowledge very freely, that the Magi who came out of the East were Arabians; that they were not without some knowledge of the courses of the stars; we do not absolutely exclude the Arabians from this science, but admit they spoke their native language well; succeeded in some works of invention, as oratory, and poetry; but we are not to infer from hence that they were philosophers, and had applied themselves strongly to the cultivation of this part of literature.

A second argument in favour of the philosophy of the ancient Arabians, and which is urged as a very forcible argument too, is the history of Sabianism, which necessarily implies philosophical knowledge, supposing all to be true which is said about it. We cannot conclude any thing from thence in favour of this opinion: for Sabianism is in itself a mixture of shameful idolatry and ridiculous superstition; much more likely to subvert and extinguish reason, than propagate true philosophy; besides, it is not agreed in what age this sect first appeared. Men of the greatest eminence for learning, who have laboured to give light to this passage in history, as Hottinger, Hyde, Pocock, and especially the learned Spencer, confess that there is no mention made of this sect either by the Greeks or Romans.

We must take care not to confound these Sabians of Arabia with those mentioned in the annals of the ancient eastern church, which were half Jews, half Christians; and boasted of being the disciples of St. John the Baptist; great numbers of which, even to this day, inhabit the city of Bassora, near the banks of the Tigris, and the neighbourhood of the Persian sea. The famous Moses Maimonides has extracted a large account of this sect from the Arabic writers, and by examining their extravagant and superstitious ceremonies with attention, has very ingeniously justified the laws of Moses in general; which at first might give offence to delicacy, if the wisdom of those laws was not shewn by their opposition to the laws of the Sabians. A stronger barrier could not be put between the Jews and Arabians, who were their neighbours. On this subject consult Spencer's Oeconomy of Moses.

The name of this sect is no less a point of controversy than its age; Pocock asserts they were so called from צבא, which in Hebrew signifies the stars or hosts of heaven; because the religion of the Sabians consisted principally in the adoration of the stars. But Scaliger thinks, that this name was originally given to the Chaldeans, because they were orientals.

 He

He has been followed in this opinion by many men of learning, and, among others, by Spencer. This signification of the word Sabian seems so much more plausible, because the Sabians pretend to draw their origin from the Chaldeans, and make Seth the founder of their sect. But it seems very indifferent which side of the question is taken, in a matter of so little importance. If we mean, by the Sabians, all those people of the East, who worshipped the stars; which seems to be the opinion of some Arabian as well as Christian writers; the name cannot properly be applied to any particular sect, but to all those who were guilty of idolatry. But it seems this name has always been thought to denote a particular sect. We do not see it given to all the people who joined the worship of fire to the adoration of the stars. If we might venture to attempt removing this darkness diffused over the history of the Sabians in general, by the light of conjecture, it seems probable that Sabianism is nothing but a mixture of judaism and paganism; that among the Arabians it was a particular religion distinct from all others; that its professors, to exalt themselves above every other sect that flourished in their time, not only affected to be very ancient, but carried back their origin even as high as the son of Seth: in which they affected to excel the Jews, who pretended to go no farther back than Abraham. We cannot think them to have been called Sabians, on account of their being orientals; because the Magi and Mahometans, who inhabit the eastern parts of Asia, have never been called by this name. Whatever be the original of the Sabians, this is certain, it is by no means so ancient as the Arabians pretend. Nay, they are far from being agreed among themselves, on this subject; some go back as far as Seth, others are contented to stop at Noah, and some even at Abraham. Eutycheus, an Arabian author, on the credit of the traditions of his country, maintains Zoroaster to have been the author of this sect, who was born in Persia, or perhaps in Chaldea; though Eutycheus observes, some of his contemporaries gave Juvan the honour of having been their founder (he doubtless means Javan) that the Greeks very eagerly embraced this opinion, because it flattered their pride, Javan having been of their kings; and that, in order to spread this doctrine, they had composed several books on the science of the stars, and the motions of the celestial bodies. Some were even of opinion, that the founder of the sect of the Sabians was one of those employed in building the tower of Babel. But by what is all this supported? If the sect of the Sabians be as ancient as they pretend, why have not the Greeks mentioned it? Why do we read nothing in scripture concerning it? To answer this objection, Spencer thinks it sufficient to say, that Sabianism, considered as a religion which teaches the worship of the sun and stars, took its origin from the ancient Chaldeans and Babylonians, and preceded the time of Abraham many ages. This he endeavours to prove from the testimonies of the Arabians, who all concur in the antiquity of Sabianism, and from the similarity between the doctrines of the Sabians and Chaldeans. But the question is not whether the worship of the sun and stars be very ancient, no doubt it is; as we shall shew under the article CHALDEANS. The difficulty consists in knowing whether the Sabians received this worship in such a manner from the Chaldeans and Babylonians, that we may be assured Sabianism first took its birth among these people. If we observe strictly, Sabianism will be found not only to consist in the worship of the sun, stars, and planets; but also to contain a form of ceremonies particular to itself, which distinguish it from any other religions; and, when we consider this, its antiquity cannot be maintained. Spencer himself, subtil as he is, and refined in his reasonings, has been forced to agree that Sabianism, considered religiously, that is, with regard to its forms and ceremonies, contains many things much more modern than the ancient Chaldeans and Babylonians. This, however, he ought to have proved at his first setting out, for if Sabianism, considered in this light, betrays a want of antiquity to carry it back beyond Abraham: how will he prove that several laws of Moses were established by divine authority in direct opposition to the superstitious ceremonies of Sabianism?

There is no sect without books, to support its particular opinions; and we find the Sabians had theirs, which were attributed to Hermes and Aristotle by some, to Seth and Abraham by others. These books, according to the account of Maimonides, contained a heap of ridiculous stories relating to the old patriarchs, Adam, Seth, Noah, and Abraham; in a word, like the fables of the Alcoran. They treated at large of dæmons and idols, the stars and planets, the culture of the vine, the sowing of corn, and every thing that concerned the worship paid to the sun, the fire, the stars, and planets. Any one, curious of these matters, may consult Maimonides. We should tire the reader to trouble him with such ridiculous fables. This reason is sufficient for us to condemn these books as apocryphal, and unworthy of credit. Indeed, they seem to have been composed about the birth of Mahomet, and by authors who had a tincture of idolatry, and the follies of modern Platonism.

The absurd notions of the Sabians will appear best by quoting some of their opinions; they held the stars were so many deities, whereof the sun was chief. These they celebrated with two kinds of worship, one performed every day, another every month; they worshipped dæmons under the form of he-goats; fed on the blood of the sacrifices which yet they held in abomination, thinking, by that means, they should have a more intimate intercourse or communication with the dæmons; they paid adoration to the rising sun, with a strict observance of ceremonies; a most surprising contrast of which we see, in general, throughout the whole law of Moses; for God, according to some learned men, chose to give the Jews laws directly opposite to those of the Sabians, in order to turn the former from the extravagant superstitions of the latter.

The Arabian philosophy, before Mahomet, was, therefore, entirely Sabian, and included the system and ceremonies of that sect of idolaters. This it was that Mahomet set himself to decry; and he is even said by some to have carried his opposition so far, as to prohibit, if not punish, all study of philosophy. But his followers, by degrees, got over this restraint; the love of learning increased; till, under the memorable caliphate of Al-Mamon, Aristotle's philosophy was introduced and established among them; and from them propagated, with their conquests, through Egypt, Africa, Spain, and other parts. Avicenna only flourished in the eleventh century, and Averrhoes a hundred years after him; so that the honour of translating the Greek philosophy, by many attributed to these authors, is not justly due to them: though they were the chief propagators of it through the counties of Europe.

Their method of philosophising was faulty; they followed Aristotle implicitly, and, in astrology, run into strange superstitions. They founded schools and academies, gave themselves much to subtilties and disputation, and divided into several sects.

As they chose Aristotle for their master, they chiefly applied themselves to that part of philosophy called λογικη, and thus became proficients in the knowledge of words, rather than things. Whence they have been sometimes denominated masters of the wisdom of words, sometimes the talking sect. Their philosophy was involved in quaint arbitrary terms and notions, and their demonstrations drawn from thence, as from certain principles, &c.

ARABIAN *Poetry*, may be divided into two ages. The antient, according to Vossius, was no other than rhiming; was a stranger to all measure and rule; the verses loose and irregular, confined to no feet, number of syllables, or any thing else, so they rhimed at the end; oftentimes all the verses in the poem ended in the same rhime. It is in such verse that the alcoran is said to be written.

The modern Arabian poetry takes its date from the caliphate of Al-Raschid, who lived towards the close of the eighth century: under him poetry became an art, and laws of prosody were laid down: but in this there is no proper distinction of long and short syllables, but the whole depends on rhime, a certain number of letters, and in the observation of certain cæsuræ, which are found, by carefully distinguishing the moveable consonants from the quiescent. A syllable to which a quiescent letter is added at the end, becomes long by position, as that where this is wanting, becomes short by position. *Bibl. Univ. t.* 9. *p.* 231. *& seq. Clark, Prosod. Arab. c.* 1.

Samuel Clark has published an express treatise on the Arabic prosody.

Renaudot adds, that the Arab compositions in verse are still wild and irregular, being neither epic, dramatic, lyric, or reducible to any other kind. Their hymns to God, and their tales and jocular stories, are in the same style.

Their comparisons, in which they abound, are taken, with little choice, from tents, camels, hunting, and the antient manners of the Arabs.

ARABIAN *Logic*, was that of Aristotle, as explained by Avicenna and Averrhoes. Those commentators had taken immense pains to illustrate their author; but the latter being born in Spain, and both of them utterly unacquainted with the Greek tongue, they had nothing but a faulty mutilated translation to go by, which frequently misrepresented the author's real sense, so that it is no wonder they made no greater advances in the art.

ARABIAN *Physic*, and *Physicians*, succeeded the Grecian, and handed down the art to us, having made considerable improvements, chiefly in the pharmaceutical and chemical parts.

Schelhammer observes, that, besides a number of observations relating to the causes and history of diseases, they greatly enlarged the list of simple medicines, adding much to the advantage of the practice of physic. It is certain, we owe to them most of our spices and aromatics, as nutmegs, cloves, mace, and other matters of the produce of India. We may add, that most of the gentler purgatives were unknown to the Greeks, and first introduced by the Arabs, as manna, sena, rhubarb, tamarinds, cassia, &c. It was they, likewise,

who

who brought sugar into use in physic, where, before, only honey was used. They also found the art of preparing waters and oils, of divers simples, by distillation and sublimation.

The first notice of the small-pox, and the measles, is, likewise, owing to them. Lastly, the restoration of physic in Europe took its rise from their writings.

ARACHNOI'DES, in natural history, the name of one of the genera of the echini marini, the distinguishing characters of which are, that it is of a circular circumference, but variously broken in at the edges. The mouth is round and placed in the center of the base, and the aperture for the anus is quadrangular, and situated in one of the sides, on the upper superficies, but near the edge. *Klein, Echin.* See *plate* IV. *fig.* 29.

ARA'CHIS, earth, or ground-nut, in botany, a genus of plants, whose characters are: it has a pea-bloom flower; the empalement is divided into two parts; the flower is succeeded by a rough cylindrical pod, containing one or two cylindrical seeds. We have but one species of this plant, viz. Arachis. Lin. The native country of this plant, I believe, is Africa, though, at present, all the settlements of America abound with it; but many persons, who have resided in that country, affirm, they were originally brought with the slaves from Africa there, where they have been spread all over the settlements.

It multiplies very fast in a warm country; but, being impatient of cold, it cannot be propagated in the open air in England; therefore, whoever has an inclination to cultivate this plant, must plant the seeds on an hot-bed in the spring of the year, keeping it covered with glasses till the end of June; after which time, if the weather proves warm, they may be exposed to the open air. The branches of this plant trail upon the ground; and the flowers (which are yellow) are produced single upon long footstalks; and, as soon as the flower begins to decay, the germen is thrust under-ground, where the pod is formed and ripened; so that, unless the ground is opened, they never appear; the negroes keep this a secret among themselves, therefore could supply themselves with these nuts unknown to their masters. The roots of these plants are annual; but the nuts under-ground sufficiently stock the ground in a warm country, where they are not very carefully taken up. In South Carolina there are great plenty of these nuts, which the inhabitants roast, and make use of as chocolate.

This was, by former botanists, called arachidna; and by some it hath been ranged with the vetches. *Miller's Gard. Dict.*

ARBITRA'TION, in matters of the foreign exchange, is the most beneficial, as well as most delicate, branch of exchange, to be thoroughly informed of.

Before any one applies himself to the study of this subject, it is necessary that he should be well skilled in all the practical operations, in regard to the reducing of the sterling money of England into the foreign monies of exchange, and of account of all places throughout Europe, according to the direct courses of exchange, established for these purposes, and vice versâ. Also,

2. That he should be acquainted with the methods of converting sterling money into the monies of exchange, and of account of all other places of commerce, wherewith England has no direct established courses of exchange, but is under the necessity of making use of the intermediate exchange of other places: together with the nature of the agios, and the manner of converting their bank monies into current, and the reverse.

3. The manner of calculating all the foreign monies throughout Europe into those of every other distinct country, either according to the direct, or intermediate exchange; which makes a much greater variety of cases, than those, who are not thoroughly acquainted with this extensive subject, can imagine. See EXCHANGE, *Dict.* and *Sup.*

4. It is previously necessary, also, to the entering upon a knowledge of the Arbitration of exchanges, to know the intrinsic value of foreign monies, according to the most accurate assays, which have been made for that purpose.

5. Lastly, It is requisite to understand the general natural causes of the rise and fall of the course of exchange between nation and nation, or between one trading city and another in the same nation.

That I may communicate my meaning with the greater perspicuity, it may be proper, for the satisfaction of others, as well as practical merchants and remitters, to premise, that as the advantages to be made by understanding how to arbitrate the exchange at all times, and in respect to all places, depend on the general rise and fall of the prices of exchange between one nation and another; so that rise and fall depends on the balance of trade being either in favour, or against a nation.

That the course of exchange is the criterion of the balance of trade, has been allowed, not only by great statesmen and speculative politicians, but by the most skilful and sagacious practical traders.

As this matter is put in a very rational and familiar light by those able and distinguished merchants of the city of London, who were instrumental, in conjunction with the late ever memorable earls of Hallifax and Stanhope, in defeating the French treaty of commerce, in the year 1712; I shall quote their reasoning upon this point, from the British Merchant. In consequence of which, the practical Application of the intricate subject under consideration, will appear the more intelligible:

'Suppose, say they, the tenant in Wiltshire is to pay for rent 100 l. to his landlord in London; and the woollen-draper in London is to pay the like sum to his clothier in Wiltshire: both these debts may be paid, without transmitting one farthing from one place to the other, by bills of exchange, or by exchanging one debtor for the other, thus: that is, the tenant may receive the landlord's order to pay 100 l. to the clothier in the country; and the woollen-draper may receive his clothier's order to pay the like sum to the landlord in town.

These two orders are properly called bills of exchange; the debts are exchanged by them; that is, the woollen-draper in town, instead of the tenant in the country, is become debtor to the landlord; and the tenant in the country, instead of the woollen-draper in town, is become debtor to the clothier: and, when these orders are complied with, the two debts between London and the country are discharged, without sending one shilling in specie from the one to the other.

In like manner, a warehouse-man in London is indebted 100 pounds for stuffs to the weaver in Norwich; and the linen-draper in Norwich is indebted in the like sum to the Hamburgh merchant in London; both these debts may be paid by bills of exchange; or by the exchange of one debtor for the other, by placing one debtor in the other's stead; that is, the warehouse-man may receive the order of his weaver, to pay 100 l. to the Hamburgh merchant; and the linen-draper may receive the order of the Hamburgh merchant, to pay the like sum to the weaver.

These orders are bills of exchange; the debtor in one place is changed for the debtor in another: and thus both debts may be paid, without sending one single shilling in specie, from the one city to the other.

But, if the debts due from both places are not equal, then only the same quantity of debts on both sides can be paid by bills of exchange. The balance must be sent in money from the city, from whence the greatest sums are due. For example:

If, by the trade between London and Norwich, the former owes 10,000 l. to the latter, and the latter no more than 9000 l. to the former; it is manifest, that only the debts of 9000 l. on each side can be discharged by bills of exchange; the balance of 1000 l. must be sent either from London, or some other place indebted to London, to even the account between both the cities.

Let us suppose then, that to send and insure 1000 l. in specie to Norwich would cost 5 l. or 10 s. per cent. which of the debtors in London would be willing to be at this charge: it is natural to believe, that every one will endeavour to shift it off from himself, that every one will endeavour to pay his money by a bill of exchange; it is natural to believe that every one, rather than stand the cost and hazard of sending 100 l. in specie, would pay 100 l. 5 s. in London for a debtor in Norwich, upon condition that the Norwich debtor should pay an 100 l. for him in that city.

By which means the Norwich debtor would pay his debt of 100 l. in London with less than that sum, while the London debtor would be obliged to give more than that sum for the payment of an 100 l. in Norwich. And, if such for years together were the courses of exchange between London and Norwich, there could be no question to which of the two cities a sum must be sent in specie to pay the balance; that city undoubtedly pays the balance, that gives more than the par; that undoubtedly receives the balance, that gives less than the par for bills of exchange.

The course of exchange, in this case, would sufficiently decide that the balance of trade is on the side of that city, that procures bills of exchange upon the most easy terms.

I have taken examples from two English cities, where the money is of the same denomination, and the same quantities are equally at par in both. But the case is the very same between two cities, where the denominations of the money are different, as long as any certain quantity of money in the one can be reduced to a par or equality with any certain quantity of money in the other.

For example, the old French crown was just equal or par to 54 pence English; and 444$\frac{4}{9}$ of these crowns were just par or equal to an 100 l. sterling; every farthing given more or less than 54 d. for a crown, in a bill of exchange between London and Paris, amounts to 9 s. 3 d. upon 444 crowns, or upon so many times 54 pence.

Suppose then the course of exchange between London and Paris stood thus heretofore. If a man in Paris, indebted to London, paid a farthing less than the par for a bill of exchange upon London to pay 54 d. there; the Parisian paid his debt to London of 100 l. by a bill of exchange that cost him in Paris 9 s. 3 d. less than that sum: and if a merchant

in

in London gave a farthing more than the par for a bill of exchange upon Paris, to pay a French crown, the Londoner gave 9 s. 3 d. more than 100 l. for a bill of exchange, to pay that sum in Paris.

If such was the course of exchange between London and Paris; if the first gave above the par, and the second less than par, for bills of exchange to pay their respective debts, there can be no doubt that bills of exchange were more easily to be had at Paris than at London; and, consequently, that greater sums were due from the latter than the former; and that we paid a balance upon our trade to that kingdom. And, as the price rose here to a penny or two pence above the par, or fell there so much below it, it shewed so much the greater scarcity here, and the greater plenty there of bills of exchange; and that so much the greater balance of bullion was going hence, by means of our trade to that country'.

ARBU'TUS, *the Strawberry-tree*, in botany, a genus of trees, whose characters are these: it is ever green: the leaves are oblong, and serrated on the edges: the flower consists of one leaf, and are shaped like a pitcher; the fruit is of a fleshy substance, and, in its outward appearance, very like a strawberry, but is divided into five cells, in which are contained many small seeds. The species are:

There are three species, which are 1. The common strawberry-tree. 2. The strawberry-tree with longer flowers, and egg-shaped fruit, and 3. the strawberry-tree with double flowers.

This tree has its name from the resemblance the fruit bears to that of a strawberry, but is of an austere sour taste; though I have been informed, that in Ireland, where this tree abounds, the fruit is sold and eaten. In England they are chiefly brought to the markets with small branches of the tree, having small branches of flowers upon them, and made up into nosegays, with other flowers, and some sprigs of the amomum Plinii, or winter-cherry; which, at that season, is very acceptable, when there are few flowers to be had.

The time of this fruit being ripe is in the months of October and November; at which season the flowers are blown for the next year's fruit; so that, from the time of flowering to the ripening of the fruit, is one whole year.

The best method of propagating these trees is by sowing their seeds, which should be preserved in dry sand till March: at which time you should sow them upon a very moderate hot-bed (which greatly promotes its vegetation) covering it about a quarter of an inch with light earth, and screening it from frosts, or great rains. Towards the latter end of April your young plants will appear; you must therefore keep them clear from weeds, and give them frequent waterings, as the season may require, and shade them in hot weather; and, if your plants have done well, they will be, by autumn, about five or six inches high: but as these trees are subject to receive damage from frosts, especially while they are young, therefore you must hoop the bed over, that, when bad weather comes, you may cover it with mats and straw to keep out the frost.

The beginning of April following you may transplant these trees, each into a small pot; but, in doing of this, be very careful to take them up with as much earth to their roots as possible; for they are bad rooting plants, and very subject to miscarry on being removed; and it is for this reason I advise their being put into small pots; for, when they have filled the pot with roots, they may be turned out into large pots, or the open ground, without any hazard of their dying.

When you have put your young plants into the small pots, you should plunge them into another very moderate hot-bed, to encourage their taking new root, shading them from the sun in the middle of the day, and giving them water as they may require: in this bed it will be proper to let the pots remain most part of the summer; for if the pots are taken out, and set upon the ground, the smallness of their size will occasion the earth to dry so fast, that watering will scarcely preserve your trees alive; but, if they are kept growing all the summer, they will be near a foot high by the next autumn: but it will be adviseable to screen them from the frost, during their continuance in pots, by plunging them into the ground in a warm place, and covering them with matts in bad weather.

When your trees are grown to three or four feet high, you may shake them out of the pots into the open ground, where they are to remain: but this should be done in April, that they may have taken good root before the winter; which would be apt to damage them, if newly planted. *Miller's Gard. Dict.*

ARCA'DIANS, the name of a society of learned persons, who formed themselves into a body at Rome, in the year 1690, with a design to preserve learning and carry Italian poetry to perfection.

They took the name of Arcadians partly from the rules of their society, and partly, because every new member, on his admission into this academy, assumed the name of some shepherd of ancient Arcadia. Once in four years they elected a president, to whom they gave the title of guardian, and appointed him every year twelve fellows, who decided all affairs of the society.

This society was founded by fourteen men of eminent learning, whom a similitude of sentiments, taste, and study, had drawn to the court of Christina queen of Sweden, who became their patroness. After her death, M. Gravina, in 1696, reduced their laws to ten in number, and wrote them in the language and stile of the twelve tables, which are yet to be seen in the serbatojo, a room used as a repository for the archives of the academy, on two fine pieces of marble. In this room are also the pictures of the most celebrated persons who have been of this academy, at the head of which is pope Clement the Eleventh, with his pastoral name Alnano Melleo. The society had for its arms a flute crowned with pine and laurel. Branches from this society, under different names, have spread themselves, through the principal cities of Italy; those of Aretio and Macerata call themselves la Forzata, those of Bologna, Venice, and Ferrara, l'Animosa, that of Sienna la Physica Critica, that of Pisa l'Alphaia, that of Ravenna the members of which are all ecclesiastics, is called la Camaldunensis. They have each a vice-guardian; they meet seven times in a year, either in a wood, a garden, or meadow, as is most convenient. Their first meetings were held on mount Palatine, but at present in the gardens of prince Salviati. At the six first meetings they read the performances of the Arcadians of Rome. The Roman ladies of the Arcadian society have their works read by gentlemen of the same academy: the seventh meeting is entirely devoted to the reading of foreign associated Arcadians. Every candidate must be eminent for accomplishments and genius, or, as the Arcadians express themselves, be possessed of nobility either by merit or birth, and be twenty-four years of age complete. The talent of poetry only gave admission to a lady into this society. Candidates are admitted into this academy, either by acclamation, enrollment, recommendation, surrogation, or destination; acclamation is the universal concurrence of all the votes without any deliberation; this is a compliment paid to cardinals, princes, and ambassadors. Ladies and foreigners are admitted by enrollment; young noblemen by the recommendation of the colleges wherein they are educated. A man of letters who follows, an academician after his death, in the same province, is said to be introduced by surrogation; what they mean by destination is this, if any person by his performances has merited the honour of being an Arcadian, the academy on his application engage to elect him on the first vacancy; they reckon by olympiads, and celebrate their festivals of wit every fourth year.

ARCH-*Angel* *, in theology, an intellectual being, or angel, of the second order in the celestial hierarchy.

* The word is compounded of the Greek ἀρχὸς, chief or principal, and ἄγγελος, an angel.

St. Michael is considered as the prince of angels, and generally stiled St. Michael the Arch-angel.

ARCH-*Angel*, in botany, a medicinal plant, called, by botanists, lamium. It is of some use as a balsamic, &c.

There are two kinds of it, viz. the white Arch-angel, lamium album; and red, whose flowers are reputed soft and lubricating, and, as such, administred in some female weaknesses, as the whites, and difficulty of urine. A conserve of them is also made in the shops, but seldom prescribed. *Quinc. Dispens.*

ARDA'SSES, in commerce, the coarsest of all the silks of Persia, and, as it were, the refuse of each kind. In this sense they say, the legis, the housets, the choufs, and the payas Ardasses, to signify the worst of those four sorts of Persian silks.

ARDASSI'NES, a very fine sort of Persia silks, little inferior in fineness to the fourbastis, or rather cherbassis. And yet it is little used in the European manufactures of silk, because it will not bear hot water in the winding of it.

A'REB, a money of account used in the dominions of the great Mogul, particularly at Amadabat. Four Arebs make a crow. A crow is worth a hundred lacs, and a lac 100000 rupies.

ARE'CA, or ARECK, a famous fruit in the East-Indies, wherein they drive an incredible trade, and make a prodigious consumption thereof, there being scarce any person, even from the richest to the poorest, who does not make use of it.

The tree which bears the areck is tall, straight, thin, and round. It is of the palm kind, and has no branches; but its leaves are charming to the sight; they form a round tuft at the top of the trunk, which is as straight as an arrow. It grows to the height of 25 or 35 feet, and is a great ornament in gardens. The shell which contains the fruit is smooth without, but rough and hairy within, in which it pretty much resembles the cocoa-nut. It is equal to that of a pretty large walnut. Its kernel is as big as a nutmeg, to which it bears a great resemblance without, and has also the same whitish veins within, when cut in two.

In the center of the fruit, when it is soft, is contained a greyish and almost liquid substance, which grows hard in proportion

proportion as it ripens. The fruit, when ripe, is aſtringent, but not unpalatable, and the ſhell is yellowiſh.

The chief uſe that is made of areck, is to chew it with the leaves of betle, mixing with it a chalk in a red paſte, made of ſea-ſhells. In order to chew it, they cut the areck into four quarters, and take out one quarter of it, which they wrap up in a leaf of betle, over which they lay a little of that chalk: afterwards they tie it, by twiſting it round. This bit prepared for chewing, or maſtication, is called pinang, which is a Malayan word, uſed all over the Eaſt-Indies. The pinang provokes ſpitting very much, whether it be made with dried or freſh areck: the ſpittle is red, which colour the areck gives it. This maſtication cools the mouth, and faſtens the teeth and gums. When they have done chewing the pinang, they ſpit out the groſs ſubſtance that remains in the mouth. They are under a miſtake who imagine that freſh areck melts intirely in the mouth. Nor is it leſs a miſtake to think that the teeth continue always of a red hue. As ſoon as they have done chewing the pinang, they waſh their mouth with freſh water, and then their teeth are white again. The Europeans who live at Batavia, at Malacca, and in the Sunda and Molucca iſlands, uſe pinang as much as the Indians do; and, by waſhing their teeth, they preſerve them white.

Some pretend that areck ſtrengthens the ſtomach, when the juice of it is ſwallowed, as moſt of the Indians do. Another property, aſcribed to it, is its curing, or carrying off, all that might be unwholeſome or corrupt in the gums.

The Siameſe call areck plou, in their language.

The beſt areck of the Indies comes from the iſland of Ceylon.

The Dutch Eaſt-India company ſend a great deal of it in their ſhips into the kingdom of Bengal. There grows in Malabar a ſort of red areck, which is very proper for dying in that colour. The ſame company ſend ſome of it from time to time to Surat and Amadabat, for the uſe of the dyers in the dominions of the great Mogul. Under the ſpecies of areck are comprehended ſix different ſorts, two of which are the beſt for maſtication.

A'REM, or AL-AREM, a vaſt mound, or dam, which formed a ſtupendous reſervoir above the city Saba, whoſe rupture cauſed an inundation, famous in eaſtern writers.

The Arem was built by Abdſhems, ſurnamed Saba, who, having built the city of that name, built this wall, or mound, to ſerve as a baſon, or reſervoir, to receive the water which came down from the mountains, not only for the accomodations of the inhabitants of that city, and the watering their lands, but alſo to keep the country better in ſubjection, by being maſter of their water. The Arem ſtood like a mountain above their city, almoſt eighty fathoms high, and was built ſo ſtrong, that there were no apprehenſions of its ever falling: but it gave way, at length, in the night, and carried away the whole city, with all the towns and people in the country.

AREOPA'GUS (*Dict.*)— Authors are divided, as to the reaſon and origin of the name: ſome imagine Areopagus the proper name of the court of juſtice, which was ſituated on a hill, in Athens; and that in this court the ſenate of that illuſtrious city aſſembled.— Others ſay, that Areopagus was the name of the whole ſuburbs of Athens, wherein ſtood the hill on which the court was built: and the name Areopagus ſeems to countenance this laſt opinion; for it ſignifies literally, the hill or rock of Mars, from πάγος, hill, and Ἄρης, the god Mars. In effect, the denomination might either ariſe hence, that the Areopagus was built in a place where had been a temple of Mars; or, becauſe the firſt cauſe pleaded there was that of this god, who was accuſed of killing Halirorrothius, the ſon of Neptune, and tried here before twelve gods, being acquitted by a majority of ſix voices: or becauſe the Amazons, whom the poets feign to be the daughters of Mars, when they beſieged Athens, pitched their tents, and offered ſacrifices to the god of war in this place.

This tribunal was in great reputation among the Greeks; and the Romans themſelves had ſo high an opinion of it, that they truſted many of their difficult cauſes to its deciſion. Authors are not agreed about the number of the judges who compoſed this auguſt court.—Some reckon thirty-one, others fifty-one, and others five hundred: in effect, their number ſeems not to have been fixed, but was more or leſs every year.— By an inſcription quoted by Volaterranus, it appears they were then three hundred.

At firſt this tribunal only conſiſted of nine perſons, who had all diſcharged the office of archons, had acquitted themſelves with honour in that truſt, and had likewiſe given an account of their adminiſtration before the logiſtæ, and undergone a very rigorous examination.— Their ſalary was equal, and paid out of the treaſury of the republic: they had three oboli for each cauſe.

The Areopagites were judges for life.— They never ſat in judgment but in the open air, and in the night-time, to the intent that their minds might be more preſent and attentive, and that no object, either of pity or averſion, might make any impreſſion on them.— All pleadings before them were to be in the ſimpleſt and moſt naked terms, without exordium, epilogue, paſſions, &c.

At firſt they only took cognizance of criminal cauſes, but in courſe of time their juriſdiction became of greater extent.— Mr. Spon, who examined the antiquities of that illuſtrious city, found ſome remains of the Areopagus ſtill exiſting, in the middle of the temple of Theſeus, which was heretofore in the middle of the city, but is now without the walls.

The foundation of the Areopagus is a ſemicircle, with an eſplanade of 140 paces round it, which properly made the hall of the Areopagus. There is a tribunal cut in the middle of a rock, with ſeats on each ſide of it, where the Areopagites ſat, expoſed to the open air.

This court is ſaid by ſome to have been inſtituted by Solon; but others carry it much higher, and aſſert it to have been eſtabliſhed by Cecrops, about the time that Aaron died, viz. in the year of the world 2553, maintaining withal, that Solon only made ſome new regulations in it, increaſed its power and privileges, and made it ſuperior to the Ephetæ, another celebrated court inſtituted by Draco.— In effect, Demoſthenes himſelf, in his oration againſt Cteſiphon, owns himſelf at a loſs on the point: the inſtitutors of this tribunal, ſays he, whatever they were, whether gods or heroes.

ARETHU'SA, in mythology, a fountain in the iſland Ortygia.

They tell us that Arethuſa, before ſhe was a fountain, was a virgin and a follower of Diana; that the river god Alpheus ſaw her one day bathing, grew enamoured of her charms, and would have enjoyed her. She, to avoid his purſuit, implored the help of Diana, who transformed her into a fountain. Alpheus knew her under this diſguiſe, and immediately mixed his ſtreams with her's. Cicero tells us, that in his time the fountain was quite ſwallowed up by the ſea, and no traces of it left. Pliny, and many of the ancients, ſeem to have thought that the river Alpheus, continuing his courſe under the ſea roſe again in Sicily, and that what was thrown into this river in Arcadia, was found again ſwimming in the Ortygian river. But Strabo, far from believing ſo ridiculous a ſtory, takes the tale of a cup's being found in the Sicilian river, that was thrown into the Alpheus, for a fiction; and does not ſcruple to ſay, that this, like other rivers, loſes itſelf in the ſea. Pliny, however, is ſo fond of the fable as to tell us, that the waters of Arethuſa ſmelt of dung, being the time of the olympic games, as if it proceeded from a mixture of the waters of the Alpheus, into which was thrown the dung of the victims, and of the horſes which ran the races at the celebration of theſe games.

ARGEMO'NE, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the roraceous kind, or compounded of ſeveral leaves, arranged in a circular form. From the center of the flower there ariſes a piſtil, which finally becomes an unicapſular ſeed-veſſel, of an oval figure, with ſeveral ribs running from its baſe to its apex, the intermediate ſpaces being occupied by valves, which finally open their tops; and from every rib there runs out a placenta, which is loaded with ſeeds, uſually of an orbicular figure. *Tourn. Inſt.*

There is only one known ſpecies of Argemone, which is the plant uſually called, by botanical writers, the thorny Mexican poppy.

The rough-headed poppies, called Argemones by ſome writers, are by no means of this genus, but properly of the corn-poppy kind.

ARGENTA'RIA *Creta*, ſilver chalk, in natural hiſtory, a name given to an earth, not properly a chalk, but a kind of tripela. It is a very beautiful earth, of a looſe friable texture, and perfectly pure white. While in the ſtratum, it is dry, friable, and duſty, and flies from the pickax in large irregular maſſes, of an obſcurely plated, or laminated ſtructure; and ſplits more readily into flat pieces, than in any other direction; but its laminæ are always very irregular; when dry, it becomes ſomething harder, and retains the ſame chalky whiteneſs, and is of a looſe, ſpongy texture, very light, and of a rough, uneven, duſty ſurface. It adheres very ſlightly to the tongue, is hard and harſh to the touch, breaks eaſily between the fingers, and a little ſtains the hands. It makes no efferveſcence with acids, and ſuffers very little change in the fire. It is dug in Pruſſia, and is much eſteemed for cleanſing plate. It has alſo been found in France, and of late in Ireland. *Hill's Hiſt. of Foſſ.*

ARGETE'NAR, in aſtronomy, a ſtar of the fourth magnitude, in the flexure of the conſtellation Eridanus.

Argetenar is repreſented, in Bayer, by the Greek letter ρ. Its longitude according to Hevelius, in 1700, was 5°. 53'. 22". and its latitude 38°. 28'. 47". ſouth.

A'RGIL, or ARGILLA, potter's-earth, a fat and gluiſh kind of earth, or clay, which potters uſe to make ſeveral ſorts of their works. Carvers and ſilver-ſmiths uſe it alſo for mouldings. It is alſo uſed by thoſe who make conduits, baſons, and reſervoirs: they lay over with this ſort of earth the bottom of the baſons, in order to make them hold water. This earth is commonly grey, and ſometimes red. It is to be met with almoſt every-where, and is of a barren nature, as being very fat and glutinous.

AR'GONAUTS (*Dict.*)—The number of the Argonauts is thought to have been about 54, besides attendants. Jason was their chief; the others, of most note, were Hercules, Castor, and Pollux; Laertes, the father of Ulysses; Oileus, the father of Ajax; Peleus, the father of Achilles; Theseus and his friend Pirithous. They set out from Cape-Magnesia, in Thessaly; failed first to Lemnos, from thence to Samothracia, through the Hellespont; and, coasting Asia Minor, arrived through the Euxine Sea, at Æa, the capital of Colchis; from whence, after having carried away the golden fleece, they returned into their own country, through a thousand dangers, which they surmounted. This expedition, according to some, was thirty years before the Trojan war; according to others, ninety years before that event. See CHRONOLOGY in the Dictionary and Supplement.

Opinions are various concerning the object that drew the Argonauts to Colchis. Diodorus Siculus thinks this golden fleece, so much talked of, to have been only the skin of a sheep, which had been sacrificed by Phrixus; and was kept very carefully, on account of an oracle, which had foretold, that whoever stole it away, should murder the king Strabo. And Justin thinks the fable of the fleece to have taken its rise from this, that gold was found in the sands of some rivers of Colchis, which they gathered up by the means of sheep skins, with the wool on; and that a fleece, well filled with the dust it had collected in this manner, might be called a golden fleece, with propriety. The same method is now in practice about Fort Louis, where gold dust is collected in the same manner. Varro and Pliny think this story proceeded from the fine wool of this country; and that a voyage some Greek merchants made thither, on this account, gave birth to the fiction. We may add, that, as it is notorious the Colchians were eminent for their merchandize in skins of all kinds, this might have been one motive why the Argonauts undertook this voyage.

Palæphatus has pretended, but nobody knows on what foundation, that, by the emblem of the golden fleece, was meant a fine golden statue, which the mother of Pelops had caused to be made, and Phrixus carried with him to Colchis. Suidas apprehends this golden fleece to have been a volume book, which contained the secret of making gold. Tollius would fain have revived this opinion; and the alchymists have, in general, embraced it.

ARISA'RUM, *friars-cowl*, in botany, the name of a genus of plants, whose characters are: the fruit, and inner part of the flower are the same with those of the arum and dragons; but the flower itself is hooded, or shaped like a friar's-cowl.

There are five species of Arisarum, enumerated by Tournefort and Miller.

The leaves and flowers of Arisarum are detersive and vulnerary, and applied either in the form of ointment, or decoction, they cure malignant ulcers. Its root, taken in powder, is esteemed against the plague; the dose being from a scruple to a drachm. Of the root also are made collyria; which are effectual in curing fistula's of the eyes; by collyria, Diascorides does not mean what we call so, but tents made in the shape of a collyrium. It corrupts the pudendum of any animal whatever, if introduced into it. *Lemery des Drog.*

ARISTO'CRACY (*Dict.*)—With regard to the laws relative to Aristocracy, we cannot, possibly, attain a better idea of them., than by consulting that excellent work of M. Montesquieu; from whence the following were extracted:

1. As the body of the nobility give their votes in an Aristocracy, these votes cannot be very secret.

2. The suffrage must not be given by lot, for this would produce many inconveniencies. In short, when distinctions, which raise one citizen above another, are once established, were the choice determined by lot, the man would not become less odious; it is not the magistrate, but the nobleman, becomes the mark of envy.

3. When the nobility is numerous, there must be a senate to regulate affairs, which the body of the nobility could not determine, and prepare such as it does determine, for the dispatch of business. In this case, we may say the Aristocracy, in some measure, resides in the senate; a democracy in the body of the nobility; and that the people are nothing.

4. It will be very happy, in an Aristocratical government, if the people, by some indirect method, are admitted to bear some degree of weight: as, at Genoa, the bank of St. George, which is directed by the people, gives them an influence over the state; which makes all their happiness.

5. The senators ought not to have the power of bringing in whom they please into their body, as members drop off; but this power should be invested in censors, to prevent corruption.

6. That is the best Aristocracy, wherein the people have so small a share of riches, or power, as not to make it the interest of the ruling party to oppress them.

7. The most imperfect Aristocracy is where that part of the people, which obeys, is under the civil bondage of that which commands it.

8. If the people under an Aristocracy are virtuous, they will enjoy almost all the happiness of a popular government; and the state will become powerful.

9. A spirit of moderation is the virtue of an Aristocracy; and holds the same place, as equality in a popular state.

10. Modesty, and simplicity of manners, constitute the strength of the nobility in an Aristocracy.

11. If any of the nobility had personal and particular prerogatives distinct from the body, it would cease to be an Aristocracy; and the form of government would approach to a monarchy.

12. The two principal springs of confusion, in an Aristocratical form of government, are the prodigious inequality between the governors and the governed; and the inequality between those that govern.

13. The first of these inequalities will exist, if the privileges and prerogatives of the rulers are honourable, by being oppressive, and taxes be levied partially.

14. Trade is the profession of people on a level, and therefore beneath the nobility in an Aristocracy.

15. The laws of an Aristocracy ought to oblige the nobility to do justice to the people.

16. The laws ought, in every respect, to curb the pride of tyrannizing.

17. There ought to be some authority, to counterbalance the power of the nobility.

18. The extreme poverty, or exorbitant riches of the nobility, are pernicious in an Aristocracy.

19. There should be no right, by seniority, among the nobility, that, the estate of the family being divided among the children, all of the same rank and family might possess an equal fortune.

20. All disputes among the nobility ought soon to be finally determined.

21. The laws ought, in particular, to tend to abolish the distinction which vanity makes among noble families.

22. If the laws are good, the nobility will rather think of the advantages which will result from obeying, than their own punctilio's.

23. Aristocracy degenerates, when, the power of the nobility becoming arbitrary, there is no more virtue in those that govern, than in those that are governed. M. Montesquieu has supported these maxims by so many instances, both antient and modern, that he has left us no room to doubt of the truth of them.

ARISTOTE'LIAN *Philosophy*—The philosopher from whom the denomination arises, was the son of Nicomachus, physician of Amyntas, king of Macedonia, born in the year of the world 3566; before Christ, 348; at Stagira, a town of Macedonia; or, as others say, of Thrace; whence he is also called the Stagirite.

At seventeen years of age he entered himself a disciple of Plato, and attended in the academy till the death of that philosopher. Repairing afterwards to the court of king Philip, at his return, he found that Xenocrates, during his absence, had put himself at the head of the Academic seat; upon which, he chose the Lyceum for the scene of his future disputations.

It being his practice to philosophize walking, he got the appellation Peripateticus; whence his followers were also called Peripatetics. Though others will have him to have been thus named, from his attending on Alexander, at his recovery from an illness, and discoursing with him, as he walked about.

Aristotle was a person of admirable genius, and of great and various learning. Averrhoes makes no scruple to call him, 'The genius of nature, the limit of human understanding;' and declares him, 'sent by providence, to teach us all that 'may be known.' He is accused of a too immoderate desire of fame, which led him to destroy the writings of all the philosophers before him, that he might stand singly, and without competitors. And hence, in the schools, Aristotle is called, The philosopher. Laertius, in his life of Aristotle, enumerates his books to the number of 4000; of which scarce above 20 have survived to our age.

This great philosopher has been deified by some, and despised by others, but a short view of his works will abundantly convince us, that both these extremes are ill founded. His first essays were on oratory and poetry; which, in all probability, he composed for the use of his royal pupil, Alexander the Great. These books are master-pieces; and his study of Homer gave him so finished a taste in poetry and rhetoric, that whoever would now speak, or write, elegantly, on those subjects, must observe his precepts; and, perhaps, these performances do most honour to his memory.

His ethics are very dry, barren, and unfruitful; offer nothing to us, but general views, and metaphysical propositions; fitter to adorn the mind, and lead the memory, than touch the heart, and correct the will: and this spirit prevails in all the moral writings of our philosopher. A sketch of his principal doctrines will sufficiently prove this assertion. 1. The happiness of man, says he, consists not in riches, pleasures, power, nobility, nor philosophical speculations; but rather in certain habits of the soul, which render him more or less perfect. 2. Virtue is full of charms; consequently, a virtuous life must be happy. 3. Though virtue be sufficient of itself, yet it cannot be denied, but that riches, honours, a noble birth, beauty of body, and things of this nature, greatly contribute to advance the happineſs of man. 4. Every virtue keeps the mean betwixt two extremes: thus courage is the mean betwixt fear and raſhneſs; liberality, betwixt avarice and extravagance, &c. from whence we may conclude, that the number of vices are twice the number of virtues; becauſe every virtue has on each ſide an oppoſite vice. 5. He diſtinguiſhes two ſorts of juſtice; the one he calls univerſal, the other particular. Univerſal juſtice tends to the preſervation of civil ſociety, by the reſpect and obedience it inſpires and enjoins for the laws. Particular juſtice conſiſts in rendering every man his due; and is of two ſorts, diſtributive and communicative. Diſtributive juſtice diſpenſes rewards and puniſhments to every citizen, according to his merit; and is founded on a geometrical proportion. Communicative juſtice has commerce for its object; conſiſts in rendering to every man his due; and muſt proceed according to arithmetical proportion. 6. Friendſhip ariſes either from the pleaſure we find in a perſon's converſation, the profit which may reſult from it, or from the merit of ſome eminent qualities, founded on virtue, we diſcover in the object: this laſt is true friendſhip; benevolence, properly ſpeaking, is not friendſhip, though it leads to it.

Ariſtotle has ſucceeded much better in his logic than in his ethics. His logic diſcovers all the principal ſprings of the art of reaſoning; he deſcends ſoon to the thoughts of man; diſtinguiſhes his ideas; ſhews their connection; purſues them through all their deviations and ſeeming contrarieties; and at laſt reduces them to a fixed point. If the extent of the mind could have been known, Ariſtotle would certainly have diſcovered it. Is it not ſurpriſing, that, by the different combinations he has made of all the forms the mind can put on in reaſoning, he has confined it in ſuch a manner, by the rules he has laid down, that it can never deviate from its object, nor reaſon abſurdly? But his method, though ſo much extolled by all philoſophers, is not free from faults. 1. He is too prolix; all his books of categories might be reduced to a few pages; the ſenſe is drowned in a ſuperfluity of words. 2. He is obſcure and intricate; he expects you to gueſs at his meaning; would have his reader, like himſelf, know what he intended. A man of the beſt capacity muſt often deſpair of having fully underſtood him in his doctrine of the analyſis and ſyllogiſm.

Let us now come to ſpeak of Ariſtotle's natural philoſophy; and here we ſhall principally follow the famous Lewis Vilis, who has proceeded very methodically on the ſubject, by taking notice of all this philoſopher's phyſical works; he begins with his eight books of natural principles; which ſeem rather ſo many different memoirs, than a book wrote on one and the ſame plan. Theſe eight books treat of bodies extended in general, which is the object of phyſics; and, in particular, of the principles of bodies, and all that is connected with theſe principles, as motion, place, time, &c. Nothing is more confuſed, than the long detail he gives us; his definitions render things, clear and evident in themſelves, obſcure and unintelligible. Ariſtotle begins with condemning all the philoſophers who went before him, and even in very harſh terms: ſome he blames for having admitted too many principles; others for having admitted only one. With regard to himſelf, he lays down three principles, which are matter, form, and privation. Matter, according to him, is the general ſubject on which nature operates: this matter is eternal; the parent of all things; which eagerly longs for motion, and deſires to be united to form. Ariſtotle's definition of his firſt matter is a kind of jargon; he defines it in theſe terms: 'That which has neither quality or quantity, or any thing by which its being can be determined'. If he only means, according to his method of conſidering things, firſt in a general view, and afterwards deſcending to particulars, that this firſt matter had no other foundation than his own conception, nor exiſtence, but in an arrangement of ideas, to reaſon on the ſubject, it may be granted him: but then this firſt matter is an imaginary being, a mere abſtract idea, which exiſts no more in general than a flower, or man, which are but parts of the univerſe. Some are of opinion, Ariſtotle meant, by his firſt matter, not only body in general, but a certain uniform paſte, which, like yielding wax, took any impreſſion; out of which all things were formed, and into which they return at their diſſolution; that all bodies were the ſame, and differed only with reſpect to their figure, quantity, motion, or reſt, which are all accidents. This opinion, which owes its origin to Ariſtotle, appeared ſo ſpecious to all philoſophers, both antient and modern, that it has been generally adopted; though nothing can be more falſe, as is abundantly proved by experiments; for, in conſequence of this doctrine, if motion produced out of this firſt matter, this original paſte or wax, an animal, a tree, or a maſs of gold; take away this motion, the animal, the tree, the gold, muſt return to their primeval paſte. Empedocles, Plato, Ariſtotle, and the ſchoolmen, aſſert this; but it is falſe. The organized body, on its diſſolution, ſeparates into different maſſes, ſkin, hair, fleſh, bone, &c. The mixed body reſolves itſelf into water, ſand, ſalt, and earth: but the moſt powerful diſſolvents, and the hotteſt fire, can never produce any change in theſe ſimple bodies. Sand remains ſand, iron remains iron, gold, purified, ſuffers no change; the caput mortuum will always remain a caput mortuum, though tried and tortured a thouſand ways. Chemical experiments have proved this paſt all doubt: we can go no further, the ſeparate elements are permanent, and incapable of change; for this reaſon, that the univerſe, which is compoſed of them, may receive different forms, by their being blended together; and yet be durable, as the principles which form its baſis. As to form, Ariſtotle's ſecond principle, he looks on it as a ſubſtance, an active, conſtituent principle of bodies, which operates on matter. It follows from this poſition, that there muſt be as many natural forms, which are born, and die by turns, as there are primitive and elementary bodies. As to privation, ſays Ariſtotle, it is not a ſubſtance; it is even, in ſome reſpects, a ſort of nothing: in ſhort, bodies which receive ſuch a form, are ſuch as could never have had that form before, but muſt even have had one abſolutely contrary to it. Thus the dead and living are directly oppoſite.

Theſe three principles premiſed, Ariſtotle proceeds to the explanation of cauſes, which he treats of diſtinctly enough; but almoſt always without mentioning the firſt cauſe, which is God. Some have taken occaſion from hence to accuſe him of atheiſm; but we are of a different opinion. Ariſtotle aſſerts, nature is an effective principle, a plenary cauſe, which renders all bodies, wherein it reſides, capable of motion or reſt in themſelves: all bodies which have this power, that cannot in one ſenſe be annihilated, and this tendency to motion, which is always equal, are properly called ſubſtances: nature, conſequently, is another principle of Ariſtotle; and nature is a term by which he could mean nothing but the Deity; wherefore he did not miſtake the firſt cauſe; but his commentators puzzled themſelves, and the ſchoolmen ran into ſo many abſurdities, by miſunderſtanding him.

After having explained the efficient cauſe of all power diſtributed throughout the univerſe, Ariſtotle proceeds to define motion; but, though the efforts of a great genius are conſpicuous, his definition is very lame and imperfect. The farther he advances, his reaſoning becomes more clear; finite and infinite, the vacuum and atoms, ſpace and time, place and the bodies contained in it, preſent themſelves to his view; he makes no confuſion; one propoſition leads to another; and, though the progreſs be extremely rapid, the connection is very plain.

The doctrine, contained in his two books of generation and corruption, neceſſarily depends on his principles which we have already explained. Before Socrates, the prevailing opinion was, that nothing abſolutely died or periſhed, but ſomething was again produced from it; that all the changes which happen in bodies were only another arrangement, a different diſtribution of the parts of matter which compoſed theſe ſame bodies: they aſſerted, that increaſe and diminution, diviſion and re-union, ſeparation and mixture, accounted for all the changes viſible in the univerſe. Ariſtotle rejected all theſe notions, though very ſimple in themſelves, and therefore probable; and eſtabliſhed the doctrine of generation and corruption, properly ſo called. He obſerved new beings produced from the womb of nature continually, which periſhed in their turns. Two things led him into this way of thinking: 1. He imagined the matter of all bodies the ſame; that they only differed in form, which he looked on as their eſſence. 2. This doctrine of privation teaches, that contraries are produced by their contraries, as white by black; whence it follows, that white muſt be annihilated before black can ſucceed. To clear up this ſyſtem, we ſhall make two remarks: 1. That generation and corruption have no connection with the other modifications of bodies, as increaſe, decreaſe, tranſparence, conſiſtence, &c. under all theſe modifications. The firſt form is not effaced, though infinitely diverſified. The ſecond remark, which naturally reſults from the firſt, is, that, as all the diverſity of nature conſiſts in generation and corruption, ſimple and primitive beings only can be ſubject to them; all other bodies are only mixtures, and various combinations of theſe firſt. Though nothing can be more chimerical than this part of Ariſtotle's ſyſtem, yet it has perplexed the ſchoolmen, who have multiplied a number of nonſenſical terms, ſuch as forma ſubſtantialis, modalitas, &c. and continually diſputed about it, without any meaning.

Ariſtotle does not content himſelf with exhibiting a general theory in phyſics, but deſcends to particulars; his meteorology is held by father Rapin to be more clear than all that has been advanced by the moderns on the ſubject. It, indeed, muſt be owned, he accounts for rain, hail, dew, &c. in an extraordinary manner, conſidering his ignorance of the experiments the moderns have made, and ſome diſcoveries, owing to time and chance. His account of the rainbow is ingenious, and really differs but little from that of Deſcartes. His definition of the wind is this, that it is a current of the air; and he ſhews, that its direction depends on an infinity of cauſes, extraneous and little known; which, ſays he, hinders me from giving a general ſyſtem of it. With regard to his hiſtory of animals, it will be ſufficient to ſay, it is highly approved of by M. de Buffon.

Thus we have given ſome account of all his works. Let us now take a ſhort view of his doctrines. The matter, according

ing to Ariſtotle, which compoſes all bodies, is the ſame, and only owes its different forms to the different combination of its parts. He admits of four elements, fire, air, water, and earth; which, according to him, are ſufficient to form all ſublunary bodies, but the beauty of the heavens made him ſuſpect them to be formed of finer materials; and, therefore, he ſuppoſed a ſort of fifth element, the quinteſſence of the other four, for the conſtruction of the heavens: and perhaps, when he had invented a new word, thought, like ſome moderns, he had made a diſcovery of ſomething new; and that what ſubſiſted in his imagination, muſt conſequently alſo ſubſiſt in the univerſe. But neither the authority of Ariſtotle or any other philoſopher, nor the pretended evidence of their arguments, can convince us of the reality of what they imagined. From theſe five principles, fire, air, water, earth, and a quinteſſence of theſe, Ariſtotle ſuppoſed the whole univerſe to be formed. Of this quinteſſence, or fifth body, being, or eſſence ſor (literally the term ſignifies no more, though taken in a metaphorical acceptance, it is generally underſtood to convey another idea) he ſuppoſes, the celeſtial bodies formed; and to this he aſcribes a circular motion. To the four elements, of which he ſuppoſes all ſublunary bodies compoſed, he aſſigns only a rectilinear motion. The fifth eſſence has neither gravity nor levity, is incorruptible and eternal; always continues an equal and uniform motion, whereas, of the four elements, two deſcend and gravitate towards the center, two aſcend and ſeek the circumference; yet they may change their places, and indeed often do ſo, becauſe of the facility they have of transforming themſelves by rarefaction, condenſation, &c.

This premiſed, Ariſtotle aſſerts the univerſe is not equally under the government of God; notwithſtanding he is the general cauſe of all, the celeſtial bodies only are worthy his care and attention, but the earth and ſublunary beings are below his notice. Diogenes Laertius tells us, it was the opinion of Ariſtotle, that the heavenly bodies were regulated by the Deity; that the earth and ſublunary beings were governed by a kind of ſympathy with the celeſtial bodies, and influenced by them. This chain of reaſoning infers the mortality of the ſoul, and excludes free agency. A prevailing notion among all the ancient philoſophers, that the ſoul was a particle of the divine Being, and ſhould return to the Being from whence it proceeded after certain revolutions, contributed not a little to confirm Ariſtotle in this notion.

The falſe Ideas this philoſopher had conceived of motion, had led him into an opinion that the world was eternal. Motion, ſays he, muſt have been eternal, conſequently the world wherein it ſubſiſts muſt have been ſo too.

We have now ſeen enough of the doctrine of Ariſtotle to be convinced he is no more to be charged with atheiſm than almoſt all the other ancient philoſophers, who were infected with the ſame errors. Ariſtotle repreſents God, as an immaterial and intelligent Being; the firſt mover of all things, who could not be moved himſelf: ſhould it be aſked, what can be thought of Ariſtotle's creation? The anſwer is eaſy; for he admits, if there had been nothing in the univerſe but matter, it could not have been formed without ſome original firſt cauſe. This plainly infers a Deity, and wipes off the imputation of atheiſm, which ſome would have fixed on him. He only differs in opinion from his maſter Plato in this; Ariſtotle thought the world a natural and powerful emanation from the Deity, like light from the ſun: whereas Plato thought the world was not an eternal and neceſſary but voluntary and deliberate choice of the Deity. The doctrine of the creation in both makes the world eternal, and is very different from that of Moſes, in which God is left ſo free with regard to creating the world, that he might have left it eternally in its original chaos.

But if Ariſtotle be acquitted of atheiſm, becauſe he admits a firſt cauſe and makes God the author and firſt mover of all things; yet his notions tend indirectly to ſubvert and deſtroy the liberty of his agency: becauſe, ſays he, motion impreſſed on matter did not proceed from his will, but the neceſſity of his nature; ſo that his god is diveſted of all the attributes we juſtly aſcribe to the divine Being. Notwithſtanding theſe abſurdities, which ſtrike at the root of the Chriſtian religion, ſome eminent men of the Romiſh perſuaſion have been ſo prejudiced in favour of his philoſophy, that his picture has been drawn in the ſame piece of painting with that of our Saviour: nay, have been wicked and weak enough to place his writings on the level of holy writ. In latter ages, even after the revival of learning in Italy, ſome have not ſcrupled to place him among the number of the bleſſed. We have two books yet extant, written expreſly on this ſubject, one intitled 'The ſalvation of Ariſtotle', which the divines of Cologne are ſaid to have publiſhed; the other, by Lambert Dumont profeſſor of philoſophy, intitled 'What may moſt probably be advanced concerning the ſalvation of Ariſtotle, drawn from the proofs of holy ſcripture, and borrowed from the teſtimonies of the ſoundeſt body of divines'. Strange infatuation!

We cannot conclude this article without giving an abſtract of the ingenious parallel father Rapin has drawn between Ariſtotle and Plato. They both, ſays he, poſſeſſed an uncommon and elevated genius. The mind of Plato was, it is true, more refined, but Ariſtotle's more penetrating and profound. Plato's imagination is lively, copious, fruitful in invention, idea, and expreſſion: he gives every ſubject he treats of a thouſand different turns, ſets it in a thouſand lights, and all are pleaſing. But, after all, this is nothing but imagination. Ariſtotle is crabbed and dry, but what he ſays, carries the force of reaſon with it. His diction, though pure, is harſh, and his natural or affected obſcurities perplex and tire his readers. Plato has a delicacy in his thought and expreſſion; Ariſtotle ſeems to avoid this, in order to be more natural: his ſtile is ſimple and even, but cloſe and nervous; that of Plato pompous and elevated, but looſe and diffuſive. In ſhort Plato's principal intention ſeems to have been elegance of diction: Ariſtotle's ſolid Reaſoning.

Of the Reſtorers of ARISTOTLE'S *Philoſophy*.—Philoſophy was never ſo much cultivated as under the Roman emperors, yet the hiſtory of thoſe times ſhews us, it by no means made ſo great a progreſs as might have been expected from the encouragement it met with from them. An inundation of Barbarians deſtroyed the Roman empire and philoſophy too. Ignorance ſucceeded, and the only ſtudy in reputation, for ſome time, was a kind of logic, which conſiſted in quirks and deſtinctions which ſignified nothing. On the revival of learning, ſome men of letters undertook to give a correct tranſlation of Ariſtotle's works into Latin; former tranſlators had given his diſciples a mean opinion of this great philoſopher, and had rather exhibited their own Gothic taſte, than Ariſtotle's genius. But the reſtoration of learning was too great a work for perſons in a private ſtation; princes intereſted themſelves in it, procured manuſcripts out of the Eaſt, and cauſed them to be tranſlated and publiſhed. Pope Paul V. acquired immortal honour by the encouragement he gave to all undertakings of this kind. He was paſſionately fond of all ſorts of literature, but eſpecially of Ariſtotle's philoſophy. Men of learning increaſed, and tranſlations of courſe. Averrois, till then, had been thought Ariſtotle's beſt commentator, but, as learning improved, taſte refined; they thought Averroïs retained ſomewhat of barbariſm, and therefore choſe Alexander to explain Ariſtotle in the Lycæum, as a man of more elegance and politeneſs. Averroïs and he, were without compariſon the moſt eminent in the Peripatetic philoſophy, but their opinions about the ſoul were not orthodox. For Alexander thought it mortal, and Averroïs, though he acknowledged the ſoul immortal, yet meant only an univerſal ſoul of which all men partook. Theſe opinions ſpread very much in the time of Thomas Aquinas, who refuted them very fully. The ſect of Averrois prevailed in Italy, inſomuch that Pope Leo X. thought proper to put a ſtop to the propagation of doctrines ſo oppoſite to Chriſtianity, and condemned the opinion of Averroïs as impious in the ſecond Lateran council. Some profeſſors, thinking the fulminations of the church inſufficient to make men of learning lay aſide theſe dangerous opinions, oppoſed the Platonic philoſophy as the beſt remedy to this growing evil; others, finding many beauties in the philoſophy of Ariſtotle, and highly reverencing the doctrines of the goſpel, were for reconciling him with Plato; others, again, ſoftened the expreſſions of Ariſtotle and gave them a religious turn.—It may not be diſagreeable to mention ſome of thoſe who diſtinguiſhed themſelves in theſe controverſies.

Among the Greeks who left their own country and came to tranſplant learning into Italy, Theodorus Gaza was one of the moſt eminent; he underſtood the opinions of every ſect of philoſophy, was a great phyſician, a profound divine, and remarkable for his ſkill in polite literature. He was of Theſſalonica; the victorious arms of Amurath that ravaged all the Eaſt, drove him to ſeek refuge in Italy. Cardinal Beſſarion received him with friendſhip, and gave him prieſt's orders. He tranſlated Ariſtotle's Hiſtory of Animals, and the Problems of Theophraſtus on Plants. His tranſlations pleaſed him ſo much, that he boaſted of them as equal to the original. But though he is eſteemed one of the beſt tranſlators, yet, as Eraſmus juſtly obſerves, his Latin phraſe has a tincture of Greek, and his opinions the tincture of the age he lived in. Coſmo of Medicis joined with cardinal Beſſarion in doing him ſervices and advancing his fortune, but Greek and Brutian ſycophants and his own want of œconomy reduced him to extreme poverty; under theſe circumſtances he ſet about the tranſlation of Ariſtotle's Animal Hiſtory, which he dedicated to Sixtus IV. from whom he only received a preſent of a hundred piſtoles, which he threw with indignation into the Tiber, and withdrew himſelf from Rome into the country of Brutii, where he would have ſtarved, had not the duke of Ferrara taken notice of him. He died of vexation ſoon after, a remarkable example of the changes of fortune.

George of Trebizond, as well as Gaza, applied himſelf to the Peripatetic philoſophy; gave himſelf this title, becauſe it was the country of his anceſtors; for he was a Cretan by birth. He went into Italy, while the council ſat about reuniting the Latin and Greek churches. He was at Venice firſt, from whence he went to Rome where he taught rhetoric and philoſophy. He was ſo zealouſly fond of Ariſtotle as to defend him in every point: and wrote the bittereſt in-

vectives

vectives againſt the followers of Plato; which created him many enemies. Nicholas V, his patron, notwithſtanding his inclination to the Ariſtotelian philoſophy, diſapproved of his conduct. Cardinal Beſſarion was the moſt powerful antagoniſt that took up the pen againſt him; he refuted him under the title of the ſlanderer of Plato. But he had a more formidable enemy than the cardinal, neceſſitous poverty; for this diſpute unhappily deprived him of all ſupport. Poſterity will more eaſily pardon his prejudices againſt the followers of Plato in his age, than the incorrectneſs of his tranſlations. His tranſlations of the Laws of Plato and Ariſtotle's Hiſtory of Animals are deficient in many reſpects; inattention, want of erudition and honeſty, manifeſt themſelves very frequently. For he took the liberty of altering the text, leaving out many things of conſequence, and changing others; as may be ſeen by the tranſlation Euſebius has given us. Thus we ſee, on the revival of learning, men of letters were divided between Plato and Ariſtotle; both ſides caſt the ſevereſt reflections on each other, which is the caſe of all parties; but neither are to be regarded more than reaſon decides in their favour.

The Ariſtotelian philoſophy, however, was continued in vogue till Des Cartes demoliſhed it; though he did not ſubſtitute any thing more rational in its ſtead; as we have obſerved in the preface to the Dictionary.

Univerſal ARITHMETIC, a name given by Sir Iſaac Newton to algebra, or the calculation of quantities in general. Nor is it without reaſon that this great man, whoſe elevated genius and profound penetration ſeem to have traced all the ſciences to their true metaphyſical principles, gave it this title.

In ſhort, in common Arithmetic are two kinds of principles; the firſt are general rules independent of the characters made uſe of to expreſs numbers: the ſecond are rules which depend on the characters; and theſe are more properly called rules of Arithmetic. The firſt principles contain only the general properties of proportions, and take place, however theſe proportions are ſtated: ſuch, for example, are theſe rules, take one number from another, and the remainder, added to that number, will give the firſt number; if you divide one number by another, the quotient multiplied by the diviſor will give the dividend; if the ſum of ſeveral numbers be multiplied by the ſum of ſeveral other numbers, the product will be equal to the ſum of the products of each part multiplied by all the others, &c.

From whence it follows, that by noting numbers by general expreſſions, though they no more denote one number than another, we may form certain rules relative to operations which may be performed on numbers ſo expreſſed. Theſe rules ſhew the reſult of one or more operations performed on numbers expreſſed in a general manner, by the moſt ſimple method; and this reſult ſo expreſſed is properly nothing more than an arithmetical operation expreſſed in characters, which will vary according to the different arithmetical values we aſſign the quantities ſubſtituted for numbers.

To ſet this idea of algebra in a clearer light, it may not be amiſs juſt to mention the four common rules in Arithmetic. To begin with addition, which conſiſts in adding any numbers propoſed into one total, without any other operation. If it were propoſed to add two diſſimilar quantities together a, b, I would write ſimply $a + b$; the reſult is only an indication that if I mean a certain number by a, and another by b, theſe numbers muſt be added together; thus, $a + b$ is nothing but the indication of an arithmetical addition, the ſum of which will be different, according to the different numerical values aſſigned to a and b. Suppoſe it were required to add $5a$ to $3a$, I might write $5a + 3a$, but it is plain, this may be expreſſed in a more ſimple manner; for $5a + 3a$, $= 8a$, and, therefore, the arithmetical operation may be expreſſed in a conciſer method than $5a + 3a$, by writing ſimply $8a$.

The general rule of addition in algebra for ſimilar quantities is performed by adding together their numerical co-efficients, and adjoining the literal quantities.

Whence it follows, that addition in algebra expreſſes the ſum or aggregate of ſeveral numbers, generally in the moſt ſimple manner, and ſaves the arithmetician as much labour as poſſible.

In ſubtraction the thing is the ſame; for, if I would ſubtract b from a, I write ſimply $a - b$; becauſe I cannot repreſent this operation in a more ſimple manner: but, were I to ſubtract $3a$ from $5a$, I would not write $5a - 3a$, becauſe that would give me the trouble of ſeveral arithmetical operations, if a had any numerical value, but ſimply $2a$, which is more convenient in calculation.

The ſame thing is true in multiplication and diviſion; if I would multiply $a + b$, by $c + d$, I might write indifferently $\overline{a + b} \times \overline{c + d}$, or $ac + bc + ad + bd$, though I ſhould prefer the firſt method, becauſe it ſeems to require fewer arithmetical operations; in the firſt, there are only wanted two additions and one multiplication; in the ſecond, three additions and four multiplications. But, were I to multiply $5a$ by $3a$, inſtead of writing $5a \times 3a$, I would write $15aa$, becauſe in the firſt caſe I ſhould have three arithmetical operations to perform, in the ſecond only two; one to find aa, the other to multiply aa by 15. In like manner, were I to multiply $a + b$ by $a - b$, I ſhould write $aa - bb$; becauſe this reſult would often prove more commodious than the other in arithmetical calculations. Beſides, a theorem reſults from it, namely, that the product of the ſum of two numbers by the difference of the ſame numbers, is equal to the difference of the ſquares of the two numbers. Thus we find the product of $a + b$ by $a + b$, that is, the ſquare of $a + b$ is $aa + 2ab + bb$, and, conſequently, contains the ſquare of both quantities, plus twice the product of one by the other; which is of uſe in extracting the ſquare root.

In diviſion, inſtead of writing $\frac{20ab}{5b}$ I would write $4a$ ſimply, and inſtead of $\frac{aa - xx}{a + x}$, $a - x$: but, were I to divide bc by bd, I would write $\frac{bc}{bd}$, becauſe I could not find a more ſimple manner of expreſſion.

Hence it is evident, that Sir Iſaac Newton was in the right to call algebra univerſal Arithmetic; becauſe it conſiſts in exhibiting all the general and common rules of every kind of Arithmetic, in a more clear, conciſe, and ſimple method.

But it may be aſked why all this perplexity? In all arithmetical queſtions the numbers are expreſſed; of what uſe is it then to give them a literal expreſſion?

It is eaſy to ſee the advantage of this expreſſion; every queſtion, that may be propoſed in Arithmetic, is not ſo ſimple as that of adding a number given to another, ſubtracting one from another, or multiplying or dividing one by another. There are queſtions much more complicated; for the ſolution of which we are obliged to form combinations of which the number or numbers muſt make a part. We muſt therefore be poſſeſſed of an art whereby we may repreſent theſe combinations, without knowing the number ſought; and, conſequently, expreſs theſe numbers by characters not numerical: becauſe it would be very improper and inconvenient to expreſs an unknown number by a numerical character, which we had no reaſon to expect would be its real value. To render this ſtill more plain by an example: let us ſuppoſe two numbers were required, whoſe ſum is 100, and their difference 60. It is eaſy to ſee that by ſetting down two unknown numbers at pleaſure in figures, as, for example, 25 and 50, the expreſſion would be falſe; becauſe theſe two numbers do not anſwer the conditions of the queſtion. The ſame inconvenience would ariſe in a multitude of other numerical expreſſions. To avoid this inconvenience, let us call the greater number x, the leſſer y, and, by this algebraic expreſſion, the conditions of the queſtion will be eaſily repreſented; thus x plus y is equal to 100, and x minus y is equal to 60; or, in algebraic characters,

$$x + y = 100$$
$$x - y = 60$$

As $x + y$ is equal to 100, and $x - y$ equal to 60, it is evident that 100 added to 60 muſt be equal to $x + y$ added to $x - y$. But to add $x + y$ to $x - y$, by the rule of addition in algebra, we muſt write $2x$, and conſequently $2x$ is equal to 160; that is, 160 is equal to twice the greater number ſought; and conſequently x, or the greater number, is equal to 80. From whence it is eaſy to find the other y, for if $x + y$ be equal to 100, and x equal to 80, then 80 plus y is equal to 100; therefore y is equal to 100 minus 80; that is, the two numbers, therefore, are 80 and 20; for their ſum is 100, and their difference 60.

In other caſes we do not inſiſt on the neceſſity of algebra; nay, if queſtions, more complicated than this were not propoſed, it would not be neceſſary; we only mean to ſhew, by this plain example, which is obvious at firſt ſight, how we arrive at a diſcovery of unknown quantities by the help of algebra.

The algebraic expreſſion of a queſtion, as Sir Iſaac Newton has well obſerved, is only a tranſlation of the ſame queſtion into algebraic characters; which has this advantage, and eſſentiality in its nature, that it confines itſelf to what is abſolutely neceſſary in the queſtion, and contracts the work by baniſhing ſuperfluous terms. See EQUATION, in the Dictionary and Supplement.

ARK, *Arca*, in the ſcripture language, denotes a kind of floating veſſel built by Noah, for the preſervation of the ſeveral ſpecies of animals from the deluge.

The Ark has afforded ſeveral points of curious enquiry among the critics and naturaliſts, relating to its form, capacity, materials, time of building, place of reſting after the flood, &c. Noah is computed to have been an hundred years in building the Ark, viz. from the year of the world 1557, to the flood, which happened in the year 1656: at leaſt, this is the common opinion of the learned. Origen and St. Auſtin aſſert as much; and are followed by Salian, Torniel, Spondeus, Pelletier, &c.

Yet Beroſus affirms, that Noah only began to build the Ark ſeventy-eight years before the flood: Solomon Jarchi, on the other hand, will have it an hundred and twenty years in building, and Tanchuma only fifty-two.

Father Fournier, in his Hydrography, embraces the opinion of the fathers; noting, that the only hands employed in it were Noah and his three ſons. To this purpoſe he alledges the inſtance of Archias of Corinth, who, with the help of three-hundred workmen, built Hiero's great ſhip in one year. Add, that Noah's eldeſt ſon was not born till about the time when the Ark was begun, and the younger, after; ſo that it was a long time before they could do their father any ſervice. However, for ſo large a building, a prodigious number of trees muſt have been required, and, conſequently, a great number of workmen employed to fell and hew them, beſides thoſe who built the Ark.

The wood whereof the ark was built, is called, in ſcripture, עצי גפר, etſe gopher, gopher wood: and in the LXX. ξύλα τετράγωνα, ſquare timbers. Onkelos and Jonathan render gopher by קדרוס, kedros, cedar: St. Jerom, in the vulgate, by ligna lævigata, planed wood; and, elſewhere, ligna bituminata, q. d. pitched wood. Kimchi tranſlates it, wood proper to float; Vatable, light wood, which ſwims in the water without corrupting: Junius, Tremellius, and Buxtorf, a kind of cedar, by the Greeks called κεδρελάτη; Avenarius and Munſter, pine; Fuller and Bochart, cypreſs; others box; others fir; Caſtalio, turpentine, &c. Pelletier prefers the opinion of thoſe who hold the Ark made of cedar: his reaſons are, the incorruptibility of that wood; the great plenty thereof in Aſia, whence Herodotus and Theophraſtus relate, that the kings of Egypt and Syria built whole fleets of it; and the common tradition, throughout the Eaſt, imports, that the Ark is preſerved intire to this day on mount Ararat.

The dimenſions of the Ark, as delivered by Moſes, are three hundred cubits in length, fifty in breadth, and thirty in height; which, compared with the great number of things it was to contain, ſeems, at firſt ſight, too ſmall. And hence an argument has been drawn againſt the authority of the relation. Celſus long ago laughed at it, calling it κιβωτὸν ἀλλόκοτον, the abſurd Ark. To ſolve this difficulty, many both of the ancient fathers and later critics have been put to miſerable ſhifts. Origen, St. Auguſtin, and others, maintain, that, by the cubits here ſpoke of, we are to underſtand the Egyptian geometrical cubit, equal, according to them, to ſix vulgar cubits, or nine feet. But the truth is, it does not appear there ever was any ſuch meaſure as a geometrical cubit either among the Egyptians or Jews. Others account for it, by aſſerting the ſtature of mankind, in the firſt ages, to have been much greater than in our days; and, conſequently, the cubit, which is taken from a part of a human body, proportionably larger. But this does not avail, ſince the ſame reaſon will infer an equal augmentation of other animals. Others ſuppoſe the ſacred cubit here ſpoken of, which was a hand's-breadth longer than the civil one: but this only affords a ſmall ſupply; beſides, that the ſacred cubit does not appear to have been ever uſed, except in ſacred edifices, as the temple and tabernacle.

This difficulty is much better ſolved by Buteo and Kircher, wherein, ſuppoſing the common cubit of a foot and a half, they prove geometrically, that the Ark was abundantly ſufficient for all the animals ſuppoſed to be lodged therein. Snellius computes the Ark to have been above half an acre in area: Cuneus, Buteo, and others, have alſo calculated the capacity of the Ark.—Dr. Arbuthnot computes it to have been 81062 tons. Father Lamy ſhews that it was an hundred and ten feet longer than the church of St. Mary at Paris, and ſixty-four feet narrower; to which his Engliſh tranſlator adds, that it muſt have been longer than St. Paul's church at London, from weſt to eaſt; broader than that church is high in the inſide, and about fifty-four feet in height, our meaſure.

The things contained in it were, beſides eight perſons of Noah's family, one pair of every ſpecies of unclean animals, and ſeven pair of every ſpecies of clean animals, with proviſions for them all, during the whole year. The former at firſt view ſeems almoſt infinite, but if we come to a calculation, the number of ſpecies of animals will be found much ſmaller than was imagined, not amounting to an hundred ſpecies of quadrupeds, nor two hundred of birds; out of which, in this caſe, are to be excepted ſuch animals as can live in the water. Zoologiſts uſually reckon but an hundred and ſeventy ſpecies in all; but biſhop Wilkins ſhews, that only ſeventy-two of the quadrupede kind needed a place in the Ark.

By the deſcription Moſes gives of the Ark, it appears to have been divided into three ſtories, each ten cubits, or fifteen feet high: and it is agreed on, as moſt probable, that the loweſt ſtory was deſtined for the beaſts, the middle for the food, and the upper for the birds, with Noah and his family; each ſtory being ſubdivided into different apartments, ſtalls, &c. Though Joſephus, Philo, and other commentators add a kind of fourth ſtory, under all the reſt, being, as it were, the hold of the veſſel, to contain the ballaſt, and receive the filth and fæces of ſo many animals.

Drexelius makes three hundred apartments; father Fournier, three hundred and thirty-three; the anonymous author of the queſtions on Geneſis, four hundred; Buteo Temporarius, Arias Montanus, Hoſtus, Wilkins, Lamy, and others, ſuppoſe as many partitions as there were different ſorts of animals. Pelletier only makes ſeventy-two, viz. thirty-ſix, of the birds, and as many for the beaſts: his reaſon is, that if we ſuppoſe a greater number, as three hundred thirty-three or four hundred, each of the eight perſons in the Ark muſt have had thirty-ſeven, forty-one, or fifty ſtalls to attend and cleanſing daily, which he thinks impoſſible. But there is not much in this; to diminiſh the number of ſtalls, without a diminution of the animals, is vain; it being, perhaps more difficult to take care of three hundred animals in ſeventy-two ſtalls, than in three hundred.

Buteo computes that all the animals contained in the Ark could not be equal to five hundred horſes; he even reduces the whole to the dimenſions of fifty-ſix pair of oxen. Father Lamy enlarges to ſixty-four pair, or an hundred and twenty-eight oxen; ſo that, ſuppoſing one ox equal to two horſes, if the Ark had room for two hundred and fifty-ſix horſes, there muſt have been room for all the animals. But the ſame author demonſtrates, that one floor would ſuffice for five hundred horſes, allowing nine ſquare feet to an horſe.

As to the food in the ſecond ſtory, it is obſerved by Buteo from Columella, that thirty or forty pounds of hay ordinarily ſuffice an ox for a day; and that a ſolid cubit of hay, as uſually preſſed down in our hay-ricks, weighs about forty pounds; ſo that a ſquare cubit of hay is more than enough for one ox for one day. Now it appears that the ſecond ſtory contained 150000 ſolid cubits, which, divided between two hundred and ſix oxen, will afford each more hay by two thirds, than he can eat in a year.

Biſhop Wilkins computes all the carnivorous animals equivalent, as to the bulk of their bodies and their food, to twenty-ſeven wolves, and all the reſt to two hundred and eighty beeves. For the former he allows 1825 ſheep, and for the latter 109500 cubits of hay: all which will be eaſily contained in the two firſt ſtories, and a deal of room to ſpare.

As to the third ſtory, no-body doubts its being ſufficient for the fowls, with Noah, his ſons and daughters.

Upon the whole, the learned biſhop remarks, that, of the two, it appears much more difficult to aſſign a number and bulk of neceſſary things to anſwer the capacity of the Ark, than to find ſufficient room for the ſeveral ſpecies of animals already known. This he attributes to the imperfection of our liſts of animals, eſpecially thoſe of the unknown parts of the earth; adding, that the moſt expert mathematician at this day could not aſſign the proportions of a veſſel better accommodated to the purpoſe, than is here done; and hence, finally, concludes, that 'the capacity of the Ark, which had been made an objection againſt ſcripture, ought to be eſteemed a confirmation of its divine authority; ſince, in thoſe ruder ages, men, being leſs verſed in arts and philoſophy, were not ſo obnoxious to vulgar prejudices as now; ſo that, had it been an human invention, it would have been contrived according to thoſe wild apprehenſions which ariſe from a confuſed and general view of things; as much too big, as it has been repreſented too little.'

ARMA'DA, or ARMATA, a naval army, or a fleet equipped for war.

ARMADI'LLA, in the Spaniſh America, denotes a ſquadron of men of war, to the number of ſix or eight, from twenty-four to fifty pieces of cannon, which the king maintains, to prevent foreigners from trading with the Spaniards and the Indians, both in time of war and peace.

The veſſels of this Armadilla are thoſe that have made ſo much noiſe, under the name of Guarda-coſta's.

ARMENI'ACA, *Apricock*, in botany, the name of a genus of trees, the characters of which are theſe: the flower is of the roſaceous kind, being compoſed of ſeveral petals, arranged in a circular form. The piſtil ariſes from the cup, and finally becomes a fleſhy fruit, of a roundiſh figure, but uſually a little compreſſed ſideways, and having a furrow down its middle. This fruit contains a flatted ſtone, which includes a kernel of the ſame figure.

We have in Engliſh gardens about ſeven ſorts of this fruit cultivated; which are,

1. The maſculine apricock. 2. The orange apricock. 3. The Algier apricock. 4. The Roman apricock. 5. The Turkey apricock. 6. The Breda apricock. 7. The Bruſſels apricock.

The maſculine is the firſt ripe of all the apricocks; it is a ſmall, roundiſh fruit, of a red colour towards the ſun; as it ripens, the colour fades to a greeniſh yellow on the other ſide. It is only preſerved for being the firſt ripe, having little flavour: the tree is very apt to be covered with flowers; but, as they come out early in the ſpring, are frequently deſtroyed by the cold, unleſs the trees are covered to protect them.

The orange is the next ripe apricock; this fruit is much larger than the former; and, as it ripens, changes to a deep yellow colour. The fleſh of this is dry, and not high-flavoured; it is better for tarts than for the table.

The Algier is the next in ſeaſon; this is of an oval ſhape, a little compreſſed on the ſides; it turns to a pale-yellow, or ſtraw-colour, when ripe; the fleſh is dry, and not high-flavoured: this, and what is by ſome perſons called the common apricock, are often confounded.

The

The Roman is the next ripe apricock; this is a larger fruit than the former, and not compreſſed on the ſides; the colour is deeper, and not ſo dry as the former.

The Turkey apricock is yet larger than either of the former, and of a globular figure; they turn to a deeper yellow than the former; the fleſh is firmer, and of an higher flavour than either of the former.

The Breda apricock (as it is called from its being brought from thence into England) was originally brought from Africa: this is a large, roundiſh fruit, changing into a deep-yellow, when ripe; the fleſh is ſoft, full of juice, and of a deep orange-colour with inſide; the ſtone is rounder and larger than of the other ſorts: this is the beſt apricock we have; and, when ripened on a ſtandard, is preferable to all other kinds.

The Bruſſels is the lateſt ripe of all the apricocks; for, when it is planted againſt a wall, it is generally the beginning of Auguſt before it is ripe, unleſs when it is planted to a full ſouth aſpect; which is what ſhould not be practiſed, becauſe the fruit is never well-taſted which grows in a warm expoſure. This fruit is of a middling ſize, rather inclining to an oval figure; red on the ſide next the ſun, with many dark ſpots, and of a greeniſh-yellow on the other ſide; the fleſh is firm, and of an high flavour; the fruit often cracks before it is ripe. This is commonly preferred to the former ſort by moſt people; but, when the other is planted as a ſtandard, the fruit is fuller of juice, and of a richer flavour than this.

Moſt people train theſe trees up to ſtems of ſix or ſeven feet high, or bud them upon ſtocks of that height; but this is a practice I would not recommend, becauſe, the higher the heads of theſe trees are, the more they are expoſed to the cutting winds in the ſpring, which too frequently deſtroy the bloſſoms; and the fruit is alſo more liable to be blown down in ſummer, eſpecially if there ſhould happen to be much wind at the time they are ripe; which, by falling from a great height, will be bruiſed and ſpoiled; therefore I prefer half-ſtandards, of about two and a half, or three feet in the ſtem, to thoſe which are much taller; or to plant them as dwarfs againſt an eſpalier, where, if they are ſkilfully managed, they will produce a large quantity of good fruit; and the trees in eſpalier may be more conveniently covered in the ſpring, when the ſeaſon proves bad; whereby there will be a certainty of fruit every year.

Theſe fruits are all propagated by budding them on plum-ſtocks, and will readily take upon almoſt any ſort of plum, provided the ſtock be free and thriving (except the Bruſſels kind, which is uſually budded on a ſort of ſtock, commonly called the St. Julian, which better ſuits the tree, as being generally planted for ſtandards, than any other ſort of plum will.) The manner of raiſing the ſtocks, and budding theſe trees, are treated of under their particular articles, to which I refer the reader, and ſhall proceed to their planting and management.

Theſe trees are all (except the two laſt ſorts) planted againſt walls, and ſhould have an eaſt or weſt aſpect; for, if they are planted full ſouth, the great heat cauſes them to be mealy before they are well eatable. The borders under theſe walls ſhould be ſix feet wide at leaſt, and, if it were more, the better; but I would never adviſe the making of them ſo deep, as is the general cuſtom; for, if the earth be two feet deep, or two and an half at moſt, it is enough.

If your ground is a wet cold loam or clay, you ſhould raiſe your borders as much above the level of the ſurface as it will admit, laying ſome ſtones or rubbiſh in the bottom, to prevent the roots from running downwards; but, if you plant upon a chalk or gravel, you muſt remove it to a conſiderable width, to make room for a good ſoil to be put in; but you need not go above two feet and an half deep at moſt.

The ſoil I would in general adviſe to be uſed for theſe and all other ſorts of fruit-trees, is freſh untried earth, from a paſture-ground, taken about ten inches deep, with the turf, and laid to rot and mellow at leaſt twelve months before it is uſed; and this muſt be kept often turned, to ſweeten and imbibe the nitrous particles of the air.

When the former ſoil of the border is taken away, this freſh earth ſhould be carried in the place; and, if the borders are filled with it two months before the trees are planted, the ground will be better ſettled, and not ſo liable to ſink after the trees are planted: in filling of the borders, the ground ſhould be raiſed four or five inches above the level they are deſigned, to allow for the ſettling.

Your borders being thus prepared, make choice of ſuch trees as are but of one year's growth from budding; and, if your ſoil is dry, or of a middling temper, you ſhould prefer October for the beſt ſeaſon for planting, eſpecially having, at that time, a greater choice of trees from the nurſeries, before they have been picked and drawn over by other people. The manner of preparing theſe trees for planting being the ſame in common as other fruit-trees, we refer the reader to the article of PEACHES, where he will find it largely treated of. But do not cut off any part of the head at that time, unleſs there are any ſtrong fore-right ſhoots which will not come to the wall, which may be taken quite away.

Your trees being thus prepared, you muſt mark out the diſtances they are to ſtand, which, in a good ſtrong ſoil, or againſt a low wall, ſhould be twenty feet, or more; but, in a moderate one, eighteen feet is a good reaſonable diſtance; then make an hole where each tree is to ſtand, and place its ſtem about four inches from the wall, inclining the head thereto: and, after having fixed the tree in the ground, nail the branches to the wall, to prevent their ſhaking, and cover the ſurface of the ground round the root with rotten dung, to keep out the froſt: in this ſtate let it remain till February, when, if the weather is good, you muſt un-nail the branches of your trees, ſo as not to diſturb the roots, and, being provided with a ſharp knife, put your foot cloſe to the ſtem of the tree; and, having placed your left-hand to the bottom of the tree, to prevent its being diſturbed, with your right-hand cut off the head of the tree, to about four or five eyes above the bud, ſo that the ſloping ſide may be towards the wall.

In the ſpring, if the weather proves dry, you muſt, now-and-then, give your trees a gentle refreſhing with water; in the doing of which, if you obſerve to water them with a roſe to the watering-pot, all over their heads, it will greatly help them; and alſo lay ſome turf, in the manner directed for apples, or ſome other mulch, round the roots, to prevent their drying during the ſummer-ſeaſon: as new branches are produced, obſerve to nail them to the wall in an horizontal poſition; and ſuch ſhoots as are produced fore-right, muſt be intirely diſplaced. This muſt be repeated, as often as is neceſſary, to prevent their hanging from the wall; but by no means ſtop any of their ſhoots in ſummer.

At Michaelmas, when the trees have done growing, you muſt un-nail their branches, and ſhorten them in proportion to their ſtrength; a vigorous branch may be left eight or nine inches long, but a weak one ſhould not be left above five or ſix. I ſuppoſe many people will wonder at this direction, eſpecially having allowed ſuch a diſtance between the trees, as believing, by this management, the wall will never be filled; but my reaſon for it is, that I would have no part of the wall left unfurniſhed with bearing-wood; which muſt conſequently be the caſe, if the branches are left to a great length at firſt; for it ſeldom happens, that more buds than two or three ſhoot for branches; and theſe are, for the moſt part, ſuch as are at the extreme part of the laſt year's wood; ſo that all the lower part of the ſhoots become naked, nor will they ever after produce ſhoots; and this is the reaſon we ſee ſo many trees which have their bearing-wood ſituated only in the extreme part of the tree.

When you have ſhortened the ſhoots, be ſure to nail them as horizontally as poſſible; for upon this it is that the future good of the tree chiefly depends.

The ſecond ſummer obſerve, as in the firſt, to diſplace all fore-right ſhoots, as they are produced, nailing-in the other cloſe to the wall horizontally, ſo that the middle of the tree may be kept open; and never ſhorten any of the ſhoots in ſummer, unleſs to furniſh branches to fill vacant places on the wall; and never do this later than April, for reaſons hereafter given in the article of PEACHES. At Michaelmas ſhorten theſe ſhoots, as was directed for the firſt year; the ſtrong ones may be left nine or ten inches, and the weak, ſix or ſeven at moſt.

The following year's management will be nearly the ſame with this; but only obſerve, that apricocks produce their bloſſom-buds, not only upon the laſt year's wood, but alſo upon the curſons or ſpurs, which are produced from the two years wood: great care ſhould therefore be had in the ſummer-management, not to hurt or diſplace theſe: obſerve alſo, to ſhorten your branches at the winter-pruning, ſo as to furniſh freſh wood in every part of the tree; and be ſure to cut out intirely all the luxuriant branches, or diſplace them, as ſoon as they are produced; which, if left to grow, would exhauſt the nouriſhment from the bearing branches, which, in my opinion, cannot be too ſtrong, provided they are kindly; for the more vigorous your tree is, the more likely it is to reſiſt the injuries of the weather: and I have often ſeen trees brought to ſo weak a condition, as to be able only faintly to blow their bloſſoms, and then moſt or all of the bearing branches have died; which has given occaſion to the owner to imagine it was the effect of a blight, when, in reality, it was only for want of right management. And, I am fully perſuaded, half the blights we here complained of, proceed from nothing elſe but this.

Theſe few rules, well executed, together with a little obſervation and care, will be ſufficient; and, to pretend to preſcribe particular directions for all the different accidents, or manners of treating fruits, would be impoſſible; but I believe the reader will find what has been ſaid, if duly attended to, will anſwer his deſign; for, without diligent obſervation, there can be no ſuch thing as a ſkilful manager, let him have ever ſo many or good inſtructions laid down to him.

The Bruſſels and Breda apricocks, being, for the moſt part, planted for ſtandards, will require very little pruning or management; only obſerve to take out all dead wood, or ſuch branches as croſs each other; this muſt be done early in autumn, or in the ſpring, after the cold weather is paſt, that the part may not canker where the inciſion is made. *Miller's Gard. Dict.*

ARME'NUS *Lapis*, Armenian stone, in natural history, a mineral substance, which is but improperly called a stone, being no other than ochreous earth, and properly called blue ochre. It is a very valuable substance in painting, being a bright and florid blue. It was in so high esteem as a paint, among the ancients, that counterfeits were continually attempted to serve in its place: and Theophrastus has recorded it as a thing judged worthy a place in the Egyptian annals, which of their kings had the honour of inventing the factitious kind; and he tells us the genuine native substance was a thing of that value, that presents were made of it to great persons; and that the Phœnicians paid their tribute in it. *Hill's Theophrastus.*

It is a very beautiful earth, of an even and regular texture, and of a fine blue; sometimes deeper, sometims paler, and sometimes mixt with green. It is soft, tender, and light; of an even, but somewhat dusty, surface; it adheres firmly to the tongue, and is dry, but not harsh to the touch. It easily breaks between the fingers, and does not stain the hands. It is of a brackish disagreeable taste, and does not ferment with acids. It is a very scarce fossil, but is found very pure, though in but small quantities, in the mines at Gosselaer in Saxony. It is frequently found spotted with green, and sometimes with black; and very often is mixed among the green ochre, called berggruen by the Germans, which has thence, by some, been erroneously called by its name. *Hill's Hist. of Fossils.*

ARMOI'SIN, a silk-stuff, or kind of taffety, of an indifferent goodness. It is made at Lyons, and in several places in Italy. There are half-Armoisins (demi-Armoisins) made at Avignon, which are of an inferior quality, and less price than the others. They manufacture also Armoisins with three threads. Armoisins of all colours are imported from the East-Indies, and particularly from Casembasar, by the way of Bengal. See the next article. Some pretend that the word Armoisin comes from the Italian armesino; or that those silks were thus called, because there were coats of arms delineated upon the cloth in which they were wrapped up.

ARMOISIN *of the Indians.* It is a taffety manufactured in the East-Indies, but slighter than those that are made in Europe, and of an inferior quality. Their colours, and particularly their crimson and red, are commonly false, and they have but little gloss, and no brightness at all.

There are two sorts of them, the arains, which are taffeties, either striped or chequered; and the damaras, or flowered taffeties. Their length is from 7 French ells to 24, and their breadth from $\frac{7}{16}$ to $\frac{7}{8}$ of an ell.

The Indian Armoisins have sold at Amsterdam from 18 to 20 guilders per piece. When you do not buy them of the company, that is to say, at second-hand, you may stipulate to pay for them either in current or bank-money, or to deduct the difference.

The Armoisins of Lucca have sold at Amsterdam from 7 to 9 sols de gros per ell. They who sell them again, buy them by deducting the interest of the money for 18 months, they not being obliged to pay for them, but after those months are elapsed: they also deduct 1 per cent. for prompt payment. But, when they sell them to retailers, they deduct but 2 per cent. upon the whole for prompt payment; that is, they allow so much discount for the payment of ready money.

It must be observed that all the silks of Italy are sold after the same manner.

A'RMORIC, or ARREMORIC, something that belongs to the province of Bretagne or Britanny in France.

Armoric, absolutely used, denotes the language in use among the inhabitants of Britanny.

The French usually call this language bas Breton.

The Armoric is a dialect of the Welch, and sister of the Cornish language.

The inhabitants of Britanny, of Cornwal, and of Wales, still understand each other's speech; though considerable diversities have crept in between these languages, since their separation from each other.

A'RMOURERS *Company, in London.* The arms and crest of the brothers and sisters of the fraternity, or guild, of St. George, of the mystery of the Armourers of the city of London (as they were stiled in their charter) were antiently borne by the said corporation, but afterwards declared and confirmed to them by Thomas Hawley, Clarencieux, by patent under the seal of his arms and office, in the third and fourth years of Philip and Mary, 1556.

Their arms are argent on a cheveron, gules; a gantlet, between four swords in saltier, on a chief, sable; a buckler, argent, charged with a cross, gules, between two helmets of the first.

Their crest is a man demi-armed at all points, surmounting a torce and a helmet. Their motto, Make all sure. Their hall is in Coleman-street.

ARMS, or ARMORIES, are used in heraldry, for marks of dignity and honour, regularly composed of figures and colours, given or authorized by sovereigns, and borne in banners, shields, coats, &c. for the distinction of persons, families, and states, and passing by descent to posterity.

They are called Arms, in regard they are borne principally on the buckler, cuirasse, banners, and other apparatus of war. They are also called coats of Arms, coat-armour, &c. because antiently embroidered on sur-coats, &c. Some will have the name to have been first occasioned by the antient knights, who, in their justs and tournaments, bore certain marks (which were frequently their mistress's favours) in their armour, i. e. their helms or shield, to distinguish them from each other.

Three flowers-de-lys, in a field azure, are the Arms of France. The Arms of England are three lions. In the Arms of Great-Britain are quartered the Arms of France, England, Scotland, and Ireland.

There has been a great dispute among the learned about the origin of Arms. Tavyn will have them to have been from the beginning of the world: Segoin, from the time of Noah; others, from that of Osiris, which is supported by some passages in Diodorus Siculus; others from the times of the Hebrews, in regard Arms were given to Moses, Joshua, the twelve tribes, David, &c.

Others will have them to have taken their rise in the heroical age, and under the empire of the Assyrians, Medes, and Persians; building upon Philostratus, Xenophon, and Quintus Curtius.

Some pretend that the use of Arms, and the rules of blazon, were regulated by Alexander. Others will have them to have had their original under the empire of Augustus; others, during the inundations of the Goths; and others, under the empire of Charlemaign.

Chorier observes, that, among the antient Gauls, each man bore a mark on his buckler, by the sight whereof he might be known to his fellows; and hence he refers the original of the Arms of noble families. Cambden has observed something like this of the ancient Picts and Britons, who, going naked to the wars, painted their bodies with blazons, and figures of divers colours, which he supposes to have been different in different families, as they fought divided by kindreds. Yet, Spelman says, that the Saxons, Danes, and Normans, first brought Arms from the north into England, and thence into France.

Upon the whole, it is certain, that, from time immemorial, there have been symbolical marks in use among men, to distinguish them in armies, and to serve as ornaments of shields and ensigns; but these were used as arbitrarily as devices, emblems, hieroglyphics, &c. and were not regular armories, like ours, which are hereditary marks of the nobility of a house, regulated according to the rules of heraldry, and authorized by princes.

Before Marius, even the eagle was not the constant ensign of the Roman army; but they bore in their standard a wolf, leopard, or eagle, indifferently, according to the fancy of the generals.

The same diversity has been observed with regard to the French and English; on which account, authors are divided, when they speak of the antient Arms of those countries. In effect, it appears from all the best authors, that the armories of houses, as well as the double names of families, were not known before the year 1000. And several have even endeavoured to prove, that the use of Arms did not begin till the time of the first croisades. See HERALDRY in the Dict.

ARO'BE, which some spell and pronounce arrobe, in Spanish Arroba, and, in the language of Peru, arroue, a weight used in Spain, in Portugal, at Goa, and throughout all Spanish America. The Portuguese use it also in Brazil, where, as well as at Goa, it is sometimes called arate. All these Arobes are scarce any otherways alike each other but in name, being very different in weight, and in their proportion to the weights of other countries.

The Arobe of Madrid, and almost over all Spain, except Seville and Cadiz, weighs 25 Spanish pounds, which do not quite make 23 pounds and one-quarter Paris weight: so that the common quintal, which is of 4 Arobes, makes but 93 pounds Paris weight.

The Arobe of Seville and Cadiz is also of 25 pounds, but these make 26 pounds and a half at Paris, Amsterdam, Strasburgh, and Besancon, where the pound is equal; 4 Arobes make the common quintal, that is to say, 100 pounds; but there must be 6 Arobes to make the quintal of Macho, which amounts to 150 pounds Seville and Cadiz weights, which may be reduced to the Paris weights upon the foot of the reduction of the Arobe of those two cities, made above.

The aroue, or Arobe, of Peru, weighs 25 pounds French weight. It is chiefly used to weigh the herb paraguay, of which the Spaniards and the Indians, who use it like tea, make so great a consumption, that there are wanted for Peru alone above 75,000 Arobes yearly.

The arate, or Portuguese Arobe, weighs much more than the Spanish Arobe; it being 32 pounds of Lisbon, which amount to near 29 pounds Paris weight. *Sav. Dict. de Com.*

A'ROPH, a term used by Paracelsus, to denote a medicine endued with a power of breaking or dissolving the stone in the human body.

Aroph Paracelsi is also a name given to a kind of chemical flowers, elegantly prepared by sublimation, from equal quantities of lapis hæmatitis and sal armoniac; said to be of great efficacy in quartan agues, the plica Polonica, and hypochondriac diseases.

A'ROUGHCAIN, an animal found in Virginia, which entirely resembles the beaver, except that it feeds and leaps upon trees like the squirrel.

The English value its furr pretty much, which makes a branch of their trade with the Indians who live near their colony.

A'RPENT, a certain measure of land, which is greater or lesser, according to different countries and provinces. But, as to the surveying, or measuring, of forests and coppices sold in France, the Arpent must be the same throughout the whole kingdom, according to the king's ordonnance of August the 13th, 1669, article 14 of the title, which relates to the policy and preservation of forests, of which here follows an extract: no measure shall be admitted, nor used, in the king's woods and forests, nor in those held in coparcenery, in eyre, in appennage, mortgage, usucaption, or held by ecclesiastical community, or private persons, without exception, but that of 12 lines per inch, 12 inches per foot, 22 feet per perch, and 100 perches per Arpent, upon pain of a fine of 1000 livres, notwithstanding all customs and possessions to the contrary.

It must be observed that the ordonnance, mentioning 100 perches per Arpent, must be understood of 100 square perches.

The Arpent is commonly divided two ways; the one into an half, a quarter, and half a quarter; and the other into a third, half a third, &c. of an Arpent.

A'RQUEBUSE, or HARQUEBUSE, a fire-arm, of the same length with a fusee, or musquet, which is commonly cocked with a spring-lock. This kind of arms was formerly very much used both in war and for hunting; but, at present, it is hardly any otherwise used than for the defence of besieged places; but it has given name to a considerable company of tradesmen at Paris, called arquebusiers, that is, gun-smiths.

A'RSCHIN, a long measure, used in China, to measure stuffs. It is of the same length with the Dutch ell, which is of 2 feet 11 lines, which amounts to four-sevenths of a French ell. So that 7 Arschins of China make 4 ells of France.

The ell of Amsterdam makes three-fourths of a yard of London, so that 4 ells of Amsterdam, or 4 Arschins of China, make 3 yards of London. So that, to reduce the Arschins to the yard of London, you must say, if your Archins make three yards, so many Arschins (thirty for instance) how many yards will they make? Answer, $22\frac{1}{2}$. And, in order to reduce the yards into Arschins, say, if 3 yards make 4 Arschins, so many yards (as 35 for instance) how many Arschins will they make? Answer, $46\frac{2}{3}$.

A'RSMART, in the botanic pharmacy, a medicinal plant, of a hot, pungent, penetrative taste, whence it is also called hydropiper, or water-pepper. Botanists call this plant persicaria, and, sometimes, persicaria non maculosa, by way of distinction from another species of that plant, called persicaria mitis, or maculosa.

Arsmart, by its heat and pungency, becomes almost intolerable to the tongue; and hence it obtains in scorbutic, hypochondriac, and other disorders, arising from a sluggish circulation of the fluids.

Several value its distilled water for its efficacy in the stone in the kidnies or bladder. Some, also, use the plant in external applications, particularly to dissipate bruised blood; others for the tooth-ach, &c.

ARRACHEE', in heraldry, is understood of representations of plants forcibly torn up by the roots, with their roots hanging at them. *Nisb. Herald.*

ARRE'ST, ARRESTS, or ARRETS, among farriers, denote a sort of mangy tumors on the sinews of the hind legs of a horse, between the ham and the pastern; called also rat-tails. *Guill. Gent. Dict.*

The name of it is taken from the resemblance they bear to the arretes or back-bones of fishes.

Arrets bear a near resemblance to scratches.

ART. See MECHANICS.

ART *and part*, in the law of Scotland, is used for being an accomplice of a crime, either by aiding or advising.

The facts, inferring Art and part, need not be particularly laid in the libel or indictment, for these general words, as terms of stated signification, are sufficient. Yet these facts may be set forth, and it is proper so to do, if the prosecutor chuses to confide in the court rather than in the jury. *Mackenz. Crim. Law.*

ARTA'BA, an antient measure of capacity used by the Persians, Medes, and Egyptians.

The Persian Artaba is represented by Herodotus as bigger than the Attic medimnus by three Attic chœnixes; from which it appears, that it was equal to $6\frac{1}{4}$ Roman modii; consequently, that it contained $166\frac{2}{3}$ pounds of wine or water, or $126\frac{2}{3}$ pounds of wheat. *Beverin. de Pond et Mens. P. 2. p.* 125.

The Egyptian Artaba contained five Roman modii, and fell short of the Attic medimnus by one modius; consequently, held $133\frac{1}{3}$ pounds of water or wine, 100 pounds of wheat, or 60 of flour.

ARTEMI'SIA, in the botanical pharmacy, a medicinal herb of great efficacy as an uterine, and promoter of the menses.

Artemisia is the same with what is popularly called mugwort; among botanists it is also under the denomination of Artemisia vulgaris major, Artemisia rubra, and Artemisia officinarum. It is much used in female complaints, both internally and externally: it is held an opener and discutient, a cleanser of the uterus, promoter of the menses, and of delivery. But it is more esteemed among midwives and nurses than among physicians. Its chief use in the shops is in a compound syrup, which takes its name from it. *Quins. Dispens.*

A'RTICHOKE, in gardening.—There are several species of this plant; but only one is at present generally cultivated, which is the red kind.

The manner of propagating this plant is from slips or suckers taken from the old roots, in February or March, which, if planted in a good soil, will produce large fair fruit the autumn following: but as this is a plant which few gardeners, that have not been instructed in the kitchen-gardens near London, understand to manage well, I shall be the more particular in my directions about it.

At the latter end of February, or in March, according to the goodness of the season, or forwardness of the old Artichoke-stocks, will be the proper time of dressing them, which must be thus performed: with your spade remove all the earth from about your stock, down below the part from whence the young shoots are produced, clearing the earth from between the shoots, so as to be able to judge of the goodness of each, with their proper position upon the stock; then make choice of two of the clearest, straightest, and most promising plants that are produced from the under-part of the stock, which you are to let remain for a crop; then with your thumb force off all the other plants and buds, close to the head of the stock, from whence they are produced, and with your spade draw the earth about the two plants which are left, and with your hands close it fast to each of them, separating them as far asunder as they can conveniently be placed without breaking them, observing to crop off the tops of the leaves, which hang down, with your hands: your ground being levelled between the stocks, you may sow thereon a small crop of spinage, which will be taken off before the Artichokes will cover the ground; and be sure to keep them clear from weeds; and towards the latter end of April, or the beginning of May, when your plants begin to shew their fruit, you must carefully look over your stocks, and draw up all young plants from them, which may have been produced since their dressing, and cut off all suckers which are produced from the stems of the Artichokes, leaving only the principal head, by which means your fruit will be larger: when your Artichokes are fit to gather, you must break, or cut them down close to the surface of the ground, that your stocks may make strong fresh shoots before the end of October, which is the season for earthing, or, as the gardeners term it, landing them up: which is thus done:

Cut off all the young shoots quite close to the surface of the ground; then dig between every stock, raising all the earth between each row of stocks into a ridge, as is done in the common method of trenching ground, so as that the row of Artichokes may be exactly in the middle of each ridge; this will be sufficient to guard them against frost: and I would here recommend it to the public, as infinitely preferrable to long dung, which is by the unskilful often used, and is the occasion of their fruit being small, and almost without any bottoms to them. Observe, that, although I have mentioned October as the season for earthing them, yet, if the weather proves mild, it may be deferred till any time in November.

When you have thus earthed them up, you have nothing more to do till February or March, by which time they will have grown through the ridge of the earth; and, when the weather is proper, must be dressed as was before directed. *Miller's Gard. Dict.*

The Artichoke is a pleasant, wholesome, and very nourishing food; the roots are reckoned to be aperitive, cleansing, and diuretic; good for the jaundice, and to provoke urine.

The French and Germans eat not only the heads, but also the young stalks boiled, and seasoned with butter and vinegar.

The Italians seldom boil the heads, but eat them raw, when young, with salt, oil, and pepper.

Artichokes have the reputation of promoting venereal inclinations to a very great degree; the stalks, preserved in honey, are said to be an excellent pectoral; but they should first be blanched, like celery.

The common leaves, boiled in white-wine whey, are much commended in the jaundice, as is also the juice of these leaves. *James's Dict. Med.*

Jerusalem ARTICHOKE, is the root of a species of sun-flower of the perennial kind, which is propagated in many gardens for the use of the kitchen; it is a very agreeably tasted root, but watery and windy, and therefore, at present, generally disregarded.

It is propagated by planting out the smaller roots, or even pieces of the larger, which have buds to them in the spring or autumn; they must be allowed a very considerable distance, for they spread immoderately, and multiply very quick. The autumn following when their stems decay, the roots may be taken up for use. They are but an unsightly plant, though very tall, and are commonly placed in obſcure corners of a garden. *Miller's Gard. Dict.*

ARTIFICERS, thoſe who work with the hands, and ſell things faſhioned by them into other forms.

Artificers amount to the ſame with what we otherwiſe call handicrafts and mechanics; ſuch as ſmiths, carpenters, taylors, ſhoemakers, weavers, and the like. See MECHANICS.

By the Engliſh laws, Artificers in wood, iron, ſteel, braſs, or other metal, going out of the kingdom into any foreign country without licence, are to be impriſoned three months, and fined in a ſum not exceeding one hundred pounds. And ſuch as going abroad and not returning on warning given by our ambaſſadors, &c. ſhall be diſabled from holding lands by deſcent or device, from receiving any legacy, &c. and be deemed aliens. *Stat.* 5. *Geo.* I. c. 27.

ARTILLERY (*Dict.*)— The larger pieces of Artillery depend upon the buſineſs of foundery, the other upon ſmithery. The former is commonly called ordnance, the other ſmall arms, &c.

To carry on manufactures or ordnance with ſucceſs, there are various circumſtances which are requiſite to be well weighed and conſidered, or the undertakers may be ſoon undone.

1. The ſituation of the place for caſting of ordnance of iron ſhould be very near ore and fuel, and water, not only for ſafe carriage, but for the conveniency of working of bellows for their caſting part, and forging hammers for the working up the heads of their cannon, and other ſuperfluous caſt iron, which is ſeparated therefrom.

2. The price of labour, as well as that of fuel, ore, and carriage, ſhould alſo be calculated, in order to be able to judge of the profits of the manufactory, according to the views and expectations of vent for the ſame.

3. Theſe things conſidered, the next is that of hiring, or erecting furnaces, forges, and water-mills, and all other conveniences neceſſary for the purpoſe.

If hiring, or building, be the intention, due regard ſhould be had to the ſtructure of furnaces, not only that they may be properly built for the occaſion, but adapted to the quantity of ore deſigned to be melted at a time; and that the bellows be ſo hung as to give the neceſſary continued blaſt. Theſe things depend on the care and ſkill of able and experienced workmen, or rather upon the maſter-founder himſelf, who has the conduct of the whole.

4. But, let his judgment and experience be ever ſo great, yet if the ſeveral workmen, the operators in the various claſſes, are not equal to their reſpective parts, the undertakers may ſoon be ruined; for there is ſuch a delicacy in the caſting of large pieces of ordnance, that I have known ſeventeen pieces out of thirty not ſtand proof upon trial, though caſt at one of the beſt founderies in the kingdom; which proved a great loſs to the proprietors.

5. There is much in this art that depends upon a careful and ingenious mould-maker; and more on the method of preparing the ore, and ſmelting it with ſuch fluxes as will render the metal conſtantly ſo tough as is neceſſary to ſtand all proof. When this is ſkilfully done, thoſe accidents before mentioned can very rarely happen; as no little defect in the moulds could change the general texture, compactneſs, and toughneſs of the metal; little exuberances in the moulds could never have that effect as to prevent ſuch metal ſtanding proof, if that itſelf was as good as it ought to be.

Theſe accidents to which our iron founderies are liable in caſting of ordnance, ſeem to indicate that this art is not yet brought to its laſt perfection.

Under the articles IRON and FOUNDERY, we ſhall ſhew the method of ſmelting the various ſpecies of ores for ordnance, and other matters, which are made of caſt iron; and endeavour to point out the cauſes of thoſe miſcarriages; which may in ſome meaſure, poſſibly, contribute to prevent their frequency.

And, in regard to the making of braſs ordnance, that will be repreſented under the articles BRASS and FOUNDERY.

ARUM, *wake-robin*, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts of one leaf, of a very ſtrange figure, repreſenting, in ſome degree, a hare's ear; from the bottom of the flower ariſes a piſtil, which, at its baſe, is ſurrounded by a great number of embryo's, each of which finally ripens into a roundiſh or oval berry, containing one or two ſeeds. To theſe marks it may be added, that the leaves are not divided.

The ſpecies of Arum, enumerated by Mr. Tournefort, are thirty-four.

The root of Arum is extremely pungent and volatile, which quality makes it recommended in all viſcidities, phlegmatic and ſcorbutic caſes; becauſe it penetrates and rarifies tough concretions and infarctions of the glands and capillary veſſels. It has alſo been preſcribed in humerous aſthma's and obſtructions of the bronchia. Van Helmont commends it greatly with vinegar, in bruiſes and falls, as ſerving to prevent the blood from ſtagnating, and falling into grumes, upon the injured parts. Some have affirmed, a drachm of this root, freſh powdered, and taken in any proper vehicle, to be an infallible remedy againſt poiſon, and the plague. Matthiolus commends, with great reaſon, a cataplaſm of it, freſh bruiſed, and cow-dung, to be applied hot, in arthritic pains. As this root, kept dry, ſoon loſes its efficacy, the compound powder of the ſhops, which takes its name from it, muſt be of little or no ſignification. *Quinſ. Pharm.*

ASH, *fraxinus*, in botany, a genus of trees, whoſe characters are: it hath pinnated leaves, which moſtly end in an odd lobe: the male flowers (which grow at a remote diſtance from the fruit) have no petals, but conſiſt in many ſtamina: the ovary becomes a ſeed-veſſel, containing one ſeed at the bottom, which is ſhaped like a bird's tongue.

There are ſix ſpecies of this tree; all which may be propagated by budding them into common Aſh; upon which they will all take very well, and become hardier than upon their own ſtock: but theſe budded trees never grow ſo large as thoſe which are raiſed from ſeeds; nor will the ſtock and bud keep pace in their growth; ſo that there will be a remarkable difference in the ſize of the ſtem, and above the place where they are budded: but few of theſe foreign kinds have yet arrived at an age to produce ſeeds in England, the nurſery-gardeners having been obliged to propagate theſe ſorts by budding and grafting.

The common Aſh is propagated by ſowing the keys in October or November, on a bed of freſh earth, which ſhould be well dug, and cleanſed from roots and noxious weeds. A ſmall bed will be ſufficient to raiſe a great quantity of theſe trees. The ſeeds ſhould be ſown pretty thick, and covered about half an inch thick with earth.

Theſe ſeeds, many times, continue until the ſecond ſpring before they come up; you ſhould, therefore, let the bed remain undiſturbed, and keep it clean from weeds. When your plants come up, you muſt alſo keep them very clear from weeds, and, if the ſeaſon ſhould prove very dry, if you give them, now-and-then, a little water, it will greatly promote their growth: in this bed they ſhould remain no longer than the autumn following, provided they have grown well; at which time you ſhould prepare a nurſery, which ſhould be well dug and cleared, as before; then with your ſpade looſen the roots of the plants before you draw them up; otherwiſe you will endanger the breaking of them. When you have drawn them out of the ground, ſhorten the downright taproot; but do not cut off any of the lateral fibres; then, having prepared your ground, plant them in rows, three feet diſtance row from row, and a foot aſunder in the rows, cloſing the earth to their roots with your feet.

In this nurſery they may remain two or three years, obſerving to keep them clear from weeds, as alſo to trim up the ſide-branches every winter, and dig the ground between the rows; after which time you may remove them where they are to remain for good. This tree will grow upon almoſt any ſoil; but, the better the ſoil is, the more the tree will increaſe in bulk. Notwithſtanding which, it ſhould not, by any means, be planted too near the other trees or plants; for it will exhauſt all the goodneſs of the ſoil from them; and the ſhade of this tree is malignant to moſt other plants. The diſtance they ſhould be planted is eight feet ſquare; and, after they have been planted one year, you may cut down every other tree, chuſing ſuch of them as are crooked, within ſix or eight inches of the ground; this will cauſe them to make many ſtrong, vigorous ſhoots; which, in ſeven or eight years time, will be fit for arbour-poles, or to make hoops; and the other ſtraight trees may be ſuffered to grow, for other timber; the number of which trees may be leſſened, as they increaſe in bulk, leaving ſtill the moſt promiſing ones to grow for larger timber.

If a wood of theſe trees is rightly managed, it will turn greatly to the advantage of its owner; for, by the underwood, which will be fit to cut every ſeven or eight years, for the uſes abovementioned, there will be a continual income, more than ſufficient to pay the rent of the ground, and all other charges; and ſtill there will be a ſtock preſerved for timber; which, in a few years, will be worth forty or fifty ſhillings per tree.

This timber is of excellent uſe to the wheelwrights and cartwrights, for plows, axle-trees, wheel-rings, harrows, bulls, oars, blocks for pullies, and many other purpoſes.

The beſt ſeaſon for felling of theſe trees is from November to February; for if it be done either too early in autumn, or too late in the ſpring, the timber will be ſubject to be infeſted with worms, and other inſects: but, for lopping of pollards, the ſpring is preferable for all ſoft woods.

ASP, in natural hiſtory, a ſmall poiſonous kind of ſerpent, whoſe bite gives a ſpeedy, but eaſy death. It is ſaid to be thus denominated from the Greek ἀσπὶς ſhield, in regard to its manner of lying involved in a circle; in the center of which is the head, which it exerts, or raiſes, like the umbo, or umbilicus, of a buckler.

This ſpecies of ſerpent is very frequently mentioned by authors; but ſo careleſly deſcribed, that it is not eaſy to determine which, if any of the ſpecies known at preſent, may properly be called by this name. It is ſaid to be common in Africa, and about the banks of the Nile: and Bellonius mentions

tions a ſmall ſpecies of ſerpent he had met with in Italy, and which had a ſort of callous excreſcence on the forehead; which he takes to have been the Aſpis of the antients. *Ray's Syn. Anim.*

ASPA'RAGUS, in botany, the name of a genus of plants; the characters of which are theſe: the flower is of the roſaceous kind, being uſually compoſed of ſix leaves, arranged in a circular form; from the center of the flower ariſes a piſtil, which finally becomes a ſoft fruit, or a roundiſh berry, containing a number of hard ſeeds. To this it may be added, that the leaves are always fine and ſlender.

The garden Aſparagus is propagated by ſowing of the ſeeds; in the procuring of which, you ſhould be particularly careful, ſince the goodneſs of your future crop, in a great meaſure, depends thereon: you ſhould, therefore, get it from ſome perſon of integrity; or, if you have any opportunity, ſave it yourſelf; or in ſome other neighbouring garden. You muſt look over the Aſparagus-beds in the beginning of the ſeaſon, and mark ſome of the largeſt and faireſt buds with a piece of ſtick; which buds, when they have branched out, may be faſtened to ſtakes thruſt into the ground, to preſerve them from breaking. Theſe buds will, many of them, produce great numbers of red berries; which ſhould be ſuffered to remain upon the branches until the latter end of September, when the haulm will begin to decay; then cut off the branches, and ſtrip the berries into a tub, where they may lie in an heap to ſweat for three weeks; by which means the outer huſks will be rotten: then fill the tub with water, and with your hands break all the huſks, by ſqueezing them between your hands. Theſe huſks will all ſwim upon the water, but the ſeed will ſink to the bottom; ſo that, by pouring off the water gently, the huſks will be carried along with it; and by puting freſh water two or three times, and ſtirring your ſeed about, you will make it entirely clean; then ſpread your ſeed upon a matt, and expoſe it to the ſun and air in dry weather, until it is perfectly dry; when you may put it into a bag, and hang it up in a dry place till the beginning of February; at which time, you muſt prepare a bed of good, rich earth, whereon you muſt ſow your ſeed (but not too thick, which will cauſe your plants to be ſmall) and, having trod your ſeed into the ground, rake it over ſmooth.

In the following ſummer keep it diligently cleared from weeds, which will greatly add to the ſtrength of your plants; and, toward the latter end of October, when the haulm is quite withered, you may ſpread a little rotten dung over the ſurface of the ground, about an inch thick; which will preſerve the young buds from being hurt by the froſts, &c.

The ſpring following your plants will be fit to plant out for good (for I would never chuſe plants of more than one year's growth, having very often experienced them to take much better than older, and to produce finer roots) you muſt therefore prepare your ground by trenching it well, burying therein a good quantity of rotten dung at the bottom of each trench, that it may lie at leaſt ſix inches below the ſurface of the ground: then level your whole plot very exactly, taking out all large ſtones; but this ſhould be done not long before you intend to plant your Aſparagus; in which you muſt be governed according to the nature of your ſoil, or the ſeaſon; for if your ſoil is dry, and the ſeaſon forward, you may plant early in March; but, in a very wet ſoil, it is better to wait till the end of that month, or the beginning of April; which is about the ſeaſon that the plants are beginning to ſhoot. I know many people have adviſed the planting of Aſparagus at Michaelmas; but this I have experienced to be very wrong, for in two different years I was obliged to tranſplant large quantities at that ſeaſon; but I had better thrown away the plants; for, upon examination, in the ſpring, I found moſt of the roots were grown mouldy, and decaying; and, I am ſure, not one in five of them ſucceeded; and thoſe which did, were ſo weak, as not to be worth their ſtanding.

The ſeaſon being now come, you muſt, with a narrow-pronged dung-fork, carefully fork up your roots, ſhaking them out of the earth, and ſeparating them from each other; obſerving to lay their heads even, for the more convenient planting them; which muſt be performed in this manner: your plot of ground being levelled, you muſt begin at one ſide thereof, ranging a line very tight croſs the piece; by which you muſt throw out a trench exactly ſtraight, and about ſix inches deep; into which you muſt lay your roots, ſpreading them with your fingers, and placing them upright againſt the back of the trench, that the buds may ſtand forward, and be about two inches below the ſurface of the ground, and at twelve inches diſtance from each other; then, with a rake, draw the earth into the trench again, laying it very level, which will preſerve the roots in their right poſition: then remove your line a foot farther back, and make another trench in like manner, laying therein your plants, as before directed, and continuing the ſame diſtance row from row; only obſerving, between every four rows, to leave the diſtance of two feet four inches, for an alley to go between the beds, to cut the Aſparagus, &c.

Your plot of ground being finiſhed and levelled, you may ſow thereon a ſmall crop of onions, which will not hurt your Aſparagus; and tread in your ſeeds, raking your ground level.

There are ſome perſons who plant the ſeed of Aſparagus in the place where the roots are to remain; which is a very good method, if it be performed with care. The way is this: after the ground has been well trenched and dunged, they lay it level, and draw a line acroſs the ground (in the ſame manner as is practiſed for planting of the young plants) then, with a dibble, make holes at a foot diſtance; into each of which you muſt drop two ſeeds, for fear one ſhould miſcarry: theſe holes ſhould not be more than half an inch deep; then cover the ſeeds, by ſtriking the earth in upon it; and go on, removing the line a foot back for another row; and, after four rows are finiſhed, leave a ſpace for an alley between the beds, if it is deſigned to ſtand for the natural ſeaſon of cutting; but, if it is to be taken up for hot-beds, there may be ſix rows planted in each bed; and the diſtance in the rows need not be more than nine inches. This ſhould be performed by the middle of February, becauſe the ſeeds lie long in the ground: but, if onions are intended to be ſown upon the ground, that may be performed a fortnight or three weeks after, provided the ground is not ſtirred ſo deep as to diſturb the Aſparagus-ſeeds, in raking the onion-ſeed into the ground.

As the roots of Aſparagus always ſend forth many long fibres, which run deep into the ground; ſo, when the ſeeds are ſown where they are to remain, theſe roots will not be broken or injured, as thoſe muſt which are tranſplanted; therefore they will ſhoot deeper into the ground, and make much greater progreſs; and the fibres will puſh out on every ſide; which will cauſe the crown of the root to be in the center; whereas, in tranſplanting, the roots are made flat againſt the ſide of the trench.

When your Aſparagus is come up (which will be in three weeks or a month after planting) you muſt, with a ſmall hoe, cut up the weeds, and thin your crop of onions, where they may have come up in bunches; but this muſt be done carefully, and in dry weather, that the weeds may die as faſt as they are cut up. This work muſt be repeated about three times; which, if well done, and the ſeaſon not too wet, will keep the ground clear from weeds, until the onions are fit to be pulled up; which is commonly Auguſt; and is known, when their greens fall down. When you have drawn off your onions, you muſt clean your ground well from weeds; which will keep it clean till you earth your beds, which muſt be done in October, when the haulm begins to decay; for if you cut off the haulm, while green, the roots will ſhoot freſh again, which will greatly weaken them. This young haulm ſhould be cut off with a knife, leaving the ſtems two or three inches above-ground; which will be a guide to you to diſtinguiſh the beds from the alleys; then, with an hoe, clear off the weeds into the alleys, and dig up the alleys, burying the weeds in the bottom; and throw the earth upon the beds, ſo that the beds may be about five inches above the level of the alleys: then you may plant a row of colworts in the middle of the alleys; but do not ſow or plant any thing upon the beds, which would greatly weaken the roots: nor would I ever adviſe the planting of beans in the alleys (as is the practice of many) for it greatly damages the two outſide rows of the Aſparagus. In this manner it muſt remain till ſpring, when you muſt hoe over the beds, to deſtroy all young weeds; then rake them ſmooth, and obſerve, all the ſucceeding ſummer, to keep them clear from weeds; and in October dig up the alleys again, as was before directed, earthing the beds, &c. The ſecond ſpring after planting, you may begin to cut ſome of your Aſparagus, though it will be much better to ſtay until the third; therefore now you muſt fork up your beds with a flat-pronged fork, made on purpoſe, which is commonly called an Aſparagus-fork: this muſt be done before the buds ſhoot in the ſpring, and with care, leſt you fork too deep, and bruiſe the head of the root; then rake the beds over ſmooth, juſt before the buds appear above-ground; which will deſtroy all young weeds, and keep your beds clean much longer, than if left unraked, or done ſo ſoon as forked: and, when your buds appear about four or five inches above-ground, you may then cut them; but it ſhould be done ſparingly, only taking the large buds, and ſuffering the ſmall to run up to ſtrengthen the roots; for, the more you cut, the more the roots will produce, but they will be ſmaller, and ſooner decay. When you cut a bud, you muſt open the ground with your knife (which ſhould be very narrow and long in the blade, and filled with teeth like a ſaw) to ſee whether any more young buds are coming up cloſe by it, which might be either broken or bruiſed in cutting the other; then, with your knife, ſaw it off about three inches under-ground. This may appear a troubleſome affair, to people unacquainted with the practical part; but thoſe who are employed in cutting Aſparagus, will perform a great deal of this work in a ſhort time; but care in doing it is abſolutely neceſſary to be obſerved by all who cut Aſparagus.

The manner of dreſſing your Aſparagus-beds is every year the ſame as directed for the ſecond; viz. keeping them from weeds, digging the alleys in October, and forking the beds towards the latter end of March, &c. only obſerve, every other year, to lay a little rotten dung (from a melon or cucumber-cumber-bed) all over your beds, burying some in the alleys also, at the time for digging them up. This will preserve your ground in heart, to maintain your roots in vigour; and, by this management, a plot of good Asparagus may be continued for ten or twelve years in cutting, and will produce good buds. *Miller's Gard. Dict.*

Asparagus is a medicinal plant, which furnishes one of those called the five opening-roots.

It is a known diuretic; its top, or head, taken in the way of food, readily discovers itself in the smell of the urine: but its root is still more strongly endued with that quality, as containing more of the salt from which it is derived. Hence it becomes, among us, an ingredient in all compositions, intended to cleanse the viscera, and guard against jaundices, dropsies, &c. It is also of some use as a pectoral; and makes a chief ingredient in the syrup of marshmallows, against the stone: though foreign physicians speak more sparingly of the use and virtues of this medicine.

ASPHODE'LUS, *asphodel*, in botany, the name of a genus of plants; the characters of which are these: the flowers are of the liliaceous kind, but consist of only one petal, divided into six segments. The pistil arises from the center of the flower, and finally becomes a fruit of a somewhat roundish, yet three-cornered form, and of a fleshy texture. This, when ripe, opens at the point, and shews that it is composed of three cells, each of which contains a number of triangular seeds.

The species of asphodel, enumerated by M. Tournefort, are ten.

All the sorts of asphodel are very pretty ornaments for a flower-garden, and, requiring very little trouble to cultivate them, are rendered more acceptable. They may be all propagated by seeds, which should be sown, soon after they are ripe, on a warm border of fresh light earth: in the spring the plants will appear, when you should carefully clear them from weeds; and, in dry weather, they must be frequently watered: if this be duly observed, the plants will have acquired strength enough to be transplanted by the Michaelmas following; at which time you must prepare a bed of fresh earth in the flower-nursery, into which you should plant the roots, at about six inches distance every way; observing to plant them so low, as that the top of the roots may be three or four inches under the surface of the bed: in this bed they may remain one year; during which time, they should be frequently refreshed with water in dry weather, and must be kept very clear from weeds. In this time, the roots, having acquired strength enough to produce flowers the following year, they should at Michaelmas, when their leaves are decayed, be carefully taken up, and transplanted into the flower-garden; observing to place them in the middle of the borders, among other hardy kinds of flowers, where, being properly intermixed, they will make an agreeable variety, and continue a long time in flower.

These plants may also be propagated by parting their roots; but this must not be too often repeated, lest it weaken the roots, and prevent their flowering so strong as they otherwise would do. Once in three years will be often enough to transplant the roots; at which times you may separate those which are grown large, so as to make two or three roots of each: but do not part them too small; for that will so weaken them, as to prevent their flowering the following summer. The best time to transplant these roots is at Michaelmas, just when their leaves begin to decay. *Miller's Gard. Dict.*

The roots of asphodel are of an acrimonious taste, and heating quality; being drank, they promote urine, and the menses; and the weight of a drachm, taken in wine, is used with success in pains in the side, coughs, convulsions, and ruptures. It is good against bites of serpents, and makes a good cataplasm for foul spreading ulcers, inflammations, &c. The ashes of the burnt root, rubbed on an alopecia, cause new hair to spring. *Lemery, des Drog.*

A'SSA, or ASA, among naturalists. The writers of the latter ages have formed the word asa from the lasar of the antients, and attributed it to a gum very different from that antiently known by the name they have thus corrupted.

The asa of the antients was an odoriferous and fragrant gum; and the asa of after ages had so little right to this epithet, that they distinguished it by one, expressing its being of an offensive or stinking smell.

The Arabian writers, according to this distinction, describe two sorts of asa, one stinking, the other aromatic; and the modern Greeks preserved the name asa, or lasar, to the stinking gum, the Latins called by this name; but added a distinctive epithet, to express its ill smell; and called it scordolasarum. Thus Myrepsus always calls the same gum scordolasarum, that the Latin writers call assafœtida.

ASSAFOE'TIDA (*Dict.*)—The plant which produces it is one of the pentandria digynia of Linnæus, and one of the herbæ umbelliferæ semine foliaceo, seu ala foliacea cincto of Ray. We had a multitude of various and false accounts of it for a long time; Garcias telling us it had leaves like the hazel; and Bontius making two plants of it, one like a willow, and the other with a root like a turnep; others have given it leaves like the fig-tree, others like those of rice; and, finally, others have made it a shrub of the phyllerea kind. Kæmpfer is the author to whom we owe the true account of it. This is given in his Amœnitates exoticæ, where he describes it fully and accurately, under the name of umbellifera levistico affinis foliis instar pœoniæ ramosis, caule pleno maximo, semine foliaceo nudo solitario brancæ ursinæ sive pastinachæ simili radice Assamsœtidam fundente. The Persians call both the plant and the juice hingesch; and the Indians, hiing; but the more accurate in both countries call the plant hingesch, and the juice or gum hiing.

The root of this plant is perennial, and very large. It is covered with a thick black rind, which easily comes off from the rest, when fresh. Within it is perfectly white, and full of a white, milky, and stinking juice, which, when collected and dried, is what the Persians call hiing, and the Europians, Assafœtida. The top of this root is furnished with a large tuft of hairy or filamentous matter, like that on the crown of the meum or spignel. The leaves are very large, and like those of the piony.

The stalk is as thick as a man's arm, and grows to eight or nine feet high. It gradually becomes taper toward the top, whence it is divided into a small number of branches. The leaves stand alternately on these stalks, and that at no great distances from one another. The flowers are small, and disposed in umbels. The seeds are flattish and striated, and of an oval figure; they have somewhat of the Assafœtida smell, but much less than might be expected. It grows in Persia, but there only in two places, at least in those only in any great plenty. These are the mountains about Heraat, and the province of Laar. In these places it abounds with juice, and yields the gum in great plenty; when found elsewhere, it yields very little. The leaves in these places are of a horrible, offensive smell, and no animal will touch them: but the people of the town of Disguum affirm, that, in the country beyond them, the plant loses much of its bad savour, and that the goats feed very greedily on the leaves, and grow fat upon the diet. Some have pretended to distinguish two species of this plant, the one yielding a smaller quantity of juice, and that of a less fetid smell; the other yielding more of it, and that more stinking: but Kæmpfer, who was upon the spot, declares the plants to be the same, and all the difference to be in the soil that produces them. If what the Persians of Disguum say be true, however, it very well accounts for the difference of the Cyrenaic and Persian kinds of silphium; for the plant, in the first of these places, might be as mild as beyond Disguum, or even more so.

It is very singular in this plant, that it seldom flowers, sometimes not till its twentieth, thirtieth, or even fortieth year; during all this time the root is increasing in size, and, consequently, it sometimes grows to an enormous bulk: roots of it have been seen of the thickness of a man's thigh, and of a yard and a half in length; those of the thickness of one's arm are frequent. When it sends forth a stalk, and has ripened its seed, it perishes. The ancients made a distinction in their silphium, as it was produced from the stalk, or from the root of the plant; but, at this time, all that we have is obtained from the root. They never make incisions in roots of less than four or five years standing; and they always find, that, the older and larger the root, the more plentifully the juice flows.

The gum or juice, as it flows from the root, is white, and perfectly resembles cream, and has no viscidity: on the contact of the air it dries or hardens, and becomes viscous and coloured. The most strongly scented Assafœtida is always esteemed the best; and Kæmpfer observes, that it is so much stronger, when fresh, than when kept and imported into Europe, that a drachm of it has more scent, than an hundred weight of what our druggists keep.

The leaves of the plant appear in autumn, and appear green the whole winter; in spring they wither. About the end of April, when their leaves are in their decaying state, the Persians ascend the mountains in search of the plants. They clear away the earth about the root for six or seven inches deep; they then twist off the leaves, and the fibrous substance at the top of the root. They next cover up the root again to its top, which is now perfectly bare; and this they cover with a bundle of weeds, to keep off the heat of the sun, which would otherwise destroy it. They lay a stone over all this, to keep it firm, that the wind may not blow it off; and in this condition they leave the roots for a month or six weeks. At the end of this time they take off the covering, bear away the earth a little from the crown of the root, and, with a sharp knife, cut it transversly off, taking off about an inch, or a little more, of the top. They then cover this wounded root with the weeds again, making them stand hollow from the wounded part, and thus leave them for two days; at the end of which time they return, and find the top of the root, where they had cut it off, covered with exsudated juice, or Assafœtida: this they collect, and put up in proper vessels; and, clearing away the earth a little lower, they cut off another slice off the top of the root, but this not thicker than a crown-piece, and cover it up again, for another gathering. As they take a large compass of ground for their search, they are kept in constant employment; the roots of their first

day's

day's cutting being ready for their taking the gum from, by that time they have cut the more distant ones, which they are regularly to return to afterwards. After they have gone through this second operation with all the roots, and collected the second quantity of gum from them, they cover them up for eight or ten days; and, after having spread their gum in the sun to harden it, they carry it home. Four or five men generally go out in a company, on these expeditions; and it is a common thing for them to bring home fifty pounds weight of it from this first gathering; this, however, is esteemed but an inferior kind of Assafœtida; after the roots have remained covered these eight or ten days, they visit them again, take off the covering of weeds, and collect the gum. They then cut off another slice of the root, and after that another, and then a third; this is done at the distance of two days between each operation, and the earth is every time cleared away to a proper depth, and the whole process managed as before.

After the third collection in this second expedition, they cover up the roots again, and return home with their stores, leaving them covered for three days. After this they return to their work, and cut them again three several times at the same distances of time; and, after the third collection of this last expedition, they leave them to perish; for they never recover this terrible operation. *Kamp. Amœn. Exot.*

Assafœtida, distilled in a retort, yields a large quantity of whitish or milky looking phlegm, smelling strongly, like garlic; there come over near three ounces of this from the pound; after this there rises near an ounce of a reddish phlegm, partly of an acid, partly of an urinous kind; this is followed by somewhat more than an ounce of a thin limpid yellowish oil, of an extremely fœtid smell, and, finally, there come over near six ounces of a reddish, stinking, and empyreumatic oil of the consistence of butter. The remainder in the retort, calcined in an open fire and lixiviated, yields about six grains of a fixed salt, but this not of the alkaline, but sal salsus kind.

In Persia and the Indies there is no drug at this time so much in use both in medicine and in sauces. They rub the vessels they are to dress their food in with it, and they give it in large doses against the rheumatism, the gout, and pains of all kinds. With us, Assafœtida is scarce at all used about our foods, and its unpleasant smell has in a great measure banished it from extemporaneous practice in physic, though it is undoubtedly a very great medicine.

The Assa fœtida plant is recommended by Mr. Lawrence to be cultivated in our fields, for the food of cattle, instead of clover, saintfoin, or such herbs as we sow among corn, and make into hay, in the succeeding summers, and use as food for cattle at other seasons.

This gentleman is of opinion, that the sheep, fed on this plant, would afford mutton of a much finer flavour than any that we are at present acquainted with. But it seems strange, that this should be the effect of these creatures feeding on a plant of so strong a scent, that, as the same author observes, one drachm of the fresh root smells more than a hundred weight of the drug, as kept by the druggists, and that the whole air is strongly and disagreeably scented with it, wherever it grows. Upon the whole, it seems probable, that though this plant, or the cytisus, or several others, might be cultivated in England for the food of cattle, yet not any one would be so easily raised, or make so great an advantage to the farmer, as the saintfoin. *Tull's Husbandry.*

A'SSES *Milk*, the milk of an animal too well known to need description.

When we examine more minutely into the medicinal virtue and disposition of Asses milk, it will appear to be fraught with an abundance of peculiar excellencies, which render it so exceedingly wholesome. In the first place, it is thinner than all other milks, and abounds with watery and serous ingredients.

Since it is known that many diseases are caused by a grossness and tenacity of the juices, which, as they pass slowly through the finer vessels, of which the principal emunctories and strainers of the glands consist, are apt to stop in those narrow passages, to fill them up, and occasion obstructions, it is very obvious and natural to conclude, that the use of Asses milk, which abounds with serous and fluid particles, must be extremely proper to open the obstructed vessels, to attenuate the gross and viscid juices, and set them in an easy and free motion. Again, when we know that multitudes of distempers proceed from an acrid, salt, and corrosive state of the fluids, we cannot but be assured that the thin serum of Asses milk will not fail of diluting, softening, and subduing them: although it must be allowed, at the same time, that the sweet oily substance contributes much towards this effect, which embraces and involves the pointed particles of salt, and by this means the crude ill-digested juices, being properly corrected, are, by the plentiful assistance of serum, conveyed in their due course through the vessels appointed for secretion.

It is another extraordinary excellence of Asses milk, that it contains but a small proportion of the grosser curdling substance. Out of eight ounces of Asses milk, which I set over hot coals in a broad vessel, after all the serum was evaporated, I could scarce gather so much as six drachms of a whitish sweet matter. I then took twelve ounces of the same milk, and set it by to curdle in a close vessel, filled about half way. In three days time a very white and thin curd settled at the bottom, which, when separated from the whey by straining through filtrating paper, and afterwards dried, scarce amounted to two drachms; all the rest of its solid parts, having in general passed with the whey through the strainer, adhered to the sides of the vessels, or lost themselves in the operation. On the contrary, the same weight of cows milk, treated in the same manner, thickened into a grosser and heavier curd, which, when cleared from the whey, spread out in a broad plate, and, dried in the sun, weighed ten drachms. From these experiments it is evident, that the quantity of the gross curdling substance is very small in Asses milk, when compared with other sorts. For this reason it easily diffuses itself into the minutest extremities of the blood-vessels, thoroughly dilutes the vital juices, liquifies the sluggish humours, and, when it has thus dissolved them, conveys them off. A third circumstance that more strongly evinces the salubrious quality of Asses milk, is, that the share of cheese-like substance which it contains is extremely soft and tender, and never makes a gross or firm curd. To make this evident, I warmed some Asses milk, and sprinkled it with vinegar, expecting to see it contract a thick consistence; but nothing appeared of that sort, except a few light thin flakes, floating here and there on the serum: when, on the contrary, cows milk, the instant it was mixed with an acid, condensed into lumps of a considerable hardness, and fell to the bottom. Now, in all cures which are sought by milk, nothing can be so hurtful and dangerous as to have it curdle in the stomach, to prevent which accident ought to be the physician's principal care and concern. For the mischiefs occasioned by a coagulation of milk in the stomach are very pernicious, and have been observed and cautioned against by the best authors. It is past dispute therefore, that the milk is the most wholesome and properest for medicinal uses, which has least tendency to curdle, which is the case with Asses milk in the most remarkable degree.

A fourth, and the most valuable excellence in Asses milk, is its exquisite sweetness, in which it exceeds all other species of milk, except the human: for you may extract from it by much the greatest quantity of delicate tasted sugar, or rather a thick substance resembling manna. To try the experiment, I boiled twelve ounces of Asses milk, in the month of July, over a gentle fire, and immediately it produced a thick concretion very sweet, weighing one ounce. Upon this, I poured it into a glass with a pint of rain water, which, when frequently shaken, almost dissolved the mass, leaving only a small sediment. The liquor was then poured through filtrating paper, and set to evaporate, and yielded half an ounce of an honey-like substance, extremely sweet, and white. As Asses milk therefore contains so plentiful a proportion of sweet salts, we cannot doubt, but it has for that reason a very singular medicinal quality which cannot be expected in other kinds of milk. For this honey-like salt greatly softens, checks, and moderates the acrimony of humours, whether acid or bilious, and, by gently irritating the fibres of the bowels, urges them to their office and operations. Hippocrates very justly observes, that Asses milk disposes to purging more than any other; and in another place advises, as a remedy for the flour albus, first to occasion a gentle purging by drinking Asses milk, and then to change it for cows milk.

From these enlarged observations which we have made on the excellencies of Asses milk, it must be evident to all that judge sensibly, that it has an admirable efficacy towards curing many distempers. The first and most remarkable instance we shall give, is by proving that no surer or more successful remedy can be invented or recommended against consumptions.

Yet, although milk of all kinds be a wholesome medicine in consumptive and decaying constitutions, yet Asses milk excels the others in a greater degree, because it fully answers every requisite that can conduce to the cure of consumptions.

Yet we must take notice, that though this be such a sovereign remedy for consumptions, and when given in a judicious manner, scarce ever fails of success, yet it will not cure every sort of consumption; but must be applied in the beginning of the distemper, and is most likely to take effect, before the ulcers be grown callous, or the corroded cavity be too deep and large, or the fever become continued and without intermission.

I likewise judge Asses milk to be very efficacious against an empyema, which is often caused by a pleurisy improperly treated, especially in bodies of a spongy habit, and shews itself by a constant and copious spitting of matter.

As Asses milk proves so very useful in relieving the pains that seize the outward parts of the body, so it is likewise no less serviceable against those that affect the inward nervous parts, the stomach and intestines, as is the case in convulsive cholics,

 When

When cramps and convulfions feize the nervous parts, which is the common fymptom in hypochondraic and hyfteric fits, I have always obferved milk, efpecially that of Affes, do great good; provided there be no coftivenefs, nor obftruction in the bowels, and the firft paffages be not clogged with fharp and vifcid phlegm.

Since, therefore, it is fo evident that Affes milk is beneficial to the nerves, and heals their feveral forementioned diforders by means of its foftening and lubricating quality, we cannot doubt but it may properly be adminiftered in other complaints, where the nervous parts are likewife afflicted and difordered with violent motions, as in epilepfies and convulfive fits.

When fcorbutic people and old men, who are naturally fubject to a falt and foul corruption of the humours, and likewife fuch as are infected with a venereal taint, are afflicted with dangerous ulcers, that feem to refemble cancers; even in thefe terrible fymptoms a very fpeedy and fure relief may be had from Affes milk, and the whey of it.

And, while we are enumerating the many noble virtues of Affes milk, we muft not omit its peculiar excellence, not only as a remedy to the diftempers of old men, but as a fort of food of great efficacy in reftoring their decayed ftrength.

Having now explained the properties of Affes milk, and its excellence in feveral diforders, I fhall proceed to the proper method of giving it, and then fhew what is neceffary to be obferved, in order to expect fuccefs from it. But it will firft be proper to fay fomewhat of the animal itfelf. A milch Afs ought to be quite free from any diforder, not very old, but of a middling age, neither too fat nor too lean, and may be efteemed the better, if fhe bring her foal in the month of May. She ought not to be fed in a houfe, but kept in meadows which produce plenty of medicinal herbs; fhe fhould drink river water, which, as it is lighter and more diluting than fpring water, paffes off quicker by the proper difcharges, and, mixing more thoroughly with the humours, cleanfes them more effectually. Helmont has an ingenious remark on this fubject: he advifes that the Afs fhould be combed or curried every morning as horfes are, for that it may eafily be known from the milk, whether fhe has been dreffed that morning or not. Without doubt there may be fome reafon for this, becaufe the ufe of the curry-comb increafes perfpiration, and cleanfes the humours, by paffing off a great many faline particles that way.

It ought to be confidered too, what the Afs is fed with, becaufe the nature and properties of the milk of animals are altered by their diet, fo as to be more or lefs wholefome, or even adapted to fome particular diforders. For as it is a common practice to make a purging or alterative medicine, given to the nurfe, communicate its properties to her milk, and take effect on the child, fo, no doubt the fame will hold good with regard to the animals whofe milk we ufe. Galen proves this by the inftance of goats, who are fed with fcammony or fpurge, whofe milk is purging. Diofcorides and Hippocrates are of the fame opinion, and in the Acta Haffniensia it is afferted, that wormwood eaten in large quantities makes the milk bitter. From hence it is that Cœlius Aurelianus commends milk in the cœliac paffion or flux, which is taken from goats that feed on willows, vine leaves, oaks, or fallows, plantain, and plants of the fame nature; giving this reafon for it, "becaufe the aftringent quality of the herbs communicates itfelf to the milk." But there is a remarkable difference between the milk which is produced in fpring from green pafture, and that in winter from dry food. Varro, who was very well acquainted with what belongs to country affairs, was of this opinion, and fays, "that milk from barley and ftubble, and all kinds of hard and dry food, is nourifhing; but that is more cleanfing which comes from green pafture." And Diofcorides thinks that the milk in fpring is thinner, and, becaufe it comes from green pafture, more laxative and foftening.

From whence it plainly appears, that milk of all forts, but more efpecially Affes, is not only moft ferviceable in the fpring, but that its virtues may, by a regulation of food, be fo prepared, as to be particularly effective againft any one diftemper. Wherefore, I would advife that a milch Afs be fed with fuch herbs as in themfelves are known proper for the difeafe you would relieve. In a confumption, and difeafes of the lungs and breaft, let her be fupplied with veronica, ground ivy, the blind or dead-nettle, colts-foot, and fcurvy-grafs; or, if you want to reftore the vigour of the folids, with fanicula, tanfey, nummularia, confolida major, flowers of St. John's wort, alchimilla, polygonum, and the like; or let the creature be drove to places where thefe plants abound. In pains and fpafms, both inward and external, it may be ufeful to mix in her food yarrow, chamomile flowers, acacia, mead-wort, tilia, melilot, fpurge, mallows, marfh-mallows, and others of this nature. In flow and hectic fevers (befides thofe we named as good for the lungs) we may add plantane, prunella, and fcurvy-grafs mixed with germander. If the hypochondria are obftructed, and caufe a fcorbutic foulnefs in the juices, chufe out fome herbs of the opening or laxative kind; fuch are fumitory, the leffer centaury, abfinthium, fcurvy-grafs, trefoil, water-crefs, nafturtium, and the leffer houfe-leek. In the fame manner may milk be rendered medicinal, and fit for almoft any complaints, by adminiftering fuch herbs and flowers as the phyfician fhall efteem moft proper and effectual.

As to the method of ufing it, thefe following rules may be obferved.

1. In cafes of neceffity, Affes milk may be drank at all times; but it is by far the moft ferviceable in the fpring and fummer, when all the herbs are full of juices, and greatly enrich the milk. 2. The milk fhould be milked into a pail fet over hot water, and immediately put into a veffel that has a narrow mouth, and fhuts clofe, and fo drank directly when it is warm; for milk, like all other liquors, has a fubtile fpirit, of a ftrengthening and invigorating quality, which by no means ought to be allowed to fly off with its warmth. Hence, Galen orders that milk be drank inftantly, and the animal brought to the patient's bed-fide; for that its nature, like that of the femen, is at once altered by the open air. 3. The morning is the beft time of day to drink it, as it will operate the eafier in an empty ftomach, and therefore no other food ought to be taken in four or five hours after it. Yet, if circumftances require a frequent repetition of it, it may be drank in the afternoon; but it fhould be about four hours after dinner has been digefted, and in but half the quantity that is drank in the morning. 4. It is impoffible to prefcribe in general any fixed quantity that fhould be ufed, becaufe of the difference of ages, conftitutions, and diftempers; but thus far may be faid, that you ought never to exceed the quantity of three common pints. 5. The time of continuing it muft be directed by the degree and ftrength of the diftemper: if that be very obftinate, it were well to continue drinking it for three months, or longer; efpecially if a favourable profpect appears of fuccefs, and the violence of the fymptoms abate very difcernably.

Yet a prudent and experienced phyfician will fo order, regulate, and methodize the ufe of this medicine, as almoft to infure fuccefs, and avoid any hurtful confequences. I fhall therefore conclude with a few cautions that fhould be obferved very accurately.

1. Before a courfe of milk is begun, the ftate and condition of the ftomach muft be carefully inquired into: whether it will bear milk, and have a fufficient degree of ftrength to concoct, digeft, and then difcharge it. For, if that be weak and infirm, if it be troubled with wind and phlegm, or be loaded with a croud of acid humours, milk muft not be taken; becaufe, until thefe things are remedied, that will curdle and ftagnate, and corrupt, and increafe the flatulence and uneafinefs. It will be proper therefore to cleanfe and relieve the ftomach firft, either downwards, by a gentle dofe of manna, or, where the cafe will allow, by a vomit with a grain or two of emetic tartar. 2. Great care muft be had that the milk be not turned into curd. And, therefore, where the food is apt to grow acid in the ftomach, as is the cafe with old and hypochondraic people, it is advifeable to give abforbent, earthy, and alcaline medicines, mixed with the milk, adding likewife fome ftomachic carminative effence, or volatile oily falt. 3. When the patient has drank milk for fix or eight days, a gentle dofe of manna fhould be given, to purge the bowels, and carry off whatever foulnefs the ftomach may have contracted, that the farther efficacy of the milk be not retarded. 4. It is beft to drink it at firft, fparingly, three or four ounces, and then, to increafe the draught gradually, that the ftomach be not too fuddenly oppreffed, and conceive a diflike and loathing to the remedy. 5. A proper regulation of diet muft be obferved during the courfe of milk. The lightnefs of food muft be chiefly confulted; avoiding not only meats hard of digeftion, but alfo thofe that are reckoned to afford little nourifhment, and likewife all flatulent victuals, fummer fruits, and acids of all kinds; abftaining from all malt-liquors, and wines, except a fmall quantity of the foundeft Spanifh wines. Nor fhould any bread be ufed that is lumpifh and fermented, but what is made of the cleaneft and fineft wheat flour. *Hoffman.*

A'STAROTH, an idol of the Philiftines, which Samuel commanded the Jews to pull down. It was alfo the name of the falfe deity of the Sidonians, adored by Solomon, when he turned idolater. The word fignifies a flock of fheep and riches: and fome fay, that, as Jupiter Ammon was adored under the fhape of a ram, fo Juno Ammon, or the moon, was worfhipped under the form of an ewe. But others believe, that Aftaroth was king of Syria, thus called for his great wealth. Tho. Goodwin de Ritibus Hebræorum.

ASTA'RTE, a certain heathen divinity, called in fcripture the goddefs of the Sidonians. Solomon, in complaifance to his concubines, built altars, to this idol. It is generally thought that Aftarte is the fame with Atergati, or Derceto, fo much worfhipped by the Syrians. Tully believes this goddefs to be one of the four Venus's, and the fame that married Adonis. *Ælian. Tertul. in Apologet. Cic. de Nat. Deor. l.* 3.

ASTE'RISCUS, in botany, the name of a genus of plants, the characters of which are thefe: the flower is of the radiated kind; its difk is compofed of feveral flofcules, and its outer edge of femi-flofcules. Thefe are all placed on the embryo feeds, and are inclofed in a cup of a ftellated form, the

parts

parts of which ſtand out beyond the flower. The embryo's finally become flat and marginated ſeeds.

The ſpecies of Aſteriſcus, enumerated by M. Tournefort, are ſeven.

ASTEROPO'DIUM, in natural hiſtory, the name given by authors to a kind of extraneous foſſil, of an imbricated texture, compoſed of a number of ſmall convex or concave plates, and ſerving, when intire, as a baſe, or root, to the aſteria, or ſtar-ſtone.

It is very plain, that this is the remains of ſome animal body, probably of the ſtar-fiſh kind, to which the aſteriæ have alſo once belonged; but our imperfect knowledge in the animal hiſtory has not yet aſcertained us of the particular creature; the moſt probable conjecture is, that it is the Magellanic ſtar-fiſh, the rays of which nicely and exactly repreſent ſome of the more perfect Aſteropodia.

ASTRÆ'A, in mythology, the daughter of Aſtræus and Themis. She was accounted the mother of natural juſtice, or that with which we are born; not that which is enforced by the fear of human laws. She lived on earth, as long as the golden age laſted; but, when mankind, blackened with enormous crimes, became deaf to her repreſentations, ſhe flew away to heaven, where ſhe placed herſelf, according to the poets, in the ſign Virgo. She ſeems to have forſaken the earth with regret, and would willingly have ſtaid, but an univerſal depravity drove her away. Baniſhed from cities, ſhe retreated into the country and reſided among the ſhepherds and huſbandmen, till vice prevailed and drove her alſo from this aſylum. She is repreſented, according to Aulus Gellius, by the figure of a virgin; her aſpect ſtern, her air mournful; which does not, however, leſſen her dignity: ſhe holds a pair of ſcales in one hand and a ſword in the other.

ASTRAGALOI'DES, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the papilionaceous kind, and its piſtil, which ariſes from the cup, ſomewhat reſembles at its extremity a ſmall boat in ſhape, and contains ſeveral kidney-ſhaped ſeeds. See *Plate* IV. *fig.* 30.

There is only one known ſpecies of this genus, which is the Portugal Aſtragaloides, called by ſome the wool aſtragalus, with thick roots. *Tourn. Inſt. p.* 398.

ASTRA'GALUS, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the papilionaceous kind, and its piſtil, which ariſes from the cup, covered with a membraneous ſheath, finally becomes a bicapſular pod, containing kidney-ſhaped ſeeds. To this it may be added, that the leaves ſtand in pairs on the middle ribs, the end of each of which is terminated by a ſingle leaf. *Tourn. Inſt.*

The root of this plant, drank in wine, ſtops a looſeneſs, and provokes urine. Dried to a powder, it is, with good effect, ſprinkled on old ulcers, and ſtops bleeding. *Lemery, des Drog.*

ASTRA'NTIA, in botany, the name of a genus of umbelliferous plants, the characters of which are theſe: the flower is of the roraceous kind, conſiſting of ſeveral petals, the ends of which are uſually bent backwards, and which are diſpoſed in a circular form, on a cup which afterwards becomes a fruit, compoſed of two ſeeds, involved in a curled calyptra. The flowers of this genus are collected into a ſort of head, and ſurrounded with a leafy crown. Some of the flowers of this genus of plants are barren, and the cups of theſe are wider. See *Plate* IV. *fig.* 31.

This plant is cultivated in the gardens of botaniſts, and flowers in July. Its black and fibrous roots are only uſed in medicine, which are ſaid to purge melancholic humours. Hildanus preſcribes it alſo for the cure of a ſchirrous ſpleen. *James's Med. Dict.*

ASTRI'NGENTS (*Dict.*)—Among the ſeveral claſſes of corroborative medicines, that of Aſtringents is none of the leaſt conſiderable and important. The ſeveral ſubſtances which come under this denomination, are alſo by the Latins ſtiled vulnerary, and by the Greeks, traumatic medicines. Their virtues, in general, conſiſt in a certain fixed and gently conſtrictive principle; by means of which, they brace up the parts and fibres that are too much relaxed, corroborate thoſe which are weakened, and conſolidate and agglutinate ſuch as are corroded and wounded.

Aſtringent medicines operate by means of a conſiderably fixed terreſtrial principle, in conjunction with an acid; and as, by conſtructing the too much relaxed fibres, they free them from a congeſtion and ſtagnation of humours; ſo, by bringing them into a nearer contract with each other, they promote their conſolidation and coaleſcence. But this conſtrictive virtue is not equally ſtrong and powerful in all medicines of this claſs.

If ſkill and uncommon caution are requiſite in the uſe of any medicines whatever, they are certainly ſo in the adminiſtration of Aſtringents; for ſince not only the ſoundneſs of the body in general, and of its ſeveral parts, but alſo life itſelf, is maintained and preſerved by the perpetual, progreſſive, and circulatory motion of ſufficiently attenuated and fluid humours, through the compages of the body, which is almoſt quite vaſcular, and compoſed of inconceivably minute and ſlender ducts; and ſince, at the ſame time, ſuch are the natures and properties of Aſtringents, as to inſpiſſate our fluids, when mixed with them, and brace up the pores and ducts of our ſolids; it is therefore obvious to every one, that remedies of this claſs muſt be unfriendly to the very natures, and vital motions, of animal bodies; for which reaſon they are not ſo ſafe and ſecure as ſome may imagine, unleſs when uſed with the utmoſt care and circumſpection: for daily experience convinces us, that medicines of an aſtringent quality, raſhly and unſkilfully applied, for ſtopping hæmorrhages or fluxes, produce numberleſs fatal conſequences, and generally bring on ſlow fevers, cachexies, œdematous ſwellings, ſpaſmodic diſorders, cholics, and hypochondriacal indiſpoſitions: for this very reaſon we are carefully to guard againſt the imprudent and immoderate uſe of the Peruvian bark, for carrying off the paroxyſms of intermitting fevers; ſince, by its violent aſtringency, the viſcid bilious, and ſalival ſordes, lodged in the primæ viæ, and which ought to be diſcharged, are ſo much the longer ſhut up and retained; by which means, a ſtill more formidable diſorder is ſometimes brought on.

If neceſſity ſhould, at any time, call for the uſe of Aſtringents of this nature, they are not to be adminiſtered all at once, but ſucceſſively, in gentle doſes, and in conjunction with a ſufficient quantity of ſome proper liquid; preſcribing, at the ſame time, a due degree of exerciſe for the patient, which I always do, when I either preſcribe the Peruvian bark, or any medicines whatever of the chalybeate kind.

It is highly unſafe and dangerous to repreſs exceſſive vomitings, diſcharges of bloody urine, hæmorrhages of the noſe, uterus, or anus, and ſpittings of blood, by means of Aſtringents; ſince the patients are always ſure to ſuffer by ſuch a practice, unleſs the ſpaſms, on which the diſcharges of blood, for the moſt part, depend, as much as effects do upon their immediate cauſes, are firſt ſoothed, the violent and impetuous motions of the fluids checked, and the exorbitant affluence of humours derived to other parts.

The traumatic, or vulnerary herbs, and decoctions of them, are of very ſingular and uncommon ſervice, not only in wounds, eroſions, and ſolutions of continuity, but alſo in ſome diſeaſes of a chronical and violent nature, ſuch as a phthiſis, ſcurvy, cachexy, and diſorders ariſing from the ſtone, when theſe indiſpoſitions draw their origin from the tone of the viſcera and glands being weakened, or from a preternatural ſtagnation of the juices. But we ought, at all times, carefully to avoid uſing them in caſes where there is too great an obſtruction of the veſſels, a conſtriction of the fibres, or in a phthiſis, when the lungs are full of hard tumors and tubercles: however, in other caſes, infuſions of vulnerary and gently aſtringent medicines are of ſingular ſervice, and produce excellent effects; eſpecially in preventing ſabulous and ſtony concretions in the kidneys, which, for the moſt part, ariſe from theſe organs being too much relaxed or ulcerated. Upon this ſubject, I would recommend Hencherus's Diſſertation, concerning the uſe of Aſtringents in the ſtone. This intention is alſo very well anſwered by infuſions of yarrow and its tops, of Paul's betony, ground-ivy, ſtrawberries, agrimony, and the bark of the Egyptian thorn-root. In involuntary diſcharges of the urine, ariſing from too great a relaxation of the ſphincter muſcle of the bladder, whether in children or in adults, I have found infuſions of this nature produce very happy effects, applying externally, at the ſame time, rectified ſpirits of wine.

In caſes where the external parts are hurt or wounded, well rectified ſpirit of wine proves by itſelf, a noble and efficacious vulnerary; ſince it puts a ſpeedy ſtop to defluxions of the blood and humours; and is of ſingular ſervice, where the more ſenſible nervous and tendinous parts have ſuffered by too great an effuſion of blood; for ſpirituous liquors not only coagulate the juices of the human body, as we find by making the experiment upon blood and lymph, but alſo, by removing the ſuperfluous humidity, render the fibres tenſe and rigid, and, by bracing them more ſtrongly up, prevent ſtagnations of the blood, and carry off pains and inflammations. *Hoffman.*

ASTROMETEOROLO'GIA, the art of foretelling the weather, and its changes, from the aſpects and configurations of the moon and planets.

This makes a ſpecies of aſtrology, diſtinguiſhed by ſome under the denomination of meteorological aſtrology.

Dr. Goad publiſhed a large work, in folio, expreſs on this ſubject, in 1686, which he afterwards tranſlated from Engliſh into Latin, and publiſhed it in London, 1690, quarto, containing a ſort of ſyſtem of prognoſtications of the weather. To the ſame head alſo belongs Coke's Meteorologia, firſt publiſhed in Engliſh, and ſince in High Dutch, at Hamburgh, 1691, octavo.

ASTRONO'MICAL *Sector*, a very uſeful mathematical inſtrument, made by the late ingenious Mr. Graham.

It is allowed that a micrometer is the moſt accurate and convenient inſtrument for obſerving the place of a planet or comet, when it happens to be near enough to any known ſtar, by taking the differences of its right aſcenſion and declination from thoſe of the ſtar. But this being frequently impracticable, by reaſon that many large places in the heavens

vens are void of stars, whose places are known; it is necessary to have recourse to moveable quadrants, or sextants, furnished with telescopic sights, for taking larger distances. But, besides the difficulty and charge of procuring good instruments of this kind, the great trouble and uncertainties, in observing with them, are very notorious, arising chiefly from the difficulty the observers find in making their observations, as each telescope correspond together at the same instant, while the instrument is following the diurnal motion of the heavens. The lovers of astronomy are therefore much obliged to the ingenious Mr. George Graham, F. R. S. not only for many useful improvements in the mechanism of several astronomical instruments, but also for contriving a very commodious and accurate one for the purpose aforesaid; that is, for taking such differences of right ascension and declination as are too large to be observed through a fixed telescope; and yet with equal facility and exactness too in proportion to the radius of the instrument. I will first give an idea of it, and then describe the particulars of the mechanism.

Let AB (*plate* V. *fig.* 1.) represent an arch of a circle, containing ten or twelve degrees well divided, having a long plate CD for its radius, fixed to the middle of the arch at D. Let this radius be applied to the side of an axis HFI, and be moveable about a joint fixed to it at F, so that the plane of the sector may be always parallel to the axis HI; which being parallel to the axis of the earth, the plane of the sector will always be parallel to the plane of some hour circle. Let a telescope CE be moveable about the center C of the arch AB, from one end of it to the other, by turning a skrew at G; and let the line of sight be parallel to the plane of the sector. Now, by turning the whole instrument about the axis HI, till the plane of it be successively directed, first to one of the stars, and then to another, it is easy to move the sector about the joint F into such a position, that the arch AB, when fixed, shall take in both the stars in their passage, by the plane of it, provided the difference of their declinations does not exceed the arch AB. Then, having fixed the plane of the sector a little to the westward of both the stars, move the telescope CE by the skrew G; and observe, by a clock, the time of each transit over the cross hairs, and also the degrees and minutes upon the arch AB, cut by the index at each transit; then, in the difference of the arches, the difference of the declinations, and by the difference of the times, we have the difference of the right ascensions of the stars.

The mechanism of the principal parts of the instrument is this: upon the side of an iron axis HIT (*fig.* 2.) wrought square, and near the top of it, there is fixed a broad circular plate, *abc*, of solid brass; upon which there lies a brass cross, KLMN, which turns about a joint at the center F: at the end of the cross plate MN are erected two equal perpendicular arms O and P, whose extremities are fixed by the skrew *de* to the backside of the radius CD; which is strengthened by a long brass rib on its backside, placed edgways from one end to the other, as represented in *fig.* 4. The arms OP are no longer than is necessary for the sector ABC to turn about the joint F quite clear of another circular plate QR; which is fixed to the upper basis of a brass cylinder I, the iron axis HF being put through a square hole in the middle of them both, and immoveably fixed in it. ST represents a long substantial plate of brass, having two short plates, VX and YZ, fixed perpendicular to the ends of it. Let us suppose the length of the plate TS to be parallel to the earth's axis, and to be firmly fixed in this position upon a pedestal, or otherwise, with its flat sides facing the north and south. Remove the axis HI, and place the conical hole, made in the end H, upon a conical point of a skrew-pin at Y; and the cylinder I into the slit VZX, whose parallel sides VX embrace, while it rests against two points of an angular notch in the bottom of the slit at Z. By this means, the whole instrument will always turn true about one and the same imaginary line. When the sector is turned about the joint F (*fig.* 2.) till the radius CD becomes parallel to the axis HI, *fig.* 4. represents a section of the whole instrument, made by a plane passing at right angles through the radius CD, and through the rib on the backside of it, and through the axis HI, and through the supporter ST. The several parts of the instrument are here denoted by the same letters in both figures. The arms O and P have two slits through the middle of their ends, to receive the edge of the rib CD. The circular plate *ac* is fixed to the axis by the skrews *bi*. The brass rod *gk* is skrewed into the axis HI, and carries a brass ball, *lm*, that slides along it, and is fixed by a skrew *m*, at a proper place for ballancing the weight of the sector and telescope placed on the opposite side of the axis. At the top of the supporter ST there is an hold-fast *nopqrstv*, whose cavity *nopq* receives the circular plate QR. The end *q*, of a springing-plate *pq*, is fixed by a skrew *r* to the inside of the upper plate *rs*, while its other end *p* may be pressed down upon the circle Q, by twisting the knob of a skrew *t*, which works in a socket *v*. And to prevent this pressure from dislocating the plane of the circle QR, and, consequently, the position of the axis HI, the hold-fast *nopq* has liberty of yielding or turning upon the ends of two skrew-pins, that go into two conical holes, in the opposite edges of the under plate *no*: one of these skrews is seen at *n*; and the fixed piece that they skrew into, is represented separately at full view at *nxyz*, *nz* being the point that the hold-fast turns upon. By this means, the same skrew at *t* causes the upper and under plates of the hold-fast *nopq* to compress the circle Q with equal forces. To the arm O there is fastened such another hold-fast, which so compresses the circle *ac*, and the cross plate MN, as to stay the sector and telescope in any given position, from turning about the joint F. This joint is nothing else but a cylindrical pin, passing through the plates MN, *ac*. The flat head of the pin is fixed by three small skrews to the plate MN; and to the opposite end of this pin a circular springing-plate is fixed by a skrew, that skrews into the end of the pin. And the joint C, at the center of the sector ABC, is made in the same manner.

Fig. 3. represents the skrew-work upon the backside of the limb AB, contrived for moving the telescope, by twisting the knob *g*. Here *gab* is a long straight skrew, which works through a skrew-hole in a brass head *c*; whose neck is moved in a long circular slit *de*, cut through the limb: the other end of this neck turns round in a hole in the nonius-plate (one end of which is fixed to the telescope) and draws it along the limb; *h* and *i* are the heads of two skrews, whose shanks go through a springing-plate, to make the motion steady, and through the slit *de*; and are skrewed into the nonius-plate on the other side of the limb. Since the length of the skrew *ab* must have a small angular motion, while it carries the head *c* along the arch *de*, the shank of it, near the end *a*, turns round in a hole made in a short flat axis *mn*, placed perpendicular to the limb, and held so by an arm *no*, while the other end *b* moves in a slit *p*, parallel to the limb, being cut in a small plate fixed perpendicular to the limb. The long skrew *gab* is kept from slipping backwards and forwards through the hole in the axis *mn*, by shoulders or nuts fixed on each side.

The dimensions of this instrument are these: the length of the telescope, or the radius of the sector, is 2½ feet; the breadth of the radius, near the end C, *fig.* 2. is 1¼ inch; and, at the end D, two inches. The breadth of the limb AB is 1½ inch; and its length six inches, containing ten degrees divided into quarters, and numbered from either end to the other. The telescope carries a nonius or subdividing plate, whose length, being equal to sixteen quarters of a degree, is divided into fifteen equal parts; which, in effect, divides the limb into minutes, and, by estimation, into smaller parts. The length of the square axis HIF is eighteen inches, and of the part HI twelve inches; and its thickness is about a quarter of an inch; the diameters of the circles QR and *abc* are each five inches: the thickness of the plates, and the other measures, may be taken at the direction of a workman.

This instrument may be rectified, for making observations, in this manner: by placing the intersection of the cross hairs at the same distance from the plane of the sector the plane described by the line of sight, during the circular motion of the telescope upon the limb, will be sufficiently true, or free from conical curvity; which may be examined by suspending a long plumb-line at a convenient distance from the instrument; and, by fixing the plane of the sector in a vertical position, and then by observing, while the telescope is moved by the skrew along the limb, whether the cross hairs appear to move along the plumb-line.

The iron axis *bfo* (*fig.* 5.) may be elevated nearly parallel to the axis of the earth, by means of a small common quadrant; and its error may be corrected, by making the line of sight follow the circular motion of any of the circum-polar stars, while the whole instrument is moved about its axis *bfo*, the telescope being fixed to the limb. For this purpose, let the telescope *kl* be directed to the star *a*, when it passes over the highest point of its diurnal circle, and let the division, cut by the nonius, be then noted: then, after twelve hours, when the star comes to the lowest point of its circle, having turned the instrument half round its axis, to bring the telescope into the position *mn*; if the cross hairs cover the same star supposed at *b*, the elevation of the axis *bfo* is exactly right; but if it be necessary to move the telescope into the position *μν*, in order to point to this star at *c*, the arch *mμ* which measures the angle *mfμ* or *bfc*, will be known; and then the axis *bfo* must be depressed half the quantity of this given angle, if the star passed below *b*; or must be raised so much higher, if above it; and then the trial must be repeated, till the true elevation of the axis be obtained. By making the like observations upon the same star on each side the pole, in the six o'clock hour-circle, the error of the axis, toward the east or west, may also be found and corrected, till the cross hairs follow the star quite round the pole. For supposing *aopbc* to be an arch of the meridian (or in the second practice of the six o'clock hour-circle) make the angle *afp* equal to half the angle *afc*, and the line *fp* will point to the pole; and the angle *ofp*, which is the error of the axis, will be equal to half the angle *bfc* or *mfμ*, found by the observation; because the difference of the two angles *afb*, *afc*, is double the difference of their halves *afo* and *afp*. Unless the star be very near the pole, allowance must be made for refractions. *Smith's Optics.*

A'STROSCOPE, *astroscopium*, a kind of astronomical instrument, composed of two cones; on whose surface the constellations,

ſtellations, with their ſtars, are delineated; by means whereof, the ſtars may eaſily be known.

The Aſtroſcope is the invention of William Schuckhard, formerly profeſſor of mathematics at Tubingen, who publiſhed a treatiſe expreſly on it, in 1698.

ASTROSCO'PIA, the art of obſerving and examining the ſtars, by means of teleſcopes, in order to diſcover their nature and properties.

A'STRUM, or ASTRON, a conſtellation, or aſſemblage of ſtars: in which ſenſe it is diſtinguiſhed from aſter, which denotes a ſingle ſtar.

Some apply the term, in a more particular ſenſe, to the great Dog, or, rather, to the great bright ſtar in his mouth.

A'TE, in mythology, a miſchievous and ill-natured goddeſs, who took delight in engaging men in troubles and quarrels, perverting their underſtanding, and dulling their reaſon. There was no way to be ſecured from her, but by having recourſe to the Lites, daughters of Jupiter, who ſaved men from her anger with this circumſtance, that, the more ſhe was in a paſſion, the leſs power they had with her, &c. This Ate is nothing elſe but the evil and injuſtice we commit; which is the real ſource of our trouble and miſfortunes. The Lites are our prayers, which we are to make uſe of in our calamities. Laſtly, it is evident, that, when our crimes are very great, then we meet with the greater difficulties in obtaining our pardon.

ATHA'NATES, or the immortal, a name the Perſians gave a body of 10000 choice men, which was always kept complete, by filling up the number, as ſoon as any were killed, or died: they had great confidence in this body of men, and never engaged them, but in deſperate caſes. Q. Curtius ſpeaks of them thus: Proximi ibant quos Perſæ immortales vocant ad decem millia.

ATHA'NOR (*Dict.*) *plate* V. *fig.* 10. repreſents an Athanor furnace. *a a a a*, the tower of the Athanor, or chief furnace, which receives the fuel of the fire: the pricked lines indicate the thickneſs of the wall. *b b b b*, the inner ſides which form the cavity, and are each ten inches long. *c*, the door of the aſh-hole. *e*, the upper door. *d*, the grate which is placed even with the bottom of the door *e*. *f*, the cover wherewith the upper aperture of the tower is ſhut. *g g*, a flue, through which the fire aſcends from the tower into the firſt furnace. *h h h h*, a hollow priſm, which forms the firſt ſecondary furnace. *i i*, a ſemi-cylindrical arch, wherewith the aforeſaid priſm is cloſed up. *k k k k*, an iron-plate coated within, wherewith the firſt ſecondary furnace is ſhut. In this plate is a round hole, through which the neck of the veſſel 7 may be paſſed. *n*, iron-bars. *o o o o*, iron-hooks, faſtened to the wall, to receive the iron-bars. *q q q q*, the funnel of the furnace. *r*, an iron-plate, wherewith the funnel may be ſhut. *t t*, another flue, through which the fire paſſes from the firſt ſecondary furnace to the ſecond. *u u u u*, another ſecondary furnace cylindrical. *v v*, its upper circular aperture, ſloped at the fore part, to receive an iron-pot, which is to be hung in this ſecondary furnace. *z*, a flue, which conveys the fire from the ſecond to the third furnace. 1 1 1 1, the third ſecondary furnace, having an iron-pot, like the ſecond. 2222, the ſecond funnel. 3, a plate to ſhut the funnel. 4, an aperture, which leads from the third furnace into the funnel. 5 5 5, the third funnel. 7, an earthen retort, placed in the firſt ſecondary furnace, with its neck through the hole in the door. 8, a receiver. 9, a glaſs-retort, placed in the iron-pot, belonging to the ſecond ſecondary furnace; which pot is filled with ſand. 10, a receiver. 11, a glaſs cucurbit, with its head placed in the pot of the third furnace. 12 12, Stands which ſupport the receivers, and which may be raiſed or lowered by the help of ſcrews.

Uſes of the ATHANOR. You muſt put in, at the upper arch-door *e*, a ſemi-cylindrical muffle, twelve inches long, of the ſame heighth and breadth of the door, three quarters of an inch thick, and open behind, being ſhut there by the hinder part of the Athanor. For this purpoſe, a tile muſt be placed on the grate *d*, to ſupport the muffle. Under this muffle you may place your cement-pots, or ſuch bodies as muſt be calcined with a long and violent fire; which may be done without a muffle, though not ſo well. In the firſt ſecondary furnace, *h h h h*, *i i*, you may perform the moſt violent diſtillations, with an open fire; for retorts, and other veſſels, may be introduced into it, by taking away the door *k k k*, and placed either upon the hearth itſelf, or on a particular ſupport of ſtone. But you muſt be careful to place thoſe veſſels in ſuch a manner, that their necks may paſs through the hole in the door *k k*. You may cloſe all the crevices of the door with lute. To the neck of the retort apply a cylindrical ſegment ten or twelve inches long, that the heat of the vapours may be gradually diminiſhed, leſt the receiver, which muſt be of glaſs, ſhould ſplit. The receiver muſt be luted to the other orifice of the ſaid ſegment, and ſupported by a kind of trivet.

In this chamber, inſtead of diſtillations, you may make cementations, calcinations, &c. in which caſe, the round hole, in the iron-plate *k k*, muſt be ſhut.

The ſecond and third ſecondary furnaces ſerve chiefly to perform ſuch operations as are made in baths of ſand, aſhes, or filings. You may alſo make in theſe furnaces diſtillations by a reverberating fire, as in the firſt; only the fire is leſs violent in theſe, though ſufficient for diſtilling aqua fortis: in order to this, you muſt take out the iron-pot, and invert it on the mouth of the furnace; by this means, the ſegment cut out from the pot, together with that cut out from the ſide of the cavity, will form a hole for the neck of the retort.

All the apparatus being thus prepared, you muſt introduce, through the top of the tower *b b b b*, a few burning coals; and then a ſufficient quantity of fuel, ſo that the tower may be entirely filled, or only in part, according to the nature of the operation. Then immediately put on the iron-cover *f*, and cloſe exactly all the crevices with lute; for, if you neglect this caution, all the fuel contained in the tower would immediately be kindled, which might be attended with very bad conſequences.

Manner of regulating the fire.—The fire may be made very ſtrong in the firſt chamber *h h h h*, *i i*, by leaving the door of the aſh-hole *c*, and the funnel *q q q q*, of the chamber, quite open, and the fire have free liberty to paſs from the tower into this cavity. But the cloſer the funnel is ſhut, together with the door of the aſh-hole, the more the violence of the heat diminiſhes: and this will be ſoon effected, if the iron ſlider, which ſeparates this cavity from the tower, be partly let down. Obſerve alſo, when the ſtrongeſt fire is required, that the hole in the door *k k* be cloſely ſtopped; becauſe, when open, the air, by ruſhing violently through it, cools the bodies placed in that cavity. At the ſame time diſtillation, or ſome other proceſs, may be performed, and with the ſame fire, in the ſecond and third furnaces; for the fire penetrates from the firſt cavity into the ſecond, and increaſes, when the funnel 2 2 2 2, erected on it, is opened. But, before you do this, the funnel of the firſt cavity muſt be ſhut as much as that of the ſecond is opened. By the ſame means, you may hinder the fire, which ſerves for the operations made in the two firſt cavities, from going out through their funnels, and force it out through the funnel 5 5 5, by which means it will alſo act upon the bodies placed in that cavity: for, the more the funnel erected on the third cavity is open, the more one or both the funnels of the other cavities muſt be cloſed: whence it is plain, that you cannot have the ſtrongeſt fire in the third cavity, unleſs there be an equal degree of fire in the other two; but, on the contrary, the heat in the third cavity may be rendered leſs, by cloſing its funnel, though it be violent in the others. The ſame is true of the ſecond cavity, with regard to the firſt. You cannot make the ſtrongeſt fire under the muffle placed within the upper door *e*, of the tower, unleſs you have an equal fire in the firſt cavity; which fire may, conſequently, be increaſed, by ſhutting the door quite againſt the muffle; and diminiſhed, by opening it; there being, at the ſame time, an equal heat in the firſt chamber, and in the following ones.

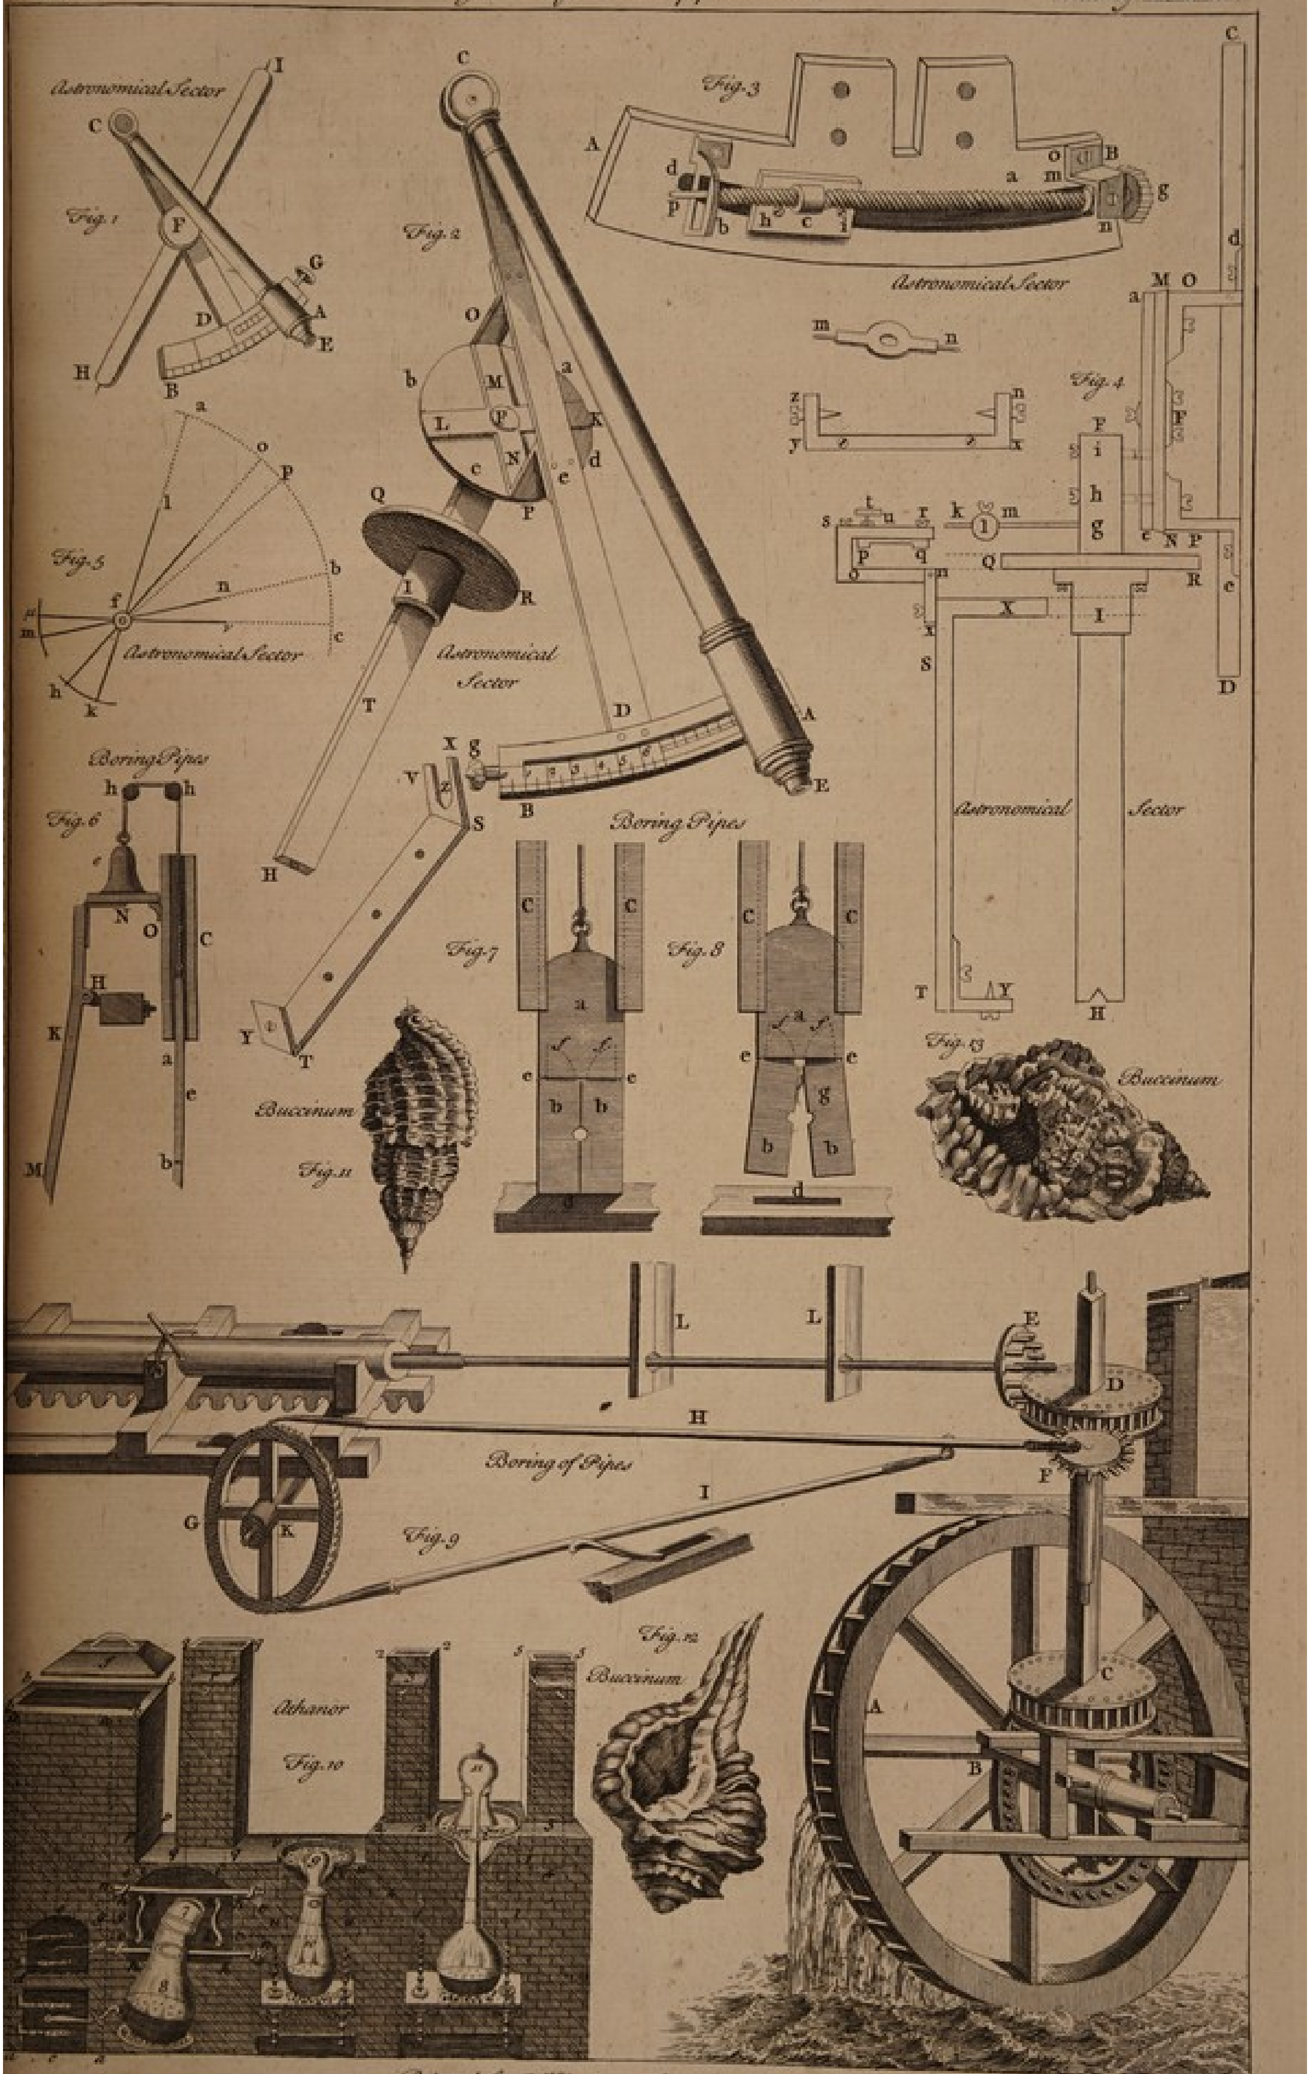
ATHEMADOU'LET, ATAMADOULET, or ETMADOULET, is the prime miniſter in the Perſian empire. The word is Arabic, compoſed of itimade, and doulet, which is the truſt of majeſty, or, according to Tavernier, the ſupport of riches. His office is the ſame as the grand vizir's in Turky, and may be compared to the antient mayors of the palace in France. In regard all the affairs of the kingdom paſs through his hands, he ought to be rather a gown-man than a ſoldier; and herein he only differs from the grand vizir, who is always to be at the head of an army, and, for every ſlight fault, or diſtaſte, is ſubject to be ſtrangled by the grand ſignior; whereas in Perſia, where the government is milder, the prime miniſters generally die in their beds; or, if they are depoſed, they are only exiled to ſome frontier city, where they live as private men. When the king is young, the prime miniſter has a hard game to play, for then the favourite eunuchs and the ſultaneſſes diſannul and cancel, in the night, whatever orders he makes in the day-time. The Athemadoulet is great chancellor of the kingdom, preſident of the council, ſuperintendant of the finances, and has the charge of commerce and all foreign affairs; he is, in effect, the vice-roy of the kingdom, and iſſues the king's mandates, or orders, in this ſtyle, Benda derga ali il alia Etmadoulet, that is, I, who am the ſupport of the power, the creature of this port, the higheſt of all ports. He draws, every lunar month, a thouſand tomans from the treaſury for his expences; which, in the year, amount to 45000 l. ſterling. This, however, is the leaſt of his revenue; for, having in his gift all the places of the government, war, finances, &c. he makes what advantage he pleaſes of them: moreover, as all the governors of provinces, and officers of the court, are obliged to ſend preſents to the Sophy, they dare not forget the Athemadoulet. He has under him ſix vizirs, and two ſecretaries.

ATHLE'TIC *Habit*, in medicine, denotes a ſtrong, hale conſtitution of body.

Anciently it ſignified a full, fleſhy, corpulent ſtate, ſuch as the athletæ endeavoured to arrive at.

The Athletic habit is eſteemed the higheſt pitch of health; yet it is dangerous, and the next door to diſeaſe; ſince, when the body is no longer capable of being improved, the next alteration muſt be for the worſe.

ATLA'NTIDES, in aſtronomy, a denomination given to the Pleiades, or ſeven ſtars, ſometimes alſo called Vergiliæ. They are thus called, as being ſuppoſed, by the poets, to have been the



Printed for J. Hinton in Newgate Street.

the daughters of Atlas, or his brother Heſperus, who were tranſlated into heaven.

A'TLAS, in commerce, a ſilk-ſattin, manufactured in the Eaſt-Indies. There are ſome plain, ſome ſtriped, and ſome flowered, the flowers of which are either gold, or only ſilk. There are Atlaſſes of all colours, but moſt of them falſe, eſpecially the red and the crimſon.

It muſt be owned, that the manufacture of them is wonderful and ſingular; and that, eſpecially in the flowered Atlaſſes, the gold and ſilver are worked together in ſuch a manner as no workman in Europe can imitate: but yet they are very far from having that fine gloſs and luſtre which the French know how to give to their ſilk-ſtuffs.

Among the ſeveral ſorts of Atlaſſes, the moſt conſiderable are, the cotonis, the caucanias, the cotonis-bouilles, and the bouilles-chaſmay, or charmay. The Atlaſſes cotonis are thus called, becauſe the ground of them is cotton, and the reſt ſilk. The caucanias are ſtriped ſattins, and thoſe of them which ſeem moſt ſilky, are ſtiled quenkas. The calquiers are ſattins made after the Turkiſh manner, or like Hungary point. The bouilles-cotonis and bouilles-charmay are thick ſilks, like thoſe ſtrong taffeties made at Tours in France.

There are Atlaſſes from four French ells and $\frac{4}{5}$ in length, by $\frac{3}{5}$ in breadth, to 14 ells in length, by $\frac{7}{8}$ in breadth. Thoſe that come near to half the uſual length are called half-pieces.

A'TMOSPHERE (*Dict.*)—There have been often ſeen in the Atmoſphere ſome very luminous parts, even near the zenith about midnight. It has been thought that theſe luminous parts are nothing elſe but terreſtrial exhalations floating in the air, at a prodigious altitude, and thereby reflecting the light of the ſun, which they are expoſed to, at that great height, to our eyes.

But Mr. Cotes juſtly obſerves, that it will be next to impoſſible to give any tolerable account, how theſe exhalations can be denſe enough to reflect ſo copious a light at that vaſt diſtance, and at the ſame time be ſupported by a medium ſo much rarer than the air we breathe in. It ſeems, therefore, more probable, that theſe extraordinary lights proceed from ſome ſelf-ſhining ſubſtance, or aerial phoſphorus.

A ſurprizing appearance of this kind was ſeen at Cambridge, on the 20th of March, in the year 1706. It was a ſemicircle of light, of about two thirds of the ordinary breadth of the milky-way, but much brighter. The top of it paſſed very near the zenith of that place, inclining about four or five degrees to the north; it croſſed the horizon at a very ſmall diſtance from the weſt, towards the ſouth, and again, about as far from the eaſt, towards the north. It was moſt vivid and moſt defined about the weſtern horizon, and moſt faint about the zenith, where it firſt began to diſappear. There was at the ſame time an Aurora borealis. The ſame appearance was ſeen in Lincolnſhire, at the diſtance of about 70 miles north of Cambridge, and there the ſemicircle ſeemed to lie in the plane of the equator. From theſe two obſervations compared together, it may be collected, that the matter, from which that light proceeded, was elevated above the earth's ſurface between 40 and 50 miles. *Cotes's Hydroſt. Lect.*

F. de Lana thought he had contrived an aeronautic machine for navigating the Atmoſphere: Sturmius, who examined it, declared it not to be impracticable: but Dr. Hook was of a different opinion, and detected the fallacy of the contrivance. Roger Bacon long before propoſed ſomething of the ſame kind. The great ſecret of this art, is to contrive an engine ſo far lighter than air, that it will raiſe itſelf in the Atmoſphere, and, together with itſelf, buoy up and carry men with it. The principle on which it is to be effected, is by exhauſting the air of a very thin light, yet firm, metalline veſſel, with an air-pump.

But the hopes of ſucceſs in ſuch an enterprize will appear very ſmall, if it be conſidered, that if a globe were to be formed of braſs, of the thickneſs only of $\frac{1}{8}$ of an inch, that globe muſt be above 277 feet in diameter, to ſwim in the air; and if, as de Lana ſuppoſes, the diameter of the globe were but 25 feet, the thickneſs of the metal could not exceed $\frac{1}{37}$ of an inch.

A'TRIPLEX, *Orach*, in botany, the name of a genus of plants, the characters of which are theſe: the flower has no petals, but is compoſed only of a number of ſtamina and a piſtil, ariſing from a five-leaved cup. The piſtil finally becomes a flat orbiculated ſeed, incloſed in the cup in the manner of a capſule. Some ſpecies of Atriplex have alſo another ſort of fruit, placed in a different part of the plant, not in that of the flowers. The embryo's of this fruit are large, and conſiſt of two angular leaves, which nicely incloſe and ſurround a ſeed of a roundiſh figure.

This plant is ſometimes cultivated in gardens as a culinary herb, being uſed as ſpinach, and, by ſome, much preferred to that herb: but there are few in England that are fond of it. It is to be ſown in the ſpring as ſpinach, and muſt be eaten, while it is young; for, when it is run up to ſeed, it is very ſtrong. If ſuffered to ſcatter its ſeed in a garden, it will make itſelf a laſting inhabitant, without farther trouble; the ſeeds often remain many years in the ground, and, every time it is turned up, ſend up new plants. *Miller's Gard. Dict.*

All the ſpecies of Atriplex are cooling and emollient. The leaves are ſometimes uſed in clyſters, and in cataplaſms, intended to ſoften tumors, and to abate pains. Some give the ſeeds internally as diuretics, and others recommend them againſt diſorders of the uterus and menſes. *Quinſ. Diſ.*

A'TROPOS, in the ancient mythology, one of the Parcæ, or fatal ſiſters; the other two were Lacheſis and Clotho.

ATTE'NTION, conſidered logically, means an operation of the mind, by which it applies itſelf more particularly to ſome part of a compound object, to arrive at a more clear and diſtinct idea of that part than the other whereof it is compoſed. Thus, in a play, the moſt lively and intereſting ſcenes draw our Attention principally, fill the whole ſoul, and abſorb or exclude our ideas of any other. Attention, like a microſcope, enlarges the objects it is applied to, and a thouſand properties are diſcovered by this Attention, that eſcaped a curſory view.

To increaſe Attention, we muſt baniſh every thing that may interrupt it, and ſeek every means to ſtrengthen and aſſiſt it. Our ſenſes are apt to divert our Attention; new ſenſations obſcure, efface, and obliterate acts of imagination. Yeſterday, you ſaw a fine piece of painting, were ſo ſtruck with it, its idea quite poſſeſſed you; another, offered to your view to-day, drives the former out of your imagination; thus external objects deſtroy Attention. For this reaſon ſome pray with their eyes ſhut, or directed ſteadily towards ſome fixed and immoveable point. Students chuſe a room remote from noiſe and the interruption of external objects, and the ſtudies of the night have been more ſucceſsful than thoſe of the day, becauſe a more univerſal calm and ſilence reigns.

The hurry of the imagination deſtroys Attention as much as that of our ſenſes; after a play, it is difficult to reſume our ſtudies immediately; next day ſome images will recur, apt to divert us and interrupt our attention. The ſenſes, the imagination, and the paſſions operate upon the ſoul and give it a kind of modification. All, therefore, who would apply themſelves ſtrenuouſly to the diſcovery of truth, ſhould be careful to avoid ſtrong and immoderate ſenſations, a great noiſe, a glaring light, exceſs of grief, or joy, &c. they ought to keep their imagination free from any thing that weakens or diſquiets the mind. They ought eſpecially to controll their paſſions, which, let looſe, make very powerful impreſſions on the ſoul and body, and exerciſe a ſtrange dominion over both. Yet the paſſions and the ſenſes may be made of uſe to preſerve our Attention. As, for inſtance, a deſire of diſcovering truth, rendering ourſelves uſeful to our neighbours, and improving ourſelves, is highly laudable, and tends to fix our Attention; but our Attention is fixed alſo by motives much leſs generous and noble, a thirſt of fame, deſire of riches, nay, even vanity. Experience ſhews us the ſenſes are of no ſmall ſervice to fix the Attention, for they have a natural connection with our ſituation; a man, retired to meditate in a ſolitary cell, will be alarmed, diſtracted, and his Attention intirely deſtroyed by an unexpected noiſe, or intermiſſion of adventitious light; ſo, if on the contrary, I reflect ſtrongly on an object amidſt day-light and noiſe, that idea baniſhes all others and poſſeſſes me; thus light and noiſe are no interruptions to Attention, but ſerve to fix it more ſtrongly. It is, in ſhort, a habit of the mind; and the philoſophers, who have ſhut their eyes to help their meditation, have furniſhed us with nothing but chimæra's. Had Deſcartes kept his eyes open to have ſurveyed the univerſe with Attention, inſtead of ſinking into meditation, he would never have publiſhed ſuch dreams as he has for a plan of the univerſe. Attention is progreſſive, and the power of it may be acquired, but depends, in ſome meaſure, on the conſtitution. Julius Cæſar could dictate to four ſecretaries; ſome no noiſe diſturbs, nothing interrupts; others the lighteſt accident.

Habit does all; we know not our ſtrength till we try it; the ſoul is as flexible and capable of impreſſions as the body; is ſo connected with it, that, like the body, it grows, improves, and ripens. Fixing our Attention properly will diſpel the gloom of ignorance, poliſh off the ruſt of idleneſs, cultivate the mind, and conduct human reaſon right in the purſuit of truth and ſcience.

ATTRA'CTION (*Dict.*)—All philoſophers agree that there is a certain force by which the primary planets tend towards the ſun, and the ſecondary planets towards their primary. As we ought carefully to avoid multiplying principles, and impulſe is the moſt known and leaſt controverted principle of the motion of bodies, it is clear, a philoſopher ought to attribute this impelling power to a fluid. To this notion, the vortices of Des Cartes owe their birth, and this opinion ſeemed more plauſible, becauſe it accounted for the motions of the planets by the circular motion of the matter of the vortices, and their tendency towards the ſun by the centrifugal force of the ſame matter. But an hypotheſis is not to be admitted which accounts only for general phænomena; particular phænomena are the teſts of an hypotheſis, and the failure of the Carteſian ſyſtem in theſe overturned it. The doctrine of vortices is therefore juſtly exploded, as ſo many difficulties attend it which never can be ſurmounted; for, if the

the planets move by virtue of the action of a fluid, this fluid muſt have contrary properties, it muſt impel in one intention, and in another make no reſiſtance, an apparent abſurdity; and the remedy is worſe than the diſeaſe, for the force by which the planets tend towards the ſun on this hypotheſis muſt be aſcribed to an occult quality, which is ſaying nothing at all: and Ariſtotle, who perhaps invented the term, is much more pardonable than many modern philoſophers who have blindly followed him.

We may therefore truly aſſert, that Attraction is a primordial quality of matter: nor is it perhaps poſſible to explain the celeſtial bodies on the principle of impulſion. If Sir Iſaac Newton ſeems to waver in ſome part of his works concerning the nature of Attraction, and admits of an impelling power, there is reaſon to think it was a kind of tribute he choſe to pay to the prejudice, or rather the general opinion of the age he lived in, than his real ſentiment; becauſe he permitted Mr. Cotes, his diſciple, to adopt Attraction without reſerve, as may be ſeen in the preface to the ſecond edition of his Principia; and this preface was written under the eye of Sir Iſaac, and had his approbation. Beſides, Sir Iſaac admits a reciprocal Attraction among the celeſtial bodies, and this very opinion ſeems to ſuppoſe Attraction a quality inherent in bodies. But be that as it may, according to Newton, the attractive force decreaſes in an inverſe ratio to the ſquares of the diſtances: this learned philoſopher has ſolved a great part of the celeſtial phænomena on this ſingle principle, and all who have tried to account for them ſince, on the ſame principle, have ſucceeded to a ſurprizing degree of exactneſs. The motion of the moon's apogee which was pretended to be irreconcileable to this ſyſtem, is now found to be intirely conformable to it, and does honour to the Newtonian ſyſtem. All the other inequalities of the motion of the moon, which are very conſiderable, may alſo eaſily be accounted for by the ſyſtem of Attraction, and demonſtrated by calculation.

All the phænomena hitherto obſerved demonſtrate a mutual tendency of the planets towards each other; wherefore, we muſt admit this for a truth on its own evidence: and, though we ſhould be forced to acknowledge this a primordial and inherent quality in matter, we may venture to ſay, that the difficulty of conceiving ſuch a cauſe would be a very weak argument againſt its exiſtence. No one doubts but that a body which meets another, communicates motion to it, but have we an idea of the power by which this communication is made? The vulgar eye here perhaps penetrates as far as that of the philoſopher. No body is ſurprized at ſeeing a ſtone fall; they have always ſeen it; philoſophers, well acquainted with the effects of impulſion, have never troubled themſelves about the cauſe which produces them. Now, if every body which meets another, ſhould ſtop without communicating motion to it, a philoſopher would be as much aſtoniſhed at this phænomenon, as a common man at ſeeing a heavy body ſuſpended in the air. If we underſtood wherein the impenetrability of matter conſiſts, we ſhould not perhaps be clearer about the nature of the impelling power. We only ſee, that, in conſequence of this impenetrability, the ſhock of one body againſt another muſt be followed by ſome change either in both or one of the bodies; but we know not, and perhaps never ſhall, by what power this change is effected; and why, for inſtance, a body which ſtrikes againſt another ſhould not always continue at reſt after the ſhock, without communicating a part of its motion to the body which reſiſts it. It is apprehended Attraction contradicts the notion we have of matter; but, if we enquire attentively we ſhall find theſe ideas no ways repugnant. The univerſe is concealed from us by a curtain, we ſee only ſome part of it; were that drawn up on a ſudden, we ſhould be ſurprized to ſee what paſſes behind it. Beſides, the pretended inconſiſtence of Attraction with the nature of matter is ſolved by admitting an intelligent being, who could as eaſily ordain bodies to act on each other at a diſtance, as in contact.

M. de Maupertuis, in his diſcourſe on the figures of the planets, has given an idea of the ſyſtem of Attraction with remarks on it; and the ſame author obſerves, in the Mem. Acad. 1734, that, long before Sir Iſaac Newton, Roberval de Fermat and Paſcal thought gravity an attractive power, and inherent in bodies. We will add, that Hook had the ſame notion, and foretold that all the motions of the planets would one day be accounted for on this ſingle principle. Theſe reflections, by increaſing the number of great men who were of the ſame opinion with Sir Iſaac, take nothing from his glory; for, as he was the firſt who actually demonſtrated this principle, he is properly the author of it.

The ingenious Dr. Knight has juſt publiſhed a treatiſe, in which he has endeavoured to demonſtrate that all the phænomena in nature may be explained by Attraction and repulſion. See MAGNETISM and REPULSION.

ATTRACTION *of Mountains*. If it be admitted that all parts of the earth attract each other mutually, it muſt be granted that there are mountains on it, whoſe magnitude is conſiderable enough to make a ſenſible Attraction. Let us ſuppoſe the earth a globe of an uniform figure, whoſe radius is equal to 1500 leagues, and ſuppoſe a mountain on the ſurface of ſome part of this globe one league in heighth, it is eaſy to demonſtrate, that a weight placed at the bottom of this mountain ſhall be attracted horizontally by the mountain, with a force equal to a 3000th part of the weight; ſo that a pendulum or plumb-line, placed at the bottom of this mountain, muſt deviate from a perpendicular about a minute; the calculation is not difficult, and this may be admitted by way of ſuppoſition. From whence it follows, that, when we obſerve the elevation of a ſtar at the foot of a great mountain, the plumb-line muſt deviate from a perpendicular; and an obſervation of this kind, certainly, would afford a very ſtrong proof in favour of the ſyſtem of Attraction; but it may be objected, how ſhall we be ſure the plumb-line actually deviates from a perpendicular, as the direction of the plumb-line only determines the vertical ſituation of the ſtar? This difficulty is eaſily ſurmounted.

Let us ſuppoſe a ſtar on the north of the mountain, and the perſon who is to make his obſervation placed on the ſouth, if the Attraction of the mountain acts ſenſibly on the plumb-line, it will deviate from a perpendicular towards the north, and, conſequently, the apparent zenith of the ſtar will go back towards the ſouth, and ſo the diſtance of the ſtar on which the obſervation is made in the zenith, muſt be greater than if there was no Attraction.

After having made this obſervation, if we go at a diſtance from the mountain, on a right line towards the eaſt or weſt, ſo far, that the Attraction no longer operates, an obſervation, made in this new ſtation, will ſhew the ſtar at a leſs diſtance than in the former.

But there is another and better method. It is certain, that, if the plumb-line on the ſouth ſide of the mountain deviates towards the north, the plumb-line on the north ſide muſt deviate towards the ſouth, and the zenith of the ſtar, which in the firſt caſe went back towards the north muſt, in the latter, advance towards the ſouth. Therefore, taking the difference of theſe two diſtances, and dividing it into two equal parts will ſhew how much the pendulum has deviated from a perpendicular by the Attraction of the mountain.

The whole theory is clearly explained, with ſeveral remarks, in an excellent Memoir of M. Bouguer's, printed in the year 1749, at the end of his book on the Figure of the Earth. In which he gives an account of the obſervations he made in company with M. Condamine, on the north and ſouth ſides of the great mountain Chimboraco, in Peru; the reſult of his obſervations is, that the Attraction of this great mountain cauſes a deviation of the plumb-line from its perpendicular of 7″ and a half. Mr. Bouguer judiciouſly remarks, that the greateſt mountain is a trifle compared to the vaſt body of the terreſtrial globe; and that a hundred obſervations, where no ſenſible Attraction is found, prove nothing againſt the Newtonian ſyſtem; but that this made at the foot of the vaſt mountain Chimboraco, which is in favour of the doctrine of Attraction, deſerves the attention of all philoſophers.

AU'DIANISM, the ſyſtem or ſentiments of Audius and his followers; particularly as to the belief of the human figure of the Deity.

Audianiſm amounts to the ſame with Anthropomorphiſm.

Audianiſm appears to be much earlier than Audius: many, both among the antient Jews, Heathens, and primitive Chriſtians, ſeem to be given into ſentiments much like thoſe of the Audians. Not to mention that M. le Clerc makes Moſes the patriarch or founder of Audianiſm: it is certain, the antient Sadducees, the Ebionites, Seleucus, Hermias, Melito biſhop of Sardis, Tertullian, and others, held the Deity corporeal.

A'VENUES (*Dict.*)—The Engliſh elm will do in all grounds, except ſuch as are very wet and ſhallow; and this is preferred to all other trees, becauſe it will bear cutting, heading, or lopping in any manner, better than moſt others. The rough or ſmooth Dutch elm is approved by ſome, becauſe of its quick growth; this is a tree that will bear removing very well; it is alſo green almoſt as ſoon as any plant whatever in ſpring, and continues ſo as long as any, and it makes an incomparable hedge, and is preferable to all other trees for lofty eſpaliers. The lime is valued for its regular growth, and fine ſhade: the horſe cheſnut is proper for all places that are not too much expoſed to rough winds. The common cheſnut will do very well in a good ſoil, and riſes to a conſiderable height, when planted ſomewhat cloſe, though, when it ſtands ſingle, it is rather inclined to ſpread than grow tall. The beech is a beautiful tree, and naturally grows well with us in its wild ſtate, but it is leſs to be choſen for Avenues than the before-mentioned, becauſe it does not bear tranſplanting well, but is very ſubject to miſcarry. Laſtly, the abele is fit for any ſoil, and is the quickeſt grower of any foreſt-tree. It ſeldom fails in tranſplanting, and ſucceeds very well in wet ſoils, in which the others are apt to fail. The oak is but little uſed for Avenues, becauſe of its ſlow growth.

The old method of planting Avenues was with regular rows of trees, and this has been always kept to till of late; but we have now a much more magnificent way of planting Avenues: this is by ſetting the trees in clumps or platoons, making the opening much wider than before, and placing the clumps of trees at about three hundred feet diſtant from one another. In each of theſe clumps there ſhould be planted either feven or nine trees; but it is to be obferved, that this is only to be practifed where the Avenue is to be of fome confiderable length, for, in fhort walks, this will not appear fo fightly as fingle rows of trees. The Avenues made by clumps are fitteft of all for parks. The trees in each clump fhould be planted thirty feet afunder, and a trench fhould be thrown up round the whole clump, to prevent the deer from coming to the trees to bark them. *Miller's Gard. Dict.*

A'VERAGE, in agriculture, a term ufed by the farmers in many parts of England, for the breaking of corn fields, eddifh, or roughings. The word fignifies, in law, either the beafts which tenants and vaffals were to provide their lords on certain occafions, or, among the merchants, the money laid out to repair loffes by fhipwreck. In the firft of thefe fenfes, the word is derived from averium, a labouring beaft: in the fecond, from averia, goods or chattles, from the French, avoir, to have or poffefs. In the laft, or the farmer's fenfe, it may be derived from haver, an Englifh name for oats, or from averia, beafts, being as much as feeding for cattle or pafturage. *Ray's Englifh Words.*

AVE'RRHOISTS, a fect of Peripatetic philofophers, who appeared in Italy fome time before the reftoration of learning, and attacked the immortality of the foul.

They took their denomination from Averrhoes, a celebrated interpreter of Ariftotle, born at Cordova in Spain, in the twelfth century, from whom they borrowed their diftinguifhing doctrine. The founder of this fect, Averrhoes, is fometimes called the commentator, by way of eminence, as being fuppofed to have entered beft of all the commentators into the fentiments of the philofopher; infomuch that fome have pretended the foul of Ariftotle had migrated into the body of Averrhoes.

The Averrhoifts, who held the foul was mortal, according to reafon, or philofophy, yet pretended to fubmit to the chriftian theology, which declares it immortal. But the diftinction was held fufpicious; and this divorce of faith from reafon was rejected by the doctors of that time, and condemned by the laft council of the Lateran, under Leo X, yet it was ftill maintained covertly: Pomponatius, Cæfalpinus, and others, were fufpected of it. But the corpufcular philofophy, now introduced into Italy, feems almoft to have extinguifhed Averhoifm.

A'VERTI, in horfemanfhip, is applied to a regular ftep or motion enjoined in the leffons. *Guill. Gent. Dict.*

AU'GUR *(Dict.)*— The college of Augurs was firft inftituted by Romulus, who was himfelf very expert in the art of foothfaying. Their number at firft was but three, one out of every tribe; then Servius Tullius added a fourth, and chofe them out of the nobility. Afterwards Quintus and Cælius Agellinus obtained that five fhould be elected out of the commonalty; the fenate at the fame time decreeing, that their number fhould not exceed nine. Notwithftanding Sylla added fix more, the eldeft whereof was called mafter of the college. They preceded all other orders of priefts, and were never depofed, nor any fubftituted in their places, though they fhould be convicted of the moft enormous crimes. When the Augur made his obfervations, he fat upon a high tower in a clear day, holding a crooked ftaff or liturus in his hand, clad in his foothfaying robe, called læna, with his face directly eaft: thus placed, he quartered out the heavens into fo many regions, obferving in which region the bird appeared, and then killing his facrifices, and having faid certain prayers, called effata, he proceeded to divination. The myftery of foothfaying came firft from the Chaldeans, who taught it the Greeks among whom Amphiaraus, Mopfus, and Colchis, were very eminent: from the Greeks it paffed to the Hetrurians, or Tufcans, and from the Tufcans to the Romans.

AU'GUST, called by the Romans, Sextilis, is the eighth month of the year, according to our method of computing, beginning with January. But is was the fixth with the Romans, who, for that reafon called it Sextilis; which name was changed to Auguftus, from Auguftus Cæfar, becaufe this emperor, being returned from the Gauls, in the 746th year of Rome, endeavoured to reform the calendar; on which occafion, and, in honour of whom, Sextilis was changed to Auguftus. Others alledge, the reafon was, becaufe he was firft made conful in this month, and becaufe he gained great victories in it. The Turks have alfo taken this name from the Greek or Roman calendars, fince they call it Agoftos.

This month was under the protection of the goddefs Ceres, and had the following remarkable feafts and facrifices On the firft, to Mars and Hope. 2. On account of Cæfar's fubduing Spain. 3. To Salus on the Quirinal mount. 7. To Hope. 8. To Soli Indigeti on the Quirinal mount. 10. To Ops and Ceres. 11. To Hercules in the circus Flaminius. 12. To the Lignapefia. 13. To Diana in the filva Aricina. To Vertumnus. The feaft of flaves and fervant-maids. 17. Portumnalia to Janus. 18. Confualia. The rape of the Sabine virgins. 19. The laft Vinalia. The death of Auguftus. 20. Vinalia Ruftica, the grand myfteries. 23. The Vulcanalia in the circus Flaminius. 24. The Feriæ of the moon. 25. Opibonfivæ, in the capitol. 27. Volturnalia. 28. To Victory in the court. 29. The ornaments of the goddefs Ceres are fhewn. About the twenty-firft of this month the fun enters the fign Virgo.

AUGUST, is reprefented in painting, by a naked man, with his hair difhevelled and drinking out of a cup. Before him is a kind of fan, which feems to be made of a peacock's tail. Upon the ground are three large melons. *Dant, Roffi, and Mounfaucon's Antiquities.*

AUGUSTE'UM *Marmor*, in the natural hiftory of the antients, a name given to the common green and white marble, fo frequent in ufe with us for tables, &c. and called by our artificers Egyptian marble. The Romans, however, made a diftinction between the differences of this marble, in regard to the difpofitions of its veins; for thofe pieces of it which had the white matter difpofed into a fort of arches, were called the Auguftan marble, while thofe which had the white in a more diffufed and regular form, were called the Tiberian marble. But thefe are too flight diftinctions; for the fame block of marble, nay, fometimes the compafs of the fame table, affords us both the Auguftan and Tiberian kind. *Hill's Hiftory of Foffils.*

A'VIS, a military order in Portugal, inftituted by Alphonfus I, after he had won the city of Evora from the Moors, called the fraternity of St. Mary of Evora: it was confirmed by Innocent IV. in 1234. They wore a black Ciftercian habit, and bare for their arms a crofs flower-de-lis in a field, Or, having for their creft, two birds fable. *Vafconcellos, Le Mire, Orig. Ordin. Equeft.*

AU'RA, in chemiftry, a certain fine and pure fpirit, found in every animal or vegetable body; but fo fubtile, as only to be fufceptible by its fmell and tafte, or other effects, not found in any other but that body. This Aura exhibits the proper characters of the body, by which it is accurately diftinguifhed from all others; but is itfelf too fine and thin to be feen by the eyes, though armed with a microfcope; or felt by the hands; and, withal, is extremely volatile; fo that, when pure and fingle, it flies off by its great mobility, mixes with the air, and is received into the great chaos of all volatiles, and there, ftill retaining its fame nature, it floats till it falls down in fnow, hail, rain, or dew, when it again enters the bofom of the earth, impregnates it with its prolific virtue, and is at length received by other juices of the earth, and conveyed into the bodies of animals and vegetables, and, by this revolution, paffes into new bodies, whofe mafs it animates and directs. This fubtile fluid is lodged in the oil of the body, to prevent its being diffipated and thrown off, and hence it is, that all the antient alchymifts fay fpirit refides in fulphur. *Boerh. Chem.*

AURI'CULA *Urfi, bear's ears*, or, as they are vulgarly called, Auriculas, in botany, a diftinct genus of plants, the characters of which are thefe: the flower is funnel-fhaped, confifting of one leaf, divided into feveral fegments at the rim. The piftil arifes from the cup, and is fixed in the manner of a nail to the hinder part of the flower. It afterwards ripens into a roundifh fruit, partly covered by the calx, and, opening at the top, is feen to be full of fmall feeds, fixed to a placenta.

Tournefort has enumerated twenty-feven fpecies of Auricula urfi.

The varieties, raifed by feeds from thefe fpecies, are endlefs, and are one of the greateft ornaments of the Dutch and Englifh gardens.

The feveral fpecies of Auricula, when not in flower, are known by their thick hoary leaves, which are ufually terminated by a point.

Though this herb is feldom kept in the fhops, it neverthelefs ftands recommended as a vulnerary, and as fuch is found of fervice, both for internal and external purpofes. Mixed with ointments and plaifters, it is reckoned good in ruptures. Four or fix fpoonfuls of the water, in which it has been boiled, taken every morning, are faid to cure coughs and ulcers of the lungs. The juice of its flowers removes fpots of the face, and beautifies the fkin; and with the fame intention fome diftil a water from it.

AURO'RA *(Dict.)*—The poets and painters have perfonified Aurora. Homer defcribes her as a young virgin having her hair difhevelled, and hanging loofe about her fhoulders; being of the colour of the pureft gold, fitting in a golden chair, with all her veftments of that hue and colour.

Virgil defcribes her, as coming, at the very inftant of fable night's departure, with one of her hands full of rofes, gilliflowers, and lilies, taken out of a bafket which fhe carries in her other hand, befprinkling them on the marble pavement of the lower heaven, adorning the fun with unfpeakable beauty.

She is alfo reprefented as a young virgin with carnation wings, and a yellow mantle, in her forehead a ftar, and golden funbeams from the crown of her head, riding upon Pegafus; with a phial of dew in one hand, and various flowers in the other, which fhe fcatters upon the earth.

She is alfo defcribed, holding in one hand a flaming torch, and drawn in a gorgeous chariot, befpangled with ftars, by winged Pegafus; which favour fhe is feigned to have obtained from Jupiter, by many importunate requests, presently after the downfal of Bellerophon.

She is fabled to be the herald and messenger of Phœbus, and as receiving her being from the virtue of his beams; and is no other than that rubicund and vermilion blush of the heavens, which the sun's first appearance works in the orient, and from thence descending beautifies our hemisphere, with such resplendency.

She is also painted in a purple robe, and a blue mantle fringed with silver.

Aurora *Borealis*.— Under this article in the Dictionary, we have mentioned several hypotheses to account for this phænomenon; we shall here give another, published by an anonymous author in the Universal Magazine.

Suppose the earth a great magnet,—that magnetic effluvia are constantly issuing great quantities from its north pole, and that these move from the north to the southward, in the direction of what is called the magnetic meridian—that these effluvia are of a martial or ferrugineous nature, nothing being magnetical but a substance of that kind, and vice versa.

Iron and sulphur, even in their gross bodies, mixed with a little water, are exceeding apt to take fire, much more so, when highly subtilized and attenuated.—The hot mineral waters, probably, arise from this, and so may volcano's—all chymists know with what eagerness sulphur acts upon iron.

Several burning mountains or volcano's have been discovered of late years, in and about the north-polar regions, which cast up sulphureous vapours, to an immense height.—There are springs near them the hottest in the world, their heat even equalling that of boiling water.—May not those sulphureous vapours, blended with the magnetic or ferrugineous effluvia, catch fire and fulgurate?—The vapour or fume of iron dissolved in spirit of vitriol is most readily set on fire.—May not the magnetic effluvia give them a kind of magnetic direction? We see, in fact, the lucid columns, or radiating flashes, of the Aurora borealis, almost always shot off from the north to the south, correspondent, in a great measure, to the magnetic meridian.—And I have constantly observed the corona, concourse, or concentration, if I may so call it, of these lucid rays near the zenith, so much to the east of it, as answered nearly to the western declination of the common magnetic needle; that is, a straight line, drawn from one to the other, would be nearly in the direction of the magnetic meridian.—I think I never observed the corona to the westward of it.—What seems not a little to confirm this notion is, that, during the appearance of a considerably great and vivid northern light, the magnetic needle suffers very great agitations; caused, probably, by the colluctation and explosion of the sulphureous and magnetic effluvia: this is more particularly observed in Sweden, and the northern parts of Europe, as being near the source of these effluvia.

But, farther, as we scarce ever see an Aurora borealis, but when the wind blows from some point, or other, between the east and west of the northern semi-circle, this, also, may help to drive the sulphureous, coruscating vapours southward.—And when the wind is very strong from E. N. E. or W. N. W. it may not a little alter their magnetic direction or current. I have several times observed, when a strong north-easterly wind hath blown some faint appearances of a northern light here and there, abundance of small, lucid, coruscating nubeculæ scattered up and down the hemisphere, now suddenly appearing, then disappearing; so that I imagined the wind had dispersed the fund of the luminous vapours; for we see such lucid, vibrating, broken, small clouds after the grand explosion, and at the end of a common Aurora borealis. Nay, frequently, such small, bright, flashing clouds are seen up and down the heavens, without any other appearance of an Aurora borealis, the lucid vapours being then but in small quantities, and much scattered: but it is remarkable, that these little, flitting, luminous clouds seemed always in a vibrating, tremulous motion, and moving very fast from north to south, though sometimes there was little or no wind. These nubeculæ were so extremely thin, that even stars of the third or fourth magnitude were seen through them.

Those northern lights are seen vastly more frequent, more bright, more beautiful, and variously coloured, in the northern parts of Europe, than here; and here much more lucid, large, and fragrant, than to the southward; because, in the polar regions, the magnetic effluvia are vastly more strong and copious, and the neighbouring volcano's send up immense quantities of sulphureous vapours (which cannot but rise very high in such a dense, cold atmosphere) and these, as it were, fermenting with one another, catch fire. In Sicily, and the surrounding seas, they see luminous appearances, very near resembling those of the Aurora borealis, when Vesuvius or Ætna burn; and these rays are commonly of various colours, as those of the northern lights, viz. red, yellow, greenish, crimson, &c. Possibly both the one and the other are tinged by some mineral substances from the volcano's. For, though globules of rain may reflect light of different colours, there seems to be nothing in the matter of an Aurora borealis that is apt to do it: besides, it is unquestionable that the Aurora borealis shines by its own light, and not from the sun, as well as the lights of Vesuvius. We well know that different minerals will tinge flame of different colours. May not then the diversity of colours of an Aurora borealis be another argument that it arises from the exhalations of volcano's?

The sulphureous vapours of vulcano's are shot up to an inconceivable height (sometimes even great stones are thrown up from them to four or five hundred feet, and the ashes vastly higher, so as oftentimes to be carried by the wind, fifty or an hundred miles, nay, leagues) so high, indeed, that they may retain very little gravity, their centripetal force continually decreasing, as their distance from the earth increases—and their centripetal force will be much increased by their revolving about the axis of the earth, in a very large circle.—But, farther, sulphureous vapours have a kind of a vis centrifuga, and will rise in vacuo, whereas all other vapours sink. It is certain, the fumes of gun-powder will rise to the top of a tall exhausted receiver, and even prove lucid, though the gun-powder itself doth not flash. Thus, the vapours over Vesuvius are sometimes very lucid, though the crater may not, at that time, actually belch out flame.

We know sulphureous vapours are sometimes carried to an astonishing height, and collected into vast bodies of inflammable matter, far above the gross terrestrial atmosphere.—The great Dr. Halley, from very just observation, estimated the meteor of the 19th of March, 1718-19 (which cast such an amazing brightness, and made such a very loud displosion) to be very near seventy miles perpendicular altitude, above the surface of the earth; whence it was seen over a great part of Europe, at one and the same time. Now if such a gross body of sulphureous vapours, as this, could be sustained at the very top of our atmosphere, or even in the æther above it, how much higher may we suppose the mere subtile vapour of the lumen boreale to be carried?—This will account for the great height and distance some of the northern lights are seen at, without having recourse to monsieur Mairan's zodiacal light, or professor Euler's impulsion of the sun-beams.

It is possible these vapours, when carried to such a vast height, and in a medium so exceeding rare, may actually become lucid, especially when mixed with the ætherial nitre, as the fumes of gun-powder mount and shine in vacuo. Indeed, this phænomenon of the gun-powder suggests to me, that a highly subtilized aerial nitre always enters the composition of an Aurora borealis (for it is every-where diffused throughout the whole atmosphere) and nothing is more like the vivid pearl-coloured flashes of an Aurora, than a deflagration of nitre and sulphur; and the flame may be tinged with red, green, yellow, &c. by the addition of different minerals. Certainly, nitre, sulphur, and iron are greatly disposed to inflame and coruscate. The Arctic regions abound with nitre.—The northern lights are vastly most frequent in cold seasons, when the atmosphere is greatly stocked with nitre.—It is scarce to be doubted, but that common lightning abounds with all these principles.

Hence may arise another conjecture, that, as lightning is certainly of an electrical nature, so possibly may be the matter of an Aurora borealis.—The incredible swiftness of its flashes, and the instantaneous propagation of its coruscations through all the northern part of the hemisphere, seem to favour such a thought. May the luminosity be conveyed on the magnetic effluvia, as the electric on an iron wire? But this is, I fear, indulging too far in whimsy.

The accounts we have had from Iceland, Greenland, and other places within the Arctic circle, by the whale-fishers, and some others, that have been given by the jesuits, &c. who travelled to the north-east parts of China and Tartary, assure us, that there are several volcano's in these parts, some of which have broken out within these few years. Is it not then the fresh erruptions of some of these volcano's, that have produced the northern lights, so common of late years? Before this present century began, it is certain, they did not appear even in Sweden, Norway, and Lapland, or, at least, very seldom; whereas monsieur Maupertuis says, they are now almost constant in these countries, during the winter months. Is it not then the more frequent and violent eruptions of these volcano's, that make the Aurora borealis more common and more illustrious? And is it not the cessation of these eruptions, that puts a stop to these luminous phænomena, as we know they cease for weeks, for months, for years; and that too, when all other circumstances seem to favour their productions? They appear vastly more frequent and great, in the most northern countries, as they lie near the source of the magnetic effluvia and sulphureous vapours. Doth not an appearance of a kind of these nocturnal lights and coruscations in Sicily, &c. on the eruption of Vesuvius, and sometimes merely from the sulphureous exhalations issuing from it, without actual flames, seem to confirm this opinion? Moreover, it is not altogether improbable, that sulphureous exhalations from more southern volcano's, swimming on the top of the atmosphere, and revolving, with the earth, round its axis, may be carried towards the pole, and contribute somewhat to the formation of an Aurora borealis?

Mr. de Maupertuis, in the relation of his voyage to the north, describes the Auroræ boreales, which appear in Lapland, during the winter, in this manner: " If the earth, says he,

makes

makes a dismal appearance in these climates, the heavens exhibit a most delightful prospect. As soon as the nights begin to grow dark, lights of a thousand colours and a thousand forms bespangle the sky, as if they were ambitious of compensating the earth for the absence of the sun. These lights have no certain situation as in the southern countries; for, though we often see a luminous arch fixed towards the north, yet they seem indifferently to possess every region of the sky. They begin sometimes with forming a kind of mantle, of clear and moveable light, the extremities of which terminate the horizon, and which rapidly overspread the whole sky with a motion, resembling that of a fisherman's net, preserving a sensible perpendicular direction towards the meridian. After these preludes, all lights generally unite near the zenith, and form a kind of corona.

Sometimes streams of light like those we see in France, towards the north, are seen towards the south; sometimes they are seen in the north and south both together; their summits meet, as their extremities separate, in descending towards the horizon. I have seen some quite of another direction, whose summits touched each other almost to the zenith; some have, besides, several concentric arches. Their summits all point towards the meridian, but with some declination towards the west, but that varies and is at sometimes insensible; some of these arches, after having extended to their largest amplitude above the horizon, open, and form the half of a large ellipsis.

There would be no end of enumerating all the forms these lights assume, and the motions in which they are directed; they sometimes emit streaks of scarlet.

Mr. de Maupertuis tells us, that, notwithstanding his being accustomed to these phænomena, one he saw at Oswer Tornea, on the 18th of December, 1736, drew his admiration; towards the south a large tract of the heavens appeared tinged with as lively a red, as if the whole constellation of Orion had been dipped in blood. This light, which was at first fixed, afterwards began to move, put on different colours and formed a dome, whose summit was a little inclined towards the south-west of the zenith, and that the brightest moon-light did not obscure this phænomenon. Mr. de Maupertuis observes, that red lights are uncommon in that country, and that the people look on them as ominous. The same learned person has given a very elegant solution of a geometrical problem relating to the Aurora borealis, in the Mem. Academ. 1733.

Mr. Monnier, in his Astronomical Institutions, observes, as well as M. de Maupertuis, that in Sweden there is scarce a winter-night, wherein these Auroræ boreales are not visible, even in every region of the hemisphere; a circumstance which ought particularly to be attended to, for the better explanation of these phænomena. M. Monnier thinks the matter of the Auroræ boreales analogous to that of the tails of the comets.

AU'RUM *musivum*, the antient name of what has been since called Aurum mosaicum. This old name is brought into use again in the London Dispensatory; the preparation directed to be made in the following manner: take tin one pound, flour of brimstone seven ounces, sal armoniac and purified quicksilver, of each half a pound; melt the tin, and add to it the quicksilver; and, when this is cold, reduce it to powder, and mix it with the other ingredients: then sublime the compound in a matrass, and the Aurum musivum will be found under the part sublimed, with a small quantity of foulness at the bottom. *Pemberton's Lond. Disp.*

AURUM *sophisticum*, mimic gold, a chymical preparation, made as follows: take fine distilled verdigrease, eighteen ounces; crude Alexandrian tutty, four ounces; borax, twelve ounces; salt-petre, one ounce and an half; pulverize, and mix them all together, tempering them with oil, to the consistence of a plaister; then put a German crucible into a wind furnace, heat it red-hot, and, putting your mass into it, let it be covered, and the furnace filled with coals over the crucible. When the mass is melted, let it cool of itself, then break the crucible, and you will find, at the bottom, a fine regulus, like gold, weighing about four ounces; which, being malleable, may be wrought into any form.

AUX, in astronomy, that point in a planet's path, or orbit, wherein it is at its greatest distance from the center of the world.

Hence the ancients, who considered the earth as the center, use Aux in the same sense with apogee. Among the moderns, on the contrary, it denotes the aphelion.

Some also use Aux to denote the arch of the ecliptic, intercepted between the first point of Aries, and the point wherein the sun, or a planet, is at its greatest distance from the earth.

AWA'RD (*Dict.*)—

1. The arbitrators ought to give their Award within the time limited by the compromise, and it will be null, if it were given after the said time is expired; for their power is then at an end, and they are no longer arbitrators.

2. The parties may give power to the arbitrators to prolong the time; and, in this case, their power lasts during the time of their prorogation.

4. If the compromise regulates a certain time for instructing the cause which the arbitrators are to decide, they cannot give their Award till the said time is expired.

4. The arbitrators having once given their Award, they cannot retract it, nor change any thing in it; for the compromise was only to give them power to give an Award; and, when that is done, their power is at an end; but their power is not at an end by an interlocutory sentence, or an incident in the cause; and they may give different interlocutory sentences, on such incidents, as often as occasion requires.

5. If there are several arbitrators named by the compromise, they cannot give their Award, unless they all see the process, and give judgment of it together; and, although the greater part had given the Award in the absence of one who was named with the others, yet the Award would be null, because the absent person ought to have been one of the judges; and, had he been present, he might have been able, by his reasoning, to bring the other arbitrators over to his opinion.

6. The arbitrators can judge of nothing else, besides that which is submitted to their judgment by the compromise; and they must observe the conditions which are there prescribed; and, if they judge otherwise, their Award is null.

Where there appears a manifest error in the body of an Award, in some cases there may be relief against it in equity; but, where the error does not appear without unravelling of it, and examining into matters of account, not relievable. 1 *Vern.* 158.

A'ZAB, in the military orders of the Turks, signifies a particular body of the soldiery taken in, or added first to the janizaries, but now become a separate body from them.

The word, in the oriental languages, signified an unmarried person; and the original order of those was, that they should be single men.

AZE'LFOGE, in astronomy, a fixed star of the second magnitude, in the Swan's tail.

Hevelius assigns its longitude, for the year 1700, ♓ 1°. 16'. 45''. and its latitude northward, 59°. 57'. 53''.

A'ZIMUTH *Compass*.—Under the article *Magnetical* NEEDLE, in the Dictionary, we have given a description of a new sea-compass, which is the invention of the learned Dr. Knight; we shall here add the contrivance of the ingenious Mr. Smeaton whereby the Doctor's compass answers the purposes of an Azimuth and amplitude compass.

The cover of the wooden box being taken off, the compass is in a condition to be made use of in the bittacle, when the weather is moderate: but if the sea runs high, as the inner box is hung very free upon its centers (the better to answer its other purposes) it will be necessary to slacken the milled nut, placed upon one of the axes that supports the ring, and to lighten the nut on the outside, that corresponds to it. By this means, the inner box and ring will be lifted up from the edges, upon which they rest, when free; and the friction will be increased, and that to any degree necessary, to prevent the too great vibrations, which otherwise would be occasioned by the motion of the ship.

To make the compass useful in taking the magnetic Azimuth, or amplitude of the sun and stars, as also the bearings of headlands, ships, and other objects at a distance, the brass edge, designed at first to support the card, and throw the weight thereof as near the circumference as possible, is itself divided into degrees and halves; which may be easily estimated into smaller parts, if necessary. The divisions are determined by means of a cat-gut line, stretched perpendicularly with the box, as near the brass edge as may be, that the parallax, arising from a different position of the observer, may be as little as possible.

Underneath the card are two small weights, sliding on two wires, placed at right angles to each other; which, being moved nearer to, or farther from, the center, counterballance the dipping of the card in different latitudes, or restore the equilibrium of it, where it happens by any other means to be got too much out of level.

There is also added an index at the top of the inner box, which may be put on, and taken off, at pleasure; and serves for all altitudes of the object. It consists of a bar, equal in length to the diameter of the inner box, each end being furnished with a perpendicular stile, with a slit parallel to the sides thereof: one of the slits is narrow, to which the eye is applied, and the other is wider, with a small cat-gut stretched up the middle of it, and from thence continued horizontally from the top of one stile to the top of the other. There is also a line drawn along the upper surface of the bar. These four, viz. the narrow slit, the horizontal cat-gut thread, the perpendicular one, and the line on the bar, are in the same plane, which disposes itself perpendicular to the horizon, when the inner box is at rest, and hangs free. This index does not move round, but is always placed on, so as to answer the same side of the box.

When the sun's Azimuth is desired, and his rays are strong enough to cast a shadow, turn about the wooden box, till the shadow of the horizontal thread, or (if the sun be too low) till that of the perpendicular thread, in one stile, or the light through the slit in the other, falls upon the line in the index bar, or vibrates to an equal distance on each side of it, gently touching

touching the box, if it vibrates too far: obſerve, at the ſame time, the degree marked upon the braſs edge by the cat-cut line. In counting the degree for the Azimuth, or any other angle that is reckoned from the meridian, make uſe of the outward circle of figures upon the braſs edge; and the ſituation of the index bar, with regard to the card and needle, will always direct upon what quarter of the compaſs the object is placed.

But, if the ſun does not ſhine out ſufficiently ſtrong, place the eye behind the narrow ſlit in one of the ſtiles, and turn the wooden box about, till ſome part of the horizontal, or perpendicular thread, appears to interſect the center of the ſun, or vibrate to an equal diſtance on each ſide of it, uſing ſmoked glaſs next the eye, if the ſun's light is too ſtrong. In this method, another obſerver will be generally neceſſary, to note the degree cut by the nonius, at the ſame time the firſt gives notice that the thread appears to ſplit the object.

From what has been ſaid, the other obſervations will be eaſily performed; only, in caſe of the ſun's amplitude, take care to number the degree by the help of the inner circle of figures on the card, which are the complements of the outer to 90, and, conſequently, ſhew the diſtance from eaſt or weſt.

The Azimuth of the ſtars may alſo be obſerved by night; a proper light ſerving equally for one obſerver to ſee the thread, and the other the degree upon the card.

It may not be amiſs to remark farther, that, in caſe the inner box ſhould loſe its equilibrium, and, conſequently, the index be out of the plane of a vertical circle, an accurate obſervation may ſtill be made, provided the ſun's ſhadow is diſtinct; for, by obſerving firſt with one end of the index towards the ſun, and then the other, a mean of the two obſervations will be the truth.

Plate IV. *fig*. 33. is a perſpective view of the compaſs, when in order for obſervation; the point of view being the center of the card, and the diſtance of the eye two feet.

A B is the wooden box.

C and D are two milled nuts; by means whereof, the axis of the inner box and ring are taken from their edges, on which they move; and the friction increaſed, when neceſſary.

E F is the ring that ſupports the inner box.

G H is the inner box; and

I is one of its axes, by which it is ſuſpended on the ring E F.

K L is the magnet or needle; and

M a ſmall brace of ivory, that confines the cap to its place.

The card is a ſingle varniſhed paper, reaching as far as the outer circle of figures, which is a circle of thin braſs; the edge whereof is turned down at right angles to the plane of the card, to make it more ſtiff.

O is a cat-gut line, drawn down the inſide of the box, for determining the degree upon the braſs edge.

P Q R S is the index bar, with its two ſtiles and cat-gut threads; which, being taken off from the top of the box, is placed in two pieces, T and V, notched properly to receive it.

W is a place cut out in the wood, ſerving as an handle.

B.

B Is one of thoſe letters which the eaſtern grammarians call labial, becauſe the principal organs, employed in its pronunciation, are the lips. It has a near affinity with the other labials P and V, and is often uſed for P, both by the Armenians and other orientals; as in Betrus for Petrus, apſens for abſens, &c. and by the Romans for V; as in amabit for amavit, berna for verna, &c. whence aroſe that jeſt of Aurelian, on the emperor Bonoſs, Non ut vivat natus eſt, ſed ut bibat.

B, in muſic, *b* is uſed to denote a flat, or the lowering of a ſound by a ſemi-tone minor. Thus A *b*, or *b* A, is the flat of A, or the ſemi-tone minor below A.

B *b*, quadro, or ♮, in the ſcale of muſical notes, ſignifies the ſound which is a tone above A, and a ſemi-tone below C.

BAA'L, or Bel, an Hebrew and Chaldaic word, which ſignifies lord, or mighty. It was the name of the idol of the Moabites and Phœnicians, and of moſt of the nations that bordered upon the Jews. It ſeems that the idolaters, amongſt them, pretended to adore the true God, under the name and figure of Baalim, Hoſ. ii. 16, 17. The Grecians, who were accuſtomed to take the eaſtern divinities for their own, called this Bel ſometimes Jupiter, ſometimes Mars; but the truth is, that the Babylonians underſtood by it either the ſtars and hoſt of heaven, or ſuch kings and heroes, whoſe memory they had conſecrated to poſterity, by a religious worſhip. The Phœnicians adored the ſun, under the names of Baal and Moloch. It is thought, this idol was the firſt invented by ſuperſtition, and the original worſhip of idolatry. *Selden de Diis Syris.*

BAALGA'D, Bagad, or Begad, an idol of the Syrians, which they accounted the goddeſs of fortune. *Kercher.*

BAA'RAS, Baharas, or Bacharas, a miraculous kind of root, ſaid to grow on Mount Lebanon, in a valley called Baaras, whence the name, near the city Macheron.

Joſephus repreſents it as of a flame colour, and emitting rays of light in the night-time, like a ſtar, but diſappearing in the day; on which footing, it ſhould make a vegetable phoſphorus. This property it may be ſuppoſed to derive from the ſoil, which abounds in bitumen; not unlike the plains of Puzzuoli; which, being replete with ſulphur, will flaſh under the horſes feet. But what the hiſtorian adds, concerning the difficulty and danger of pulling up this root, its ſhunning the hand, and retiring under-ground, with the extraordinary means uſed to ſtop it, and the expedient to pull it up, are ſo much on the marvellous, that we dare not relate them. The root, it ſeems, was highly prized for its virtue in curing epilepſies, &c.

BABYLO'NICS, *Babylonica*, in literary hiſtory, a fragment of the antient hiſtory of the world, ending at 267 years before Chriſt; and compoſed by Beroſus, or Beroſſus, a prieſt of Babylon, about the time of Alexander.

Babylonics are ſometimes alſo cited in ancient writers, by the title of Chaldaics.

The Babylonics conſiſted of three books, including the hiſtory of the ancient Babylonians, Medes, &c. but only a few imperfect extracts are now remaining of the work, preſerved chiefly by Joſephus and Syncellus, where all the paſſages of citations of ancient authors, out of Beroſus, are collected with great exactneſs. Annius of Viterbo kindly offered his aſſiſtance to ſupply the loſs, and forged a complete Beroſus out of his own head. The world has not thanked him for his impoſture. *Fabric. Bibl. Græc.*

BAC, or Back, in brewing, a large flat kind of tub, or veſſel, wherein the wort is put to ſtand and cool before boiling. *Savar. Dict. de Com.*

The ingredients of beer paſs through three kinds of veſſels. They are maſhed in one, worked in another, and cooled in a third, called Bacs or coolers.

To gauge a brewer's Bac.—Moſt Bacs have their ſides ſtraight; and, in caſe the ſides be not ſtraight, but make either an obtuſe, or acute angle, with the bottom, you muſt then be careful to take the true length and breadth in the middle of every inch in depth; from whence the area may be found upon every tenth.

For finding the area of the Bac, obſerve this rule: multiply the length by the breadth, and divide by 282: this gives the contents in ale gallons.

To find the true dip of a Bac.—Becauſe Bacs are not placed level, but ſloping, for conveniency of drawing off the wort; therefore, if you ſhould dip in too deep a place, you would wrong the ſubject, and, if in too ſhallow a place, you would wrong the king; to remedy which, take as many dips as you think convenient, and add them all together, and divide them by the number of dips, which will give a mean depth: when this is done, you muſt make trial in many places of the Bac, till you find a dip that anſwers your mean depth exactly; right againſt which, at the ſide of the Bac, make a mark, or notch, with a knife, and let that be your conſtant true dipping-place.

The bottoms of common brewers large Bacs generally warp, after they have been a little time uſed, and become more and more uneven, as they grow older, eſpecially ſuch as are not every-where well and equally ſupported: many of them are ſo large and uneven, that it is hardly poſſible to find a true medium of the depth of the wort, without taking a very great number of depths; beſides, ſome are ſo ſituate, that it is difficult to take depths in every part, where it may be neceſſary; and therefore it is a common practice to take one depth at a place in the back (cloſe to the ſide) which may be always moſt conveniently come at; then ſee all the wort let down into a tun, in which it may be exactly gauged, and (if the dip taken in the Bac doth not happen to be a mean one) mark, on the ſide of the Bac, ſuch addition or abatement as will make the gauge of the wort in the Bac equal to the gauge of the wort in the tun, which is called ſetting a Bac, by ſeeing the wort come down; and this is frequently done, becauſe moſt large Bacs are continually ſetting more one way than another. Beſides, the dimenſions of large Bacs, for want of proper inſtruments, are generally taken with inched tapes, which are ſeldom very exactly divided, and the alteration of the weather affects them in their lengths, and a very ſmall error, in the dimenſions of ſuch a large veſſel, cauſes a very conſiderable one in the area: but, by ſetting the Bac as above, there will be a compenſation in the depth, for any error that may happen in taking the other dimenſions.

Bac, in the diſtillery, is a veſſel in which the liquor to be fermented is put.

To gauge and tabulate a diſtiller's Bac.—*Plate* VI. *fig.* 1. repreſents a Bac, whoſe baſes are elliptical and unequal, but alike ſituated.

Find the center of the Bac, and in that center ſtrike a nail, as at *w*. Then, with a line and a bit of chalk, deſcribe a circle; this done, take a line and find the tranſverſe diameter, by holding the line from L to M, over the center *w*, and, at L and M, make a mark. Then find the conjugate diameter as Y Z, and mark it with chalk. Then take the depth in that place, where the officer propoſes to take his gauge, which ſuppoſe at *m*, and the depth from *m* to *w* is = to 36 inches; at which place make a notch. Then draw ſtraight lines with chalk, from M to B, from L to A, from Y to N, and from Z to O; the Bac being thus quartered, proceed to take the diameters thus: on the ſtraight lines make a mark in the middle of every ſix inches (with your chalk) as at A B, C D, EF, G H, I K, L M, which are the ſix tranſverſe diameters (as the depth of the bac is thirty-ſix inches) and, for the ſix conjugate diameters, make the like marks at N O, PQ, R S, TV, WX, Y Z; then take the ſeveral lengths and breadths in inches, and enter them on a piece of paper, as under:

Depth in inches.	Length, or tranſverſe diameters.	Breadth, or conjugate diameters.
6	A B = 62	N O = 32
6	C D = 65	P Q = 33
6	E F = 69	R S = 35
6	G H = 72	T V = 36
6	I K = 75	W X = 37
6	L M = 79	Y Z = 39

Then, to find the drip of the Bac, take a regular veſſel, and fill it with water, and continue pouring in water, till you have juſt covered the bottom of the Bac; then, with your rule, dip it, to know how much it wets; which ſuppoſe to be 1.5 inch, and that the quantity of water, poured in to cover the bottom, is juſt fifteen gallons.

Now, to find the areas of the ſeveral diameters, multiply the diameters ſixty-two by thirty-two, and that product divided by 294 (the cubical inches in a wine gallon) the quotient will be the area = to 6.74 gallons, which multiply by ſix, that product will be 40.44 gallons = to the content of the firſt ſix inches. By this method, the other five areas are found: but you muſt obſerve, as the drip of the Bac is found to be 1.5 inches inch, it muſt be ſubtracted from the whole depth thirty-ſix inches, and the remainder will be 34.5 inches. See the whole work, as under.

Inches.	Longeſt diameter. Inches.	Shorteſt diameter. Inches.	Mean area in wine gallons.		Inches.		Content of the ſeveral depths in wine galls.
6 —	62 —	32 —	6.74	×	6	is	40.44
6 —	65 —	33 —	7.29	×	6	is	43.74
6 —	69 —	35 —	8.21	×	6	is	49.26
6 —	72 —	36 —	8.81	×	6	is	52.86
6 —	75 —	37 —	9.43	×	6	is	56.58
4.5 —	79 —	39 —	10.47	×	4.5	is	47.11
1.4 The drip	—	—	—		—	is	16.00
36 The whole depth.						The content is	305.99

By this work it appears, that the Bac contains 305.99 gallons, and that the laſt mean area 10.47 gallons is multiplied by 4.5, becauſe the depth of the drip is ſubtracted from the laſt ſix inches.

To tabulate the Bac, ſet down the content 305.99 gallons, and ſubtract the ſeveral mean areas, as often as you multiplied them, and the ſeveral remainders will give you the contents of the Bac at any dry inch, from top to bottom; but, to prove the truth of the work, ſubtract the ſeveral contents of the ſeveral depths from the content of the Bac, and it veriſies your work at every ſix inches, and likewiſe at the laſt 4.5 inches, with the content of the drip.

BAC-MAKER is one who makes liquor-bacs, under-bacs, coolers, maſh-tuns, and working tuns, for the brewers. The workmanſhip is partly carpentry, in a particular manner; for it muſt be high enough to hold liquor; and partly cooperage, viz. the maſh-tun, or vat, which is hooped. See COOPERAGE.

There are not many of this trade, and it requires chiefly ſtrength, with a little art. A ſmall ſtock of ſtuff, beſides tools, will ſet a man up tolerably well; but, with 200 *l.* or 300 *l.* he will make a good figure in buſineſs.

BACCHANA'LIA (*Dict.*)—The Bacchanalia are ſometimes alſo called orgia, from the Greek ὀργὴ, fury, tranſport; by reaſon of the madneſs and enthuſiaſm wherewith the people appeared to be poſſeſſed at the time of their celebration.

They were held in autumn, and took their riſe from Egypt; whence, according to Diodorus, they were brought into Greece by Melampus.

The form and diſpoſition of the ſolemnity depended, at Athens, on the archon, and was at firſt exceedingly ſimple, but, by degrees, became incumbered with a number of ridiculous ceremonies, and attended with a world of diſſoluteneſs and debauchery; inſomuch that the Romans, who grew aſhamed of them, ſuppreſſed them, by a ſenatus-conſultum, throughout all Italy.

The women had a great ſhare in the ſolemnity, which is ſaid to have been inſtituted on their account; for a great number of them attended Bacchus to the conqueſt of the Indies, and carried in their hands the thyrſus, i. e. a little lance, covered with ivy and vine-leaves, ſinging his victories and triumphs where-ever they went: the ceremony was kept up, after Bacchus's deification, under the title of Bacchanalia; and the women were inſtalled prieſteſſes thereof, under that of bacchæ or bacchantes.

Theſe prieſteſſes, at the time of the feaſt, ran through the ſtreets, and over the mountains, covered with tygers ſkins, their hair diſhevelled, their thyrſus in one hand, and torches in the other, howling and ſhrieking.

Men and women met promiſcuouſly at the feaſt, all perfectly naked, except for the vine-leaves and cluſters of grapes which bound their heads and hips: here they danced and jumped tumultuouſly, and, with ſtrange geſticulations, ſung hymns to Bacchus, till, weary and giddy, they tumbled down diſtracted.

BACCHA'NTES, the name of ſuch women as followed Bacchus in the conqueſt of the Eaſt-Indies. It was afterwards given to the female prieſts of that falſe god, who celebrated his feaſt covered with ſkins of tygers or panthers, and running all the night, ſome with their hair looſe, with torches and links in their hands; others crowned with vine and ivy-leaves, carrying a thyrſus or ſtick covered with the like leaves. They had along with them cymbal-players, drummers, and others with hunting-horns; and they themſelves made a terrible noiſe, ſhouting and bawling, as they went along. The men were apparelled like ſatyrs, ſome riding upon aſſes, and others led he-goats to ſacrifice them. *Tertul. St. Auſtin.*

BACCHA'RACH *Wine*, a name of a particular kind of wine by ſome eſteemed a kind of Rheniſh; but Portzius, who has written expreſly on the ſubject, obſerves, that it differs from all the common Rheniſh wines, in colour, odour, taſte, and virtue. When the wine is firſt made, it is of a yellowiſh colour; but they take off this, by means of ichthyocolla, cut and ſteeped in fair water for ten or twelve hours, and then torn to pieces, and mixed with the wine, but only in a ſmall quantity. They add only ſo much of the wine, as they ſuppoſe capable of diſſolving it; and then, letting it ſtand ſix or ſeven days, they put it into a ſieve; and, pouring ſome more wine on it, they waſh it through; and, thus percolated, they pour it out of one veſſel into another, till it froths; they then pour the whole into a proper quantity of wine, to clarify it and take away its colour. Some add, at the ſame time, a quantity of ſand, or of powdered white glaſs, which being heavy, and entangling themſelves in the foul matter of wine, carry it to the bottom with them. When they pour this ſolution into the veſſel, they uſe a little ſtick with a piece of thin board perforated at the end of it, with which they beat the wine in the veſſel, to mix the ſolution of iſinglaſs every-where with it. Four or five days ſtanding quiet, after this, ſeparates all the fæces, and the wine is then drawn out into other veſſels, pure and colourleſs. *Portzius de Vin. Rhen.*

BACCHUS in the antient mythology, a god of the heathens. There were two eminent gods of this name; the Ægyptian Bacchus, ſon of Ammon, the ſame as Oſiris; and the Theban Bacchus, ſon of Jupiter and Semele.

The Ægyptian Bacchus was bred at Niſa, a city of Arabia Felix, and conquer'd the Indies. Orpheus carried his worſhip into Greece, and, out of flattery, attributed the wonders related of him to a prince of the race of Cadmus.

The Theban Bacchus, on the death of his mother Semele, which was effected by the arts of jealous Juno, in the ſeventh month of her pregnancy, was taken out of her womb by Jupiter, and ſewed up in his thigh, where he completed the time of ripening him for birth. Euripides, in his Bacchantes, ſays, that Jupiter hid the child in a cloud, to conceal him from his wife. Euſtathius tells us, he was bred on mount Meros (μηρὸς) which ſignifies thigh, and from hence it is probable the fable had its origin.

Bacchus went to the conqueſt of the Indies, at the head of a number of men and women, armed with thyrſi and drums. The people, terrified at the multitude and noiſe, received him as a god; and why ſhould they oppoſe him? He did not come to load them with chains, but to teach them the culture of the vine. He is ſaid to have performed wonders in the war of the giants.

Painters repreſent him by the figure of a young man, beardleſs, full-cheeked, crowned with ivy or vine leaves, a thyrſus in one hand, and bunch of grapes, or cup, in the other.

BACCI'FEROUS *Plants*, are ſuch as bear berries, i. e. fruit covered with a thin membrane, wherein is contained a pulp, which grows ſoft and moiſt, when ripe, and incloſes the ſeed within its ſubſtance.

Bacciferous trees Mr. Ray divides into four kinds. 1. Such as bear a caliculate, or naked berry; the flower and calix both falling off together, and leaving the berry bare; as the ſaſſafras trees, &c.

2. Such as have a naked monopyreneous fruit, that is, containing in it only one ſeed; as the arbutus, terebinthus, lentiſcus, &c.

3. Such as have a naked but polypyreneous fruit, that is, containing two or more kernels or ſeeds within it; as the jaſminum, liguſtrum, &c.

4. Such as have their fruit compoſed of many acini, or round ſoft balls, ſet cloſe together like a bunch of grapes; as the uva marina, rubus vulgaris, rubus Idæus, and the rubus minor fructu cæruleo.

BACK *of a chimney*, the hind part between the jaumbs and the hearth, uſually formed of brick, ſometimes tiles.

Iron BACK, is a large plate of caſt-iron, frequently adorned with figures in low relievo, ſerving not only to preſerve the ſtone-work of a chimney-back, but alſo to reflect the heat of the fire forwards. For the method of caſt-iron Backs; See IRON and FOUNDERY.

BACK *of a hip*, among builders, denotes the two planes on the outſide of a hip, lying parallel with the adjoining ſide and end of the roof. *Neve, Build. Dict.*

BACK-PAINTING, the method of painting metzo-tincto prints, paſted on glaſs, with oil-colours.

The art conſiſts chiefly in laying the print upon a piece of crown-glaſs, of ſuch a ſize as fits the print.

In order to do this, take your print and lay it in clean water for two days and two nights, if the print be on very ſtrong, cloſe, and hard gummed paper; but, if upon an open, ſoft, ſpungy paper, two hours will ſometimes ſuffice, or more, according as the paper is.

The paper or picture having been ſufficiently ſoaked, take it out and lay it upon two ſheets of paper, and cover it with two more, and let it lie there a little to ſuck out the moiſture.

In the mean time, take the glaſs the picture is to be put upon, and ſet it near the fire to warm; take Straſburg turpentine, warm it over the fire, till it is grown fluid; then with a hogs hair bruſh, ſpread the turpentine very ſmoothly and evenly on the glaſs.

When this has been done, take the metzo-tincto print from between the papers, and lay upon the glaſs; beginning firſt at one end, rubbing it down gently as you go on, till it lie cloſe, and there be no wind bladders between.

Then, with your finger or fingers, rub or roll off the paper from the backſide of the print, till it looks black, i. e. till you can ſee nothing but the print like a thin film left upon the glaſs, and ſet it by to dry.

When it is dry, varniſh it over with ſome white tranſparent varniſh,

varnish, that the print may be seen through it, and then it is fit for painting.

Note, You must be very careful in rubbing or rolling the paper off the print, so as not to tear it.

You may, instead of soaking your prints two days and two nights, roll them up and boil them for about two hours, more or less, according to the quality of the paper, in water, and that will render it as fit for rubbing, rolling or peeling, as the other way.

This being done, and your oil colours prepared, ground very fine, and tempered up very stiff, lay, on the backside of the transparent prints, such colours as each particular part requires; letting the master lines of the print still guide your pencil, and so each particular colour will lie fair to the eye on the other side of the glass, and look almost as well as a painted piece, if it be done neatly.

The shadows of the print are generally sufficient for the shadow of every colour, but, if you have a mind to give a shadow by your pencil, then let the shadows be laid on first, and the other colours afterward.

In laying on colours in this kind of backside-painting, you need not be curious as to the laying them on smooth. This is not at all requisite here, where the chief aim is only to have the colours appear well on the foreside of the print; and therefore the only care to be used in this work, is to lay the colours on thick enough, that its body may strike the colour of it plainly through the glass.

BA'CON's *Philosophy*.—Lord Bacon, baron of Verulam, and viscount of St. Albans, was born in the year 1560. He gave marks in his youth of what his manhood would produce. Queen Elizabeth was an admirer of his remarkable sagacity. He studied the Aristotelian philosophy at Cambridge, and, before he was sixteen years of age, discovered the absurdity of that jargon in vogue at that time. He afterwards applied himself to the study of the law; and his merit raised him to the dignity of lord chancellor, under king James I. He was accused of bribery, and, the king refusing him protection, was fined by the house of lords, stripped of his chancellorship, and cast into prison. He was soon after reinstated in his honours and fortune, but what he had undergone gave him a dislike to business, and increased his passion for study. At last he died aged 66 years, poor, and in very mean circumstances.

No man has contributed more to the advancement of learning than lord chancellor Bacon: he saw the imperfection of the philosophy of the schools, and taught the only way to amend it. This great man, indeed, did not know nature, but he knew and pointed out all the ways that lead to her. He entertained an early contempt for what the universities called philosophy, and did every thing in his power, to prevent societies, instituted for the improvement of human reason, from continuing to spoil it by a heap of impertinent terms, substantial forms, &c. which not only had made ignorance to be reverenced, but was, by a ridiculous mixture with religion, rendered sacred.

He composed two works with a design to improve the sciences, and carry them to perfection. In the first, intitled de Augmentis Scientiarum, he shews the state of learning, and points out a method of carrying it to greater perfection; but adds, that we must never hope to carry our discoveries to any great length, unless other methods were pursued, than those then in use. He shews that the logic, then taught in the schools, was fitter for wrangling, than to direct the mind in its search after truth. Aristotle, says he, from whom we have this art, has proceeded on wrong principles; he has made his physics conformable to his logic, instead of making his logic conformable to his physics; and, thus everturning the order of nature, has subjected the end to the means.

To correct the faults in the common logic, Bacon composed a second work, intitled Organum Scientiarum, wherein he has taught a new logic, the principal end of which is to shew how to make a good induction, as the end of Aristotle is how to make a good syllogism. Bacon looked on this as his master-piece, and spent eighteen years in composing it.

Nor was the cause of our errors hid from this great man; he saw that our ideas were operations of the mind; and that, in order to discover truth, they must be directed in a new method. This advice he frequently repeats in the work just mentioned. But who, in an age so prejudiced in favour of the jargon of schools, and the notion of innate ideas, listened to his doctrine? Who did not look on his new method of improving the human understanding, as a chimerical project? The method Bacon proposed was too perfect to be accepted at once: errors of long standing maintain their post with some obstinacy, and the Cartesian philosophy was embraced, because it admitted some of the former errors. Besides, lord Bacon's employments took up much of his time, and prevented him from carrying into execution himself the advice he gave to others; whereas Descartes gave himself up entirely to philosophy, and, being a man of a very lively and fruitful imagination, has substituted, in the room of the errors of the schools, others of a more seducing nature.

Lord Bacon's attention to the sciences in general did not hinder him from applying himself to some in particular; and, as he thought natural philosophy the basis of all the other sciences, he principally applied himself to bring that to some degree of perfection. But in this he acted like some great architects, who, scorning to work after others, begin with pulling every thing down, and raise their building on a plan entirely new. He, like these, never thought once about embellishing or repairing what had been already begun by others; but proposed to establish a new system of physics, without making any use of what had been left us by the antients, whose principles he suspected. To accomplish this great design, he resolved to publish a physical treatise every month, and began with one upon the winds; he afterwards published one on heat, another on motion, and, at last, one on life and death. But as it was impossible for a single man to give a complete system of physics in general, with equal exactness; after having given directions to serve as a rule for those who were desirous of proceeding on his principles, he contented himself with drawing the out-lines of four other treatises, and furnished materials for them, in a work intitled Sylva Sylvarum, wherein he has collected a vast number of experiments, to serve as a foundation for his new physics. In short, before lord Bacon, no-body knew any thing of natural philosophy; and all the experiments, made since his time, seem to have been pointed out by this great genius.

His moral essays are much esteemed; but they are wrote rather to instruct than entertain: an easy genius, a sound judgment, the sensible philosopher, and man of reflection, shine in these essays by turns. This was one of the fruits of the retreat of a man who had quitted the world, after having long supported a great share in its prosperity and adversity. There are also some very fine things in his book concerning the wisdom of the antients, wherein he has moralized the fables which compose the mythology of the Greeks and Romans. He wrote, besides, the history of Henry VII. in which, notwithstanding there are some traces of the bad taste of his age, yet it abounds in judicious remarks, and shews he was a refined politician, as well as a great philosopher.

BA'DGER, *taxus*, in zoology, called, in some parts of England, the brock, the grey, and the pate.

Authors who have described this animal, have all made two kinds; the taxus canius and taxus porcinus, the dog and hog Badger. The last of these is our common kind; and it is indeed doubted whether there be any such animal as the authors describe under the other name.

The body of the Badger is short and thick, its neck very short, and its hairs long, and very rigid, and stiff like hog's bristles. Those of the back are of a pale yellow, near the root: brown in the middle, and at the extremities yellow again; so that the creature appears, upon the whole, of a mixt colour, or what we call grey, on the back. The sides and belly are covered with hairs, which are all over of a pale yellowish hue; and the legs and shoulders, as also the belly, are wholly black. It has a broad white line from the top of the head to the nose, and, on each side of this, a very regular pyramidal black mark reaching up to the ears; and below these the jaws are whitish, so that the creature's face looks very odly variegated. Its eyes are small, and its snout wholly like a dog's. The teeth are like those of a dog also, and the legs short; its fore feet have sharp claws, with which it digs itself burrows in the earth; its face, like that of the fox, being broad at the top of the forehead, and sharpening to a point at the nose, so as to appear triangular in shape; and its cheeks are tumid, and furnished with strong muscles, whence it bites very hard. It feeds on insects and small animals, and on the roots of vegetables. We have them in many parts of England, particularly in the counties of Essex, Sussex, and Warwickshire. *Ray's Syn. Quad.*

The Badger's skin is of some use in commerce. Their fat is sold by the druggists, as a remedy against disorders of the kidneys and the sciatica; and their hair for making pencils for painters and gilders. *Savar. Dict. de Comm.*

BADIA'GA, in the materia medica, the name of a sort of spungy plant, common in the shops of Moscow, and some other northern kingdoms.

The use of it is the taking away the livid marks from blows and bruises, which the powder of this plant is said to do in a night's time.

We owe the knowledge of this medicine, and its history, to the accurate Buxbaum. He observes, that the plant is always found under water, and is of a very singular and peculiar nature.

It somewhat resembles the alcyoniums, and somewhat the spunges; but differs greatly from both, in that it is full of small round granules, resembling seeds. It is of a loose, light, and spungy structure, and is made up of a number of fibres of an herbaceous matter, and is dry, rigid, and friable, between the fingers.

BADI'GEON, a mixture of plaister and free-stone, well ground together, and sifted; used by statuaries, to fill up the little holes, and repair the defects in stones, whereof they make their statues and other work. *Savar. Dict. de Com.*

Masons give the same name to a kind of mortar made of the dust or fragments of free-stone, wherewith they colour or ſmear over the common plaiſter, to give it a reſemblance of free-ſtone.

The ſame term is alſo uſed by the joiners, for ſaw-duſt mixt with ſtrong glue, wherewith they fill up the chaps, and other defects in wood, after it is wrought.

BAFFE'TAS, or Baftas, a cloth made intirely of coarſe white cotton-thread, which comes from the Eaſt-Indies. Thoſe of Surat are the beſt. They are from thirteen French ells and three quarters to fourteen long, and ſeven eighths broad. There are alſo ſome which meaſure but five ſixths of an ell, or even but half of an ell in breadth. Theſe narrow Baffetas are called orgagis, gaudivis, nerindes, and dabouis, according to the names of the places where manufactured.

There are alſo narrow-white Baffetas, which meaſure thirteen ells and an half in length, by half an ell in breadth.

Broad-white Baffetas, 14 ells by three quarters.

Broad-brown and narrow-brown Baffetas. Theſe two laſt ſorts are made of raw thread, that is, which was never wetted or blanched. The former are fourteen ells long, by half an ell broad; the latter are of the ſame length, and three quarters in breadth.

BAGAU'Z.—Thus they call, in the Antilles iſlands, the ſugar-canes, after they have paſſed through the mill; they keep them under cover in ſmall huts, in order to uſe them, when dry, for boiling the ſugar. Theſe huts are called the Bagauz huts.

As ſoon as theſe Bagauz are taken from between the firſt and third roller, two or three negro women bind them up in bundles, which they pile up under the covers. In caſe the Bagauz be not long enough to be made up into bundles, as being too much broken, they carry them in large baſkets to a corner of the mill, where the horſes, oxen, and hogs, come and eat them.

Sometimes when they are ſtreightened for fuel, they only dry them in the ſun for three or four hours, which is ſufficient to make them fit for burning. In ſome places, where they have plenty of wood, they ſerve only to burn under the firſt boilers; but, where wood is ſcarce, they keep them for the two laſt, and under the firſt they burn ſtraw, and the dry leaves of the canes.

BA'GGAGE, is particularly uſed in the military art, for the neceſſaries, utenſils, apparel, &c. of the officers and ſoldiers.

The Baggage includes alſo women, children, ſuttlers, &c.

The Baggage-waggons before a march are appointed a rendezvous, where they are marſhalled by the waggon-maſter-general, according to the rank the ſeveral regiments bear in the army. On a march, they are ſometimes ordered to follow the reſpective columns of the army, ſometimes to follow the march of the artillery, and ſometimes to make a column of themſelves. The general's Baggage is commonly firſt. If the army march from the right, the Baggage of that wing has the van; if from the left, the Baggage of the left has the van. Each waggon has a diſtinguiſhing flag, to ſhew to what regiment it belongs. *Guillet.*

BA'HAR, or Barr, a weight uſed at Ternate, Mocha, in the Moluccas, Achem, and divers other parts of the Eaſt-Indies.

There are two kinds, the great, wherewith ſpice is weighed, equivalent to 200 catis, at 26 taels to the cati, amounting to 481 pounds 4 ounces, Paris meaſure.

The little Bahar ſerves for the weighing quick-ſilver, vermilion, ivory, ſilk, muſk, and other precious wares, containing likewiſe 200 catis, but at 22 taels to the cati, amounting to about 401 pounds ſeven ounces, Paris meaſure. The Chineſe Bahar is 300 catis, but each cati only equal to 16 taels.

BAIO'CCO, a money in modern Rome, equivalent to the tenth part of a julio, or hundredth part of the ducat.

BAIT.— Baits make a capital article in angling; on the choice whereof, much of the ſport depends; different ſeaſons, and different game, having their appropriated Baits. The red, or earth worm, is good for the ſmall fry moſt of the year round; and ſmall fiſh are good Baits for pikes at all times; ſheep's blood and cheeſe are good Baits in April; the bobs, dried waſps, and bees, for May; brown flies for June; maggots, hornets, waſps, and bees, for July; ſnails in Auguſt; graſhoppers in September; corn, bramble-berries, and ſeeds, at the fall of the leaf; artificial paſtes are for May, June, and July; and frogs, for March. *Sport. Dict.*

Natural Baits, include all kinds of worms, as the red-worm, maggot, and the like; alſo frogs, graſhoppers, hornets, bees, brown-flies, ſnails, roaches, bleak, gudgeon, and loaches.

Artificial Baits, are flies of all kinds and ſhapes, made of ſilk, feathers, and the like. The variety of which is very great; there being not only different ones for every ſeaſon and month of the year, but almoſt for every fiſh.

There are ſeveral artificial Baits, for intoxicating of fowl, and yet, without tainting or hurting the fleſh, as to make it unfit to eat.

Dead Baits, are paſtes of divers ſorts, made of corn, cheeſe, fruit, waſps dried or undried, ſheep's blood, boiled beans, and the like.

Ledger Bait, is that which remains fixed in one certain place, while the angler may be abſent; uſed eſpecially in fiſhing for pike.

Walking Bait, is that which the angler attends, while he keeps moving from place to place, in queſt of the fiſh.

Live Baits, are to be kept each ſort ſeparate, and fed with thoſe things which they like beſt.

The red-worm is to be kept in rich black mould, with a little fennel chopped among it; a little ox or cow-dung, newly made, is alſo a very acceptable thing to them. They may be kept in a box, with ſmall holes in it, or in a bag. Red-worms, and all other ſorts, ſcour quickly, and grow very tough and bright, on putting them into a thin rag, greaſed with freſh butter, or greaſe, before they are put into moſs.

This is the beſt of all things to keep them in; but the moſs muſt be firſt very well waſhed, and the water ſqueezed dry out again. As to food, a ſpoonful of cream, dropped into the moſs once in three or four days, is better than any thing elſe. The moſs is to be changed every week, and kept in a cool place.

White large maggots are an excellent Bait for many ſorts of fiſh, and they are to be kept on ſheep's-ſuet and liver, chopped ſmall. They will thrive extremely on this ſort of food.

Frogs and graſhoppers are to be kept in wet moſs and long graſs; and, on moiſtening this afreſh every evening, it will keep a long time. They are to have their legs and wings cut off, when they are uſed.

Live flies muſt be uſed as they are caught; but waſps, bees, hornets, and humble-bees, may be preſerved dry.

The beſt method of drying them, is putting them in an oven after the bread is drawn: care muſt be taken that they are not ſcorched; and, when they are taken out, they are to have their heads dipped in ſheep's blood. This is to be ſuffered to dry on, and then they are to be preſerved in a box. They will keep very well for three or four months.

BA'KERS.— This is a very ancient as well as uſeful trade; and the moſt general and extenſive branch of it is that of making, as well as baking, houſhold or family bread; though there are ſeveral others, as,

Biſcuit-baking, which is chiefly to prepare, in a particular manner for long-keeping, what is called ſea-biſcuit, or bread. See BISCUIT.

Of French bread, ſo called for its peculiar delicacy; who alſo makes various ſorts of the nicer ſweet, as well as inſipid, biſcuits, &c.

Of ginger-bread, or ſweet-ſpiced bread, and cakes of ſeveral kinds.

Of theſe three laſt there are but few of each, there not being ſuch a general call for their produce, as for the common bread; the Bakers of which, indeed, are many in number, yet not ſo numerous, but that moſt of them get a decent maintenance, if careful, and ſome acquire handſome eſtates. The principal expence they are at, when they ſet up, is that of building their ovens, one of which will coſt 20 pounds and upwards, according to the ſize; next to this, is their ſtock of flour and faggots: ſo that 2 or 300 pounds will ſerve very well to begin with.

BA'KING *of Porcelain.* The determining the due degree of heat for the Baking the China-ware, and the finding out the proper time it ſhould remain in that heat, are two very eſſential points in the manufactory of this elegant ware. Perhaps, our Engliſh attempts to imitate it would be brought nearer the perfection we are aiming at, by a juſt regard to theſe particulars, than by many other leſs material articles, about which we ſeem more ſollicitous.

It is generally ſaid, that the Chineſe judge of the proper degree of Baking for their ware, by obſerving when the gold and colours appear moſt perfect and brilliant, and then taking the thing out of the fire. But this is an idle opinion; for the colours are not ſeen at all, while the veſſel is red-hot in the fire, but only appear gradually, as it cools. The way they judge of the Baking being enough, is by looking down into the furnace; when they can diſtinguiſh the whole range of the veſſels equally red-hot, and ſee one from another to the very bottom of the furnace, they know that the fire is ſtrong enough, and ought not to be increaſed any farther. From this time they diligently watch the things; and, when they perceive the inequalities on the ſurface of the coloured parts diſappear, and theſe coloured parts blend themſelves ſo with the reſt, as to make one even ſurface, they then know that the whole is done, and have nothing farther to do, but to let them cool as gradually as poſſible, to prevent their cracking.

This method of judging ſerves them very exactly for their ſmall furnaces; but, when they are employed about the larger, they are forced to judge by other ſort of ſigns. When the flame that comes out of the furnace is not ſo red as at firſt, but becomes whitiſh, and the veſſels, as far as can be ſeen, appear thoroughly red, and when the whole furnace

furnace is so perfectly heated, that, on looking in at the top, the floor is seen bright and shining; these are the tokens of the things being almost done, and what remains is to be performed by trial. The usual way is to take out the pieces singly, at different times, and observing when the colours and the varnishing are as bright and perfect as they should be. The fire is then to be put out by degrees, and the furnace gradually cooled. *Observat. sur les Coutumes de l'Asie.*

BA'LANCE *(Dict.)*— If a weight of a known magnitude be hung at one end of a Balance, we may find the fixed point about which the Balance and weight will be in equilibrio, in the following manner:

Having suspended the given weight D (see *Plate* IX. *fig.* 28. of the Dictionary) equal to four pounds (for example) at the end A of the Balance A B, which weighs also four pounds; since the weight of the Balance is considered in this operation, we must suppose the whole weight of the Balance reduced into its center of gravity, as if the weight E of four pounds hung at C the center of gravity of the Balance, which is at its middle division 6: then we shall have a new Balance (viz. A C) without weight, at whose ends hang the weights D and E, whose fixed point will (by a known prop.) be easily found; or more generally by this analogy:

As D + E (or the weight of the body and the weight of the Balance):

Is to E (the weight of the Balance)::

So is C A (half the length of the Balance):

To A 3 (the distance of the fixed point from the given heavy body.)

Let the steel-yard P W (See *Plate* IX. *fig.* 27, in the Dictionary) be taken off of its hook K, and let its center of gravity C be placed upon a fulcrum or triangular prism D E; and, instead of the weight 1 hanging at P to keep in equilibrio the weight W of 4 pounds, let an animate power, as the hand, be applied at P: the statera or steel-yard will then be turned into a lever, whose fulcrum or fixed point is between the ends as at C, in which case the power may be four times less in intensity than the weight; but equal to it, if C or the fulcrum was removed to M (the middle point of P W) and four times greater, if C was removed to 3. See LEVER, in the Dictionary.

Assay BALANCE, a very nice Balance, used in docimastical operations, to determine exactly the weight of minute bodies.

This Balance should be made of the best steel: for it may be constructed much better of this metal, which must be of the hardest kind, though sufficiently tractable, than of any other matter. Besides, steel is not so easily spoiled with rust, as iron; and it is more apt than other metals to take a perfect polish, which at the same time prevents the rust.

The structure of the assayer's scale is little different from that of common scales, otherwise than by its nicety and smallness. The longer the beam of it *(Plate* VI. *fig.* 2.) is, the more exact may the weight of a body be found: however, ten or twelve inches are a sufficient length. Let the thickness of it be so very small, that two drachms may hardly be hung at either of its extremities, *a*, *b*, without its bending. For the largest weight put upon it seldom exceeds one drachm. The whole surface of this beam must be altogether without ornaments, which only increase the weight, and gather dust, &c. The beam is suspended in a fork, *fig.* 3. the two legs of which are steel-springs joined at top, but kept together below with a brass, pliant clasp, *fig.* 4. parallel, and two lines and an half distant from each other. This clasp being taken off, and the legs of the fork being stretched out, the axis of the beam may be put into two holes *a a* made for that purpose at the ends of the legs, or be taken away from them. Let a very sharp needle *c* be fixed in the head of the fork, standing perpendicularly downwards, if the fork is suspended, and so long, as that it may almost touch the top of the tongue of the beam *(plate* VI. *fig.* 2. *c)* put into the fork, when in equilibrio. This needle is the mark of the equilibrium; and, that the artists may be able to observe this, the legs of the fork must be broader in that place, and have an opening two or three lines wide. However, this fork may be adorned at pleasure, provided the motion of the Balance is not hindered by such ornaments. Then take two scales (A A *fig.* 5.) made of a thin plate of silver, one inch and a half in diameter, hanging on three small silk-strings, almost as long as the beam, tied together at top with a silver hook, in form of an *S*, and hang them to the extremities of the beam. A smaller silver-dish, somewhat less than one inch in diameter, belongs to each of these scales, as B, or, if made of steel blued over charcoal, they are less apt to wear. You first put into these dishes, with a pair of pincers, the bodies to be weighed, or with a spoon or a small shovel, when they are pounded, and then you put them into the scales: therefore, the small dishes must be perfectly equal in weight. We use them, that bodies may be more conveniently put into and taken out of the scales, and that these, which are vastly thin, may not be bent or soiled, and so be rendered false by wiping.

This Balance is suspended on a moveable brass or copper-support, which consists of a pedestal, *fig.* 6. *a*, and of a column set upon it *b* about twenty inches high, at the top of which comes out at right-angles an arm *c* one inch long. At the extremity of this arm, put a small pulley *d* three lines in diameter: put another at the top of the column *e*, and a third near the bottom of it *f*: all which pullies must turn very easily on their axes. At the distance of one inch and a half below the upper arm, let another arm *g* one inch and a half long come out of the column at right-angles, having a hole through it *h* two lines long, a quarter of a line broad, and placed perpendicularly below the pulley of the upper arm *f*, to receive a small plate *i*, one inch and a half long; and of such breadth and thickness, as that it may freely move up and down, and yet not have too much play within the hole. This plate must also have a small hook at each extremity.

And as such a Balance will hardly stand still in the open air, and becomes false, when spoiled with dust: it must be put together with its support into a small case, *fig.* 7. having glasses *a*, *a*, *a*, at top and all round it, that you may see what is within.

Manner of using the Assay BALANCE.— Pass a silk string over the three pullies of the support, *fig.* 6. *e f d*, and tie it at its upper extremity to the small hook of the plate *i*, which is then introduced into the hole of the inferior arm *h*. Then put the support in the middle of the small case, and pass the other extremity of the silk-string below, through a hole bored in the middle of the lower border of the frame, containing the window in the fore-part of the case, and fasten it to a weight of a few ounces *k*, reduced into a cubic form. Suspend the fork of the Balance, *fig.* 3, on the inferior hook of the plate *i*, *fig.* 6. By this means, if you move backwards and forwards, the weight fastened to the string *k*, placed upon the top of the draw, that juts out beyond the fore-part of the case, the Balance within is either lifted up, or let down. But you must put the bodies to be weighed, and the weights themselves, in the small silver-dishes, *fig.* 5, and these, when loaded, into the scales, through the side-windows, which must be opened for that purpose. When any thing is to be added to, or taken out of them, you do it with the small pincers, or, if it is powder, with the small shovel or spoon. However, you must let the Balance down, every time any thing is to be added, or taken away; that the scales may rest upon the bottom of the case: but then you must shut the windows, before the Balance is lifted up again, especially if the air is not perfectly calm.

BALANCE, in merchants accounts, is, when the debtor and creditor sides of any distinct account are equal. When that is the case, such account is said to be balanced.

Balance of a merchant's or trader's books. This is a branch of the art of accountantship. In the method of keeping the books of traders, according to that admirable art of charge and discharge, by double entry, such books, if kept as they ought to be, will be always fit for a general Balance. For such is the excellency of that method, that the books of themselves must be necessarily upon a Balance upon the whole, though not in every distinct account throughout the ledger.

BALANCE *of Trade (Dict.)*— It is necessary that this Balance be kept in trading nations; and, if it cannot be made in commodities, it must in specie.

Hereby it is that we know whether a nation gains, or loses, by foreign trade, or any branch thereof; and consequently, whether that nation grows richer or poorer.

There are divers methods of arriving at this knowledge.

1. That most received is, by taking a strict survey of what proportion the value of the commodities exported bears to those imported. If the exports exceed the imports, it is concluded that nation is in a gaining way, it being supposed that the overplus is imported in bullion, and so increases the treasure of the nation.— But this method is uncertain, by reason of the difficulty of obtaining a true account either of the exports or imports. 1. Custom-house books are no rule in this case; by reason of the running of goods, especially many fine commodities of small bulk but great value: as point, lace, ribbands, silks, jewels, fine linens, &c. also wines, brandies, teas, and the like. 2. To which add various accidents which affect the value of the stock either sent out or brought in; as losses at sea, markets, bankrupts, seizures, &c. 3. Then, as to particular trades, there are divers countries to which the manufactures we send out are inconsiderable, yet the goods we import are necessary to the carrying on our trade in general; as the trade to Norway, &c. for timber and naval stores. Also the East-India company, whose imports much exceed their exports, yet is their trade highly advantageous to the nation: as we sell much of these imports to foreigners, and wear others, *e. gr.* callico's and silks in lieu of linens, and silks, from other countries, which would cost us dearer.

2. The second method is by observing the course of exchange, which if generally above the intrinsic value or par of the coins of foreign countries, we not only lose by such exchanges, but the same is a proof that we lose by the general course of our trade.— But this method is imperfect; since we

trade

trade to many countries with which there is no ſettled courſe of exchange.

3. The third method (which is Sir Joſ. Child's) is made from the increaſe or diminution of our trade, and ſhipping in general: for, if theſe diminiſh, whatever profit particular men may make, the nation loſes: and vice verſa. He lays it down as an infallible rule, that in all parts of the world wherever trade is great, and continues ſo, and grows daily greater, and the ſhipping increaſes for a ſucceſſion of ages; that trade muſt be nationally profitable. Even in the caſe of a merchant, who by driving a great trade ruins himſelf; though he loſe, what a multitude are gainers by him? as the king, and cuſtom-houſe officers; beſides ſhip-wrights, butchers, brewers, bakers, ropemakers, porters, carmen, manufacturers, mariners, &c.

4. A fourth way is, by obſerving the increaſe and diminution of our coin and bullion.—But this is the leaſt obvious and palpable of any; for the money ſeems to vulgar eyes moſt plentiful, when there is leaſt occaſion for it; and more ſcarce, as the occaſions for employing it are more numerous and advantageous: by which means we ſeem to have moſt money when we have leaſt trade. Thus *e. gr.* when the Eaſt-India company have a great ſale to make, money is generally found to be ſcarce in London; becauſe the occaſion engages people to employ quantities which they had provided for that purpoſe. So a high rate of intereſt will make money ſeem ſcarce, becauſe every man, as ſoon as he can make up a ſmall ſum, ſends it to the goldſmith to be employed. *Child's Diſc. on Trade, c.* 9.

BALE *Goods*, in the Eaſt-India trade, the bulky goods, as ſalt-petre, pepper, red-earth, tea, &c.

BALES *of Camelet*, at Smyrna, are called tables, on account of their flat ſquare figure.

BALE *of Paper*, denotes a certain number of reams packed together in a bundle.

There are Bales of more and fewer reams. Thoſe ſent from Marſeilles to Conſtantinople uſually contain twenty-four reams.

A Bale or ballon of crown paper, manufactured in ſome parts of Provence, conſiſts of 14 reams, and is ſold in the Levant for Venice paper.

BALE *of Dice*, denotes a little packet or paper containing ſome dozens of dice for playing with.

BALL, a ſpherical and round body, either naturally ſo, or turned into that form. There are Balls of common wood, of box, of iron, &c.

The word Ball is alſo uſed to ſignify ſome tools and inſtruments of ſeveral arts and trades, becauſe they bear ſome reſemblance to Balls. Thus,

A Ball, or ſphere, is an inſtrument uſed by the optic-glaſs-makers: it is a piece of copper, iron, or ſome compound metal, cut into the form of an hemiſphere, or half Ball, to which a handle is joined with maſtic; with this inſtrument, thoſe workmen make the concave-glaſſes, which ſerve for teleſcopes, or ſpying-glaſſes, microſcopes, and other inſtruments of that kind.

There are Balls or ſpheres of ſeveral ſizes, according to the radius of the focus which the glaſſes require. They uſe thoſe Balls for concave-glaſſes, by applying them hard, and turning them upon the plate of glaſs, which is laid flat upon the former; contrary to what is done with regard to convex-glaſſes, which are worked in a kind of baſon. This difference excepted, the ſame methods are uſed in forming, ſmoothing, and poliſhing both ſorts. Balls are alſo ſet upon a lath or turning-wheel, as are likewiſe baſons for the ſame purpoſe. See the article TURNING.

BALL, in the military and pyrotechnical arts, is a compoſition of divers ingredients, generally of the combuſtible kinds, ſerving to burn, ſmoak, give light, &c.

Fire BALLS, *globi incendiarii* are bags of canvas filled with gun-powder, ſulphur, ſalt-petre, pitch, &c. to be thrown by the ſoldiers, or out of mortars, in order to fire the houſes, incommoding trenches, advanced poſts, or the like.

The preparations of fire Balls, among the moderns, conſiſts of ſeveral operations, viz. making the bag, preparing the compoſition, tying, and laſtly dipping the Ball.

The Bags for this purpoſe are either oval or round. *V. Wolf. l. c. ſect.* 48.

The compoſition wherewith fire Balls are filled, is various, To ten pounds of meal-gunpowder, add two of ſalt-petre, one of ſulphur, and one of colophony: or, to ſix pounds of gunpowder, add four of ſalt-petre, four of ſulphur, one of powdered-glaſs, half a pound of antimony, as much camphor, an ounce of ſal-ammoniac, and four of common ſalt, all pulverized. Sometimes they even fill fire Balls with hand-granadoes.

For tying the fire Balls, they prepare two iron rings, one fitted around the aperture, where the Ball is to be lighted, the other near its baſe. A cord is tied to theſe rings, in ſuch a manner, as that the ſeveral turns repreſent ſemicircles of the ſphere, cutting the globe through the poles: over the cords, extended according to the length of the Ball, others are tied, cutting the former at right-angles, and parallel to each other, making a knot at each interſection. Laſtly, putting in a leaden bullet, the reſt of the ſpace is filled with tow or paper. Thus compleated, the fire Ball remains to be dipped in a compoſition of melted pitch four pounds, colophony two, and linſeed-oil, or oil of turpentine two; after dipping, they cover it round with tow, and dip again, till it be brought to the juſt diameter required.

Light BALLS, *Globi lucentes*, are ſuch as diffuſe an intenſe light around; or they are Balls which, being caſt out of a mortar, or the hand, burn for ſome time, and illuminate the adjacent parts.

Luminous or light Balls, for the hand, are made of ground powder, ſalt-petre, brimſtone, camphor, and borax, all ſprinkled with oil, and mouldered into a maſs with ſuet and common and Greek pitch, to the ſize of an ordinary granado: this is wrapped up in tow, with a ſheet of ſtrong paper over it. To fire it, they make a hole into it with a bodkin, into which they put ſome priming, that will burn ſlow. Its uſe is to be caſt into any works they would diſcover in the night-time. *Millit. Dict.*

For the larger light Balls, or thoſe to be thrown to a greater diſtance, they melt equal quantities of ſulphur, turpentine, and pitch; and herein dip an earthen, or ſtone Ball, of a diameter much leſs than that of the mortar out of which the fire Ball is to be caſt: then rolling it in gunpowder, and covering it round with gauſe, they dip it again, and repeat the reſt till it come to fit the cavity of the mortar: laſtly, they ſprinkle it around with gunpowder. This, being once kindled, will ſtrongly illuminate all round the place where it is thrown, and give opportunity to examine the ſtate and condition thereof.

Smoak or Dark BALLS, thoſe which fill the air with ſmoak, and thus darken a place, to prevent diſcoveries. To prepare a darkening Ball, make an oval or ſpherical bag, melt roſin over the coals, and add an equal part of ſalt-petre not purified, alſo of ſulphur, and a fifth part of charcoal. The whole being well incorporated, put in tow firſt ſhred, and fill the bags with this compoſition, and dip it after the ſame manner as a fire Ball.

Stink BALLS, *globi fœtentes*, thoſe which yield a great ſtench, where fired to annoy the enemy.

Their preparation is thus; melt ten pounds of pitch, ſix of roſin, twenty of ſalt-petre, eight of gunpowder, and four of colophony; to theſe add two of charcoal, ſix of horſe-hoofs cut ſmall, three of aſſafœtida, one of ſtinking ſaracen, and any other offenſive ingredients. The reſt as in the former.

Sky BALLS, *globi aerii*, thoſe caſt on high out of mortars, and which, when arrived at their height, burſting like rockets, afford a ſpectacle of decoration. Sky Balls are made of a wooden ſhell, filled with various compoſitions, particularly that of the ſtars of rockets.

Theſe are ſometimes intermixed with crackers, and other combuſtibles, making rains of fire, &c.

Water BALLS, *globi aquatici*, thoſe which ſwim, and burn a conſiderable time in the water, and at length burſt therein.

Theſe are made in a wooden ſhell, the cavity of which is filled with refined ſalt-petre, ſulphur, ſaw-duſt boiled in water of ſalt-petre, and dried; to which ſometimes other ingredients are added, as iron-filings, Greek pitch, amber-duſt, glaſs powdered, and camphor. The ingredients are to be ground, mixed up, and moiſtened with linſeed-oil, nut-oil, olive-oil, hempſeed-oil, or petrol. At the bottom is placed an iron coffin, filled with whole gunpowder, that the Ball may at laſt burſt with a greater noiſe; and, laſtly, the Ball is, by the addition of lead, or otherwiſe, made of the ſame ſpecific gravity with water.

BALL *of a Pendulum*, the weight at the bottom. In ſhorter pendulums, this is called the bob.

BALL, among the Corniſh miners, ſignifies a tin-mine.

BALL, among printers, a kind of wooden tunnel ſtuffed with wool, contained in a leather cover, which is nailed to the wood; with which the ink is applied on the forms to be wrought off.

The preſs-man, holding one of theſe Balls with either hand, firſt daubs them on the ink-block, and afterwards on the forms, which retain the ink neceſſary to make an impreſſion.

Horſe BALLS, among farriers, a kind of cordial medicine, adminiſtered in the form of Balls, ſuppoſed of great virtue for feeding and ſtrengthening ſound, as well as healing and raiſing unſound horſes.

Markham's horſe Balls, are a preparation of aniſeeds, carthamus, elicampane, and other ingredients, wrought into a ſtiff paſte, and thence formed into Balls. They are cleanſing and emollient, efficacious in colds, ſurfeits, and hard labour, and eſpecially uſeful where any of the chief viſcera are decayed: nothing raiſes a lean jade ſo ſoon, being partly food and partly phyſic. *Ruſt. Dict. Farr. Dict.*

Chewing BALLS, are thoſe which the horſe is to keep champing, or maſticating in his mouth, a conſiderable time, without ſwallowing. Theſe are chiefly uſed for a loſt appetite, a thing very incidental to horſes.

They are uſually made of aſſafœtida, liver of antimony, juniper, bay-wood, and pellitory of Spain, beaten and incorporated into a maſs with verjuice. The method of adminiſtration

ſtration is to wrap one of the Balls in a linen cloth, and, having a ſtring faſtened to it, make the horſe chew it three or four hours at a time. *Ruſt. Dict.*

BALL *Vein*, in minerology, a name given by the miners of Suſſex to a ſort of iron ore, common there, and wrought to conſiderable advantage. It yields not any great quantity of metal, but what it has runs freely in the fire; it is uſually found in looſe maſſes, not in the form of ſtrata, and is of ten covered with one or more cruſts. It generally contains ſome ſparkling particles, and is uſually of a circular form, in the perfect maſſes; thickeſt in the middle, and gradually thinner, as it approaches the ſides. The ores of Suſſex in general are poor, but they require very little trouble in the working; ſo that a conſiderable profit is made annually from them.

BA'LLANCERS, in natural hiſtory, two ſmall oblong bodies, placed under the wings of the two-winged flies, and in ſome meaſure ſupply the office of the two other wings, which thoſe of the four-winged claſs are poſſeſſed of.

BA'LLUSTER, or BALLISTER, in architecture, a kind of column or pillar, whereof balluſtrades are formed.

BA'LSAM *of Life*. See BALSAMUM *Vitæ*.

Odoriferous BALSAMS, are a fragrant kind of unguents, generally of a thick conſiſtence, compoſed of ſome fatty, denſe juice, joined with ſome diſtilled oils of divers kinds.

Boerhaave's method of preparing theſe Balſams, which is this: melt an ounce of fine pomatum, in a China veſſel, over a ſmall and perfectly clear fire; then gradually add a drachm of white wax, ſhaved into thin pieces. After theſe are perfectly blended together, remove the veſſel from the fire; and, when the matter begins to thicken in cooling, drop in, by ſlow degrees, a drachm of any of the fragrant eſſential oils; keep the whole continually ſtirring, all the time the oil is dropping in, that it may perfectly mix. After which, ſet the veſſel in cold water, that the whole matter, immediately condenſing by the cold, may keep in the oil and ſpirit. When the Balſam is thoroughly cold, put it immediately up in veſſels of lead or pewter; and, if theſe are cloſe covered, it will keep perfect a great many years.

Inſtead of pomatum and wax, the expreſſed oil of nutmeg may be uſed in this proceſs, after it has been waſhed in water, till perfectly inſipid, white, and inodorous.

If theſe Balſams are required to be of any colour, it may be eaſily given at pleaſure. A ſcruple of fine cochineal, in fine powder, will tinge the Balſam of a fine purple; or the ſame quantity of the inſpiſſated juice of buckthorn-berries, to a fine green; a little native cinnabar will turn it ſcarlet: turmeric yellow; and ſmalt, to a beautiful blue. Any of theſe may be uſed at pleaſure, provided that they have no ill ſmell, or hurtful properties.

Theſe Balſams are prepared as rich perfumes, to raiſe the languid ſpirit; and the nobleſt and richeſt of the eſſential oils ſhould therefore be uſed in them. The oils, principally directed by Boerhaave to this purpoſe, are thoſe of balm, calamus aromaticus, cinnamon, cedar, citron, cloves, jaſmin, lavender, white lillies, marjoram, mace, nutmegs, origanum, oranges, both thoſe of China and Seville; roſes, rhodium, and yellow ſaunders; to which may be added, the natural Balſams of Peru and Gilead; theſe two being ſpontaneouſly fragrant without diſtillation. *Vid. Boerh. Chem.*

BA'LSAMINA, *Balſamine*, in botany, the name of a genus of plants, whoſe characters are: the flower is of the polypetalous anomalous kind, and is, in ſome ſpecies, four-leaved, and, in others, ſix-leaved. In the four-leaved flowers, the upper leaf is arched, and the lower hollowed, and terminated by a tail, and the two ſide-leaves are large. In the ſix-leaved flowers of this genus, the flower-leaf has no tail.

In both the piſtil, which is furniſhed with two leaves, occupies the middle part of the flower, and, at laſt, becomes a fruit; ſometimes turbinated at one end, or both, and ſometimes emulating the ſhape of a pod, conſiſting of ſeveral muſcles, as it were, and endued with an elaſtic force, and flying open with great violence. The ſeeds it contains, are fixed to the axis or placenta. See it repreſented in *Plate* VI. *fig.* 8.

Mr. Miller has enumerated nine, and M. Tournefort nineteen ſpecies of Balſamina.

The common white, red, and purple kinds of this plant will come up in common ground, without any artificial heat; and even be the ſtronger, and flower better, than if raiſed on hot beds. All the other varieties are raiſed from ſeeds ſown on hot beds in the ſpring, and afterwards planted into pots and borders. But the fine double large kind, or immortal eagle-flower, as it is called, requires to be ſet on a freſh hot bed, after it has been raiſed on one, in order to bring it forward; otherwiſe it will not get into flower till late in the year, and will not ripen its ſeeds; there are two kinds of this beautiful ſpecies; one brought from the Weſt-Indies, and called the cock's-ſpur, which produces large and ſtrong plants, but flowers very late: the other is from China, and called the immortal eagle-flower, and is one of the fineſt annual plants we have, producing large double flowers, and continuing a long time in flower, if ſheltered from violent winds and rain. This produces ſeeds very well with us; but, after a few years, they are apt to degenerate into ſingle flowers.

When the young plants are raiſed in a hot bed, and are to be planted out into pots, ſuch are always to be preferred as have ſtalks finely ſpotted with red; for theſe always produce red and double flowers. *Miller's Gard. Dict.*

BALSA'MUM *Traumaticum*, vulnerary balſam, a form of medicine preſcribed in the London Diſpenſatory, intended to ſupply the place of the tincture, commonly called the Friars balſam, ſo famous for curing freſh wounds. It is made thus: take of benjamin three ounces, ſtrained ſtorax two ounces, balſam of Tolu one ounce, ſuccotrine aloes half an ounce, rectified ſpirit of wine a quart; digeſt them together, till as much as may be of the gums are diſſolved, and then ſtrain off the ſpirit. *Pemberton's Lond. Diſpenſ.*

BALSAMUM *Vitæ*, *balſam of life*, the name of a celebrated medicine, prepared by the learned Hoffman.

This preparation is found under the title of Balſamum Vitæ Hoffmani, in the Straſburg and Ratiſbon Diſpenſatories; and is taken, with a little variation, from the author's notes on Poterius; where the following inſtructions are given for its preparation:

Take of the freſh diſtilled oils of lavender, marjoram, cloves, cubebs, cardamoms, and citron, each one ſcruple; of the oil of cinnamon, twenty-four drops: of the oils of rue and white amber, each half a ſcruple: let theſe oils be mixed together, and ſtand for ſome weeks.

When therefore we want the extemporaneous balſam of life, let ten drops of theſe oils be poured into an ounce of highly rectified ſpirit of wine. And, if we intend it ſhould be rendered more grateful, half a ſcruple of ambergriſe may be previouſly diſſolved in the oils. But this medicine will ſtill be impregnated with higher balſamic qualities, if to one ounce of it we add half a drachm of Peruvian balſam, by which it is rendered good againſt apoplexies, and is of ſingular uſe both internally and externally. Internally, it may be given from ten to twenty drops in weakneſſes, cholic pains, faintings, and lowneſs of ſpirits; and, externally, in all weakneſſes of the head, as alſo in ſpaſmodic and lethargic diſorders; it may be applied to the noſe, the wriſts, the nape of the neck, and the crown of the head.

BA'MBOE, or BAMBOU, as they ſpell that word in the Indies, and not bamboue. It is a plant that multiplies very much by its root, from which ſprings a ramous or branchy tuft, after the manner of ſome gramina, or, to ſpeak more naturally, after the manner of the European reeds; for the Bamboe is of the kind of reeds, as well as the ſugar-cane. The Indian Bamboe is the largeſt kind of cane that is known. It is of an extraordinary heighth and bigneſs, when it bears its bloſſom; each ſhoot or cane is often, towards the bottom, of the bigneſs of a man's thigh, and decreaſes gradually to the top, where it bears a bloſſom or flower, like our reeds, in their proper ſeaſon. The Bamboe grows in all the maritime countries of the Eaſt-Indies. Monſieur Lemery calls it a tree, whoſe leaves reſemble thoſe of the olive-tree. But John Bohin, from whom he has extracted his deſcription, has miſled him: for it is not a tree, though it grows very high, even to 20 or 25 feet, and ſometimes to 30. Its leaves are like thoſe of the other canes or reeds, except that they are not ſo long, nor ſo broad at their baſe, as thoſe of the other kinds: they are but half a foot long, and their breadth, towards the middle, is an inch, or ſometimes more. With theſe canes of Bamboe, the Indians build their houſes. and make all ſorts of furniture, in a very ingenious manner. The wood of theſe canes is ſo hard and ſtrong, that they ſerve very well to make piles for ſupporting their little houſes, built over rivers, which have a gentle courſe, as it were over ſtanding waters. They alſo make, with this wood, all ſorts of utenſils for their kitchens and tables. The thickeſt Bamboes ſerve to make the ſticks or poles, with which the ſlaves or other perſons carry thoſe ſorts of litters, which are called palanquins, and are of ſo common an uſe, and ſo convenient in all the Eaſt. They alſo make of that wood a kind of pales, in which the water keeps extremely cool. The walking-canes which we ſee in Europe, are the firſt and ſmalleſt ſtocks of the Bamboes. The Malays and theſe Chineſe, who are diſperſed in the Molucca and Sunda iſlands, uſe the young ſmall ſhoots of the Bamboes, preſerved in vinegar, after their manner, with very ſtrong or peppered ingredients. This they call achior Bamboe. For they give the name of achior to all that is preſerved in vinegar, and, to diſtinguiſh it, they add, to the name of achior, that of the thing preſerved.

BANA'NA, a name uſed by many authors for the muſa, or plaintain-tree, of the common kind; but more frequently, with us, underſtood to mean another ſpecies of the ſame genus, which the Portugueſe call pacoeira, and we, particularly, the Banana-tree. *Piſo.*

The difference between the two is this; the muſa has a green ſtalk, and a long, crooked, angular, fruit, reſembling a crooked cucumber; the Banana, a ſpotted ſtalk, and a round fruit. *Dale Pharm.*

BANDALEER, or BANDALEER, a kind of belt worn over the body, from the left to the right. It is uſed by horſemen to carry their carbines and muſketoons, and was formerly

uſed

ufed by the foot, to faften to it thofe fmall leather cafes, which they call charges. The ordonnance, or regulation publifhed in France, in the year 1687, puts the Bandaliers among the contraband merchandizes, the exportation of which is prohibited.

BANDS *of iron*, a term ufed by blackfmiths and others, to fignify thofe long, narrow, and flat pieces of iron, which they forge, to faften, ftrengthen, or fupport, feveral works of timber or bricks.

Bands are alfo thofe iron plates which are faftened with large nails to the jaunts of the wheels of coaches, carts, and other carriages. In France and elfewhere, thefe Bands are made of feveral pieces, but, in Holland and Lombardy, the Band is but one large iron hoop, which covers all the jaunts. This method of ftrengthening wheels begins to be ufed at Paris, and is indeed the beft.

BANK, in natural hiftory, denotes an elevation of the ground, or bottom of the fea, fo as fometimes to furmount the furface of the water, or, at leaft, to leave the water fo fhallow, as ufually not to allow a veffel to remain a-float over it.

In this fenfe, Bank amounts to much the fame as flat, fhoal, &c. There are Banks of fand, and others of ftone, called alfo fhelves, or rocks. In the North-fea, they alfo fpeak of Banks of ice, which are large pieces of that matter floating. *Aubin. Dict. Marin.*

Banks are ufually diftinguifhed by a buoy, poft, or the like. On charts, fand Banks are ufually marked by little dots, and banks of ftone, by croffes. The colours of the buoys are alfo varied accordingly; fand Banks being denoted by light-coloured buoys, and rocks by black ones.

In large rivers, as the Elbe, &c. fand Banks, by high tides and inundations, are liable to change places; care is therefore taken to fhift the buoys from time to time, to fhew the true channel of the river.

An exact knowledge of the Banks, their extent, and the depth of water on them, makes the moft effential part of the fcience of a pilot, and a mafter of a fhip; if the veffel be large, and draw much water, great attention will be neceffary to keep clear of the Banks; on the contrary, if it be fmall, the fame Banks afford a fure afylum, where it may brave the largeft and ftouteft veffels, which dare not follow it here. By means of this barrier, many fmall craft have efcaped its enemy.

BA'NKER, in bricklaying, a piece of timber whereon they cut the bricks.

The Banker is fix feet long, or more, according to the number of men to work at it, and nine or ten inches fquare: it is to be laid on two piers of timber, three feet high from the floor they ftand on. *Moxon. Mech. Exerc.*

BA'NKING, the making of banks to oppofe the force of the fea, rivers, or the like, and fecure the land from being overflowed thereby.

With refpect to the water which is to be kept out, this is called Banking; with refpect to the land, which is thereby to be defended, imbanking.

BANKING, in a falt work, the raifing a fence againft the fea, whereby its waters may be kept out, excepting fo much as is neceffary for the preparation of the falt.

BA'NNER, properly denotes a fquare flag, faftened like a cornet to a lance. *Dict. de Trev.*

A Banner differed from a pennon, or guidon, which had a long tail, or train; the cutting of which, in the ceremony of creating a banneret, converted it into a Banner.

BA'NQUET, in the manage, denotes that fmall part of the branch of a bridle under the eye; which, being rounded like a fmall rod, gathers and joins the extremities of the bit to the branch, in fuch a manner, that the Banquet is not feen, but covered by the cap, or that part of the bit next the branch.

BA'NTAM-WORK, a kind of Indian painting, and carving on wood, refembling Japan work, only more gay, and decorated with a great variety of gaudy colours.

Bantam work is of lefs value among conoiffeurs, though fometimes preferred, by the unfkilful, to the true Japan work. Formerly it was in more ufe, and efteem, than at prefent, and the imitation of it much practifed by our Japanners.

There are two forts of Bantam, as well as of Japan work; as, in the latter, fome are flat, lying even with the black, and others high or emboffed; fo, in Bantam work, fome are flat, and others in-cut, or carved into the wood, as we find in many large fcreens; with this difference, that the Japan artifts work chiefly in gold and other metals, and the Bantam generally in colours, with a fmall fprinkling of gold here and there.

For the flat Bantam work, it is done in colours, mixed with gum-water, proper for the thing defigned to be imitated.

For the carved, or in-cut kind, the method of performing it is thus defcribed by an ingenius artift: 1. The wood is to be primed with whiting and fize, fo often, till the primer lie near a quarter of an inch thick; then it is to be water-plained, i. e. rubbed with a fine wet cloth, and, fome time after, rubed very fmooth, the blacks laid on, varnifhed up with a good body, and polifhed well, though with a gentle hand. This done, the defign is to be traced out with vermilion and gum-water, exactly in the manner wherein it is intended to be cut; the figures, trees, buildings, &c. in their due proportions. Then the graver is applied, with other tools of proper fhapes, differing according to the workman's fancy. With thefe he cuts deep or fhallow, as is found convenient, but never deeper than the whiting lies; the wood being never to feel the edge of the inftrument. Lines, or parts of the black, are ftill to be left, for the draperies, and other outlines, and for the diftinction of one thing from another; the rule being to cut where the white is, and leave the black untouched. The carving being finifhed, then take to the pencil, with which the coloursare laid into the cut work. After this, the gold is to be laid in thofe places which the defign requires; for which purpofe, a ftrong, thick gum arabic water is taken, and laid with a pencil on the work; and, while this remains wet, leaf gold is cut with a fharp fmooth-edged knife, in little pieces, fhaped to the bignefs and figure of the places where they are to be laid. Thefe being taken up with a little cotton, they dab them with the fame clofe to the gum water, which affords a rich luftre. The work thus finifhed, they clear up the black with oil, taking care not to touch the colours. The European workmen ordinarily ufe brafs duft, which is lefs bright and beautiful. *Park. Treat. of Japan, c.* 13. *p.* 37 *& feq.*

BA'RBERRY-*Tree*, *berberis*, is very eafily and plentifully propagated from the fuckers taken from the roots of the old plants, which may be planted either in October or February, and fucceed beft in a ftrong loamy foil. They may be either produced from feeds, or by laying down the branches; but the fuckers are commonly fo plentiful, as to make it unneceffary. *Miller's Gard. Dict.*

This medicinal fhrub is ufed, both in the berry and bark, though with oppofite intentions.

The berry is of an agreeable, cooling, aftringent tafte, ufed chiefly in conferve to quench thirft, and ftrengthen the ftomach: yet the bark is, by experience, found an aperient and detergent. That which grows neareft the tree is moft efteemed. It is rarely found in difpenfatory compofitions, but much in extemporaneous prefcription, againft the jaundice, and other diforders from foulnefs and obftructions of the vifcera. *Quinf. Difpenf.*

BA'RBUS, in zoology, the fifh called in Englifh the barbel, and, by fome writers in natural hiftory, muftus fluviatilis. It grows to a foot, or fomewhat more, in length: its back is of a dufky, brownifh, olive colour, but with a palenefs not common with other fifh: its belly is of a filver white: its back and fides are fpotted with black fpots: the figure of its body is long and rounded, and its back rifes into a prominence and fharp ridge; its fcales are of a moderate fize, and its fide lines dotted: its mouth is large, but toothlefs: and its upper jaw hangs out a great way beyond the lower: it has four beards, two at the angles of the mouth, and two near the edge of the jaws; and in the middle of thefe there runs a flender red vein: it has only one fin on the back, and its tail is forked. Its flefh is lax and foft, and there is an opinion that its fpawn is poifonous. It is caught in many of our rivers, and in thofe of other parts of the world. *Ray's Ichthyog. Gefner, de Pifc.*

The barbel is a fifh commonly known, and fo called, on account of the barb or beard under its nofe, or chaps. It is of the leather-mouthed kind.

This is but a moderately well tafted fifh. The male is efteemed better than the female; but neither of them is very much valued. The worft feafon for them is April. They ufually fwim together in great fhoals, and love to be among weeds, where there is a hard, gravelly bottom. In fummer they frequent the ftrongeft and fwifteft current of the water, as deep bridges, weirs, and the like places, and are apt to get in among the piles, weeds, and other fhelter; but, in winter, they retire into the deepeft and ftilleft waters.

The time for taking this fifh is very early in the morning, or late in the evening: the place fhould be baited with chopped worms fome time before; and no bait is fo good for the hook as the fpawn of the falmon, or fome other fifh: in defect of thefe, lob-worms will do; but they muft be very clean and nice, and the hook carefully covered, otherwife he will not touch them. Old cheefe fteeped in honey is alfo a very fine bait. The rod and line for fifhing for this fifh ought to be very ftrong: the line fhould have a running plummet, that is, a bullet with a hole through it; and a piece of lead muft be placed a foot or more above the hook, to keep the plummet from falling upon it; the worm, or other bait, will, by this means, always be at the bottom; and the plummet will lie, and not choak the fifh: the bending of the rod will fhew when he bites, but indeed it will be felt in the hand by the twitch he gives; but, if not carefully managed, he will often break the tackle, for he is a very ftrong fifh. The beft feafon for fifhing for this fifh is from May to Auguft.

BARDA'NA, *burdock*, in botany, the name of a genus of plants, the characters of which are thefe: the flower is of the flofculous kind, being compofed of feveral flofcules, jagged at the ends, placed upon the embryo feeds, and contained in one general cup, which is of a fquammofe ftructure; each of the hooks of the whole being fo bent back, as to lay hold of any thing which touches it. The embryo's finally ripen into feeds, winged with a fhort down.

The

The root of the common burdock is a very powerful diuretic and diaphoretic. It is given, with great ſucceſs, in decoction, in obſtructions of the ſpleen, and in dropſies. It is alſo recommended by ſome in all diſeaſes of the breaſt and lungs, in aſthmas, in the ſtone, and in the ſciatica. The ſeed of it is eſteemed by many to be one of the greateſt lithontriptics known; and, by the inſtances that have been produced of its doing ſervice in nephritic complaints, it ſeems to merit a fair trial. The freſh leaves are by ſome recommended as a dreſſing for old ulcers, and for burns and uxations. They are alſo applied, by the good women, to the ſoles of the feet, as a remedy in hyſteric complaints.

The ſection of a burdock-root, viewed with a microſcope, has the appearance repreſented in *plate* VI. *fig.* 10.

BARDE'LLE, in the manage, denotes a ſaddle made in form of a great ſaddle, but only of cloth ſtuffed with ſtraw, and tied tight down with packthread, without either leather, wood, or iron.

BA'RGAIN and *Sale*, in law, is properly a contract made of manors, lands, and other things, transferring the property thereof from the bagainer to the bargainee, for a conſideration in money.

It is a good contract for land, and the fee paſſes, though it be not ſaid in the deed, to have and to hold to him and his heirs; and though there be no livery and ſeiſin given by the vender, ſo it be by deed indented, ſealed, and inrolled, either in the county where the land lies, or in one of the king's courts of record at Weſtminſter, within ſix months after the date of the deed. *Blount.*

This manner of conveying lands was created and eſtabliſhed by the 27th of Henry VIII. cap. 10. which executes all uſes raiſed; and, as this introduced a more ſecret way of conveying than was known to the policy of the common law, therefore, the inrollment of the deed of Bargain and ſale was made neceſſary, by the ſixteenth chapter of the Statute. *New Abridgement of the Law.*

BA'RGHMOTE, or BARMOTE, a court which takes cognizance of cauſes and diſputes between miners. *Pett. Fodin. Regal. in fine.*

BARI'LLIA, in the glaſs-trade, a ſort of pot-aſhes, imported from Spain, inferior in goodneſs to that of the Levant; called pulverine, when looſe, ſmall, and in powder; and rochetta, when in hard, rocky lumps. *Neri's Art of Glaſs*, page 27.

BA'RKING of trees, is the peeling off, or ſtripping the bark from the wood.

The month of May is the ſeaſon for Barking of trees, becauſe then the ſap looſens the bark from the wood; which it is very hard to effect in any other time, unleſs the ſeaſon be very wet; heat and drineſs being always oppoſite thereto.

Maliciouſly Barking of apple-trees, or other fruit-trees, is made felony, by the 37th of Henry VIII. chap. 6.

BA'RLEY, *hordeum*, a gramineous frumentaceous plant, whoſe ſeeds are of the larger ſort, being covered with a huſk growing in a ſpike, and the grains bearded.

Cultivation of BARLEY.—Some people ſow Barley upon land where wheat grew the former year; but, when this is practiſed, the ground ſhould be plowed the beginning of October, in a dry time, laying it in ſmall ridges, that the froſt may mellow it the better; and this will improve the land greatly: then, in March, the ground is plowed again, and laid even, where it is not very wet; but in ſtrong wet lands the ground ſhould be laid round, and the furrows made deep, to receive the wet. When this is finiſhed, the ſeed ſhould be ſown with a broad caſt, at two ſowings; the firſt being harrowed in once, the ſecond ſhould be harrowed until the ſeed is buried: the common allowance of ſeed is four buſhels to an acre.

It is a very common fault with farmers to ſow too much grain of all ſorts on their land; not conſidering, that, if the roots of corn ſtand very cloſe together, there will not be room for them to put out many ſtems; ſo that, frequently, there is not more than two or three ſtalks to a root; whereas, if the roots were farther diſtant, there might be ten or twelve, and, on good land, many more. I have counted upward of ſeventy ſtalks of Barley from one root, which was tranſplanted in a garden, where the ground was light, but not rich: and I am ſatisfied, by ſeveral experiments, that, where Barley is ſown early upon light ground, it ſhould not be too thick; for, if it is rolled two or three times before it ſtalks, the roots, by being preſſed, will ſhoot out a greater number of ſtalks; and it will not be ſo liable to lodge with wet, as the Barley which is ſown thick; ſo muſt, conſequently, be drawn up much taller, and have weaker ſtalks.

When the Barley is ſown, the ground ſhould be rolled after the firſt ſhower of rain, to break the clods, and lay the earth ſmooth; which will render it better to mow, and alſo cauſe the earth to lie cloſer to the roots of the corn, which will be of great ſervice to it in dry weather.

Where Barley is ſown upon new broken up-land, the uſual method is, to plow up the land in March, and let it lie fallow until June; at which time it is plowed again, and ſown with turneps, which are eaten by ſheep in winter; by whoſe dung the land is greatly improved; and then in March following the ground is plowed again, and ſown with Barley as before.

There are many people who ſow clover with their Barley; and ſome have ſown the lucern with Barley; but neither of theſe methods is to be commended; for, where there is a good crop of Barley, the clover or lucern muſt be ſo weak, as not to pay for ſtanding; ſo that the better way is to ſow the Barley alone, without any other crop among it; and then the land will be at liberty for any other crop, when the Barley is taken off the ground: but this practice of ſowing clover, rye-graſs, and other graſs ſeeds, with corn, has been ſo long and univerſally eſtabliſhed among farmers, that there is little hope of prevailing with thoſe people to alter a cuſtom which has been handed down to them from their predeceſſors; although there ſhould be many examples produced, to ſhew the abſurdity of this practice.

The time for cutting of Barley is, when the red colour of the ears is off, and the ſtraw turns yellow, and the ears begin to hang down: in the north of England they always reap their Barley, and make it up in ſheaves, as is practiſed here for wheat; by which method, they do not loſe near ſo much corn, and it is alſo more handy to ſtack; but this method cannot ſo well be practiſed, where there are many weeds amongſt the corn; which is too frequently the caſe in the rich lands near London, eſpecially in moiſt ſeaſons; therefore, when this is the caſe, the Barley muſt lie on the ſwarth till all the weeds are dead: but, as it is apt to ſprout in wet weather, it muſt be ſhook up, and turned every fair day, after rain, to prevent it. When it is carried, it ſhould be thoroughly dry; otherwiſe, if it be ſtacked wet, it will turn muſty; or, if too green, it is ſubject to burn in the mow.

The common produce of Barley is two and an half, or three quarters, on an acre; but I have ſometimes known four quarters on an acre.

Pearl BARLEY, and French Barley, are both of the ſame kind, though differing ſomewhat in the whiteneſs and ſize of the grain; and are thoſe chiefly uſed in phyſic.

Barley-water is a decoction of either of theſe, reputed ſoft and lubricating, of frequent uſe in phyſic.

This well known decoction is a very uſeful drink in many diſorders; and is recommended, with nitre, by ſome authors of reputation, in ſlow fevers.

BA'RNACLES, in farriery, are alſo called horſe-twiſters, or brakes.

Barnacles differ from pinchers, as the latter have handles to hold them; whereas the former are faſtened to the noſe with a lace or cord.

There is another meaner ſort of Barnacles, uſed in defect of the former, called roller Barnacles, or wood twiſters, which are only two rollers of wood bound together, with the horſe's noſe between them. *Dict. Ruſt.*

BARO'METER (*Dict.*)—The principal uſe of the Barometer is to eſtimate the gravity of the air at different times, in order to foreſee the alterations of the weather, which are conſequent thereon. To this end, Dr. Halley, in the 181ſt number of the Philoſophical Tranſactions, has laid down the more remarkable phænomena, relating to the different heights of the mercury at different times, together with the ſolution of each; which are ſo juſt, and ſo agreeable to true philoſophy, that I doubt not but the reader will be glad to ſee the account in his own words.

1. In calm weather, when the air is inclined to rain, the mercury is commonly low.

2. In ſerene, good, and ſettled weather, the mercury is generally high.

3. Upon very great winds, though they be not accompanied with rain, the mercury ſinks loweſt of all, with relation to the point of the compaſs the wind blows upon.

4. Cæteris paribus, the greateſt heights of the mercury are found upon eaſterly and north-eaſterly winds.

5. In calm froſty weather, the mercury generally ſtands high.

6. After very great ſtorms of wind, when the mercury has been low, it generally riſes again very faſt.

7. The more northerly places have greater alterations of the Barometer, than the more ſoutherly.

8. Within the tropics, and near them, thoſe accounts we have had from others, and my own obſervations at St. Helena, make very little or no variation of the height of the mercury in all weathers.

Hence I conceive, that the principal cauſe of the riſe and fall of the mercury, is from the variable winds which are found in the temperate zone, and whoſe great unconſtancy, here in England, is moſt notorious.

A ſecond cauſe is the uncertain exhalation and precipitation of the vapours lodging in the air, whereby it comes to be, at one time, much more crouded than at another, and, conſequently, heavier; but this latter, in a great meaſure, depends upon the former. Now, from theſe principles, I ſhall endeavour to explicate the ſeveral phænomena of the Barometer, taking them in the ſame order I laid them down: thus,

1. The mercury's being low inclines it to rain, becauſe, the air being light, the vapours are no longer ſupported thereby,

being become specifically heavier than the medium wherein they floated; so that they descend towards the earth, and, in their fall, meeting with other aqueous particles, they incorporate together; and form little drops of rain; but the mercury's being at one time lower than at another, is the effect of two contrary winds blowing from the place where the Barometer stands; whereby the air of that place is carried both ways from it, and, consequently, the incumbent cylinder of the air is diminished, and, accordingly, the mercury sinks: as for instance, if in the German ocean it should blow a gale of westerly wind, and, at the same time, an easterly wind in the Irish sea; or if in France it should blow a northerly wind, and in Scotland a southerly; it must be granted, that that part of the atmosphere impendent over England, would thereby be exhausted and attenuated, and the mercury would subside, and the vapours, which before floated in those parts of the air of equal gravity with themselves, would sink to the earth.

2. The greater height of the Barometer is occasioned by two contrary winds blowing towards the place of observation, whereby the air of other places is brought thither, and accumulated; so that the incumbent cylinder of air, being increased both in height and weight, the mercury pressed thereby must needs stand high, as long as the winds continue so to blow; and then, the air, being specifically heavier, the vapours are better kept suspended; so that they have no inclination to precipitate and fall down in drops, which is the reason of the serene good weather which attends the greater heighths of the mercury.

3. The mercury sinks the lowest of all, by the very rapid motion of the air in storms of wind. For, the tract or region of the earth's surface, wherein the winds rage, not extending all round the globe, that stagnant air which is left behind, as likewise that on the sides, cannot come in so fast as to supply the evacuation made by so swift a current; so that the air must necessarily be attenuated, when and where the said winds continue to blow, and that more or less, according to their violence; add to which, that the horizontal motion of the air, being so quick as it is, may, in all probability, take off some part of the perpendicular pressure thereof; and the great agitation of its particles is the reason why the vapours are dissipated, and do not condense into drops, so as to form rain, otherwise the natural consequence of the air's rarefaction.

4. The mercury stands the highest upon the easterly and north-easterly wind, because, in the great Atlantic ocean, on this side the thirty-fifth degree of north latitude, the winds are almost always westerly or south-westerly; so that, whenever here the winds come up at east and north-east, it is sure to be checked by a contrary gale, as soon as it reaches the ocean; wherefore, according to what is made put in our second remark, the air must needs be heaped over this island, and, consequently, the mercury must stand high, as often as these winds blow. This holds true in this country, but is not a general rule for others, where the winds are under different circumstances; and I have sometimes seen the mercury here as low as at twenty-nine inches upon an easterly wind, but then it blew exceeding hard, and so comes to be accounted for, by what was observed upon the third remark.

5. In calm frosty weather the mercury generally stands high, because (as I conceive) it seldom freezes, but when the winds come out of the northern and north-eastern quarters; or, at least, unless those winds blow at no great distance off; for the north parts of Germany, Denmark, Sweden, Norway, and all that tract from whence north-easterly winds come, are subject to almost continual frost all the winter; and thereby the lower air is very much condensed, and in that state is brought hitherwards by those winds; and, being accumulated by the opposition of the westerly wind blowing in the ocean, the mercury must needs be pressed to a more than ordinary height; and, as a concurring cause, the shrinking of the lower parts of the air into lesser room by cold, must needs cause a descent of the upper parts of the atmosphere, to reduce the cavity made by this contraction to an æquilibrium.

6. After great storms, when the mercury has been very low, it generally rises again very fast: I once observed it to rise one inch and an half in less than six hours, after a long continued storm of south-west wind. The reason is, because, the air, being very much rarefied by the great evacuations which such continued storms make thereof, the neighbouring air runs in the more swiftly, to bring it to an æquilibrium; as we see water runs the faster for having a greater declivity.

7. The variations are greater in the more northerly places, as at Stockholm, greater than that at Paris (compared by M. Paschal) because the more northerly parts have usually greater storms of wind than the more southerly, whereby the mercury should sink lower in that extreme; and then the northerly winds bringing the more dense and ponderous air from the neighbourhood of the Pole; and that again being checked by a southerly wind at no great distance, and so heaped, must of necessity make the mercury, in such case, stand higher in the other extreme.

8. Lastly, this remark, that there is little or no variation near the equinoctial, does, above all others, confirm the hypothesis of the variable winds being the cause of these variations of the height of the mercury; for, in the places above-named, there is always an easy gale of wind blowing nearly upon the same point, viz. east-north-east, at Barbadoes; and east-south-east, at St. Helena; so that, there being no contrary currents of air to exhaust or accumulate it, the atmosphere continues much in the same state: however, upon hurricanes (the most violent of storms) the mercury has been observed very low; but this is but once in two or three years, and it soon recovers its settled state about 29½ inches.

M. Leibnitz accounted for the descent of the mercury before rain, upon another principle, viz. as a body specifically lighter than a fluid, while it is suspended by it, adds more weight to that fluid, than when, by being reduced in its bulk, it becomes specifically heavier, and descends; so the vapours, after it is reduced into the form of clouds, and descends, adds less weight to the air, than before; and therefore the mercury falls. To which it is answered; 1. That, when a body descends in a fluid, its motion, in a very little time, becomes uniform (or nearly so) a farther acceleration of it being prevented by the resistance of the fluid; and then, by the third law of nature, it presses the fluid downwards, with a force equal to that whereby it tends to be farther accelerated; that is, with a force equal to its whole weight. 2. The mercury, by its descent, foretels rain a much longer time before it comes, than the vapour, after it is condensed into clouds, can be supposed to take up in falling. 3. Supposing, that as many vapours, as fall in rain, during the space of a whole year, were at once to be condensed into clouds, and even quite cease to gravitate upon the air, its gravity would scarce be diminished thereby, so much as is equivalent to the descent of two inches of mercury in the Barometer. Farther, in many places between the tropics, the rains fall at certain seasons, in very great quantities; and yet the Barometer shews there were little or no alterations in the weight of the air.

The following are Mr. Patrick's observations on the rising and falling of the mercury: they are very just, and are to be accounted for on the same principles with those of Doctor Halley.

1. The rising of the mercury presages, in general, fair weather; and its falling, foul weather; as rain, snow, high winds and storms.

2. In very hot weather, the falling of the mercury foreshews thunder.

3. In winter, the rising presages frost; and in frosty weather, if the mercury falls three or four divisions, there will certainly follow a thaw: but in a continued frost, if the mercury rises, it will certainly snow.

4. When foul weather happens, soon after the falling of the mercury, expect but little of it: and, on the contrary, expect but little fair weather, when it proves fair shortly after the mercury has risen.

5. In foul weather, when the mercury rises much and high, and so continues for two or three days before the foul weather is quite over, then expect a continuance of fair weather to follow.

6. In fair weather, when the mercury falls much and low, and thus continues for two or three days before the rain comes, then expect a great deal of wet, and, probably, high winds.

7. The unsettled motion of the mercury denotes uncertain and changeable weather.

8. You are not so strictly to observe the words engraved on the plates (though, for the most part, it will agree with them) as the mercury's rising and falling; for if it stands at Much Rain, and then rises up to Changeable, it presages fair weather, although not to continue so long, as it would have done, if the mercury were higher: and so, on the contrary, if the mercury stood at Fair, and falls to Changeable, it presages foul weather; though not so much of it, as if it had sunk down lower.

From these observations, it appears, that it is not so much the height of the mercury in the tube, that indicates the weather, as the motion of it up and down; wherefore, in order to pass a right judgment of what weather is to be expected, we ought to know, whether the mercury is exactly rising or falling; to which end, the following rules are of use.

1. If the surface of the mercury is convex, standing higher in the middle of the tube than at the sides, it is generally a sign that the mercury is then rising.

2. If the surface is concave, or hollow in the middle, it is sinking. And,

3. If it is plain, the mercury is stationary; or rather, if it is a little convex; for mercury being put into a glass tube, especially a small one, will naturally have its surface a little convex; because the particles of mercury attract each other more forcibly than they are attracted by glass. Further,

4. If the glass is small, shake the tube; and if the air is grown heavier, the mercury will rise about half the tenth of an inch higher, than it stood before; if it is growing lighter, it will sink as much. This proceeds from the mercury's sticking to the sides of the tube, which prevents the free motion of it, till it is disengaged by the shock: and therefore, when

when an obſervation is to be made with ſuch a tube, it ought always to be ſhaken firſt, for ſometimes the mercury will not vary of its own accord, till the weather, it ought to have indicated, is preſent.

Phoſphorus of the BAROMETER.—M. Picard firſt obſerved, in the year 1676, that, on ſhaking the mercury in the Barometer, in the dark, a light iſſued; but, on trying others, found few which exhibited the ſame phænomenon.

M. Bernouilli, having tried the experiment on his Barometer, found, that, though ſhaken very forcibly, in the dark, it emitted only a weak light. He obſerved, that, on ſhaking of the Barometer, ſo as to force the mercury above and below its æquilibrium by turns, this light never ſhewed itſelf but on the deſcent of the mercury, and always ſeemed to adhere to the upper ſurface; from whence he conjectured, that there might proceed, out of the mercury, a thin ſubtile matter, which was before locked up in the cloſe interſtices of this mineral, to ſupply the uncommon vacuum in the tube, which followed on a violent concuſſion; and that there might, poſſibly, on this occaſion, ſome particles, finer than air, pervade the glaſs tube, and, by meeting thoſe which proceeded from the quickſilver, produce the effect. But why is not this phænomenon common to all Barometers? M. Bernouilli imagined that the motion of the ſubtile matter, which proceeds from the mercury in its deſcent, might be weakened, deſtroyed, or interrupted, by ſome matter heterogeneous to the mercury; which might be collected on the upper ſurface, being forced thither by the mineral, which was heavier than it; that this pellicula always formed itſelf on quickſilver, unleſs very well purified; and even then it would ſoon contract it on the admiſſion of air; that this pellicula was formed by the impurities of the air; that this concuſſion made the quickſilver collect more impurities in an inſtant, than it would have done in many days in a ſtate of reſt; and that the certain method to have a luminous Barometer, was to take care, that, in the conſtruction of it, the mercury poured into the tube ſhould be well cleanſed, and free from any foulneſs of air.

Experiments have juſtified M. Bernouilli's reaſoning exactly, except, perhaps, what he advances about the pellicula formed on the ſurface of the quickſilver.

Nothing obſtructs this phænomenon more than moiſture; for if water gets in with the quickſilver, or even rectified ſpirit of wine, though in its nature apt to take fire; yet they have the ſame effect as the pellicula, to prevent the production of the phoſphorus. The tube muſt, therefore, be thoroughly dry and clean on the inſide.

Scale of the BAROMETER.—The ingenious Mr. Biſſet, of Newington-green, has favoured us with the following method, for graduating the ſcales of common or perpendicular Barometers, when the ciſterns or baſons are cylindrical.

Rule.—Deduct the ſquare of the external diameter of the tube, from the ſquare of the internal diameter of the ciſtern; to the remainder add the ſquare of the internal diameter of the tube, and compare the amount with the ſquare of the internal diameter of the tube; and, whatever part the ſaid ſquare appears to be of the ſaid amount, deduct or cut off a like part from the three inches, for the ſcale; divide the remainder into three equal parts; which parts treat as inches, by placing the numbers 28, 29, 30, and 31, and ſubdivide them into tenths, &c. as uſual.

This rule is founded on the twelfth book of Euclid's Elements, where we learn, that cylinders are to each other as the products of their heighths, multiplied by the area of their baſes; that their baſes (being circles) are to each other as the ſquare of their diameters; hence it would follow, that, when the mercury riſes in the tube, it, at the ſame time, falls in the ciſtern, and vice verſa, in an inverſe proportion of the ſquares of their internal diameters.—But, before a true compariſon can be made, we are to conſider the two following particulars, viz. 1. That, as the tube is immerſed in the mercury in the ciſtern, the ſquare of the external diameter thereof is to be deducted from the ſquare of the internal diameter of the ciſtern, to obtain the true ſuperficial contents of the mercury in the ciſtern. 2. That, whenever the mercury riſes in the tube, it, at the ſame time, falls in the ciſtern; and that theſe two ſpaces are to be added together, to expreſs the true riſe of the mercury; ſo, vice verſa, when the mercury falls in the tube, the riſe thereof in the ciſtern is to be deducted. Hence it is plain, that the mercury always riſes more, and falls leſs, than a ſcale with full inch diviſions can expreſs; and that, in the direct proportion, that the ſquare of the internal diameter of the ciſtern, leſs by the ſquare of the external diameter of the tube, bears to the ſquare of the internal diameter of the tube: ſo that, to obtain a ſcale that will expreſs the riſe and fall of the mercury, within the compaſs of three inches, we muſt proceed by the above rule; or ſay, as the ſquare of the internal diameter of the ciſtern, minus the ſquare of the external diameter, and plus the ſquare of the internal diameter of the tube, is to three inches; ſo is the ſquare of the internal diameter of the ciſtern, minus the ſquare of the external diameter of the tube, to the length of the ſcale; which proportion will, for the following example, ſtand in figures thus: $16 - 4 + 1 : 3$ inches $: : 16 - 4 : 2$ inches $7\frac{9}{13}$.

But, perhaps, this may be better underſtood by a figure. Let therefore A B (*plate* VI. *fig.* 9.) repreſent a tube immerſed in the ciſtern B C, with the mercury ſtanding in the former, at *b*, and in the latter at *c*. Now, let us ſuppoſe the mercury in the tube to riſe to *a* (three inches) and, at the ſame time, to fall in the ciſtern to *d*; it is certain the two ſurfaces of the mercury, viz. in the tube and in the ciſtern, have removed further from each other than they were before, by the ſpaces marked *a b* in the tube, and *c d* in the ciſtern, i. e. more than three inches by the ſpace *c d*.—Now, to aſcertain the diſtance of *c* from *d*, it is firſt to be conſidered, that the mercury that paſſed out of it exactly fills that part of the tube marked *a b*; conſequently, the ſolid contents of theſe two cylindrical ſpaces are equal: and as the internal diameter of the ciſtern, the external and internal diameters of the tube, and the diſtance from *a* to *b*, are given, the diſtance from *c* to *d* may be found, from the nature and effect of cylinders; by ſaying, as the ſquare of the internal diameter of the ciſtern, minus the ſquare of the external diameter of the tube (for, as the tube occupies part of the ciſtern, the ſquare thereof muſt be deducted from the ſquare of the ciſtern) is to the ſquare of the internal diameter of the tube; ſo is the diſtance *a b* to the diſtance *c d*; which, being thus obtained, muſt be added to *a b*, to expreſs the true riſe of the mercury. Hence it is plain, a ſcale, with full inch diviſions, cannot ſhew the true riſe of the mercury; and it will appear as plain, by carefully conſidering the figure, that it cannot ſhew the true fall thereof. In both caſes it is deficient; therefore the ſcale *a b*, which we have hitherto ſuppoſed to be three inches, ſhould exceed it, by the addition of a ſpace equal to *c d*; but as this cannot be done without marking fractional quantities on the ſcale (which would puzzle common obſervers) the beſt method is to let the ſcale expreſs only three inches, by making it proportionably ſhort thereof; by ſaying, as $ab + cd$: three inches : : three inches to the length required; which, when found, muſt be divided into three equal parts, and numbered as inches, as above directed.

Example.—Suppoſe the diameter of the bore of the tube to be $\frac{1}{4}$ inch, the external diameter thereof $\frac{2}{4}$ or $\frac{1}{2}$ inch, and the internal diameter of the ciſtern to be only * $\frac{4}{4}$ or one inch; and let us ſuppoſe the ſquare of the diameter of the bore of the tube to be the integer, then will the ſquare of the internal diameter of the ciſtern be (in ſuch parts) ſixteen; from which deducting the ſquare of the external diameter of the tube, viz. four, there will remain twelve; to this remainder, add the ſquare of the diameter of the bore, viz. 1, the amount will be 13; i. e. $\frac{1}{13}$ part of three inches (equal to $2\frac{4}{13}$ tenths of an inch) is to be deducted from the common ſcale of three inches; or, in other words, the ſcale ſhould, for this example, be only two inches $\frac{7}{10}$ and $\frac{9}{13}$ of a tenth long. Now, ſuch a ſcale, being divided as above, will, in every point thereof, ſhew, in inches and tenths, the true height of the mercury in the tube, from the ſurface of that in the ciſtern; which is the diſtance that ſhould be expreſſed: whereas the beſt Barometers, with the preſent ſcale (of full three inches) will ſhew the true diſtance at one point only, viz. that where the mercury ſtood when the ſcale was fixed; but, whenever the mercury riſes above, or falls below, that point, the expreſſion is erroneous.

* I chuſe to give an example, by a ciſtern of a ſmall diameter, as ſuch an one will ſave much mercury, and, at the ſame time, be equally true with one of a larger diameter.

BA'RRACKS, in military affairs, buildings to lodge ſoldiers in fortified towns, or others. Thus we ſay the Barracks of the Savoy, of Dublin, &c.

Barracks, when damp, are greatly prejudicial to the health of the ſoldiers lodged in them; occaſioning dyſenteries, intermitting fevers, coughs, rheumatic pains, &c. For which reaſon quarter-maſters ought to be very careful in examining every Barrack, offered by the magiſtrates of a place; rejecting all ground-floors in houſes that have either been uninhabited, or have any ſigns of moiſture. *Vid. Pringle, Obſerv. on the Diſeaſes of the Army.*

BA'RREL *of a pump*, is the wooden tube, which makes the body of the engine, and wherein the piſton moves. *Ozan. Dict. Math.*

BARREL *of a muſket, firelock, piſtol, or the like*, is that part wherein the charge or load is put.

BARREL *of a clock*, is a cylindrical part, about which the ſtring is wound, anſwering to what in watches is properly called the fuſy. *Derham's Artif. Clock-maker.*

BARREL *of a jack*, is the cylindrical part whereon the line is wound. *Moxon's Mech. Exer.*

BA'RRING *a vein*, an operation performed by farriers on the veins of horſes legs, and of other parts, in order to ſtop the courſe, and leſſen the quantity of the malignant humours which prevail there.

It is done by opening the ſkin above the part, and, after diſengaging it, and tying it both above and below, ſtriking between the two ligatures.

When

When horſes have got traverſe mules, or kibed heels, and rat-tails, or arreſts in the hinder legs, it is common to bar a vein. *Farr. Dict.*

BA'RRY-*Pily*, in heraldry, is when a coat is divided as repreſented in *Plate* VI. *fig.* 11. which is blazoned, Barry-pily, of eight pieces.

BARS *of iron*, are made of the metal of the ſows and pigs, as they come from the furnaces.

Theſe paſs through two forges, called the finery and the chaufery, where, undergoing five ſeveral heats, they are formed into Bars. See IRON *Works*.

BA'SKET *Salt*. This is a brine ſalt, made from the water of our ſalt ſprings in Cheſhire and elſewhere, differing from the common brine ſalt in the fineneſs of the grain, and in its whiteneſs and purity. See SALT.

BA'SON, *pelvis*, in anatomy, a round cavity in the form of a tunnel, ſituate between the anterior ventricles of the brain, deſcending from its baſe, and ending in a point at the glandula pituitaria.

It is formed of the pia mater, and receives the pituita which comes from the brain and paſſes through the pituitary gland, and from thence into the veins.

That capacity alſo is called pelvis, or baſon, which is formed by the oſſa ilia and ſacrum, and contains the bladder of urine, the matrix, and the inteſtines.

BASONS *of a balance*, two pieces of braſs, or other matter, faſtened to the extremities of the ſtrings; the one to hold the weight, the other the thing to be weighed.

BASON, or *diſh*, among glaſs-grinders. Theſe artificers uſe various kinds of Baſons, of copper, iron, &c. and of various forms, ſome deeper, other ſhallower, according to the focus of the glaſſes to be ground. In theſe Baſons it is, that convex-glaſſes are formed, as concave ones are formed on ſpheres or bowls.

Glaſſes are worked in baſons two ways. In the firſt, the Baſon is fitted to the arbor or tree of a lath, and the glaſs (fixed with cement to a handle of wood) preſented and held faſt in the right hand within the Baſon, while the proper motion is given by the foot of the Baſon. In the other, the Baſon is fixed to a ſtand or block, and the glaſs with its wooden handle moved.

The moveable Baſons are very ſmall, ſeldom exceeding five or ſix inches in diameter, the others are larger; ſometimes above ten feet diameter.

After the glaſs has been ground in the Baſon, it is brought ſmoother with greaſe and emery; and poliſhed firſt with tripoli, and finiſhed with paper cemented to the bottom of the Baſon.

BASON, among hatters, is a large round ſhell, or caſe, ordinarily of iron, placed over a furnace; wherein the matter of the hat is moulded into form.

The hatters have alſo Baſons for the brims of hats, uſually of lead, having an aperture in the middle, of a diameter ſufficient for the largeſt block to go through.

BASON, is alſo uſed on various occaſions for a ſmall reſervatory of water: as the Baſon of a jet d'eau, or fountain, the Baſon of a port, of a bath, &c. which laſt Vitruvius calls labrum.

BASON *of a port*, denotes the place where the ſhips lie.

The word is alſo uſed for a ſmall private port contrived in a large one, for the refitting of veſſels, more frequently called a dock. See DOCK.

BASONS *or Fountains*, among gardeners, are reſervoirs for holding water either for the ornament or uſe of the garden.

They are made in divers forms, ſome round, ſome oblong or oval, others ſquare, octangular, &c. but their moſt common form is circular; and, if the ground will permit, the larger they are, the better: and, when they exceed in ſize, they are called pieces of water, canals, fiſh-ponds, pools, &c.

In making theſe, care ought to be taken to avoid both extremes, and not to make them too big or too little; that a water-work may not take up the beſt part of a ſmall piece of ground; nor to make too little a Baſon in a large ſpot. This muſt depend intirely on the judgment of the deſigner of the garden.

Some would have the ſize of a Baſon to be proportioned to the jet d'eau, that the water, thrown up in the air, may not, by being blown by the air, be carried beyond the edge of the Baſon, but all fall down without wetting the walk.

As to the depth of Baſons, it uſually from two to three feet; this depth being ſufficient to ſecure the bottom of the Baſons from froſt, and to dip watering-pots.

But if they are to ſerve as reſervoirs, or to keep fiſh in, then they may be made four or five feet deep, which will both hold water enough, and be deep enough for the fiſh to breed in, and alſo to bear a boat.

Deeper than this they ſhould not be; for, if they were deeper, they would be dangerous as to the drowning of perſons, who might chance to fall in.

In making Baſons, great care ought to be taken of making them at firſt; for the water always naturally endeavouring to run away, and, by its weight and preſſure in a Baſon, making its way out at the leaſt cranny, it will grow conſtantly bigger and bigger; ſo that, if it be not well made at firſt, it will be very difficult to repair it.

Baſons are made either with clay, cement, or lead; they are moſt uſually made of clay: in making ſuch, at the marking out the dimenſions, the diameter ought to be four feet bigger on each ſide; yet the Baſon will not be the wider, for it will be taken up with the walls on each ſide; and the clay-work, which is to fill the ſpace between the Baſon, muſt alſo be dug two feet deeper than the depth of the water is deſigned to be, becauſe it is to be laid over eighteen inches thick with clay, and ſix inches with gravel and paving.

The clay ought to be well wrought with the hands and water; and, when it is ſpread, ſhould be trodden in with the naked feet, that the water of the Baſon may not dilute through it, and the roots of any trees that may grow near, may not penetrate into the outward wall; which may be made of ſhards, rubble, or flints, with mortar made of the natural earth, and is called the ground-wall, becauſe it is only made to reſiſt the preſſure of the ground about it. The inward wall ought to be made with good rubble-ſtones, that will not ſcale and come off in flaſhes in the water; or elſe of flints and ſtones from the hills, which will make durable works, but will not look ſo neat as the pointed rubble; and there ought to be laid here and there ſtones, the thickneſs of the wall, to render it the more ſubſtantial.

The method of making Baſons of cement is as follows: after you have marked out the dimenſions of the Baſon, as before, if you inlarge it one foot nine inches, it will be ſufficient; and the ſame depth deeper at the bottom will be enough.

This being done, you muſt begin to back up and raiſe againſt the ground: cut perpendicularly a wall of maſonry a foot thick, which muſt go to the bottom, and ſhould be built with ſhards and rubble-ſtones laid in a mortar of lime and ſand. When the wall is finiſhed round the circumference, then the bottom is to be wrought a foot thick with the ſame materials; and the ſolid work or lining of cement is to be backed up againſt the walls nine inches thick, including the plaiſtering and inward ſurface.

This ſolid ought to be made of ſmall flints, laid in beds of mortar made of lime and cement.

When this ſolid is eight inches thick, it ought to be plaiſtered over the whole ſurface of the bottom with cement well ſifted before it be tempered with lime; and with this it ſhould be wrought over ſmooth with the trowel.

The proportion of this cement ſhould be two-thirds of cement or powdered tile to one-third of lime.

This cement has the property ſo to harden under-water, that it will be as hard as ſtone or marble, and the body will be ſo ſolid as never to decay.

After the finiſhing of the Baſon, the plaiſtering ſhould be for four or five days ſucceſſively anointed over with oil, or bullocks blood, to prevent it from cracking or flawing: this being done, the water ſhould be let into the Baſon as ſoon as may be.

Thoſe Baſons which are made of lead, are to be thus wrought: the out-lines ought to be inlarged one foot of a ſide, and digged half a foot deeper than the Baſon is to be. The wall muſt be made a foot thick, that it may be able to bear up againſt the earth lying againſt it; but the bottom will not require to be more than half a foot thick.

Theſe walls muſt be built with rubble laid in mortar all of plaiſter, becauſe the lime will corrode the lead; and then the lead muſt be laid on the walls and bottom, and be ſeamed with ſolder.

But Baſons of lead are not much in uſe, becauſe of their great charge in making, and the danger of the lead being ſtolen.

Great care ought to be taken to keep the upper edge and ſuperficies of a Baſon upon a level, that the water may cover all the wall equally.

As for the waſte pipes of Baſons, whether at the bottom or ſuperficies, they ought not to be made too ſmall, leſt they ſhould be choaked, notwithſtanding the cauls that are drawn before them.

When this waſte water is only to be loſt in ſinks and common-ſewers, it is carried away in drains, or earthen-pipes; but, when it ſerves to play the Baſons that lie below it, it muſt paſs through leaden-pipes.

Theſe Baſons are now pretty generally rejected by perſons of good taſte, as being no-ways ornamental: therefore, where there is a neceſſity to make reſervoirs for water for the uſe of gardens, they are commonly dug in the loweſt part of gardens, or where the ſpot is moſt convenient for receiving the water which may run from the adjacent grounds in hard rains. Theſe ponds ſhould have their ſides made very eaſy; for, if they are too upright, the earth frequently breaks down, by the water waſhing and making it hollow below: the ſides and bottom of theſe ponds ſhould be laid nine or ten inches thick with well wrought clay; and, as the clay is finiſhed, it ſhould be well covered to prevent the ſun and wind from cracking it before the water is let in: the figures of of these ponds should not be regular; for the shape of the hollow, where they are made, should be followed, which will save expence and have a better appearance.

BA'SIL, among joiners, denotes the angle to which the edge of an iron tool is ground.

To work on soft wood they usually make their Basil twelve degrees, for hard wood eighteen; it being observed, that, the more acute or thin the Basil is, the better and smoother it cuts; and, the more obtuse, the stronger and fitter for service.

BA'SSETING, in the coal-mines, denotes the rise of the vein of coal towards the surface of the earth, till it come within two or three feet of the surface itself.

This is also called by the workmen croping, and stands opposed to dipping, which is the descent of the vein to such a depth, that it is rarely, if ever, followed to the end.

BA'STION (*Dict.*)— To construct the plan of a Bastion.

1. Draw a capital line B K (*Plate* VI. *fig.* 12.) and make the angles M B K, F B K, each equal to half the flanked angle.

2. Take the lines B F, B M, each of the length of the face.

3. At the points F, M, make the angles of the shoulder B F H, B M N.

4. Make the lines F H, M N, each the length of the flank.

5. At the points H, N, make the angles F H G, M N *a*, equal to the angle of the curtin, and draw the pieces of the curtin H G, N *a*.

This problem may be found useful on many occasions; particularly when the drawings of works in a Bastion are to be represented with that Bastion only, on a large scale; therefore it was here introduced, more especially for beginners, who are for the most part apt to be somewhat puzzled about constructing part of a work, independent on the whole.

BAT, in physiology, a mongrel or amphibious sort of animal, partaking both of the mouse and the bird, and flying, but without feathers.

The Bat, called also by us lapwing, and flittermouse, by the Latins, vespertilio, seems a medium between the quadruped and the feathered kinds; but it partakes more of the former tribe, agreeing only with the birds in the sternum, and the position of its liver; and with the quadrupeds in the kidneys, bladder, teeth, penis, testicles, diaphragm, and lungs. In reality, it only appears to be a bird by its flying. They lay themselves up in the winter in the driest apartments of caves; where planting their talons to the roof, they cover their bodies with their wings, and so hanging perpendicularly in great numbers, but so as not to touch each other, they sleep for some months.

BAT-*Fowling*, a method of catching birds in the night, by lighting some straw or torches near the place where they roost: for, upon beating them up, they fly to the flames, where, being amazed they are easily caught in nets, or beat down with bushes fixed to the ends of poles, &c.

BA'TEMENT, a term in carpentry, signifying an abatement or waste of a piece of stuff, by forming it to a designed purpose or use: thus, instead of asking how much was cut off from such a board or piece of stuff, they say what abatement had that piece of stuff.

BATH *Metal*, a preparation of copper with zink, which gives a more beautiful colour than the calamine used in the preparation of the common brass. See PRINCE'S *Metal*.

BA'TISTE, in commerce, a fine white kind of linen cloth, manufactured in divers parts of the Spanish Netherlands. There are three kinds of Batiste; the first very thin; the second less thin; and the third much thicker, called holland. The chief use of Batiste is for neck-cloths, head-cloaths, surplices, &c. *Savar. Dict. Comm.*

BA'TMAN, a weight in Turkey consisting of six okes. Forty of these Batman's make a camel's load, and amount to about seven hundred and twenty pounds English weight. *Pocock's Egypt.*

BATRACHOMYOMA'CHIA *, battle of the frogs and the mice; the title of a fine burlesque poem, usually ascribed to Homer.

* The word comes from the Greek βάτραχος, frog, μῦς mouse, and μάχη, battle.

The subject of the war is the death of Psycharpax, a mouse, son of Toxartes, who, being mounted on the back of Physignates, a frog, on a voyage to her palace, to which she had invited him, was seized with fear when he saw himself in the middle of the pond, so that he tumbled off and was drowned. Physignates being suspected to have shook him off with design, the mice demanded satisfaction, and unanimously declared war against the frogs.

Stephens, Nunnesius, and other modern authors, take the poem not to be Homer's; but several of the ancients seem of another opinion; and Statius, who wrote under Domitian, makes no doubt of it.

BA'TTEN (*Dict.*)— This term is chiefly used in speaking of doors, and windows of shops, &c. which are not framed of whole deal, or one quarter inch-oak, with stiles, rails, and pannels, as wainscot is framed; and yet they are made to appear as if they were, by means of these pieces or Battens, bradded on upon the plain boards which are joined together for the door, or window, all round, and sometimes cross them, and up and down, &c. according to the number of the pannels, the workman designs the door, or window, shall appear to have.

These pieces, which are thus bradded on, to represent stiles, rails, and montans, and are of different breadths according to the design of the workman, as from two to six or seven inches; and there is usually some moulding struck, as a bead, an ogee, or the like, on one edge of those that represent the stiles, and the upper and lower rails, and on both the edges of those which are designed to appear like montans and middle rails.

BATTEN *Doors*, are such as seem to be wainscot ones, but are not; for, in wainscot ones, the pannels are grooved into the framing; but, in these, they first joint and glue the boards, which are cut to the full length and breadth of the door-case; which gluing being dry, they traverse them over with a long plane; and, being smoothed, the Battens are fitted on, on the front-side. And these are called single Batten-doors; for there are others, called double Batten-doors, viz. such as are battened on both; though this is but rarely done.

But there are battened doors, which are called double doors, such as front or outer-doors; which are usually made of whole deal, and afterwards battened on the outside, and pieces, four or five inches broad, mitred round the edges on the inside of the door; and then it is lined cross the door betwixt these pieces, with thin slit-deal, which renders it level with the mitred pieces.

Some doors have been lined with pieces laid bevelling, and not at right-angles, but near mitre to the sides of the door; and, when all has been plained off level, it has been divided into rhombus's, and struck with a pencil, and round-headed nails driven in at the angles of the rhombus's, which added something of beauty to the work.

This way of lining upon the doors, viz. pointing from the lower corner behind, towards the upper corner before, seems to be a good way to prevent a door from sagging or sinking at the fore-corner, whenever the joints shall happen to unglue. *Builder's Dict.*

BA'TTER, a term used by bricklayers, carpenters, &c. to signify that a wall, piece of timber, &c. doth not stand upright, but leans from you, when you stand before it.

BA'TTERY (*Dict.*)— All field Batteries consist of four chief parts, namely, the ditch, the parapet, the platform, and the magazine.

The Ditch is usually dug in the front and sides, and sometimes quite round; and serves not only to furnish the earth necessary for the parapet, but it also prevents the enemy from entering the Battery so readily as he might otherwise do.

The ditch in front is commonly eighteen or twenty feet broad, and the depth about seven or eight feet; the sides sloping towards the bottom, which is about six feet wide: but the ditches on the sides are about ten feet wide, and six feet deep. These are the dimensions usually given; but the general practice seems to be, only to get earth sufficient for the work, and not mind the regularity of the ditch: for, as these works in attacks are usually done by night, the keeping strictly to the assigned dimensions is hardly practicable.

The parapet is generally raised about three or four feet distant from the brink of the ditch, the space left between, called the berm or foreland, serving to lodge the rubbish beat down by the enemies shot, that it may not fall into the ditch.

The thickness of the parapet should be about eighteen or twenty feet, in order to be cannon-proof, and about seven or eight feet high, when the enemy has no command above the Battery: but, if they have a command over this height, the parapet should be raised high enough to cover the men when they load the guns.

The length of the parapet depends on the number of guns to be employed in the Battery.

Thus, for one gun allow eight yards in length. And six yards more for every other gun. So two guns have fourteen yards, three guns twenty yards, four guns twenty-six yards, &c.

There should be great care taken that the Battery be not enfiladed or raked by the enemies cannon: neglects of this kind are often fatal to the officers and gunners, as was well known at the siege of Carthagena, anno 1741. But this is easily prevented by raising at one, or both ends of the parapet, a bank across the Battery called an epaulment, of the same thickness and height with the parapet, and about fifteen or eighteen feet long.

The parapet consists of two parts, namely, the wall and the merlons.

The wall is that part of the parapet, which is contained in one piece from end to end, and is about two and a half of three feet high.

The merlons are detached pieces of the parapet, leaving openings called embrasures, through which the cannon deliver their shot.

The embrasures should, as much as is possible, be cut perpendicular to the parapet; therefore the Battery should be parallel, or nearly so, to the object to be battered: for the direct shots have most force; and oblique embrasures weaken the merlons, or parts of the parapet standing between the embrasures.

The embrasures are usually about two or two and a half feet wide on the inside, and about nine or ten feet on the outside: whereby the cannon may be traversed from the right to the left, so as to command a pretty large extent in front.

The distance from the middle of one embrasure to the middle of the next should be about eighteen feet, in order to leave sufficient room for the working of the guns, and the stowage of the shot and other necessaries.

Platforms are generally laid sloping towards the parapet nine or ten inches; this carries off the rain, prevents the gun from recoiling so much when fired as it would do if laid level; and, when loaded, it is more easily brought to the embrasure.

In temporary Batteries, the platforms are made of planks laid across some ground timbers or sleepers: there is usually a platform made to each gun; it is about eighteen feet long, eight feet broad next the parapet, and about fourteen feet broad at the tail, the intermediate spaces between the platforms serving for the shot and other necessaries.

When a platform is to be laid on marshy ground, first lay a floor or two of fascines; cover these with hurdles of twelve or fifteen feet long, and six or seven broad; on these lay a floor of three or four inches of earth, and therein lay the sleepers, and over these the planks.

When a Battery is built of stone or brick, the platform is generally a flat-stone pavement ranging the whole length of the Battery: this, on account of its resisting the injuries of the weather for a long time, is to be preferred to planks; but, in case of a bombardment, such a platform is to be avoided, because the shells will not only break the pavement, but also, by driving about the broken stones, do the troops much mischief.

The magazine to a field Battery is usually made about fifty or sixty yards behind the platform: it is a cavity dug in the ground, about four feet deep; the earth whereof is thrown between the pit and the platform; the sides of the pit are sometimes planked round to keep it dry, and prevent the earth from crumbling in; and the powder barrels placed herein are covered with hurdles and earth, or tanned hides, to preserve the powder from wet and fire.

The communication to the magazine is by a sloping trench beginning to descend about five or six yards behind the platform; and the earth thrown on that side where it will most conveniently cover the persons who remove the barrels of powder from the great magazine to the Battery, or small magazine.

When there are many cannon in Battery, and the service is quick, it is customary to have to every two pieces a small magazine to hold twenty or thirty barrels of powder: this is placed about fifteen or twenty yards behind the platform, and against the merlon between the cannon; and, as these barrels are used, they are replaced by others from the great magazine.

At each magazine a centinel is placed to prevent accidents.

And, to prevent persons coming into the Battery and magazines who have no business there, a trench is sometimes dug behind the magazine, and carried into the trenches which communicate between the magazine and Battery.

To construct a Fascine BATTERY.— For one gun provide fascines, of 9 feet, 600; of 6 feet, 100; of 3 feet, 120.

And, for every other piece of 9 feet, 400; of 6 feet, 100; of 3 feet, 100; each fascine being about nine inches thick; and let there be three or four pickets for every fascine, for many will break in driving.

Trace the limits of the parapet in two parallel lines about eighteen feet distant, allowing eight yards in length for one gun, and six yards for every other gun; and along these line cut a trench about half a spade deep.

Lay a row of nine feet fascines along one trench, observing that their ends be well jammed one into the other, and let each be pegged down with two pickets, drove into the ground till the head is sunk into the fascine.

Close to this row lay another, letting the two end ones be of six feet, and the rest nine feet, whereby the joinings in this row will not fall against the joinings in the first row: let these be also staked down as before. Close to the second row lay a third all of nine feet. Close to the third lay a fourth, the two end ones being six feet, and the rest nine feet. In this manner lay the rows of fascines within the limits staked out, which will be covered with twenty-four rows; then over this floor of fascines sprinkle earth to fill up the hollows, and let the whole be trod or rammed down.

On the first floor lay a second, observing, that as in the first floor every second row ended with six feet fascines; so in the second floor let every odd row end with six feet ones, whereby the joinings of no two fascines in this floor will fall over the joining of the fascines below them. Let the outside rows in the second floor be so placed over those of the lower, that there be a little sloping preserved, the work narrowing upwards. The pickets which stake down this floor are to be drove up to the head, and the channels or hollows in the floor are to be filled up with earth. In this manner lay four floors, which will raise the work to about two and a half or three feet; and that part of the breast-work called the wall will be compleated.

Measure from each end of the wall twelve feet, there stick a stake; and plant other stakes at every intermediate eighteen feet: this being done on the inside of the wall, let other stakes be planted on the outside, either directly opposite the former, or in the line towards the place where the gun is more particularly intended to deliver its shot. Plant other stakes on the inside, one a foot distant on each side the former, and this will leave spaces of two feet each for the inner opening of the embrasures: Then, on the outside, plant other stakes at five or six feet distance from the former ones, one on each side, and spaces of ten or twelve feet will be marked out for the outside openings of the embrasures.

In the direction of the pickets which limit the inner and outer openings of the embrasures, let single rows of fascines be staked down across the wall, and these will be the sides of the embrasures: fill the intermediate spaces or merlons with rows of fascines laid lengthwise to the wall, and this will be the first floor of the merlon, which is to be picketed down, and the hollows filled with earth as before directed. Let other floors be raised in like manner, until the merlons are carried up to about five or six feet, or more, if necessary; and on the top of each let a bed or floor of earth be laid of about 8 or 12 inches thick.

Across the top of the inner opening of the embrasure, either lay a bundle of 10 or 12 fascines bound together, or as many stuffed into a kind of basket open at both ends, and the bundle well staked to the merlons.

Provide a blind made of planks three or four inches thick, to fit the inner opening of the embrasure, which is to be put up, while the gunners are loading the piece, to preserve them from the fire of the musketry.

The cheeks or sides of the embrasures are to slope so, as to have the top wider than the bottom; which not only leaves a greater opening for the blast of the gun, but these slopes in works of this kind give a greater degree of strength to support themselves against the thrust of the upper parts.

Against each embrasure lay on the ground five pieces of timber called sleepers, of about eighteen feet long and six or eight inches square; let the ends next the embrasure be placed at such a distance from one another, that the distance from out to out be about six feet, the other ends spreading about twelve or fourteen feet from out to out; drive two stakes of about three inches square into the ground on both sides of each end of every sleeper, whereby they will be kept steady in their places, and let the earth be well rammed and beat up close to them: but observe to let the tails of the sleepers be raised about six or eight inches higher than the ends next the wall, to prevent the cannon from recoiling too much, when fired.

Cover the sleepers with planks of about two inches thick laid crosswise; that next the embrasures being about eight feet long, the rest gradually increasing, so that the plank at the tail be about fourteen feet long; and let the planks be nailed to the sleepers.

On this floor fix a piece of timber of about six or eight inches square next the embrasure, to serve as a spur for the carriage wheels to knock against (and is therefore usually called the knocker) when the gun is run up to the wall; observing that the spur be laid parallel to the object to be battered.

The whole platform should be of oak, if it can be had.

If there is any danger of the Batteries being raked by the enemies cannon, let an epaulment or screen be raised at one or both ends of the parapet, joining to it, and constructed by floors of fascines, as before shewn: then, all the straggling twigs of the fascines being cut off, the Battery is constructed.

A Battery thus made will do in case of haste, and where earth enough is not easily had: but, as it is subject to be fired when the wood is dry, it is not so much in use as another sort called a coffer Battery, especially where wood is scarce and earth plenty.

A Coffer BATTERY, is that where the sides of the wall and merlons only are formed of fascines, and all the cavities or included spaces filled with earth.

The place of the Battery being determined, make out, with a line of some kind, the limits of the parapet of about eighteen or twenty feet thick; and, three or four feet before the parapet, mark out with lines, or stakes, the limits of the ditch of about ten or twelve feet broad, or more, if earth is wanted; allowing eight yards in length for one gun, and six yards more for every other gun.

On the outlines of the parapet, cut a trench of about five or

six

six inches wide and deep, and therein lay a row of fascines, the ends being jammed one into the other; let these be staked down: lay on them another row, so that the joinings of these be not directly over the joinings of the lower one, and the knots of all the bands turned inwards; stake these down, and on them lay, in like manner, a third and a fourth row, &c. until the height be about three feet. The same kind of work being done at the ends, and for the epaulment, if wanted, the coffer for the wall will be made.

Then let the men be disposed along the place intended for the ditch, and, with the proper tools, break the ground, and throw it into the coffer; where another set of men are, as the earth is thrown in, to spread it and stamp it down with rammers; and this work is to be continued until the coffer is filled.

When the wall is finished, let the embrasures be staked out as before, and a coffer formed in like manner, as for the wall, for each merlon, which is also to be filled with earth, and rammed down.

The other articles in the preceding Battery are to be followed in this, the only difference being in the making of the parapet.

When a proper place for a temporary Battery is destitute both of dry earth and wood, then materials must be carried to the place; these usually are gabions and earth-sacks.

To make a gabion BATTERY.—Along the line, pitched out for the Battery, let the gabions be planted in the places where the merlons are to be: the gabions used are of five, six, and seven feet diameter, and eight feet high. Each merlon must have seven; that is, three within, of six feet diameter, next, two of seven feet diameter, and, on the outside, two of five feet diameter; observing to leave proper openings for the embrasures, of about two feet on the inside, and nine or ten on the outside.

Or thus: let the merlons be made of gabions five feet diameter; then put four within, three in the middle, and two on the outside; this construction being rather stronger than the former.

The ends and epaulments are also formed by three rows of gabions.

The floors or bottoms of the embrasures are to be filled with gabions of about three feet high, and of a proper diameter, to fill up the spaces between the merlons.

The gabions being placed, they are to be filled with earth brought from the nearest places that will afford it, in the earth-sacks; or else they may be filled with dung, mingled with sand; and, in cases of necessity, they may be filled with large faggots, or billet-wood, observing that the voids between the gabions are also filled.

Batteries of this construction are usually made on marshy or rocky ground. *Robertson's Elem. Nav.*

BATTERY is sometimes used in speaking of the fabric of metalline utensils.

In this sense, Battery-works include pots, saucepans, kettles, and the like vessels, which, though cast at first, are to be afterwards hammered or beaten into form.

A society for the mineral and Battery-work of England was incorporated by queen Elizabeth, to whom she granted all mines, minerals, and subterraneous treasures, except copperas and alum, in all parts of England, not mentioned in the patent of the society of the mines royal. This society has a governor, court of assistants, and other officers, who are the same as those for the mines royal, with whom they are now associated.

BAY, among carpenters, part of the capacity of a barn.—Thus, if a barn consists of a floor and two heads, where they lay the corn, they call it a barn of two Bays.

BAY-*window*, in architecture, one that is composed of an arch of a circle, and stands without the stress of the building.

BAYS *(Dict.)*—This stuff is without wheal, and is wrought on a loom, with two treddles, like flannel. It is chiefly manufactured at Colchester and Bockin in Essex, in England, where there is a hall, called the Dutch Bay-hall, or Raw-hall. By the statute, 12 Car. II. cap. 22, no person shall weave at Colchester any Bay, known by the name of four and fifties, sixty-eights, eighties, or hundred Bays, but, within two days after weaving any such, shall carry it to the Dutch Bay-hall, to be viewed and examined, that it may appear whether it be well and substantially wrought, before it be carried to be scoured and thickened. No scourer or thickener shall receive any such Bay, before it has been marked or stamped at the said hall. This manufacture, which is very considerable, was first introduced into England with that of says, serges, &c. by the Flemings, who, being persecuted by the duke of Alva, for the sake of their religion, fled hither, about the sixth year of queen Elizabeth's reign.

The exportation of Bays was formerly much more considerable than it is as present, the English then furnishing the French and Italians with those stuffs; but, of late years, the French have attempted to imitate them, and have admirably well succeeded, particularly at Beauvais, Castres, Montpelier, and Nismes. They also manufacture vast quantities of Bays in Flanders, and especially at Tournay, Lisle, and Neuf-Eglises. The people of that country call them baigues: however, the export of English Bays is still very considerable to Spain and Portugal, where they are called baetas; and even Italy. Their chief use is for dressing the monks and nuns, and for linings, especially in the army. The looking-glass-makers also use them behind their glasses, to preserve the tin, or quicksilver; and the case-makers, to line their cases.

The breadth of Bays is commonly a yard and an half, a yard and three quarters, or two yards, by forty-two and forty-eight in length. Those of a yard and three quarters are most proper for the Spanish trade.

BA'ZAC, or BAZA, spun cotton, very beautiful and very fine, which comes from Jerusalem, whence it is called Jerusalem cotton. The half Bazac, and the middling Bazac, come from the same place, but are of a much inferior quality.

BAZGE'NDGES, in natural history, the name of a substance used by the Turks, and other eastern nations, in their scarlet dying: they mix it for this purpose with cochineal and tartar, the proportions being two ounces of the Bazgendges to one ounce of cochineal.

The Bazgendges seem to be no other than the horns of the turpentine-tree in the eastern parts of the world: and it is not only in Syria that they are found, but China also affords them. Many things of this kind were sent over to Mr. Geoffroy at Paris, from China, as the substances used in the scarlet dying of that country; and they all proved wholly the same with the Syrian and Turkish Bazgendges, and with the common turpentine horns. The lentisk or mastic-tree is also frequently found producing many horns of a like kind with these, and of the same origin, all being owing to the pucerons, which make their way into the leaves, to breed their young there. *Reaumur, Hist. Insect.*

BEACH-*Tree, fagus*, a large and beautiful tree, whose leaves somewhat resemble those of the horn-beam: the male flowers grow together in a round bunch, and are produced at remote distances from the fruit on the same tree: the fruit consists of two or three triangular nuts, which are inclosed in a rough hairy rind, divided into four parts.

There is but one species of this tree at present known (except the two varieties with striped leaves, which are accidental) though the planters would distinguish two or three sorts; one of which they call the mountain Beach; and, as they say, affords a much whiter timber than the other, which they call the wild Beach: but as those have never been distinguished by the botanists, nor can I perceive any real difference amongst all the trees of this kind I have yet seen, I rather think the difference in the colour of the wood is occasioned by the place of their growth; which is often observed to be the case with most other sorts of timber.

This tree is propagated by sowing the mast; the season for which is any time from October to February; only observing to secure the seeds from vermin, when early sowed; which, if carefully done, the sooner they are sown, the better, after they are fully ripe: a small spot of ground will be sufficient to raise a great number of those trees from the seeds; but you must be very careful to keep them clear from weeds; and, if the plants come up very thick, you should not fail to draw out the strongest of them the autumn following, that those left may have room to grow: so that, if you husband a seed-bed carefully, it will afford a three years draught of young plants, which should be planted in a nursery; and, if designed for timber-trees, at three feet distance, row from row; and eighteen inches asunder in the rows.

But if they are designed for hedges (to which the tree is very well adapted) the distance need not be so great; two feet, row from row, and one foot in the rows will be sufficient. In this nursery they may remain two or three years, observing to clear them from weeds, as also to dig up the ground between their roots, at least once a year, that their tender roots may the better extend themselves each way; but be careful not to cut or bruise their roots, which is injurious to all young trees; and never dig the ground in summer, when the earth is hot and dry; which, by letting in the rays of the sun to the roots, is often the destruction of the young trees.

This tree will grow to a considerable stature, though the soil be stony and barren; as also upon the declivities of hills and chalky mountains, where they will resist the winds better than most other trees; but then the nurseries for the young plants ought to be upon the same soil; for, if they are raised in a good soil, and a warm exposure, and afterwards transplanted into a weak barren situation, they seldom thrive, which holds true in most other trees; therefore I would advise the nursery to be made upon the same soil where the plantation is intended: but of this we shall say more under the article NURSERY.

The tree is very proper to form large hedges, to surround plantations, or large wilderness-quarters; and may be kept in a regular figure, if sheared twice a year, especially if they shoot strong; in which case, if they are neglected but a season or two, it will be difficult to reduce them again. The shade of this tree is very injurious to most sorts of plants which grow near it, but is generally believed to be very salubrious to human bodies.

The timber is of great use to turners, for making trenchers; dishes,

dishes, trays, buckets; and likewise to the joiners for stools, bedsteads, coffers, &c. The mast is very good to fat swine and deer; it also affords a sweet oil, and hath, in some families, supported men with bread.

This tree delights in a chalky or stony ground, where it generally grows very fast; and the bark of the trees, in such land, is clear and smooth; and, although the timber is not so valuable, as that of many other trees, yet, as it will thrive on such soils, and such situations, where few better trees will grow, the planting of them should be encouraged; especially as the trees afford an agreeable shade, and the leaves make a fine appearance in summer, and continue green as long in autumn as any of the deciduous trees; therefore, in parks, and other plantations for pleasure, this tree deserves to be cultivated among those of the first class; especially where the soil is adapted to it.

The two sorts with variegated leaves may be propagated by budding or grafting them upon the common Beach, observing not to plant them in a good earth; which will cause the buds or cyons to shoot vigorously, whereby the leaves will become plain; which often happens to most variegated plants.

This tree affords us two articles for trade, namely, its timber, and its fruit, or seed. The wood of the Beach is whitish, hard, dry, and crackles in the fire. In France it is commonly sold in the forests, cut into boards, stakes, and shingles, to be afterwards used in making houshold furniture, and other joiners work. The boards ought to be from eleven to twelve inches broad, thirteen lines thick, and six, nine, or twelve feet long.

The Beach-timber is also sold in laths, which are small thin boards, designed for the drawer and trunk-makers.

They likewise make of this wood staves, saddle-bows, &c.

It is very useful for making the keel and inside of ships.

Beach-wood is also used for making shovels, spoons, wooden-shoes, and other such small-wares.

Of the largest trunks of Beach-trees are made forms, and kitchen-tables, which are four, five, six, and seven inches thick, and of different breadths and lengths, according as the trunks are more or less thick and long.

Beach-wood also makes good fuel; for which reason, there is a great deal of it sold in faggots, in cords of wood, in logs, &c.

The fruit or seed of the Beach-tree, which is a kind of nut, or acorn, called mast, contains a kind of white and oily marrow, or pulp, of a sweet taste, and agreeable to eat; of which they make oil, very much esteemed for frying, and for sallads. This oil, which is very common in Picardy, and those places where there are many Beach-trees, is extracted cold by expression, after the shell of the mast has been taken off, and the pith broke or bruised. There are some countries where hogs are fattened with Beach-masts, as they are with acorns in other places.

The common people in France use that oil instead of butter; but most of those who use a great deal of it, complain of pains and heaviness in the stomach. M. Danty d'Isnard has prescribed a method to prevent those inconveniencies. We must pour the oil of masts, newly expressed, into stone pitchers, very closely shut; put them into the ground, and leave them there a year; after which time the oil will have lost all its bad qualities.

BEAD-PROOF, a term used by our distillers, to express that sort of proof of the standard strength of spirituous liquors, which consists in their having, when shaken in a phial, or poured from on high into a glass, a crown of bubbles, which stand on the surface some time after. This is esteemed a proof that the spirit consists of equal parts of rectified spirits and phlegm.

BEAM, or ROLLER, used by weavers, is a long and thick wooden cylinder, placed lengthways on the back part of the loom of those who work with the shuttle. The threads of the warp of linen or woollen cloth, serges, and other woollen stuffs, are rolled upon the Beam, and enroll, as the work goes on. That cylinder, on which the stuff is rolled, as it is weaved, is also called the Beam or roller, and is placed on the fore-part of the loom.

BEAM *of a plough*, a name given by our farmers to the great timber of the plough, into which all the other parts of the plough-tail are infixed.

This is usually made of ash, and is straight, and eight feet long in the common plough; but, in the four-coultered plough, it is ten feet long, and its upper part arched. The head of this Beam lies on the pillow of the plough, and is raised higher, or sunk lower, as that pillow is elevated or depressed, by being slipped along the crow-staves. Near the middle, it has an iron collar, which receives the tow-chain from the box; and the bridle-chain from the stake or gallows of the plough is fixed into it a little below the collar. Some inches below this, there is an hole, which lets through the coulter; and below that there are two other small ones, through which the heads of the retches pass. These are the irons which support the sheat, and with it the share. Farther backward still is a large perforation, through which the body of the sheat passes; and behind that, very near the extremity, is another hole, through which the piece called the hinder-sheat passes. *Tull's Husb.* See PLOUGH.

BEAM, in building (*Dict.*)—The proportions of Beams near London are fixed by statute, as follows; a Beam, fifteen feet long, must be seven inches on one side its square, and five on the other; if it be sixteen feet long, one side must be eight inches, the other six; if seventeen feet long, one side must be ten inches, the other six: in the country they usually make them stronger. Sir H. Wotton advises these to be of the strongest and most durable timber.

Herrera tells us, that, in Fer. Cortez's palace, in Mexico, there were 7000 Beams of cedar; but he must certainly use the word Beam in a greater latitude than we do. In effect, the French, under poutre, Beam, take in not only the pieces which support the rafters, but also those which sustain the joists of the cielings.

Some of their best authors have considered the force or strength of Beams, and brought their resistance to a precise calculation; particularly M. Varignon and M. Parent; the system of the latter is as follows:

When, in a Beam breaking parallel to its base, which is supposed to be a parallelogram, two plans of fibres, which were before contiguous, are separated, there is nothing to be considered in those fibres, but their number, bigness, tension before they broke, and the lever by which they act; all these together making the strength or resistance of the Beam to be broke.

Suppose then another Beam of the same wood, where the base is likewise a parallelogram, and of any bigness, with regard to the other, at pleasure; the height or thickness of each of these, when laid horizontal, being divided into an indefinite number of equal parts, and their breadth into the same number, in each of their bases will be found an equal number of quadrangular cells, proportionable to the bases whereof they are parts. These then will represent little bases, or, which is the same thing, the thicknesses of the fibres to be separated for the fracture of each Beam: and, since the number of cells is equal in each, the ratio of the bases of both Beams will be that of the resistance of their fibres, both with regard to number and thickness.

Now, the two Beams being supposed of the same wood, the fibres most remote from the points of support, which are those which break the first, must be equally stretched when they break. Thus the fibres, *v. gr.* of the tenth division, are equally stretched in each case, when the first breaks; and, in whatever proportion the tension be supposed, it will be still the same in both cases; so that the doctrine is intirely free, and unembarrassed with any physical system.

Lastly, it is evident, the levers whereby the fibres of the two Beams act, are represented by the heighth or depth of their bases; and, of consequence, the whole resistance of each Beam is the product of its base, by its height; or, which is the same thing, it is the square of the height, multiplied by the breadth; which holds, not only in case of parallelogramatic, but also of elliptic bases.

Hence, if the bases of two Beams be equal, though both their heighths and breadths be unequal, their resistance will be as their heighths alone; and, by consequence, one and the same Beam, laid on the smallest side of its base, will resist more than when laid flat, in proportion as the first situation gives it a greater height than the second; and thus an elliptic base will resist more, when laid on its greatest axis, than when on its smallest.

Since, in Beams equally long, it is the bases that determine the proportion of their weights or solidities; and since, their bases being equal, their heighths may be different; two Beams of the same weight may have resistances differing to infinity; thus, if, in the one, the height of the base be conceived infinitely great, and the breadth infinitely small, while in the other the dimensions of the base are infinite; the resistance of the first will be infinitely greater than that of the second, though their solidity and weight be the same. If, therefore, all required in architecture were to have Beams capable of supporting vast loads, and, at the same time, be of the least weight possible, it is plain they must be cut thin as laths, and laid edge-wise.

If the base of two Beams be supposed unequal, but the sum of the sides of the two bases equal, *v. gr.* if they be either twelve and twelve, or eleven and thirteen, or ten and fourteen, &c. so that they always make twenty-four; and further, if they be supposed to be laid edge-wise, pursuing the series, it will appear, that, in the Beam of twelve and twelve, the resistance will be 1728; and the solidity or weight 144; and that in the last, or one and twenty-three, the resistance will be 529, and the weight twenty-three; the first, therefore, which is square, will have less than half the strength of the last, with regard to its weight.

Hence M. Parent remarks, that the common practice of cutting Beams out of trees as square as possible is ill husbandry: he hence takes occasion to determine, geometrically, what dimensions the base of a Beam, to be cut off any tree proposed, shall have, in order to its being of the greatest possible strength; or, which is the same thing, a circular base being given,

given, he determines the rectangle of the greatest resistance that can be inscribed; and finds, that the sides must be nearly as seven to five, which agrees with observation.

Hitherto the length of the Beams has been supposed equal; if it be unequal, the bases will resist so much the less, as the Beams are longer.

To this it may be added, that a Beam sustained at each end, breaking by a weight suspended from its middle, does not only break at the middle, but also at each extreme; or, if it does not actually break there, at least immediately before the moment of the fracture, which is that of the equilibrium, between the resistance and the weight, its fibres are as much stretched at the extremes, as in the middle. So that, of the weight sustained by the middle, there is but one third part which acts at the middle, to make the fracture; the other two only acting to induce a fracture in the two extremes.

A Beam may either be supposed laden only with its own weight, or with other foreign weights applied at any distance, or else only with those foreign weights. Since, according to M. Parent, the weight of a Beam is not ordinarily above $\frac{1}{70}$ part of the load given it to sustain, it is evident, that, in considering several weights, they must all be reduced, by the common rules, to one common center of gravity.

M. Parent has calculated tables of the weights that will be sustained by the middle, in Beams of various bases and lengths, fitted at each end into walls, on a supposition, that a piece of oak an inch square, and a foot long, retained horizontally by the two extremes, will sustain 315 *lb.* in its middle before it breaks, which it is found by experience it will. *See Mem. Acad. R. Scienc. An.* 1708.

BEAN, *faba*, in botany, the name of a genus of plants; whose characters are: the flower is of the papilionaceous kind, and from its cup there arises a pistil, which finally becomes a large pod, containing large, flatted, and, in some degree, kidney-shaped seeds. To this it is to be added, that the stalks are firm and erect, and the leaves stand by pairs, on a middle rib, which is terminated by an odd one.

Mr. Tournefort has enumerated eight species of this plant, But we have only the four following sorts, commonly sowed in our Gardens. 1. The small Lisbon. 2. The Spanish. 3. The Sandwich. And, 4. The Windsor Beans.

The first and second sorts are to be planted in October and November, under warm walls and hedges, where if they stand through the winter, they produce Beans early in the spring. They may also be raised very close in beds, and covered with hoops and matts in the winter, and in the spring planted out; but there is some hazard in the transplanting, and they will be a fortnight, or more, later than those which have stood the winter abroad.

The Lisbon Bean is preferred to the Spanish; and the curious ought to have fresh seed every two years from abroad, for they are apt to degenerate, though not in goodness, yet in their earliness.

The Spanish and Windsor Beans are not to be planted till Christmas, but especially the Windsor, which are subject, more than any other kind, to be hurt by the cold. These Beans should have an open ground, and be planted at the distance of two feet and a half, row from row, and four inches from one another in the rows; but, if the place is closely surrounded with hedges or walls, the distance must be greater, else the stalks will run high, but they will bear very little fruit.

The Sandwich Beans are hardier than the Windsor, and may be planted to come in between the early crops and them, and, though not much regarded at present, they are a very good Bean.

The first plantation of Windsor Beans should be made in the middle of January; and, after that, a new plantation should be made every three weeks, till the middle of May, that there may be a succession of crops. *Miller's Gard. Dict.*

Beans, with a proper management, make one of the finest of all baits for fish. The method of preparing of them for this purpose is this: take a new earthen pot, glazed on the inside, boil some Beans in it, suppose a quarter of a peck: they must be boiled in river water, and should be beforehand steeped in some warm water, for six or seven hours. When they are about half boiled, put in three or four ounces of honey, and two or three grains of musk: let them boil a little on, then take them off the fire, and use them in this manner: seek out a clean place, where there are no weeds, that the fish may see and take the Beans at the bottom of the water. Throw in some Beans at five or six in the morning, and in the evening, for some days. This will draw them together, and they may be taken in a casting-net, vast numbers together.

BEAR, in zoology, denotes a well known quadruped of the cat kind, of some use in medicine, but more in commerce and sport. See *Plate* VI. *fig.* 34.

Some distinguish two kinds of Bears, terrestrial and marine; the former of which keep to the mountains; whereas the latter come out on the ice, as far as the middle of the North sea. Some of this kind are found in Nova Zembla, of an incredible size.

Bear-skins are a sort of furs, very much esteemed, and there is a very large trade of them, whether they be skins of young Bears, or of old ones. The latter are commonly used to make housings, or horse-cloaths, or, in the more northern climes, for bags to keep the feet-warm, in the sharpest cold of the winter. The skins of young Bears serve to make muffs, and other such things for warmth or ornament.

Besides the great quantity of Bears-skins which the fellmongers sell, the druggists sell also Bear's-fat, or grease, which they commonly get from Switzerland, Savoy, and Canada.

That grease is a powerful remedy for the cure of the king's evil, and the rheumatism. It is also used with success for curing the gout, and it is also employed in several Galenic compositions. Bear's-grease, in order to be of a good quality, must be chosen newly melted, greyish, clammy, of a strong and pretty bad smell, and of a middling consistence or thickness. That which is too white is adulterated, and mixed with common tallow.

BEA'RINGS, in heraldry, a term used to express a coat of arms, or the figures of armories, by which the nobility and gentry are distinguished from the vulgar, and from one another.

BEAST *of burden*, a name given to all four-footed animals, which serve to carry burdens and merchandizes on their backs. Those that are most commonly used, are elephants, dromedaries, camels, horses, mules, asses, the sheep of Mexico and Peru, and the vicnua. There are also some places on the coast of Africa, where they use oxen; nay, even large dogs are sometimes employed for that purpose, as may be seen in Flanders, and in some other countries.

Gold-BEA'TING.—First a quantity of pure gold is melted, and formed into an ingot; this, by forging, is reduced to a plate about the thickness of a sheet of paper, which plate is afterwards cut into little pieces, about an inch square, and laid in the first and smallest mould, to begin to stretch them.

These moulds are made of vellum, consisting of forty or fifty leaves, and, after they have hammered a while thus with the smallest hammer, they cut each of them into four, and put them into the second mould of vellum, which consists of two leaves, to be extended farther.

Then they are taken out again, and cut into four, and put into the third mould, which is made of bullock's gut, well scoured and prepared, and consisting of five hundred leaves, and beaten; then they are taken out and divided into four again, and laid in the last and finishing mould, which is also of bullock's gut, and containing five hundred leaves; and there they are beaten to the degree of thinness required.

The leaves, being thus finished, are taken out of the mould, and disposed in little paper books prepared with red bole, for the gold not to stick to; each book usually containing twenty-five leaves. These books are of two sizes, twenty-five leaves of the smallest of which weigh but five or six grains: and twenty-five of the largest, nine or ten grains.

Gold is beaten more or less, according to the quality or kind of work it is designed for; that which is for the use of gold wire-drawers, to gild their ingots withal, is left much thicker than that for gilding picture frames, &c.

The gold-beaters use three hammers of different sizes, of well polished iron, something in the form of mallets. The first, which weighs three or four pounds, serves to chase or drive; the second, eleven or twelve pounds, which is to close; and the third, which weighs fourteen or fifteen pounds, to stretch and finish.

BEATING *flax*, or *hemp*, is an operation in the dressing of these matters, contrived to render them more soft and pliant. *Hought. Collect.*

When hemp has been swingled a second time, and the hurds laid by, they take the strikes, and dividing them into dozens, and half dozens, make them up into large thick rolls, which, being broached on long sticks, are set in the chimney corner to dry; after which they lay them in a round trough made for the purpose, and there with beetles beat them soundly, till that they handle, both without and within, as pliant as possible, without any hardness or roughness to be felt: that done, they take them from the trough, open and divide the strikes as before, and, if any be found not sufficiently beaten, they roll them up, and beat them over as before. *Dict. Rust.*

BEATING, in the paper works, signifies the Beating of paper on a stone, with a heavy hammer with a large, smooth head, and short handle, in order to render it more smooth and uniform, and fit for writing. *Savar. Dict. Comm.*

BEAVER, *(Dict.)*—This creature is about four feet in length, and twelve or fifteen inches broad. His skin, in the northern regions, is generally black, but it brightens into a reddish tincture, in the temperate climates. He is covered with two sorts of hair, one long, and the other a soft down; the latter, which is an inch in length, is extremely fine and compact, and accommodates the animal with a necessary warmth. The long hair preserves the down from dirt and humidity. *See Plate* VI. *fig.* 35.

The Beaver, whether male or female, has four bags under his intestines, impregnated with a resinous and liquid substance, which, when it is ejected, settles into a thick consistence.

tence. See the article CASTOREUM in the Dictionary.

His teeth are ſtrong, and deeply riveted into his jaws, with a long and crooked root; with theſe he cuts as well the wood with which he builds, as that which furniſhes him with food. His fore feet reſemble thoſe of ſuch animals as hold what they eat with their paws, as apes, for inſtance, and rats, and ſquirrels; with theſe feet he digs, ſoftens, and works the clay, which is extremely ſerviceable to him. His hind feet are accommodated with membranes, or large ſkins, extending between his toes, like thoſe of ducks, and all other water-fowl: this makes it evident that the author of nature intended the creature ſhould be amphibious. His tail is long, a little flat, entirely covered with ſcales, ſupplied with muſcles, and perpetually lubricated with oil or fat: this animal, who is an architect from his nativity, uſes his tail inſtead of a hod, for the conveyance of his clay or mortar, and a trowel to ſpread and form it into an incruſtation; the ſcales prevent theſe materials from penetrating the tail with their coldneſs and humidity. But the ſcales, as well as the tail, would be injured by the air and water, were it not for the prevention of an oil, which he diſtributes all over them with his ſnout; the bags we have already mentioned, are undoubtedly the magazines of this fluid.

The Beavers inhabit the ſame manſion in great numbers, unleſs violent heats, or inundations, the purſuits of hunters, ſcarcity of proviſions, or the extraordinary increaſe of their offſpring, obliges them to ſeparate. In order to raiſe themſelves a convenient abode, they chuſe a ſituation that abounds with ſuſtenance, and is waſhed by a rivulet, and where they may form a convenient reſervoir of water for their habitation. They begin with building a mole or cauſey, in which the water may riſe to a level with the firſt ſtory.

This cauſey, at the foundation, may contain ten or a dozen feet in thickneſs; it deſcends in a ſlope on the ſide next the water, which, in proportion to its elevation, gravitates upon the work, and preſſes it with a ſtrong tendency towards the earth. The oppoſite ſide is raiſed perpendicularly, like our walls; and the ſlope which at its baſis is twelve feet broad, diminiſhes towards the top, whoſe breadth does not exceed two feet: the materials of this work are wood and clay. The Beavers, with an admirable facility, cut the pieces of wood, ſome as thick as a man's arm, and others as large as the thigh, and from two to four, five, or ſix feet in length, and ſometimes more, in proportion to the aſcent of the ſlope. They drive the extremity of theſe, very near each other, into the earth, and take care to interlace them with other ſtakes, more ſlender and ſupple. But as the water, without ſome other prevention, would glide through the cavities, and leave the reſervoir dry, they have recourſe to a clay, which they perfectly know how to procure, and with which they cloſe up all the interſtices, both within and without, and this entirely prevents all evacuation. They continue to raiſe the dike proportionably to the water's elevation and plenty. They are likewiſe very ſenſible, that their materials are not ſo eaſily tranſported by land as by water, and therefore take the opportunity of it's increaſe to ſwim, with mortar placed on their tail, and ſtakes of wood between their teeth, to every place where they have occaſion for theſe materials. If the violence of the water, or the footſteps of hunters, who paſs over their work, damage it in any degree, they immediately repair the fracture, viſit all the edifice, and, with indefatigable application, refit and adjuſt whatever happens to be diſconcerted. But, when they are too frequently perſecuted by the hunters, they only work in the night, or entirely diſcontinue their labours.

When the cauſey, or dike, is compleated, they begin to form their cells, which are round, or oval apartments, divided into three partitions, raiſed one above another. The firſt is ſunk below the level of the dike, and generally full of water; the other two are formed above it. They raiſe this ſtructure, in a very ſolid manner, on the edge of their cauſey, and always in ſtories, that, in caſe the water ſhould aſcend, they may dwell in an higher ſituation. If they find any little iſland near the reſervoir, they fix their dwelling there, which is then more ſolid, and they are leſs incommoded with the water, in which they are capable of continuing but a ſhort time: but, if they are not favoured with this advantage, they drive ſtakes into the earth with their teeth, to fortify the building againſt the winds and water. At the bottom they ſtrike the two openings to the ſtream; one conducts them to the place where they bathe, and which they always keep very decent; the other is a paſſage to that quarter, where they carry out every thing that would ſoil or rot the upper apartments. There is a third aperture much higher, calculated to prevent their being ſhut up, when the ice hath cloſed the openings into the lower lodgments. They ſometimes build their houſes entirely on dry land, and ſink ditches, five or ſix feet deep, in order to deſcend to the water. They employ the ſame materials and induſtry in the ſtructure of their dwellings, as they uſe for the cauſey. The walls of the building are perpendicular, and two feet thick. As their teeth are more ſerviceable than ſaws, they cut off all the projections from the wood, that ſhoot out beyond the perpendicular of the wall; after which they work up a mixture of clay and dry graſs, into a kind of mortar, with which, by the aid of their tails, they rough-caſt the out and inſides of the work.

The edifice is vaulted within, and generally riſes in an oval figure. The dimenſions are proportioned to the number of the intended inhabitants. Twelve feet in length, and ten in breadth, are ſufficient for eight or ten Beavers. If the number increaſes, they enlarge the place accordingly. It has been aſſerted for a truth, that there have been found above an hundred of theſe creatures, in different lodgments, communicating with one another. But theſe populous ſocieties are very rare, becauſe they are too unmanageable and tumultuous, and the Beavers are generally better acquainted with their own intereſt. They aſſociate to the number of ten or twelve, and ſometimes a few more.

There are ſome Beavers, called terriers, who make their abode in caverns, dug in a riſing ground, either on the ſhore, or at ſome diſtance from the water, to which they ſcoop out ſubterraneous trenches from their caverns, which deſcend from ten to an hundred feet in depth. Theſe trenches furniſh them with retreats, ſituated at unequal heights, and wherein they enjoy a ſhelter from the water, when it riſes.

All theſe works, eſpecially in the cold regions, are compleated in Auguſt, or September, after which period, they furniſh themſelves with proviſions. During the ſummer ſeaſon, they regale themſelves with all the fruits and plants the country produces. In the winter, they eat the wood of the aſh, the plane, and other trees, which they ſteep in water, in quantities proportionable to their neceſſary conſumption; and they are ſupplied with a double ſtomach, to facilitate the digeſtion of ſuch a ſolid food, at two operations. They cut twigs from three to ſix feet in length; the large ones are conveyed by ſeveral Beavers to the magazine, and the ſmaller by a ſingle animal, but they take different ways; each individual hath his walk aſſigned him, to prevent the labourers from being interrupted by their mutual occaſions. The dimenſions of their pile of timber are regulated in proportion to the number of the inhabitants; and it has been obſerved, that the proviſion of wood for ten Beavers comprehended thirty feet in a ſquare ſurface, and ten in thickneſs. Theſe parcels of wood are not piled up in one continued heap, but laid acroſs one another, with interſtices between them, that they may the better draw out what quantity they want, and always take the parcel at the bottom, which lies in the water. They cut this wood into ſmall pieces, and convey it to their cell, where the whole family comes to receive their particular ſhare.

Merchants diſtinguiſh three ſorts of Beavers, though they are all the ſkins of the ſame animal: the new Beaver, the dry Beaver, and the fat Beaver.

The new Beaver, which is alſo called white Beaver, or Muſcovy Beaver, becauſe it is commonly kept to be ſent into Muſcovy, is that which the ſavages catch in their winter hunting. It is the beſt, and the moſt proper for making fine furs, becauſe it has loſt none of its hair by ſhedding.

The dry Beaver, which is ſometimes called lean Beaver, comes from the ſummer hunting, which is the time when theſe animals loſe part of their hair.

Though this ſort of Beaver be much inferior to the former, yet it may alſo be employed in furs; but it is chiefly uſed in the manufacture of hats. The French call it ſummer caſtor, or Beaver.

The fat Beaver is that which has contracted a certain groſs and oily humour, from the ſweat which exhales from the bodies of the ſavages, who wear it for ſome time. Though this ſort be better than the dry Beaver, yet is uſed only in the making of hats.

Beſides hats and furs, in which the Beaver's hair is commonly uſed, they attempted in France, in the year 1699, to make other manufactures with it; and, accordingly, they made cloths, flannels, ſtockings, &c. partly of Beaver's hair, and partly of Segovia wool. This manufactory, which was ſet up at Paris, in St. Anthony's ſuburb, ſucceeded, at firſt, pretty well; and, according to the genius of the French, the novelty of the thing brought into ſome repute the ſtuffs, ſtockings, gloves, and cloth, made of Beaver's hair. But they went out of faſhion of a ſudden, becauſe it was found, by experience, that they were of a very bad wear, and, beſides, that the colours faded very much: when they had been wet, they became dry and hard, like felt, which occaſioned the miſcarriage of the manufactory for that time.

When the hair has been cut off from the Beaver's ſkin, to be uſed in the manufactory of hats, thoſe ſkins are ſtill employed by ſeveral workmen; namely, by the trunk-makers, to cover trunks and boxes; by the ſhoe-makers, to put into ſlippers; and by turners, to make ſieves for ſifting grain and ſeeds.

Hot-BEDS, in gardening, are enriched with extraordinary plenty of manure, and ſheltered from the cold air, by ſtraw coverings, frames, and the like, ſerving to help forward the growth of plants, and force a vegetation, where either the ſeaſon, or the climate of itſelf, is not warm enough.

To make a Hot-Bed in February, for the raiſing of colli-flowers, cucumbers, melons, radiſhes, or other tender plants or flowers, they provide a warm place, defended from all winds, by being incloſed with a pale or hedge, made of reed or ſtraw, and laid with freſh horſe-dung, ſix or eight days old, trodden down hard, and level on the top; over which they lay rich earth, three or four inches thick. When the extreme heat of the bed is over, which may be perceived by thruſting in the finger, then plant their ſeeds. This done, they ſet up forks, four or five inches above the bed, to ſupport a frame made of ſticks, and covered with ſtraw or baſs matt, to ſecure the ſeedlings from the weather. As the plants ſhoot in height, they earth them up; and, when able to bear the cold, tranſplant them into natural beds. *Bradley.*

BEE, *Dict.* — The ſting of the Bee is a very curious weapon, and, when examined by the microſcope, appears of a very ſurprizing ſtructure. It has a horny ſheath or ſcabbard, which includes two bearded darts. This ſheath ends in a ſharp point, near the extremity of which, a ſlit opens, through which, at the time of ſtinging, the two bearded darts are protruded beyond the end of the ſheath: one of theſe is a little longer than the other, and fixes its beard firſt, and, the other inſtantly following, they penetrate alternately deeper and deeper, taking hold of the fleſh with their beards, or hooks, till the whole ſting is buried in the fleſh; and then a venomous juice is injected through the ſame ſheath, from a little bag, at the root of the ſting, which occaſions an acute pain, and a ſwelling of the part, which ſometimes continues for ſeveral days. But this is beſt prevented, by enlarging the wound directly, to give it ſome diſcharge. Mr. Derham counted, on the ſting of a waſp, eight beards on the ſide of each dart, ſomewhat like the beards of fiſh-hooks; and the ſame number are to be counted on the darts of the Bee's ſting.

When theſe beards are ſtruck deep in the fleſh, if the wounded perſon ſtarts, or diſcompoſes the Bee, before it can diſengage them, the ſting is left behind ſticking in the wound; but, if he have patience to ſtand quiet, the creature brings the hooks down cloſe to the ſides of the darts, and withdraws the weapon; in which caſe, the wound is always much leſs painful. A waſp is not ſo liable to leave its ſting in the wound as a Bee, the beards of it being ſhorter, and the creature more vigorous and nimble in its motions.

To view the ſting of a Bee by the microſcope, the end of the tail is to be cut off, and then, touching it with a pin or needle, it will thruſt out the ſting and darts, which may be cut off with a nice pair of ſciſſars, and kept for obſervation: or, if a Bee be caught in a leather glove, its ſting will be left in the glove, the creature being unable to diſengage it from the leather. The bag, containing the poiſonous juice, may eaſily be found at the bottom of the ſting, and examined, it being commonly pulled out with it; and, if a living Bee be provoked to ſtrike with its ſting, againſt a plate of glaſs, enough of the liquor will be left on the glaſs, for examination; and the ſalts of it may be ſeen, forming themſelves into cryſtals. *Baker on the Microſcope.*

Mr. Dudley ſpeaks of a method of hunting, or finding of Bee's neſts, practiſed, of late years, in the woods of New England. It conſiſts in catching a Bee, then letting it fly, and obſerving the way it ſteers; this ſhews the hunter the courſe, or bearing of the neſt. To find the diſtance, he takes an off-ſet of an hundred perches, and lets fly another Bee; the angle, or point wherein theſe two courſes interſect, is the place of the neſt. *Phil. Tranſ.* N°. 367.

BEET, *beta*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the ſtaminous kind, conſiſting of ſtamina, ariſing from a five-leaved cup. Great numbers of theſe flowers are uſually collected into a ſort of head; and the cups finally become capſules, nearly of a globular figure, in which are contained the ſeeds.

Mr. Tournefort has enumerated two ſpecies of this plant.

All the ſpecies of this plant are propagated by ſowing their ſeeds in February, or March, in a looſe, deep ſoil, not over dunged. When they are come up, they muſt be hoed out, ſo as to leave them ten or twelve inches aſunder; for, if they have not room, the roots ſeldom grow large. It is a cuſtom, with the gardeners about London, to ſow carrots on the ſame ground with their Beets. The carrots are drawn off in the ſummer time, and the Beets have then ſufficient time to grow to their ſize. *Miller's Gard. Dict.*

BEE'TLE, in zoology. See the article SCARABÆUS.

Beetle, in a mechanical ſenſe, denotes a large wooden inſtrument, formed after the manner of the mallet, and uſed for driving piles, paliſades, wedges, and the like.

BE'ING, entity, or thing, ſomething which has an eſſence and exiſtence diſtinct from other things; it is conſidered as poſſible or actual: when poſſible, it is ſaid to have an eſſence or nature; ſuch were all things before their creation: when it is conſidered as actual, then it is ſaid to have exiſtence alſo; ſuch are all things which are created, and God himſelf the creator. Eſſence, therefore, is but the very nature of any Being, whether it be actually exiſting or no. A roſe in winter has an eſſence, in ſummer it has exiſtence alſo: it may not be improper to remark, that there is but one Being that includes exiſtence, in the very eſſence of it, and that is God, who therefore actually exiſts by natural and eternal neceſſity; but the actual exiſtence of any other Being is very diſtinct from its eſſence: for it may be, or may not be, as God pleaſes. Again, every Being is conſidered either as ſubſiſting in and by itſelf, and then it is called a ſubſtance; or ſubſiſts in and by another, and then it is called a mode, or manner of Being. Though few writers allow mode to be called a Being, in the ſame perfect ſenſe as the ſubſtance is; and ſome modes have evidently more of real entity or Being than others, See the article Mode. Mr. Locke ſays, there are but two ſorts of Beings that man knows and conceives. Firſt, ſuch as are purely material, without ſenſe, perception or thought, as the clipping of our beard, and paring or cutting our nails. Secondly, ſenſible, thinking, perceiving Beings. ſuch as we find ourſelves, which he calls cogitative; and cogitative exiſtence is a bleſſing to thoſe Beings only, which are endowed with perception, and is in a manner thrown away upon dead matter, any farther than as it is ſubſervient to Beings, which are conſcious of their own exiſtence. See the ſenſible ſcale of Beings, beautifully conſidered, by Mr. Addiſon, *Spect.* 219.

BELEMNITE, *or thunder-ſtone. Lapis Belemnites,* (*Dict.*)— The Belemnites is of the number of thoſe extraneous foſſils, which we have not yet been able to reduce to their kindred anomala: we only know that it is a petrifaction of an animal body, or part of an animal body; but, till we are much better acquainted with the creatures which inhabit the depths of the ſea, we are not to expect to find the mould in which every figured foſſil in the world has been caſt. See *Plate* VI. *fig.* 33.

The Belemnite is an oblong and ſlender body, ſomewhat pellucid, and of a browniſh or yellowiſh colour. It has ſeveral varieties in ſhape, which make ſo many ſpecies of it among the naturaliſts; but all agree in the main characters, and all are indifferently received as Belemnites in the ſhops.

The Belemnites are all compoſed of multitudes of thin coats, or cruſts, encircling one another, and are all of them of a tranſverſely ſtriated texture; they have always a hollow or cavity of a conic form, wide at the mouth, and tapering to a point at the bottom, placed at their large end; but this is uſually not exactly in the center, but on one ſide. In ſome, indeed, it grows ſo wide at the very extremity, as to take in the whole body of the Belemnite, and leave only a thin cruſt for its circumference. This cavity is frequently found empty, ſometimes it is filled up with earthy or ſtony matter, and ſometimes there is lodged in it a concamerated ſhell of a peculiar kind, which ſo exactly fits and fills it every way, that it is hard to doubt of its being the original inhabitant; though we know very well, that petrifactions of the ſame concamerated ſhell-fiſh are found in ſtone and earth, where there are no Belemnites. This is of the nature of thoſe foſſils, called orthoceratitæ, or ſtraight nautili, all which are, though common enough in their foſſil ſtate, as wholly unknown to us in their recent one, as the Belemnite itſelf. The inſide of the cavity in many of the Belemnites, in which it is found empty, is regularly marked with alternate ridges and furrows all the way round, ſuch as would exactly correſpond to the concamerated ſhell, found in the others, and plainly indicating that ſuch had once alſo been there.

The Belemnites have, in general, a ſingle crack or ſlit, running down the whole length of the body, or nearly ſo, in the form of a ſtraight line. Some we find, however, that have no mark of any fiſſure of this kind, and, on the other hand, ſome that have two or three of them inſtead of one; but the additional ones only begin at the apex, or end, and never run any great way up.

The uſual form of the Belemnites is that of a long and ſlender cone, tapering by degrees, from a not very large baſe, to an obtuſe point; and the general ſize is about the length and thickneſs of a finger, though there are vaſt numbers found much ſmaller, and ſome conſiderably larger. But, beſides theſe conic ones, there are ſome of a regularly cylindric form, and ſome others which are thickeſt near one of the ends, and grow gradually thinner and ſmaller, as they approach to both. Some are found of all the intermediate figures, between the cylindric and conic, and ſome are almoſt orbicular; theſe laſt are always very ſhort and ſmall: ſome of them taper off to a point very gradually, and others very abruptly, and ſome are, inſtead of being rounded, flatted on one ſide, and ſometimes on both; and we alſo ſometimes find them cruſhed and cracked by accidents, as the other petrifactions of animals frequently are. We find of them as far as to eight inches in length, and they ſometimes vary in colour from their uſual yellowiſh brown, and are found of a blackiſh or bluiſh grey, and ſometimes of a cheſnut colour, ſometimes of a darker or paler brown, with no admixture of yellow in it.

The Belemnites are found in almoſt all parts of the world, they are extremely common in Germany; we find them alſo in ſufficient plenty in England, and France and Italy abound with them. They are ſometimes brought to us from Syria, among the lapides Judaici, and very frequently among the coarſer ſtones from the Eaſt-Indies. Authors have called them, beſide their common name, by thoſe of dactyli idæi,

and

and lapides lyncis, or lyncurii; but this last name has been an occasion of error, and has occasioned the Belemnite to be confounded with the hyacinth, which gem the ancients called by that name.

BELL (*Dict.*)— There is a curious observation in a paper of Mr. Reaumur's, in the Memoirs of the Paris Academy, relating to the shape most proper for Bells, to give them the loudest and clearest sound. He observes, that as pots, and other vessels, more immediately necessary to the service of life, were doubtless made before Bells, it probably happened, that the observing these vessels to have a sound, when struck, gave occasion to making Bells, intended only for sound, in that form; but that it does not appear that this is the most eligible figure; for lead, a metal which is, in its common state, not at all sonorous, yet becomes greatly so on its being cast into a particular form, and that very different from the common shape of Bells. In melting lead for the common occasions of casting in small quantities, it is usually done in an iron ladle; and, as the whole is seldom poured out, the remainder, which falls to the bottom of the ladle, cools into a mass of the shape of that bottom. This is consequently a segment of a sphere, thickest in the middle, and thinner towards the edges: nor is the ladle any necessary part of the operation, since, if a mass of lead be cast in that form in a mould of earth or sand, in any of those cases it is found to be very sonorous. Now, if this shape alone can give sound to a metal which in other forms is perfectly mute, how much more must it necessarily give it to other metals naturally sonorous, in whatever form? It should seem, that Bells would much better perform their office in this than in any other form, and that it must particularly be a thing of great advantage to the small Bells of common house-clocks, which are required to have a shrill note, and yet are not allowed any great size. Mr. Reaumur very judiciously observes, that, had our forefathers had opportunities of being acquainted with the sound of metals in this shape, we should probably have had all our Bells at present of this form. *Vid. Mem. Acad. Par. An.* 1726.

BE'LLOWS (*Dict.*)— This instrument is composed of two flat boards, sometimes of an oval, and sometimes of a triangular figure. Two or more hoops, bent according to the figure of the boards, are placed between them: a piece of leather, broad in the middle, and narrow at both ends, is nailed on the edges of the boards, which it thus unites together, as also on the hoops, which separate the boards, that the leather may the easier open and fold again. A tube of iron or copper, and sometimes of silver, for chamber Bellows, is fastened to the undermost board, in which there are several holes; that tube is called the nose, or nozel; finally, there is a piece of leather within the machine, which serves as a valve, or sucker, and covers the holes in the under board, that the air, which comes in through those holes, when the upper board is raised, may be expelled with force through the nozel, when that board is moved down.

Smiths and founders Bellows, whether single or double, are wrought by means of a rocker, with a string or chain fastened thereto, which the workman pulls. The Bellows pipe is fitted into that of the tuvel. One of the boards is fixed, so as not to play at all. By drawing down the handle of the rocker, the moveable board rises, and, by means of a weight on the top of the upper board, sinks again. *Moxon, Mech. Exerc.*

The Bellows of forges, and furnaces of mines, usually receive their motion from the wheels of a water-mill. Others, as the Bellows of enamellers, are wrought by means of one or more steps or treddles under the workman's feet. *Hought. Collect.*

BELLA'TRIX, in astronomy, a ruddy, glittering star of the second magnitude, in the left shoulder of Orion. Its longitude, according to Hevelius, for the year 1700, was 16°. 47'. 20"; and its latitude southward 16°. 52'. 11".

BE'NDING. Divers methods have been contrived for Bending timber, in order to supply crooked planks, and pieces for building ships: M. Dalesme ingeniously enough proposed to have the young trees bent, while growing in the forest. The method of bending planks by a sand-heat, now used in the king's yard at Deptford, was invented by Captain Cumberland. See SHIP-BUILDING.

The Bending of boards, and other pieces of timber for curved works in joinery, is effected by holding them to the fire, then giving them the figure required, and keeping them in this figure by tools for the purpose.

BENE'NAIM, BENENATH, BENENASCH, or BENENAT, in astronomy, the outermost star of the second magnitude, in the tail of the great Bear.

Its longitude, according to Hevelius, for the year 1700, was 22°. 39'. 24", and its latitude 54°. 25'. 7". north.

BE'RAMS, a coarse cloth, all made with cotton thread, which comes from the East-Indies, and particularly from Surat. There are white plain Berams, and others striped with colours. The white are about eleven yards long, and about a yard wide; the red are fifteen yards long, and something less than a yard wide.

BE'RCHEROIT, or BERKEROITS, a weight used at Archangel, and in all the dominions of the czar of Muscovy, to weigh such merchandizes as are very heavy, or very bulky, such as pot-ashes, &c. The Bercheroit weighs 400 pounds of Muscovy, which amount to about 364 pounds English avoirdupoise weight.

BE'RGAMO, a coarse tapestry, which is manufactured with several sorts of spun thread, as flocks of silk, wool, cotton, hemp, ox, cow, or goats hair. It is properly a weft of all those sorts of thread, the warp of which is commonly of hemp. It is wove on a loom, almost like linen cloth. Some pretend it was called Bergamo, because the people of Bergamo in Italy were the first inventors of it.

French BE'RRY, *graine d'Avignon*, or *graine jaune*, is the fruit of a shrub called by the ancients lycium and pizacanta, frequent about Avignon, and in the south parts of France; of considerable use among dyers and illuminers for a yellow colour.

This shrub grows in a rough stony soil. Its branches are beset with prickles two or three inches long: its bark is blackish; its leaves small and thick, like that of box, but disposed like that of myrtle: its root yellow and woody: its Berry is green, bordering on yellow, of the size of a grain of wheat, bitter and astringent to the taste. *Savar. Dict. Comm.*

BE'SISTAN, or BERSTAN, a name given at Constantinople, Adrianople, and in some other towns within the grand seignior's dominions, to those places where the merchants have their shops, and expose their merchandize to sale. Each sort of merchant have their particular Besistan, which must also be understood of the workmen, all those of the same trade working in the same place. These Besistans are commonly large galleries, vaulted over, whose gates are shut every night. Sometimes the wardens and keepers of the Besistans will answer for the merchandizes, on paying them a very moderate perquisite for each shop.

BE'TEL, in botany, an Indian plant, in great use and esteem throughout the East, where it makes a considerable article of commerce.

The Betel bears some resemblance to the pepper-tree. Its leaves are like those of ivy, only softer, and full of a red juice, which, among the orientals, is reputed of wonderful virtue for preserving the teeth, and rendering the breath sweet. The Indians are continually chewing these leaves, which renders their lips so red, and teeth black, a colour by them vastly preferred to the whiteness affected by the Europeans.

The consumption of Betel leaves is incredible, no body, rich or poor, being without their box of Betel, which they present to each other by way of civility, as we do snuff. *Savar. Dict. Comm.*

BE'TILLES, muslins, or white cotton cloths, manufactured in the East-Indies, particularly at Pondicherry. There are three sorts of them.

The first, called only Betille, is somewhat coarse. The piece is from 16 to 20 ells long, and ⅞ of an ell wide, French measure.

The second sort, called Betille organdy, has a round grain, and is very fine. It measures 12 ells and ½, by ¾ and ⅝, French measure.

The third sort, which is called tarantane Betille, is very clear, and is from 12 ½ to 13 ells long, and ⅞ wide. See MUSLIN.

Betilles. These are also white cotton cloths, which used formerly to be imported into France, to be there dyed of several colours. Some are 16, and others 20 ells long, French measure. The red and white Betilles which come from Bengal, are pretty near of the same length and breadth.

B'ETONY, *Betonica*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, and is of the labiated kind: the upper lip is erect, imbricated, and bifid; and the lower is divided into three segments, the middle one being larger than the rest, and bifid: the pistil arises from the cup, and is fixed in the manner of a nail to the hinder part of the flower: this is surrounded by four embryo's, which afterwards become so many seeds, of an oblong form, to which the flower-cup serves as a capsule. The flowers of Betony usually grow verticillately in short spikes on the tops of the stalks.

The species of Betony, enumerated by Mr. Tournefort, are eight.

Betony is chiefly administered in the way of decoction, sometimes of smoak, sometimes as an ingredient of a cerat or plaister, hence called emplastrum de betonica. Some also give its juice boiled to the consistence of honey, mixed with a little balsam of Peru, as a pectoral healer.

BE'ZANS, cotton cloths, which come from Bengal. Some are white, and others striped with several colours.

BIA, a name given by the Siamese to those white shells which come from the Maldives, and which are called coris, or couries, almost throughout the East-Indies, where they serve for small coin, or money. We shall give under its proper article a full account of that small money of the Indies, which is current also in several parts of the African coast. See COURIES.

BI'DENS, in botany, the name of a genus of plants, the characters

racters of which are theſe: the flower is uſually of the regular floſculous kind, compoſed of a number of ſmall floſcules, divided into ſeveral ſegments at their ends, placed on the embryo's, and contained in one common ſcaly cup. Sometimes there are alſo a number of ſemi-floſcules in the flower; but this is leſs common. The embryo's finally ripen into ſeeds, terminating in ſeveral prickly points. See *Plate* VI. *fig.* 36.

BIGHT, in the ſea language, denotes any part of a rope, as it is taken compaſſing, coiled up. When they cannot, or would not, take the end in hand, becauſe of the cables being coiled up; they ſay, give me the Bight, or hold by the Bight, i. e. by one of the flakes, which lies rolled up one over the other. *Manw. Seam. Direct. p.* 8. *Butel. Seam. Dial.* 4. *p.* 194.

BI'LANDER, in navigation, a ſmall flat-bottomed veſſel uſed in northern countries, with one large maſt and ſail, having its deck raiſed from head to ſtern, half a foot above the platboard. *Ozan. Dict. Math.*

BI'LIOUS *Fever*. Dr. Pringle, in his Obſervations on the Diſeaſes of the Army, remarks, that the Bilious or putrid fever is epidemic in camps, eſpecially in low and marſhy countries, where the air, being full of moiſt and putrid effluvia, tends to relax the fibres and promote putrefaction. As to the ſymptoms of the Bilious fever, it always begins with chillneſs and laſſitude, pains of the head and bones, and a diſorder at the ſtomach. At night the fever runs high; the heat and thirſt are great; the tongue is parched; the head aches violently; the perſon gets no reſt, and often becomes delirious; but, generally in the morning, an imperfect ſweat brings on a remiſſion of all the ſymptoms. In the evening the paroxyſm returns, but without any cold fit, and is commonly worſe than the former: on the ſecond morning it remits as before. Theſe periods go on daily, until the fever changes inſenſibly, either into a confirmed or into an intermitting ſhape. Sometimes looſe ſtools carry off the fit, and ſupply the place of ſweats: however, though it reſembles an ague in many particulars, yet it is rare to meet with a real ague in the camp, unleſs the perſon has been ill of it before he took the field. The remiſſions uſually appear from the beginning, eſpecially if the patient has been plentifully blooded: but ſometimes there are no remiſſions for the laſt two or three days. Hæmorrhages of the noſe happen frequently in the height of the paroxyſm, and always bring on the remiſſion ſooner, and make it fuller. Vomiting or purging have the like effects. The fits are ſeldom preceded by ſhiverings, or any ſenſe of cold after the firſt attack; the pulſe is always full and quick during the paroxyſms, and in the remiſſions it ſtill indicates ſome degree of fever. The blood is florid, the craſſamentum is firm, in a large quantity, and ſinks in the ſerum. Whilſt the weather continues warm, the Bilious ſymptoms are moſt frequent, but, as winter approaches, the inflammatory ones prevail. See INFLAMMATORY *Fever*.

The doctor enumerates other ſymptoms, as crudeneſs of the urine, Bilious ſtools, coſtiveneſs, &c. and farther obſerves, that the infantry are more liable to it than the cavalry.

As to the cure of the camp-fever, before it becomes continued, it depends upon the proper uſe of evacuations, the neutral ſalts, and the bark. Bleeding he judges indiſpenſable; which he would have repeated once or oftener, according to the urgency of the ſymptoms. After bleeding it will be neceſſary to give an emetic, the beſt time for doing which is in the remiſſion of the fever, and rather ſooner after a paroxyſm than before one. He adds, however, that vomits do harm when the ſtomach is any wiſe inflamed; in which caſe they ought never to be given. Ipecacuanha is the ſafeſt and eaſieſt, but antimonials make the moſt efficacious vomit. If the body remains coſtive, it is neceſſary to open it with ſome lenient phyſic, and eſpecially if the bowels are affected with pains, or a teneſmus. He likewiſe recommends ſalt of wormwood, lemon-juice, ſpiritus mindereri, and the bark; which laſt ought not to be given till the urine breaks, and the intermiſſions take place. Bleeding and purging are alſo neceſſary before the bark ought to be given: it anſwers beſt in ſubſtance, adminiſtered in Rheniſh wine, after ſtanding a night in infuſion.

If, after remiſſion, or intermiſſions, the diſeaſe changes into a continued fever, bleeding becomes neceſſary, unleſs other ſymptoms forbid it; but whether there be room for bleeding or no, bliſters are not only uſeful, but the beſt remedy. To theſe may be joined neutral ſalts and diaphoretic powders. But, though a ſweat be the proper criſis, it ought never to be promoted by theriaca, or the like hot medicines; unleſs the pulſe ſhould ſink, and the petechiæ or other bad ſymptoms appear: in which caſe the warmer alexipharmics are neceſſary, as the diſeaſe has changed into a malignant fever. *Pringle's Obſerv. on the Diſeaſes of the Army.*

BILL, among mechanics, an iron inſtrument, flat and edged, in the form of a creſcent, and adapted to a handle. It is, beſides the ax, one of the chief inſtruments uſed by the wood-fellers. The gardeners uſe a bill to prune trees. Plumbers likewiſe have a ſort of Bills, to perform ſeveral parts of their work. Baſket-makers uſe alſo Bills to cut the largeſt pieces of cheſnut-trees, and other wood: for ſmaller pieces of other they employ only the working-knife.

BILL, in trade, both wholeſale and retail, as alſo among trades-people and workmen, ſignifies an account of merchandizes or goods delivered to a perſon, or of work done for one.

In thoſe Bills muſt be ſet down the ſums of money received on account, which ought to be deducted from the ſum total.

BILL *of Credit*, is a Bill which a merchant, or banker, gives to a perſon whom he can truſt, impowering him to receive money from the ſaid merchant or banker's correſpondents in foreign countries.

Though Bills of credit be different from Bills of exchange, yet they enjoy the ſame privileges, for the money paid in conſequence of them is recoverable by law.

A merchant, or banker, ought to be very well acquainted with the character of thoſe to whom he gives letters of credit, eſpecially if the ſum be not limited. It is adviſeable, therefore, as much as it is poſſible, to determine the ſum, that a perſon may exactly know what engagement he enters into.

There is another caution to be obſerved, which is, to acquaint the correſpondents who are to furniſh the money, with the departure of him who is to receive it, and to deſcribe his perſon as accurately as can be, or even to agree about ſome peculiar word or ſentence, by which the correſpondents may know that the perſon who applies to them for money, is really the identical perſon meant: for he may be killed, and his Bill of credit ſtolen, whereby another might perſonate him, and receive the money in his ſtead, which has frequently happened.

BILL *of Store*, is a licence granted at the cuſtom-houſe to merchants, whereby they have liberty to carry, cuſtom-free, all ſuch ſtores and proviſions, as they may have occaſion for during their voyage.

BINO'MIAL (*Dict.*)—Sir Iſaac Newton, in his Univerſal Arithmetic, has given us the two following theorems for reducing Binomials, conſiſting of rational and ſurd quantities, to more ſimple terms. 1. If A expreſſes the greater part of a quantity, and B the leſſer part: then will $\frac{A+\sqrt{AA-BB}}{2}$ be the ſquare of the greater part of the root; and $\frac{A-\sqrt{AA-BB}}{2}$ the ſquare of the leſſer part, to be added to the greater with the ſign of B. So that if the Binomial be $3+\sqrt{8}$; (A being $=3$, and $B=\sqrt{8}$) we ſhall have the ſquare root of $3+\sqrt{8}=1+\sqrt{2}$. In like manner $\sqrt{32}-\sqrt{24}=\sqrt{18}-\sqrt{2}$. Secondly, if $A\pm B$ be a Binomial, whoſe greater part is A, and the index of the root to be extracted c, and n be found to be the leaſt number, whoſe power n^c can be divided by $AA-BB$, without a remainder, and Q be the quotient: and if $\sqrt[c]{A+B\times\sqrt{Q}}$ be computed in the neareſt integral numbers, and the ſame be called r, and if $A\sqrt{Q}$ be divided by the greateſt rational diviſor, and the quotient be s, and if $\frac{r+\frac{n}{r}}{2s}$ in the neareſt integral numbers be t, then will $\frac{ts\pm\sqrt{ttss-n}}{\sqrt[2c]{Q}}$ be the root whoſe index is c, provided the root can be extracted. So that the cube root of $\sqrt{968}+25$ will from hence be $2\sqrt{2}+1$. $AA-BB$ being $=343$, its diviſors 7, 7, 7; $n=7$, and $Q=1$. alſo the root of the firſt part of $\overline{A+B}\times\sqrt{Q}$, or $\sqrt{968}+25$ being extracted, will be a little greater than 56; its cube root in the neareſt number 4; and ſo $r=4$. Moreover, by extracting all that is rational from $A\sqrt{Q}$ or $\sqrt{968}$, it will be $22\sqrt{2}$: therefore $\sqrt{2}$ the radical part of it will be s, $\frac{r+\frac{n}{r}}{2s}$, or $\frac{5}{2\sqrt{2}}$ in the neareſt integral numbers is 2; therefore $t=2$. Laſtly, ts is $2\sqrt{2}$. $\sqrt{ttss-n}$ is 1. and $\sqrt[2c]{Q}$ or $\sqrt[6]{1}$ is 1.

Sir Iſaac Newton has not thought fit to lay down a demonſtration of theſe two theorems, or rules, which are much more elegant and general than thoſe given us for extracting the roots of Binomials, in Van Schouten's Commentary upon Des Cartes's Geometry. But Mr. s'Graveſande, at the latter part of his Algebra, has been at the pains to give us a demonſtration of the latter of the ſaid theorems, judging, I ſuppoſe, the former to be ſo eaſy, as not to ſpend time about evincing its truth. In order to which, he premiſes eight lemma's, which are theſe:

1. If to any power whoſe index is c be raiſed the Binomial

mial $a + b$, and the terms of this power alternately taken (that is, the 1ſt, 3d, 5th, 7th, &c. and the 2d, 4th, 6th, 8th, &c.) be united into one ſum, and ſo the whole power be divided into two parts; the difference of the ſquares of the parts will be $\overline{aa - bb}|^{c}$.

2. If a and b repreſent numbers, whereof a is the greater, and the Binomial $\sqrt{a} + \sqrt{b}$ be raiſed to the power c, and this number be odd, this power will be a Binomial, one of whoſe members is multiplied by $\sqrt{a}$, and the other by $\sqrt{b}$; and theſe members will be the parts (lemma 1.) of which the greater is that which is multiplied by $\sqrt{a}$.

3. If, the ſame things being ſuppoſed, the number c be even, the power forms a Binomial, one of whoſe members is rational, and the other multiplied by $\sqrt{ab}$, the members will be alſo the parts mentioned in lem. 1.

4. Any power of a numerical Binomial $\sqrt{a} + \sqrt{b}$ has both its members poſitive; the power of a Binomial or apotome $\sqrt{a} - \sqrt{b}$ has one member negative; and the members themſelves do not differ, whether it be $+ \sqrt{b}$ or $- \sqrt{b}$.

5. If a Binomial $\sqrt{a} + \sqrt{b}$ be raiſed to a power whoſe index is c, the difference of the ſquares of the members of the power is $\overline{a - b}|^{c}$.

6. The root of a Binomial whoſe index is c, that is $\sqrt[c]{\ }$, cannot be extracted, unleſs the difference of the ſquares of the parts of the given Binomial has $\sqrt[c]{\ }$ rational.

7. If two continual decreaſing geometrical progreſſions have the middle term common, the difference between the firſt terms of the progreſſion will be greater than the difference between the laſt.

8. The $\sqrt[c]{\ }$ of a Binomial cannot be extracted, if c be an even number, unleſs the greater member of the given Binomial be rational.

BIRCH *Tree*, *betula*, in botany, a genus of trees, containing but one ſpecies. The leaves reſemble thoſe of the poplar; the ſhoots are very ſlender and weak; the juli or katkins are produced at remote diſtances from the fruits on the ſame tree; the fruit becomes a little ſquamous cone; the ſeeds are winged; and the tree caſts its bark every year.

This tree is propagated by ſuckers taken from the roots of old trees, which may be tranſplanted either in October or February; but October is to be preferred; for, if the ſpring ſhould prove dry, thoſe planted in February will many of them fail: it delights in a poor ſoil, and will grow in either moiſt ſpringy ſoils, or in ſtony or gravelly marſhes or bogs: when the young trees have been planted two years, you ſhould (if deſigned for underwood) cut them down within ſix inches of the ſurface, which will cauſe them to ſhoot out ſtrong and vigorous branches; but, if they are deſigned for large trees, it will be much better to let them ſtand three years, before you head them down; and, when you do it, cut them within three inches of the ground, that their ſtems may be ſtraight and handſome: but you muſt obſerve, when they begin to put out, whether they produce more than one ſhoot; which if they do, you muſt cut off all but the ſtrongeſt and moſt convenient ſhoot, which muſt be trained up for a ſtem.

The timber of this tree, though accounted the worſt of all others, yet it is not without its various uſes: the turners often uſe it, to make chairs, &c. and the huſbandmen, for making ox-yokes; it is alſo planted for hop-poles, hoops, &c. but, in places within twenty miles of London, it is kept often cut to make brooms, and turns to great account.

There are three or four other ſorts of this tree growing in the northern parts of Germany, Sweden, and Lapland, which are all of them rather ſhrubs than trees, the talleſt of them ſeldom riſing above ten feet high, the others about three or four feet; but, being of little uſe, I ſhall not enumerate them.

There is alſo a Birch-tree, which has been raiſed in the gardens lately, whoſe ſeeds came from America: the leaves of this ſort are larger than thoſe of the common Birch-tree; but this may be only from the plant's being young and vigorous; ſo cannot be pronounced different, by its preſent appearance.

The piercing and bleeding of Birch is performed thus: about the beginning of March, when the buds begin to be proud and turgid, and before they expand into leaves, with a chizel and a mallet cut a ſlit almoſt as deep as the pith, under ſome branch of a well ſpreading Birch; cut it oblique, and not long-ways, as a ſurgeon does a vein; and inſert a ſmall ſtone or chip, to keep the lips of the wound a little open; laſtly, to this orifice faſten a bottle, or other convenient veſſel, appendant, into which will diſtil a limpid and clear water, retaining an obſcure ſmack both of the taſte and odour of the tree. The miracle is, that, in the ſpace of twelve or fourteen days, as much juice may be gathered, as will outweigh the whole tree, body and roots.

The liquor or juice, thus procured, is uſed, in ſome northern countries, as a preſervative againſt the ſtone. Van Helmont extols a drink prepared with this juice, daucus-ſeeds, and brook-lime. Mr. Boyle, tells us, he has ſeen extraordinary medicinal effects of the juice itſelf, even when other remedies failed; ſo that he uſually provided a quantity of it every ſpring. He ſays, it may eaſily be preſerved, by pouring a little oil on the top of it; or by diſtillation; but that the beſt way is, to impregnate it with the fumes of ſulphur.

This juice is uſed both to make wine of, and to brew withal, being here employed in lieu of water; a barrel of malt will afford as much, and as good ale, as four with common water.

A great difference is found between the efficacy of that liquor which diſtils from the body, or parts of the tree nearer to the root, and that which weeps out from the more ſublime branches; the former being more crude and watery, the latter purer, and more refined.

Birch-wine is made by fermenting the vernal juice: formerly it was in great repute againſt all nephritic diſorders, but is left out in the modern London practice. *Quinc. Pharmac.*

BIRD *of Phœbus*, the raven, one of the ſouthern conſtellations, containing ſeven ſtars; five of the third magnitude, one of the fourth, and one of the fifth.

BIRDS, in heraldry, are figures frequently borne in arms.

Birds are eſteemed a more honourable bearing than fiſhes; and wild and ravenous Birds, than tame ones.

Birds, according to Leigh, are to be numbered as far as ten; according to Chaſſaneus to ſixteen; after which they are to be blazoned without number. When their bills and feet are of a different colour from the firſt, they are ſaid to be membered. Birds of prey are more properly ſaid to be armed.

Birds borne of their natural colour are to be blazoned by proper, without mention of the colour. In the blazoning of fowls much exerciſed in flight, if the wings be not diſplayed, they are ſaid to be borne cloſe, *e. gr.* he beareth an eagle, a hawk, or a ſwallow, cloſe. In the general, wherever a Bird is found in any action or poſture, to which nature does not ordinarily incline it, ſuch action or poſture is to be named, otherwiſe not. *Coat's Her. Dict.*

BIRD-LIME, among ſportſmen, a tenacious compoſition uſed in taking birds.

The common method of making it is to peel a good quantity of holly bark about midſummer; fill a veſſel with it, put ſpring water to it; boil it till the grey and white bark ariſe from the green, which will require twelve hours boiling; then take it off the fire, drain the water well from it, ſeparate the barks, lay the green bark on the ground in ſome cool cellar, covered with any green rank weeds, ſuch as dock thiſtles, hemlock, &c. to a good thickneſs; let it lie ſo fourteen days, by which time it will be a perfect mucilage; then pound it well in a ſtone mortar, till it becomes a tough paſte, and that none of the bark be diſcernable; next, after waſh it well in ſome running ſtream, as long as you perceive the leaſt motes in it: then put it into an earthen pot to ferment; ſcum it for four or five days, as often as any thing riſes, and, when no more comes, change it into a freſh earthen veſſel, and preſerve it for uſe in this manner: take what quantity you think fit, put it into an earthen pipkin, add a third part of capons or gooſe greaſe to it, well clarified, or oil of walnuts, which is better; incorporate them on a gentle fire, and ſtir it continually till it is cold, and thus it is finiſhed.

To prevent froſt; take a quarter of as much oil of petroleum as you do gooſe greaſe, and no cold will congeal it: the Italians make theirs of the berries of the miſletoe-tree treated after the ſame manner, and mix it with nut-oil, an ounce to a pound of lime, and, taking it from the fire, add half an ounce of turpentine, which qualifies it alſo for the water.

When the twigs, or cords, are to be put in places ſubject to wet, the common Bird-lime is apt to have its force ſoon taken away. It is neceſſary, therefore, to have recourſe to a particular ſort, which, from its property of bearing water unhurt, is called water Bird-lime; and is prepared thus:

Take a pound of ſtrong and good Bird-lime, waſh it thoroughly in ſpring water, till the hardneſs is all removed; and then beat it well, that the water may be clean ſeparated, ſo as not a drop remains; add to it as much capon's greaſe as will make it run. Then add two ſpoonfuls of ſtrong vinegar, one ſpoonful of oil, and a ſmall quantity of Venice turpentine. Let the whole boil for ſome minutes over a moderate fire, ſtirring it all the time. Then take it off; and, when there is occaſion to uſe it, warm it, and cover the ſticks well with it. This is the beſt ſort of Bird-lime for ſnipes, and other birds that love wet places.

The moſt ſucceſsful method of uſing the common Bird-lime is this: cut down the main branch or bough of any buſhy tree, whoſe twigs are thick, ſtraight, long, and ſmooth, and have neither knots nor prickles. The willow and the birch-tree afford the beſt of this kind. Let all the ſuperfluous ſhoots be trimmed off, and the twigs all made neat and clean;

clean; they muſt all be well covered with the Bird-lime, within four inches of the bottom; but the main bough, from which they grow, muſt not be touched with the lime. No part of the bark, where the lime ſhould come, muſt be left bare; but it is a nice matter to lay it on properly, for, if it be too thick, it will give the birds a diſtaſte, and they will not come near it; and, if there be too little of it, it will not hold them when they are there. When the buſh is thus prepared, it muſt be ſet up in ſome dead hedge, or among ſome growing buſhes near the outſkirts of a town, a farmer's back-yard, or the like, if it be in ſpring; for theſe places are the reſort of ſmall birds at that time. If it be uſed in ſummer, the buſh muſt be placed in the midſt of a quick-ſet-hedge, or in groves, buſhes, white-thorn trees, near fields of corn, hemp, flax, and the like; and, in the winter, the proper places are about ſtacks of corn, hovels, barns, and the like. When the lime buſh is thus planted, the ſportſman muſt ſtand as near it as he can, without being diſcovered; and with the mouth, or otherwiſe, make ſuch ſort of notes, as the birds do when they attack, or call to one another. There are bird-calls to be bought for this uſe; but the moſt expert method is to learn the notes of call of the ſeveral birds, and imitate them by a ſort of whiſtling. When one bird is thus enticed to the buſh, and hung faſt, the buſineſs of the ſportſman is not to run up to take it, but to be patient; for it will hang itſelf more faſt, by its ſtruggling to get away; and its fluttering will bring more to the buſh; ſo that ſeveral may be taken together. The time of the day of this ſport is from ſun-riſe to ten o'clock, and from one to ſun-ſet. Another very good method of bringing the birds together is by a ſtale; a bat makes a very good ſtale, but it muſt be faſtened, ſo as to be in ſight at a diſtance. An owl is a ſtill better ſtale, for this bird never goes abroad, but it is followed by all the ſmall birds in the neighbourhood. They will gather together in great numbers about it, and, having no convenient place to ſit on, but the lime buſh, will be taken in great numbers. If a living owl or bat is not to be had, the ſkin ſtuffed will ſerve the purpoſe, and will laſt twenty years. Some have uſed the image of an owl carved in wood, and painted in the natural colours, and it has been found to ſucceed very well.

A method of deſtroying ſmall birds in great numbers by lime twigs is this: take two or three hundred ſmall twigs, about as thick as ruſhes, and three or four inches long; ſtick theſe on the tops of ten or a dozen cocks of hemp, or other produce of the field, cut and cocked up. There are generally in theſe fields of hemp vaſt numbers of linnets, and other ſmall birds, feeding on the ſeeds; the whole field is to be beat over, after the twigs are planted, and the birds will naturally ſettle on the cocks, and many dozen of the ſeveral kinds will be taken at once.

Another method of taking great numbers in the winter ſeaſon is this: take a number of wheat ears, with the ſtraws about a foot long to them; melt ſome good Bird-lime gently over the fire, adding one fourth part of its weight of ſome light fat, ſuch as the greaſe of fowls, or the like. When this runs thin, cover the ſtraws with it for ſix inches below the ears. Then take into a field, where the ſmall birds reſort in flocks, as they do at this ſeaſon of the year, a quantity of theſe limed ſtraws, and a peck or two of chaff; ſpread the chaff over a large ſpace of ground, and among it place the limed ſtraws, ſticking them in the ground at the bottom, and letting the ears droop down. When the place is thus planted, the ſportſman muſt beat the neighbouring fields and hedges; and the birds being diſturbed will riſe, and they will naturally make their way to where they ſee the chaff. They will then ſoon be pecking at the ears of corn; and, as the limed ſtraws will ſoon begin to ſtick to them, they will mount up into the air with them; but, in their flight, the ſtraws ſoon get under their wings, and faſten them together; ſo that they can no longer fly, but fall ſtruggling to the ground.

As ſoon as they begin to fall, the ſportſman's buſineſs is to watch, not to run to take them up, for, in a little time, more will be entangled; and, with patience, ſometimes five or ſix dozen may be taken in this manner at a time. This method ſucceeds better, as the weather is more and more ſevere; and beſt of all, when the ground is covered with ſnow. The ſame place will ſerve for many repeated flights. The limed ſtraws are to be taken away, as ſoon as the firſt flight is taken, and the place new bated with chaff; the birds may then be left to feed with freedom; and the next morning, the limed ſtraws being ſet up again, they will be caught in greater numbers, than at the firſt attempt.

BIRD's-NESTS, in natural hiſtory, a kind of ſpice very much eſteemed in China, and throughout all the Eaſt-Indies; it is to be found in Tonquin and Cochinchina, but more particularly in the kingdom of Campa or Champa, which is ſituated between both. The birds which make thoſe neſts to lay their eggs, and hatch their young ones in, are pretty much like the ſwallows: in coupling time, there iſſues from their bills a clammy foam or glutinous matter, which is the only material they build their neſts with; they faſten them to the rocks, by applying to them that glutinous ſubſtance; by ſeveral layers the one over the other, the former becomes dry. Theſe neſts are of the form of a middle-ſized ſpoon, but the brims are higher.

There are ſo many of theſe kinds of neſts, that they gather every year ſeveral hundred weight of them, which are almoſt all carried into China, where they are ſold for five taels per hundred weight, which amounts to about a hundred Spaniſh ducats. They are thought to be good for the ſtomach and the head, and give a delicious taſte to the meat ſeaſoned with them.

BI'RMINGHAM *Hard-ware-men*, or dealers in the city of London, in Sheffield and Birmingham wares, are ſo called, becauſe they principally trade in, and moſtly wholeſale, all ſorts of tools, ſmaller utenſils, toys, buckles, buttons, in iron, ſteel, braſs, &c. made in London, and the great trading towns of Birmingham in Warwickſhire, and Sheffield in Yorkſhire, where many thouſands of artiſans, in different branches, are conſtantly employed, but for the moſt part in the ſmithery and cutlery ways.

There are but few of theſe in London; yet almoſt all of them carry on a moſt extenſive trade, and are reputed wealthy. It is not eaſy to conceive, much leſs to deſcribe, the numerous articles that paſs through their hands: therefore, a youth, deſirous to ſerve an apprenticeſhip to this buſineſs, ſhould be ready and acute, not want a good memory, write a plain hand, know arithmetic, and ſomewhat of book-keeping.

BI'SCUIT, or BISKIT, a general name for that bread which is made for voyages by ſea, eſpecially for long voyages.

Biſket, in order to be good, ſhould be made ſix months before it is put on board a ſhip; it muſt be of good wheat flour, thoroughly cleaned from bran.

Water and Biſket are the moſt neceſſary proviſions in the fitting out of ſhips, and, if either of theſe two be loſt or ſpoiled, the crew languiſh away, and often periſh moſt miſerably, eſpecially if they happen to be bound for a very long voyage.

Manner of making Sea BISCUITS.— The flour is firſt wet in the kneading-trough with a ſufficient quantity of water, and covered for ſome time with a cloth. It is then well kneaded, and the dough divided into pieces of about three ounces each. Theſe pieces are again kneaded ſingly, and laid in rows; and, after having ſome flour ſhaken over them, others are laid upon them, till the whole quantity to be baked at once is finiſhed. The pieces of dough are then flatted into cakes, pricked with an inſtrument for that purpoſe, and placed regularly in the oven; where they ſtand about half an hour, and are then drawn out of the oven, and carried into the ſtore-room.

The Manner of making Sea BISCUIT *in France.*— In order to make the leaven, which the French put in their Biſket, a piece of dough weighing about twenty pounds, from the leaven of the laſt oven full, ſhould be prepared, which is done, we will ſuppoſe, between eleven and twelve at noon. At four of the clock in the afternoon, the baker puts that dough into the kneading-trough, and pours over it about five gallons of very clean water, a little more than luke-warm, but hotter in winter than in ſummer; he dilutes afterwards with the quantity of flour neceſſary to conſume all that water, ſo as to make a dough neither too ſoft nor too hard. This new maſs of dough weighs commonly about ſixty pounds. In this condition the baker puts it in a corner of the kneading-trough, ſurrounding it on all ſides with flour to ſupport it. When it has been riſing five or ſix hours, the ſame operation is repeated, by adding water and flour to the dough, which increaſes it by about thirty pounds.

About one or two o'clock the next morning, which is the time when the baker would knead, he adds thirty pounds more to the paſte, which makes a maſs of 120 pounds; of this he takes half to ſerve as leaven for the next baking, and at the ſame time kneads the remaining ſixty pounds in the kneading-trough for the firſt oven full, and, for the other bakings, he is to make the reſt of the day, he increaſes the leaven at once with ſixty pounds, which he puts into a tub or bucket, in order to continue the ſame alternately, except that for the laſt oven full he adds but twenty pounds to the leaven, which is to ſerve for beginning the ſame operation the next day.

The kneader takes water out of the kettle or copper which he uſed for the leavens, and dilutes that which he would employ into a whitiſh and thick water; and, putting flour to it two or three times, he kneads it quickly and very ſtrongly with his fiſts, going from the right to the left, and beginning again from one end to the other, and from the left to the right, he reduces it to one ſingle maſs. After this, he flattens it with the palms of his hands, and divides it into four parts: then he flattens them again, and handles them and kneads them with all his might one after another; afterwards he puts them again one upon another, and, having cleaned his kneading-trough, he puts the whole into one maſs, turning and kneading it ſtill. After which he cuts it again into four parts, which having rejoined for the laſt time, he takes the dough out of the kneading-trough, and puts it upon a table, where another workman turns it ſeveral times during a quarter of an hour, till it be very firm and dry.

As

As ſoon as the dough is in the above-mentioned condition, it muſt immediately be made into cakes. Each cake muſt weigh fourteen ounces of dough, that, when baked, it may weigh eight, or at moſt nine ounces.

The dough is cut into pieces of that weight, which pieces are afterwards turned upon the table with the hands into balls, to make it harder ſtill: then it is flattened with a kind of rolling-pin, the middle of which is thicker than the two ends, obſerving, however, to make the cake ſomething hollow in the middle; as for the edges, they muſt be even, and be above one third part of an inch thick.

The cake being thus formed, they make the mark, a croſs, or ſome other figure, upon it, with an inſtrument for that purpoſe; after which they turn it on the other ſide, laying it upon the table, as near as poſſible to thoſe already made; finally, a little before they put it into the oven, they prick it four or five times with an iron inſtrument that has three points.

Before they prick the cakes and put them into the oven, they muſt let them reſt half an hour upon the table, or even more, if need be, that they may have time to riſe, which the baker ought to know and direct.

At Breſt, they put the cakes into the oven, as ſoon as they are pricked, without letting them reſt or riſe, becauſe they pretend they are ſufficiently furniſhed with leaven, and in that caſe they do not cover them.

For the firſt oven full, they muſt begin to heat the oven, as ſoon as they begin to work the dough with the rolling-pin; and they know that the oven is hot, when the roof of it is of a whitiſh aſh colour. But, for the other oven full, they do not warm the oven; but after they have rolled the dough, or a little ſooner or later, according as the baker thinks fit, or as the dough requires it, and the oven is not to be quite ſo white.

It muſt be obſerved, that for the firſt oven full they may heat the oven with green wood, becauſe it has time to dry and burn: but, for the others, the drieſt wood is beſt, becauſe the dough requires to be ſoon put into the oven, leſt it ſhould dry too much.

After the fire is taken out of the oven, and it has been well ſwept, the baker thruſts the cakes into the oven, the one after the other, on an iron or wooden ſhovel, obſerving to place them regularly, ſo that there may be no void ſpace between them. He afterwards ſhuts the oven very cloſe, and puts a few ſhovels full of live coals againſt the door; a quarter of an hour after he opens the oven, to ſee whether the Biſkets begin to colour: if he find them ſufficiently coloured, he leaves the oven open for half a quarter of an hour, during which he takes away the coals from before the door, which he ſhuts again. When the cakes have remained in the oven a full quarter of an hour longer, he takes out ſome of the cakes which were firſt put in, and breaks them to ſee whether they be baked. When they are ſo, the edges are reddiſh within; and the little which remains in the middle, is ſpongy but dry. They put their hand upon that crumb, and, if they obſerve any moiſture in it, it is a ſign that the cakes are not baked enough; and they muſt leave them in the oven, as long as they judge it neceſſary to dry up all the moiſture.

As ſoon as the Biſkets are taken out of the oven, they carry them out into the ſtore-room, which has been well cleaned and warmed, during four days. The ſtore-rooms, to be good, ſhould be built over the ovens, wainſcotted at top and bottom, and on all ſides, and the joints of the boards well caulked.

BISTORT, *Biſtorta*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the apetalous kind, conſiſting of a number of ſtamina, which ariſe from a cup, divided into ſeveral ſegments at the edge: the piſtil becomes afterwards a ſeed, uſually of a triangular figure, and contained in a capſule, which was before the cup of the flower. See *Plate* VI. *fig*. 37.

To this it is to be added, that the flowers are diſpoſed in ſpikes; and the roots are large and fleſhy, oddly twiſted or contorted, and furniſhed with a number of ſmall fibres, like hairs. There are alſo ſome ſpecies of Biſtort, in which, beſides the common flowers and ſeeds, there are certain tubercles, which have their roots, and rudiments of leaves.

The roots of the common Biſtort are a ſtanding medicine in the ſhops; they are given in decoction, and ſometimes in powder, as an aſtringent, and generally in conjunction with the tormentil root. They give a bright red colour to the common hartſhorn drink, and add conſiderably to its virtue. It is good in diarrhœas, and hæmorrhages of all kinds.

Some alſo commend it as an alexipharmic, and ſudorific.

BITTACLE, a ſea term, ſignifying a frame with two ſtories, placed in the ſteerage, before the place where the ſteerſman ſtands, by the miſſen-maſt; it is all made of boards faſtened together with wooden pegs, without any iron, to prevent the direction of the needle of the compaſs, which is incloſed in it, from being altered by the proximity of that metal. They alſo put a watch or clock in it, with a candle or lamp to light the ſteerſman.

In large ſhips, beſides this Bittacle, they have another for the pilot or mate.

BITTERN, in zoology, the name of a bird of the heron kind called by authors ardea ſtellaris: and by ſome taurus, botaurus, butorius, and ocnus.

In Engliſh, the butter-bump, and mire-drum. It is nearly of the ſize of a common heron; its head is ſmall and narrow; its crown is black; and there is alſo a black ſpot on each ſide, near the angle of the mouth. Its throat and ſides are reddiſh, variegated with black tranſverſe lines; the neck is covered with very long feathers, which make it appear much thicker and ſhorter than it really is; its belly is of a duſky white, with a caſt of browniſh red, and its back is variegated with a pale reddiſh brown and black. It makes a very remarkable noiſe, which it repeats either three or five times. It is heard only in the building-time, which begins in February. The common people, from the ſingularity of the noiſe, think the bird, in order to make it, ſticks its beak in a reed, or in the mud. It is commonly found in ſedgy and reedy places, near the waters, and ſometimes in hedges. Towards autumn, this bird flies very high in an evening after ſun-ſet, riſing with a ſpiral aſcent, till quite out of ſight; and, as they riſe, they make an odd noiſe, not at all like their uſual note. This they repeat alſo very often, as they are on the wing in the night; and hence they are called by ſome, though improperly, the night-raven. It builds on the ground, and lays five or ſix eggs, which are roundiſh, and of a greeniſh white. When wounded, and going to be taken, it ſtrikes at the perſon's eye, and ought carefully to be guarded againſt.

BITTS, are two perpendicular pieces of timber in the fore part of the ſhip, bolted to the gun-deck and orlop beams, their lower ends ſtepping in the foot waaling, the heads of which are braced with a croſs piece, and, when ſeveral turns of the cable are taken over them, is for ſecuring the ſhip at anchor; there are generally two pair of them; beſides, there are others upon the upper deck, which are fixed by the main and fore maſt, and called the top-ſail ſheet and jeer Bitts.

Currier's BLACK, ſignifies a teint or dye laid on tanned leather; of which there are uſually two, the firſt made of galls, ſour ale, and old iron; the ſecond of galls, copperas, and gum arabic.

BLACK-*Bird*, *merula*, in zoology. See the article MERULA.

BLACK *Land*, in agriculture, a term by which the huſbandmen denote a particular ſort of clayey ſoil, which, however, they know more by its other properties than by its colour, which is rarely any thing like a true Black, and often but a pale grey. This, however pale when dry, always blackens by means of rains; and, when ploughed up at thoſe ſeaſons, it ſticks to the plough-ſhares, and, the more it is wrought, the muddier and duſkier-coloured it appears. This ſort of ſoil always contains a large quantity of ſand, and uſually a great number of ſmall white ſtones.

BLACK *Flux*, in mineralogy, a flux uſed in the aſſaying of ores, and is made as follows: take one part of nitre, and two parts common tartar; reduce each to powder, mix them together, and deflagrate the whole in a crucible, by lighting the mixture a-top; which thus turns to a kind of alkaline coal, that is to be pulverized, and kept in a cloſe glaſs, to prevent its diſſolving, as it would do in a moiſt air.

This flux is of general uſe; and, to have it ready at hand, ſhortens the buſineſs of making aſſays in metallurgy; and renders the operation more exact, than when crude tartar and nitre are employed; becauſe the deflagration might thus carry off ſome part of the ore, and defraud the account. For the ſame reaſon, the mixture is here directed to be fired at top; otherwiſe a conſiderable part might be loſt in the deflagration, which would prove much more tumultuous and violent, if the matter was thrown into a red-hot crucible. *Shaw's Chem. Lectures*.

BLACK *Tin*, in minerology, a denomination given to the tin-ore when dreſſed, ſtamped, and waſhed ready for the melting-houſes, where it is refined into a pure metal.

It is prepared into this ſtate by means of beating and waſhing; and, when it has paſſed through ſeveral baddles or waſhing-troughs, it is taken up in the form of a Black powder like fine ſand, called Black tin.

BLADE, in botany, that part of the flower, or florid attire of a plant, which ariſes out of the concave of the ſheath, and, at the top, uſually divides into two parts, which are covered with globules of the ſame nature as thoſe of the apices, but not ſo copious.

The Blade runs through the hollow of the ſheath and baſe, and is faſtened to the convex of the ſeed-caſe, having its head and ſides beſet with globules, which, through a glaſs, appear like turnip-ſeeds, and which, in ſome plants, grow cloſe to the blade, and in others adhere to it by little pedicles, or foot-ſtalks. Theſe globules, as the Blade ſprings up from within the ſheath, are ſtill rubbed off, and ſo ſtand like a powder on both. In ſome plants, as knap-weed, they ſeem alſo to grow on the inſide of the ſheath, as appears on ſplitting it with a pin. The head of a Blade is divided uſually into two; but ſometimes, as in cichory, into three parts, which, by degrees, curl outward, like ſcorpion-graſs.

BLADE, in commerce, a thin, ſlender piece of metal, either forged

forged by the hammer, or run and caſt in moulds, to be afterwards ſharpened to a point, edge, or the like.

Blade *of a Chiſſel*, is the iron or ſteel part, as diſtinguiſhed from the wooden handle.

Blade *of Mace, or Cinnamon*, among apothecaries, are little ſlips or ſlices of thoſe barks.

Blade *of an Oar*, is the flat part which is plunged into the water in rowing. On the length of this does the force and effect of the oar depend.

Blade *of a Saw*, the thin part wherein the teeth are cut, which, to be good, muſt be ſtiff, yet bend equally into a regular bow all the way, without yielding more in one place than another.

Blade-*Mill*, is that contrived for grinding iron-tools, as ſcithes, reaping-hooks, axes, chiſſels, and the like, to a bright edge.

BLA'NCHING, in gardening, an operation performed on certain ſallets, roots, &c. as of cellery and endives, to render them fairer and fitter for the table. The time for Blanching of cellery is about the middle of June, when ſome of the firſt ſowing will be fit to plant out in trenches for this purpoſe. Theſe trenches are to be cut by a line eight or ten inches wide, and about as many deep; into which they put their plants, after having firſt pruned off the tops and roots. As they grow large, they earth them up within four or five inches of their tops, and ſo continue to do at ſeveral times, till whitened ſufficiently for uſe; which they will not ordinarily be till ſix weeks after earthing them up. For endive, as ſoon as it is well grown, they tie up ſome of it to whiten; and continue every fortnight, as long as it laſts, to tie up freſh parcels.

Blanching is alſo a term uſed by the people who cover thin plates of iron with tin, for that part of the work, which conſiſts in dipping the plates into the melted tin, in order to the covering of them. The people who do this part of the buſineſs are hence called Blanchers.

BLA'NKET, in commerce, a warm woolly ſort of ſtuff, light and looſe woven, chiefly uſed in bedding.

The manufacture of Blankets is chiefly confined to Witney in Oxfordſhire, where it is advanced to that height, that no other place comes near it. Some attribute a great part of the excellency of the Witney Blankets to the abſterſive, nitrous water of the river Windruſh, wherewith they are ſcoured; others rather think they owe it to a peculiar way of looſe ſpinning, which the people have thereabouts. Be this as it will, the place has engroſſed almoſt the whole trade of the nation for this commodity; inſomuch that the wool fit for it centers here from the furthermoſt parts of the kingdom. There are ſaid to be at leaſt threeſcore blanketers in this town, who, amongſt them, have at leaſt 150 looms, and employ 3000 perſons, from children of eight years old, who work out about a hundred packs of wool per week.

BLA'STING, among miners, a term for the tearing up rocks, which they find in their way, by gunpowder. The method of doing which is this: they make a long hole, like the hollow of a large gun-barrel, in the rock they would ſplit; this they fill with gun-powder, then they firmly ſtop up the mouth of the hole with clay, except a touch-hole, at which they leave a match to fire it. A ſmall quantity of powder does great things this way.

BLEA, in vegetables, is that part of a tree which lies immediately under the bark, and between that and the hard wood, and is the firſt progreſs of the alteration of the bark into wood, by the natural growth and ſtrengthening of the fibres.

BLEE'DING, according to Dr. Pringle, is the moſt indiſpenſable of all remedies in inflammatory diſeaſes; to the delaying of which too long, or not repeating it, are chiefly owing the bad conſequences of colds, as dangerous fevers, rheumatiſms, and conſumptions. He obſerves farther, that, in general, young practitioners are apt to be too ſparing in letting blood, by which means many lives are loſt: for a ſurgeon may be aſſured a ſoldier will never complain of a cough, or pains with inflammatory ſymptoms, wherein Bleeding is not neceſſary; and from the ſizineſs of the blood, and continuance of the complaints, he is to judge of the neceſſity of repeating it, which, in caſe of a ſtitch, or difficult breathing, is never to be delayed. In inflammatory caſes, from twelve to fifteen ounces may be taken for the firſt Bleeding, and ſomewhat leſs for all the reſt; and, when it is neceſſary to exceed this quantity, it may be proper to follow Celſus's rule, in minding the colour of the blood whilſt it flows, and when it is of a blackiſh caſt, which is always the caſe in difficult breathing and great inflammations, to let it run till it becomes more florid. In all caſes where plentiful Bleeding is indicated, it is beſt to do it in bed, to prevent fainting; and we may obſerve, that a perſon will bear the loſs of a much greater quantity of blood, if the ſtream is ſmall, than by a large orifice, which ſome have thought neceſſary for making a more ſpeedy revulſion.

Bleeding is highly neceſſary in the phrenitis, ophthalmia, quinſy, rheumatiſm, cough, hectic fits, and, in general, in all inflammatory caſes. *Pringle's Obſerv. on the Diſeaſes of the Army.*

It is to be obſerved, however, that, in malignant and putrid diſorders, Bleeding frequently renders them more malignant, and therefore to be omitted, or at leaſt not repeated, unleſs there appear evident marks of inflammations. See PHLEBOTOMY *Dict. and Suppl.*

BLEND-*Metal iron*, a coarſe ſort of iron from Staffordſhire mines, uſed for making nails and heavy ware; in ſome places alſo for horſe-ſhoes. *Plott, Nat. Hiſt. of Staffordſhire.*

BLEYME, in farriery, an inflammation in a horſe's hoof, occaſioned by blood putrified in the inner part of the coffin towards the heel, between the ſole and the coffin-bone.

There are three ſorts of Bleymes; the firſt, bred in ſpoiled wrinkled feet with narrow heels, are uſually ſeated in the inward or weakeſt quarter; the ſecond, beſides the uſual ſymptoms of the firſt, infects the griſtle, and muſt be extirpated, as in the cure of a guitter bone; the third is occaſioned by ſmall ſtones and gravel between the ſhoe and the ſole. For a cure, they pare the foot, let out the matter, if any, and dreſs the ſore, like the prick of the nail. *Dict. Ruſt. T. 1. in Voc.*

BLIGHT *(Dict.)*— There is nothing ſo deſtructive to a fruit-garden as Blights; nor is there any thing in the buſineſs of gardening which requires more of our ſerious attention, than the endeavouring to prevent or guard againſt this great enemy of gardens.

In order, therefore, to remedy this evil, it will be neceſſary firſt to underſtand the true cauſes of Blights: and, although many curious perſons have attempted to explain the cauſes of them, yet very few of them have yet come near the truth, except the reverend and learned Dr. Hales, who hath, in his curious book, intitled, Vegetable Statics, given us ſome accurate experiments upon the growth and perſpiration of plants; together with the various effects the air has upon vegetables; that, by carefully attending thereto, together with diligent obſervations, we need ſeldom to be at a loſs how to account for the cauſes of Blights, whenever they may happen.

Blights are often cauſed by a continued eaſterly wind, for ſeveral days together, without the intervention of ſhowers, or any morning dew, by which the perſpiration of the tender bloſſoms is ſtopped; ſo that, in a ſhort time, their colour is changed, and they wither and decay: and if it ſo happens, that there is a long continuance of the ſame weather, it equally affects the tender leaves; for their preſpiring matter is hereby thickened, and rendered glutinous, cloſely adhering to the ſurfaces of the leaves, and becomes a proper nutriment to thoſe ſmall inſects, which are always found preying upon the leaves and tender branches of fruit-trees, whenever this Blight happens.

The beſt remedy for this diſtemper, that I have yet known to ſucceed, is, gently to waſh and ſprinkle over the trees, from time to time, with common water (that is, ſuch as hath not had any thing ſteeped in it) and the ſooner this is performed (whenever we apprehend danger) the better; and, if the young and tender ſhoots ſeem to be much infected, waſh them with a woollen cloth, ſo as to clear them, if poſſible, from all this glutinous matter, that their reſpiration and perſpiration may not be obſtructed; and if we place ſome broad flat pans or tubs of water near the trees, that the vapours exhaled from it may be received by the trees, it will keep their tender parts in a ductile ſtate, and greatly help them; but, whenever this operation of waſhing the trees is performed, it ſhould be early in the day, that the moiſture may be exhaled before the cold of the night comes on; eſpecially if the nights are froſty: nor ſhould it be done when the ſun ſhines very hot upon the wall, which would be ſubject to ſcorch up the tender bloſſoms.

Another cauſe of Blights in the ſpring is, ſharp hoary froſts, which are often ſucceeded by hot ſunſhine in the day-time; which is the moſt ſudden and certain deſtroyer of fruits that is known: for the cold of the night ſtarves the tender parts of the bloſſoms, and the ſun riſing hot upon the walls before the moiſture is dried from the bloſſoms (which, being in ſmall globules, collects the rays of the ſun) a ſcalding heat is thereby acquired, which ſcorches the tender flowers, and other parts of plants.

But there is another ſort of Blight, againſt which it is very difficult to guard our fruit-trees; this is ſharp pinching froſty mornings, which often happen at the time when the trees are in flower, or while the fruit is very young, and occaſion the bloſſoms or fruit to drop off; and, ſometimes, the tender parts of the ſhoots and leaves are greatly injured thereby.

The only method yet found out to prevent this miſchief, is, by carefully covering the walls, either with matts, canvas, reeds, &c. which being faſtened ſo as not to be diſturbed with the wind, and ſuffered to remain on during the night, by taking them off every day, if the weather permits, is the beſt and ſureſt method that hath yet been uſed in this caſe; which, although it has been ſlighted, and thought of little ſervice by ſome, yet the reaſon of their being not ſo ſerviceable, as has been expected, was, becauſe they have not been rightly uſed, by ſuffering the trees to remain too long covered; by which means, the younger branches and leaves have been rendered too weak to endure the open air, when they are expoſed to it; which has often proved of worſe conſequence to trees, than if they had remained intirely uncovered.

Whereas,

Whereas, when the covering before-mentioned has been performed, as it ought to be, it has proved very serviceable to fruits; and many times, when there has been almost a general destruction of fruits, in the neighbouring gardens, there has been a plenty of them in such places where they have been covered; and, though it may to some seem very great, yet, if these coverings are fixed near the upper part of the wall, and are fastened to pullies, so as to be drawn up, or let down, it will be soon and easily done; and the success will sufficiently pay the trouble.

But there is another sort of Blight, that sometimes comes later in the spring, viz. in April or May, which is often very destructive to orchards, and open plantations, and against which we know no remedy. This is what is called a fire-blast, which, in a few hours, hath not only destroyed the fruit and leaves, but, many times, parts of trees, and, sometimes, whole ones, have been killed by it.

This is supposed to be effected by volumes of transparent flying vapours, which, among the many forms they revolve into, may sometimes approach so near to an hemisphere, or hemicylinder, either in their upper or lower surfaces, as thereby to make the beams of the sun converge enough to scorch the plants or trees they fall upon, in proportion to the greater or less convergency of the sun's rays.

The learned Boerhaave, in his Theory of Chemistry, observes, That those white clouds, which appear in summer-time, are, as it were, so many mirrors, and occasion excessive heat; these cloudy mirrors are sometimes round, sometimes concave, polygonous, &c. when the face of the heavens is covered with such white clouds, the sun, shining among them, must, of necessity, produce a vehement heat; since many of his rays, which would otherwise, perhaps, never touch our earth, are hereby reflected to us: thus, if the sun be on one side, and the clouds on the opposite one, they will be perfect burning-glasses.

I have sometimes, continues he, observed a kind of hollow clouds, full of hail and snow; during the continuance of which, the heat was extreme; since, by such condensation, they were enabled to reflect more strongly: after this came a sharp cold, and then the clouds discharged their hail in great quantities; to which succeeded a moderate warmth. Frozen concave clouds, therefore, by their great reflexions, produce a vigorous heat; and the same, when resolved, excessive cold.

Whence (as Dr. Hales observes) we see, that blasts may be occasioned by the reflexions of the clouds, as well as by the above-mentioned refraction of dense transparent vapours.

Against this enemy to fruits, &c. as hath been said, there is no guard to our plantations, nor any remedy to cure it: but as this more frequently happens in close plantations (where the stagnating vapours from the earth, and the plentiful perspirations from the trees, are pent in for want of a free air to dissipate and dispel them; which are often observed, in still weather, to ascend in so plentiful a manner, as to be seen by the naked eye, but especially with reflecting telescopes, so as to make a clear and distinct object become dim and tremulous) than in those that are planted at a greater distance, or are not surrounded with hills or woods; this directs us, in the first planting of orchards, &c. that we should allow a greater distance between the trees, and make choice of clear healthy situations, that the air may freely pass between the trees, to dissipate those vapours before they are formed into such volumes, whereby the circumambient air will be clear, and less subject to injuries; as also the fruits which are produced in this clearer air, will be much better tasted than those that are surrounded with a thick rancid air; for, as fruits are often in a respiring state, so they consequently, by imbibing a part of these vapours, are rendered crude and ill-tasted; which is often the case with a great part of our fruits in England. *Miller's Gard. Dict.*

BLIND, deprived of the sense of sight.

Blind is also used in speaking of vessels which are not perforated.

Thus the chemists say, a Blind alembic; that is, one which has no aperture. A tube is said to be Blind, when it is closed at top.

Blind, or Blinde, among mineralists, a kind of lead marcasite, by our miners called mock-ore, mock-lead, and wild-lead.

Blinde is a mineral mass, flaky, glossy, and breaking in angles, much like the potters lead ore, only of a colour more dusky, and approaching to black. In it are veins of a yellow shining marcasite, with a little white spar, and on one side a greenish æruginous matter. On a trial by the fire, it yielded a very little copper, less lead, and no tin. It is very obstinate, several attempts having been made with the alcaline fluxes to run it, in vain.

BLOCK-*Makers*.—Blocks are very material articles in a ship's rigging; and the making of them, and many other things, for the use of shipping, is a pretty handicraft enough, in which there is more ingenuity than some people imagine; and a very useful employ, though not a great number of masters in it; for, as the Blocks are what the ships ropes are fastened to, and run in by the help of the pullies fixed therein, if they are not made exactly to fit one another, the tackling will work but heavily, to the great hindrance of business, and fatigue of the seamen, &c.

They require ten pounds, or more, with a lad to be an apprentice; their hours are from six to eight, working altogether dry, and under cover; and the wages are fifteen or eighteen shillings a week.

This will take four hundred pounds, at least, to set a master up well.

The shivers and pins in large Blocks are generally made of lignum vitæ, by turning them in a lathe. See TURNING.

BLOOD (*Dict.*)—In order to ascertain the colour of the different parts of corrupted Blood, Dr. Pringle made the following experiment: he took a fresh quantity, without any inflammatory crust, and divided it into the crassamentum, the serum with a few red globules in it, and the pure serum. The phials containing these several liquors were put into a furnace, where they stood some days, till they became thoroughly putrid.

The crassamentum was changed from a deep crimson to a dark livid colour; so that, when any portion of it was diluted with water, it appeared of a tawny hue: of the same colour was the serum, in which the red globules remained: but the pure serum, after becoming turbid, dropped a white purulent sediment, and changed into a faint olive-green.

From this experiment he concludes, that the ichor of sordes, and that of dysentery fluxes, consist of the serum tinged with a small quantity of red Blood putrified; and that, when the serous vessels are of a tawny cast, we are not to refer that colour to inflammation, but to a sudden solution of some of the red globules mixed with the serum.

A few drops of this putrid crassamentum was mixed with the recent urine of a healthy person, which it immediately changed into a flame-coloured water, common in fevers and in the scurvy. After standing an hour or two, the same gathered a cloud, resembling what is seen in the crude urine of persons in acute distempers.

As to a green serum, it is, perhaps, never to be seen in the vessels of a living body, since it is not to be supposed that a person could survive so great a change of the blood. In foul ulcers, indeed, and in other sores, where the serum is left to stagnate long, the matter is found of a greenish colour, and is then always acrimonious. But the effects of a green serum are no where to be so much dreaded, as in the case of an ascites, where it is collected in so large a quantity: of which we had, some time since, almost a fatal instance in Mr. Cox, surgeon at Petersburg, who, upon tapping a woman but a few hours after death, was so affected with the poisonous steams of a green serum, that he was presently seized with a pestilential fever, and narrowly escaped with his life.

In regard to the sediment which the serum dropped on becoming turbid, and which resembled well digested matter, the doctor thinks it a terrestrial substance, intended for the nourishment or reparation of the solids; in which opinion he was the more confirmed, by observing it in the urine of men in perfect health; and therefore concludes, that the pus, or digested matter, of sores, is nothing but this substance separated from the serum of the blood: and hence it is, that all large ulcers are extremely weakening, from the great expence of blood in furnishing this substance: hence also it is, that issues are of more consequence for making drains, than one would expect from the visible evacuation: as near as the doctor could guess, an ounce of serum, after standing some days, not furnishing more of this matter than what might be produced in the daily discharge of a large pea-issue, or from a seton.

There are frequent instances of the tawny colour of the serum, the resolution of the crassamentum, and even of the offensive smell of blood recently drawn. And, indeed, if we reflect how putrescent blood is in a heat equal to that of the human body, we may be convinced, that no sooner is the perspiration by the lungs impeded, than a corruption begins in the whole mass; which, if not timely prevented, brings on some putrid disease. If the acrimony is great and sudden, a fever or flux will ensue; but, if the accumulation is so slow, that the body grows habituated to the putrefaction, a scurvy prevails. This is the case in long voyages, on board unventilated ships; in marshy countries; and, in a lesser degree, in all northerly climates, in most situations. *Pringle on the Diseases of the Army.*

BLOW-*Pipe*, among jewellers and other artificers, is a glass tube, of a length and thickness at discretion, wherewith they quicken the flame of their lamp, by blowing through it with their mouth. It is used in works of quicker dispatch, which do not need the bellows.

BLOWING *of a flower*, among florists, an artificial process, in order to bring a flower to display itself with greater perfection and beauty than it would arrive at in the natural way of Blowing. The usual method is thus: about April, when the flower-stems begin to put forth, or spindle, as the gardeners call it, they place by each flower a straight stick four feet long, and tie the spindles to it, as they shoot. As soon as the flower-buds appear, they leave only one of the largest on each flower-stem to blossom. About ten days before the flowers open themselves, the round-podded kinds will begin to to crack their husks on one side; when the careful gardener, with a fine needle, splits or opens the husk on the opposite side to the natural fraction; and, about three or four days before the complete opening of the flower, cuts off, with a pair of scissars, the points on the top of the flower-pod, and supplies the vacancies or openings on each side the husk with two small pieces of vellum, or oil cloth, slipped in between the flower-leaves on the inside of the husk; by which means the blossom will display its parts equally on all sides; and be of a regular figure. Besides this care, when the blossom begins to shew its colours, they use to shade it from the extreme heat of the sun with a trencher-like board, or other device of the like nature, fastened to the stick which supports it; for the flowers, as well as fruits, grow larger in the shade, and ripen and decay soonest in the sun. *Bradl. new Improv. Gard.*

BLUE *Azure*, in chemistry.—This colour may be drawn from silver: but Boyle and Henckel justly observe, that this happens only according to the proportion of copper, found mixed in this metal. The following is the shortest process of making it: dissolve sal gem, salt of tartar, and roche allum, in the strongest double-distilled vinegar; suspend, over the vinegar so prepared, thin plates of silver; and bury the vessel in the husks of grapes. Every three days remove the plates, and wipe off the Blue, which will be formed on them. Another method: put laminæ of silver, as thin as paper, into a pint of the strongest vinegar; add to it two ounces of sal armoniac, well pulverized; put this into a glazed earthen pot, carefully stopped; bury this in horse-dung for fifteen or twenty days; at the end of which time you will find the laminæ covered with a fine azure Blue.

Another method.—Take an ounce of silver dissolved in spirit of nitre, two scruples and an half of sal armoniac, and as much vinegar as will be sufficient to precipitate the silver. Decant the vinegar, put the precipitated matter into a bottle well corked, and let it stand for a month, and you will have a fine azure Blue.

Azure Blue is also extracted from copper, quicksilver, and lead: to extract it from copper, take of verdigrise and sal armoniac, of each three ounces; mix these two ingredients with water wherein tartar has been dissolved; make up the mass into a soft paste; put the whole into a vessel well stopped, and let it stand still for some days, and the operation will be finished.

Another.—Take æs ustum and lees of wine, of each two ounces; sulphur, one ounce; pulverize the sulphur and æs ustum; pour vinegar or urine upon them; put the mixture in a glazed pot, well stopped, and let it stand fifteen days.

BLUE *Enamel*, in chemistry, is a very beautiful Blue colour, of great use to enamellers.

Neri, in his Art of making Glass, has given us the following method of preparing it:—Take four pounds of the fritt, or matter, of which the enamel is made (see ENAMEL) four ounces of zaffer pulverized, and forty-eight grains of æs ustum, or copper three times calcined; these three ingredients being mixed carefully together, put them into the furnace of a glass-house in a white glazed pot; when the mixture is thoroughly melted, it must be poured into clean water, to purge it from any filth; and then melted again, and again quenched in clean water, to purify it. This operation, repeated two or three times, will produce very fine Blue enamel.

Kunckel, in his Remarks on Neri, observes it is scarce possible to prescribe the exact quantity of zaffer necessary to make Blue enamel. It is, therefore, best to begin with a little, by way of experiment; and, if the Blue be too light, to increase the quantity of zaffer, but cautiously; if it be too deep, more fritt of the enamel must be added. By varying the quantities of the ingredients properly, every different shade of the Blue may be produced: as, for example, if we would make a light Blue, we must alter the quantities given before, and then take four pounds of the fritt of enamel, two ounces of æs ustum, and only forty-eight grains of zaffer; mix these ingredients well together, and observe the same directions in their melting and cleansing as before. All these operations are very nice, and require a particular attention; for, without it, effects are produced quite contrary to our expectation; which Kunckel acknowleges happened to him in the operation of the light Blue we have just mentioned. He tried this method of Neri's, and, as he did not succeed, thought this author mistaken; but, on repeating the operation with more nicety, found his ill success owing to his inattention, in having kept the ingredients too long in the furnace.

The coarser the grain of the enamel, the Blue is more lively, and approaches to the violet, like the azure; but the best enamel is the finest sky-blue. The grain of this blue is so coarse, that it is not made use of without great difficulty, except in water colours, or put into starch, with which it mixes very well. They call it powder-blue, because, in order to make a fine ground for a Turkish Blue, it is thrown on a white, covered with oil, as thick as possible. This is immediately spread with a feather, or light brush; but care must be taken first to dry the Blue well on a paper before the fire. It must be laid on to a proper thickness, left there till the bottom is quite dry; by which means the white imbibes as much as it can; afterwards it must be shaken off; and what does not adhere to the white, is taken off by a feather or light brush. This is a lively colour, and lasts a long time, though exposed to the weather.

Enamel, which is so much the finer the paler it is, is made use of in water-colours and fresco, but not in oil, because it turns black, unless mixed with a great deal of white.

Ultramarine BLUE.—The basis of this colour is lapis lazuli, which makes it very dear; besides, the operations, necessary to procure it, are both tedious and expensive. See LAPIS *Lazuli* in the Dictionary.

In order to know whether the lapis lazuli be of a good quality, and proper to produce a fine Blue, put bits of it into a coal fire, and make them red-hot; if they do not split by the calcination, and, when they are taken and grown cold, lose nothing of the brightness of their colour, it is a proof of the goodness of the lapis. There is also another method of trying it: heat bits of the lapis, on a plate of iron red-hot and quench them in the strongest white-wine vinegar: if the lapis lazuli be really good, it will not lose its colour by this operation. After being assured of the goodness of the lapis, proceed thus to make the ultramarine Blue: heat it several times red-hot, and constantly quench it in water; or, which is better, in strong vinegar. The oftener this operation is repeated, the more easily it may be pulverized; this being done, pound the pieces of the lapis, levigate them on a porphyry stone, moistening them with water, vinegar, or spirits of wine; continue to levigate the whole, till it is reduced to an impalpable powder; then wash it in water, dry it, and put it up where it may be kept clean from dust. Then take clean linseed oil, yellow bee's-wax, black and yellow resin, of each one pound; mastic, two ounces; warm the linseed-oil gently; mix the other ingredients, by stirring the mixture well, as it boils over the fire, which should be for the space of half an hour; after which pass this mixture through a linen cloth, and let it stand to be cool. To eight ounces of this paste put four ounces of the lapis, prepared as above; knead the mass well for a considerable time; when the powder is well incorporated, pour warm water on the mass, and knead it again, which will become of a Blue colour; then let it stand still for some days, till the colour subsides to the bottom of the vessel; decant the water, and dry the powder, which is the ultramarine.

There are several methods of making this paste; but we shall content ourselves with giving only one more: take yellow resin, virgin's wax, turpentine, mastic, frankincense, and linseed-oil, of each two ounces; melt these together in a glazed dish, according to the directions given in the preceding operation. Kunckel recommends the following method of making this fine Blue, and assures us he has practised with success.

After having broke the lapis lazuli into pieces about the bigness of a pea, calcine it, quench it in the strongest vinegar, and reduce it into a very fine powder: then take virgin's wax, and black resin, of each half the weight of the powder of the lapis; melt them together in a glazed earthen pot; throw in the powder by degrees, mixing it carefully, and stirring the ingredients well; pour this mixture into clean water; let it continue there eight days; at the end of which time, fill a large glass vessel with water, as warm as the hand can bear; take a clean cloth, and knead the mass till the water is very much tinged; then take out the mass, and put it in another vessel of the same kind, knead it in like manner; and so continue the operation, till the colour be totally expressed from the mass. In three or four days the ultramarine will subside to the bottom of the vessels; but that contained in the first water, is by far the most valuable: thus the same mass will produce three or four sorts of ultramarine; but the finest is produced in very small quantities.

There are other methods of making ultramarine Blue; but, as the difference consists only in the pastes, with which the pulverized lapis is mixed, we thought it needless to mention them. It is known whether the ultramarine Blue be genuine by its weight; for the counterfeit is lighter; and, besides, it loses its colour before the fire.

BLUE *ashes* are very much used in water-colours; some are very lively; but in oil they grow dull and greenish; for they are something of the nature of verdigrise; and, the more oil you put to them, the colour becomes weaker. They are found in the form of a soft stone, in places where there are copper mines; and water only is made use of in levigating them, to reduce them to a fine powder. This kind of Blue ought to be used principally in water-colours, seen by candle-light, as in scene-painting; for, though a great deal of white be mixed with it, it appears very beautiful, notwithstanding it has a greenish cast, quite contrary to enamel, which looks bright by day, and dull by candle-light.

Some of these Blue ashes look as beautiful as ultramarine; but, by mixing them with a little oil, the difference is easily discovered; for they acquire no body of colour from the mixture, whereas the ultramarine becomes much higher on being mixed with oil.

BLUE. Mr. Boyle has given us the following method of making

ing tranſparent Blue, nearly equal to ultramarine. The principal ingredient of this beautiful colour is the cyanus, or Blue corn-bottle flower, which abounds almoſt in every corn-field, and may eaſily be had, during four of the ſummer-months; and may be gathered by children about the ſkirts or verges of corn-fields, without doing any damage to the corn.

This flower has two Blues in it, one of a pale colour in the larger outward leaves, and the other of a deeper Blue, that lies in the middle of the flower.

Both theſe will do, being ſeparated from the buttons or caſes, in which they grow; but the deep Blue leaves in the middle produce by much the beſt colour; which may be obſerved, by rubbing the leaves, while they are freſh, ſo hard upon a piece of good writing-paper, as to preſs out the juice, and it will yield an excellent colour, which will not fade, as has been found by the experience of two or three years.

This part of the flower is, therefore, the principal and what may be depended upon; which ſhould be picked from the reſt of the flower-leaves, the ſame day, if it may be, or the next; or at leaſt as ſoon as poſſibly can be.

A good quantity of theſe middle leaves being procured, preſs out what juice you can from them, and add to it a little alum, and you will have a laſting, tranſparent Blue, of as bright a ſtaining colour as can be deſired, ſcarce inferior in beauty to ultramarine, and is durable.

As for the outward flower-leaves which are paler, it is not certain that they will anſwer the end; but, upon ſome trials being made, that may alſo be known.

Let the flowers be gathered about the beginning of June, or in July or Auguſt; and ſome may be found in May; but the preparation of the colour, by picking out the middle deep Blue flower-leaves, and preſſing out the juice, muſt be performed with all the expedition poſſible, or they will loſe their perfections.

It is very probable, that, if the chives of theſe blue corn-bottle-flowers were cured in the ſame manner as ſaffron is, they would produce a much greater body of colour, from which a tincture might be drawn with more eaſe, than if preſſed raw or freſh from the field.

BLUE *of turnſole*. This blue is proper to paint on wood, and is made of the ſeed of the plant from which it has its name. They uſe four ounces of turnſole, which they boil, for an hour, in three pints of water. There is a famous Blue uſed in callico-printing, made from turnſole; for which, ſee CALICO-*Printing*.

BLUE.—To give the Blue to linens ſignifies, with the whitſters, or bleachers, to dip it into water, wherein they have diſſolved a little ſtarch with ſmalt, or Dutch azure. They commonly give two Blues to cambrics: the firſt is the bleaching Blue, given by the whitſters, and the other the ſtiffening Blue, given by the merchants.

BLUE is alſo uſed in the bleaching of ſilks, to give them that bluiſh caſt, which heightens their whiteneſs and luſtre. Silks are blued, by dipping them in a tub of cold water, in which a little ſoap and indigo have been diluted.

BLUE *Dyes* are rendered more lively and bright, if the ſtuff, after being dyed, and well waſhed, be dipped into lukewarm water; but it is much better done, by fulling the dyed ſtuff with melted ſoap, and waſhing it afterwards very clean.

Very deep Blues are brightened by boiling the ſtuffs once in clear water, and then putting them into a decoction of cochineal; but the azure and lighter Blues would loſe their colour, and become grey, if they were put into ſuch a decoction.

Stuffs, dyed Blue, paſs immediately from white to that colour, without any other preparations but what they have undergone at the fuller's mill.

BLUE *Japan*, is made in the following manner: take gum-water, what quantity you pleaſe, and white-lead, a ſufficient quantity; grind them well upon a porphyry. Then take iſing-glaſs ſize, what quantity you pleaſe, of the fineſt and beſt ſmalt a ſufficient quantity, mix them well; to which add of your white-lead, before ground, ſo much as may give it a ſufficient body; mix theſe together to the conſiſtence of paint.

With this mixture do over your work, and repeat this three or four times, till you ſee your Blue lies with a good fair body, letting it dry thoroughly between each time; if the Blue be too pale, put any more ſmalt into the ſize, without white-lead.

Then rub it very ſmooth, and go over it again with a ſtronger Blue; and, when it is thoroughly dry, waſh it twice over with the cleareſt iſing-glaſs-ſize alone; then cover it, and let it dry two days.

Then warm the piece gently before the fire, and, with a clean pencil, waſh your work over with the fineſt white varniſh, repeating it ſeven or eight times, and then let it dry two days as before; then repeat again your waſhes ſeven or eight times in the like manner.

Then let it ſtand to dry for a week, and then poliſh it as before directed; and, laſtly, to give it a poliſhed and gloſſed appearance, clear it up with lamp-black and oil.

You may make the colour either light or deep, according to your fancy; if it have but a ſmall proportion of the lead, it will be deep; but, if it has a larger, it will be lighter.

Alſo the ſize for laying Blues, white, or any other colour, ought not to be too ſtrong, rather weaker, and juſt ſufficient to bind the colours and make them ſtick on the work; for, if it be two ſtiff, it will be apt to crack and fly off; and the reaſon of waſhing twice, with clear ſize, is to keep the varniſh from ſinking into, or tarniſhing the colours.

A BLUE *colour for painting or ſtaining glaſs*.—Take, of fine white ſand, twelve ounces; zaffer and minium, of each three ounces; reduce them to a fine powder in a bell-metal mortar; then put this powder into a very ſtrong crucible, cover it and lute it well; and, being dry, calcine over a quick fire for an hour; then take out the matter, and pound it well in the mortar, as before; then, to ſixteen ounces of this powder, add fourteen ounces of nitre, powdered; mix them well together, and put them into the crucible again, cover and lute it, and calcine for two hours in a very ſtrong fire.

Take it out, and grind it as before; then add to it a ſixth part of nitre, and calcine again, as before, for three hours more; then take out the matter with an iron ſpatula red-hot, leſt it ſhould ſtick; it being very clammy, and not eaſily emptied.

Pruſſian BLUE, a very fine Blue colour, made in the following manner:

Take, of crude tartar and nitre, each four ounces, pulverize and mix them together; and, by decrepitation, bring them to a fixed ſalt; which, being powdered hot, add to it four ounces of thoroughly dried ox-blood, reduced to fine powder: calcine the mixture in a cloſe crucible, whereof it may fill two-thirds: then, lightly, grind the matter in a mortar, and throw it hot into two quarts of boiling water; boil them together for half an hour; afterwards ſtrain off the liquor, waſh the black remaining ſubſtance with freſh water, and ſtrain as before; continuing to do thus till the water poured off becomes inſipid: put the ſeveral liquors together, and evaporate them to two quarts: now diſſolve an ounce of green vitriol, firſt calcined to whiteneſs, in ſix ounces of rain-water, and filtre the ſolution: diſſolve alſo half a pound of crude alum, in two quarts of boiling water; and add this to the ſolution of vitriol, taken hot from the fire; pouring to them likewiſe the firſt lixivium, whilſt thoroughly hot, in a large veſſel: a great ebullition, and a green colour, will immediately enſue. Whilſt this ebullition continues, pour the mixture out of one veſſel into another, and afterwards let it reſt; then ſtrain the liquor through a linen cloth, and let the matter or pigment remain in the ſtrainer; from whence put it, with a wooden ſpatula, into a ſmall new pot; pour upon it two or three ounces of ſpirit of ſalt; and a beautiful Blue colour will immediately appear. Let the matter be now well ſtirred; then ſuffered to reſt for a night; afterwards thoroughly edulcorate it by repeated affuſions of rain water; allowing a proper time for the precipitate to ſubſide; and thus, at length, it will become exquiſitely Blue. Laſtly, let it drain upon a linen ſtrainer, and dry it gently; by all which means, it becomes the pigment that goes by the name of the Pruſſian Blue.

The ſucceſs of the experiment has a great dependence on the calcination. The crucible is firſt to be ſurrounded with coals, at ſome diſtance, that it may grow gradually hot, and the matter leiſurely flame and glow. Let this degree of heat be continued, till the flame and glowing decreaſe; then raiſe the fire again, that the matter may glow with an exceeding white heat, and but little flame appear above the crucible. The lixiviums ſhould be very hot, and mixed together with the utmoſt expedition.

The method of making this Pruſſian Blue in perfection has been held and purchaſed as a very valuable ſecret, both in England, Germany, and elſewhere; but it is now got into ſeveral hands. Its proceſs is very extraordinary, and could ſcarce be derived, a priori, from any reaſoning about the nature of colours. It is allowed an excellent Blue pigment, and by ſome preferred to ultramarine; though its durability might have been ſuſpected, from the vegetable and animal matters uſed in its preparation, if the colour did not ſeem wonderfully fixed by the operation.

Stone or powder BLUE, uſed in waſhing of linen, is the ſame with ſmalt, either in the lump or powdered.

When the ſmalt is taken from the pot, it is thrown into a large veſſel of cold water; this makes it more tractable, and eaſily powdered. Afterwards, when examined after cooling, it is found to be mixed with a greyiſh matter, reſembling aſhes, which they call eſchel. This grey matter is ſeparated by waſhing; and then the Blue ſubſtance is powdered and ſifted through fine ſieves, to bring it to what we call powder Blue. *Phil. Tranſ.* No. 396.

BLUING *of iron*, a method of beautifying that metal, ſometimes practiſed; as for mourning buckles, ſwords, and the like. The manner is thus: take a piece of grindſtone, or whetſtone, and rub hard on the work, to take off the black ſcurf from it; then heat it in the fire, and, as it grows hot, the colour changes by degrees, coming firſt to a light, then to a darker gold colour, and, laſtly, to a Blue. Sometimes alſo they grind indigo

indigo and sallad-oil together; and rub the mixture on the work with a woollen rag, while it is heating, leaving it to cool of itself. *New, Build. Dict.*

Among sculptors we also find mention of Bluing a figure of bronze, by which is meant the heating of it, to prepare it for the application of gold-leaf, because of the bluish cast it acquires in the operation. *Felib. Princ. Archit.*

BLUFF-*head*, or BLUFF-*headed*, in the sea language, is when a ship has but a small rake forward on, being built with her stern too streight up.

BOAR.—The wild Boar, among the huntsmen, has several names, according to its different ages; the first year, it is called a pig of the saunder; the second, it is called a hog; the third, a hog-steer; and the fourth, a Boar; when leaving the saunder, he is called a singler.

The Boar generally lives to twenty-five or thirty years, if he escapes accidents. The time of going to rut is in December, and lasts about three weeks. They feed on all sorts of fruits, and on the roots of many sorts of plants; the roots of fern, in particular, seem a great favourite with them: and, when they frequent places near the sea-coasts, they will descend to the shores, and demolish the tenderer shell-fish in very great numbers. Their general place of rest is among the thickest bushes that can be found; and they are easily put up out of them, but will stand the bay a long time. In April or May they sleep more sound than at any other time of the year; and this is therefore the successful time for taking them in the toils. When a Boar is rouzed out of the thicket, he always goes from it, if possible, the same way by which he came to it; and, when he is once up, he will never stop till he comes to some place of more security. If it happens, that a saunder of them are found together, when any one breaks away, the rest all follow the same way. When the Boar is hunted in the wood, where he was bred, he will scarce ever be brought to quit it; he will sometimes make towards the sides, to listen to the noise of the dogs; but retires into the middle again, and usually dies or escapes there. When it happens, that a Boar runs a-head, he will not be stopped, or put out of his way, by man or beast, so long as he has any strength left. He makes no doubles or crossings, when chaced; and, when killed, makes no noise, if an old Boar; the sows and pigs will squeak, when wounded.

The season for hunting the wild Boar begins in September, and ends in December, when they go to rut. If it be a large Boar, and one that has lain long at rest, he must be hunted with a great number of dogs, and those such as will keep close to him; and the huntsman, with his spear, should always be riding in among them, and charging the Boar as often as he can, to discourage him: such a Boar as this, with five or six couple of dogs, will run to the first convenient place of shelter, and there stand at bay, and make at them, as they attempt to come up with him.

There ought always to be relays also set of the best and staunchest hounds in the kennel; for, if they are of young eager dogs, they will be apt to seize him, and be killed or spoiled before the rest come up. The putting collars with bells about the dogs necks is a great security for them, for the Boar will not so soon strike at them, when they have these, but will rather run before them. The huntsmen generally kill the Boar with their swords or spears; but great caution is necessary in making the blows, for he is very apt to catch them upon his snout or tusks; and if wounded, and not killed, he will attack the huntsmen in the most furious manner. The places to give the wound with the spear, are either between the eyes, in the middle of the forehead, or in the shoulder; both these places make the wound mortal.

When this creature makes at the hunter, there is no avoiding him but by courage and address; if he flies for it, he is surely overtaken and killed; if the Boar comes straight up, he is to be received at the point of the spear; but, if he makes doublers and windings, he is to be watched very cautiously, for he will attempt getting hold of the spear in his mouth; and, if he does so, nothing can save the huntsman, but another person attacking him behind; he will, on this, attack the second person, and the first must then attack him again; two people will thus have enough to do with him; and, were it not for the forks of the Boar-spears, that make it impossible to press forward upon them, the huntsman, who gives the creature his death's wound, would seldom escape falling a sacrifice to his revenge for it.

The modern way of Boar-hunting is generally to dispatch the creature by all the huntsmen striking him at once; but the ancient Roman way was, for a person, on foot, armed with a spear, to keep the creature at bay; and, in this case, the Boar would run of himself upon the spear, to come at the huntsman, and push forward till the spear pierced him through.

The hinder claws of a Boar are called guards.

In the corn he is said to feed; in the meadows, or fallow fields, to rout, worm, or fern; in a close, to graze.

The Boar is farrowed with as many teeth as he will ever have, his teeth increasing only in bigness, not in number; among these there are four called tushes, or tusks, the two biggest of which do not hurt, when he strikes, but serve only to whet the other two lowest, with which the beast defends himself, and frequently kills, as being greater and longer than the rest. *Gent. Rur.* p. 1, 7, and 119. *Trev. Dict. Univ.* tom. 4.

It is very remarkable, that these creatures, in the West-Indies, are subject to the stone, in a very remarkable manner; few of them are absolutely free from it; yet scarce any have the stones of any considerable size. It is common to find a great number in the same bladder, and they are usually of about a scruple weight, and are angular, and that with great regularity, each having five angles. *Phil. Trans.* N°. 36.

Among the ancient Romans, Boar's flesh was a delicacy: a Boar, served up whole, was a dish of state. *Pitisc. Lex. Ant.* tom. 1. p. 123. voc. *Aper.*

The Boar was sometimes also the military ensign borne by the Roman armies, in lieu of the eagle. *Salmuth. ad Pancirol.* tit. 53. p. 278.

Among physicians, a Boar's bladder has been reputed a specific for the epilepsy. *Friend's Hist. of Phys.*

The tusk of the wild Boar still passes with some as of great efficacy in quinsies and pleurisies. *Alleyn's Dispens.*

BOB *of a pendulum*, the same with its ball, except that the former is used in speaking of short pendulums, the latter of long ones.

BO'BBING, or BOBBIN, in the manufactory of lace, a little piece of turned wood, whereon thread is wound, to be used in the weaving of bone-lace. *Hought. Collect.*

BO'CCA, in glass-making, the round hole in the working furnace, by which the metal is taken out of the great pots, and by which the pots are put into the furnaces. This is to be stopped with a cover made of earth and brick, and removeable at pleasure, to preserve the eyes of the workmen from the violence of the heat. *Neri's Art of Glass.*

BO'DY (*Dict.*)—The existence of Bodies is a thing incapable of being demonstrated: the order in which we arrive at the knowledge of their existence, seems to be this.—We first find we have sensations: then observe we have not those sensations, when we please: and thence conclude, we are not the absolute cause thereof, but that there is required some other cause for their production. Thus we begin to know, that we do not exist alone, but that there are several other things in the world together with us.—But this, Dr. Clarke owns, comes far short of a demonstration of the existence of a corporeal world: he adds, that all the proof we have of it is this, that God would not create us such, as that all judgments we make about things existing without us, must necessarily be false. If there be no external Bodies, it follows, that it is God who represents the appearance of Bodies to us; and that he does it in such a manner, as to deceive us.—Some think this has the force of a demonstration: "It is evident God cannot deceive us; it is evident he does deceive and delude us every moment, if there be no Bodies; it is evident, therefore, there must be Bodies.—But the minor of this argument may be denied without any suspicion of scepticism.

"In effect, were it possible for Bodies, i. e. solid, figured, &c. substances to exist without the mind corresponding to those ideas we have of external objects, yet how were it possible for us to know it? Either we must know it by sense, or reason: as for our senses, by them we have only the knowledge of our sensations or ideas: they do not inform us that things exist without the mind, or unperceived, like those which are perceived. It remains, therefore, that, if we have any knowledge at all of external things, it must be by reason inferring their existence from what is immediately perceived by sense. But how shall reason induce us to believe the existence of Bodies without the mind, when the patrons of matter themselves deny that there is any necessary connection betwixt them and our ideas? In effect, it is granted on all hands, and what happens in dreams, phrenzies, deliriums, extasies, &c. puts it beyond dispute, that we might be affected with all the ideas we have now, though there were no Bodies existing without, resembling them. Hence, it is evident, the supposition of external bodies is not necessary for the production of our ideas." *Berkeley's Princ. of Human Knowledge, p.* 59.

"Granting the materialists their external Bodies, they, by their own confession, are never the nearer knowing how our ideas are produced; since they own themselves unable to comprehend in what manner Body can act upon spirit, or how it is possible it should imprint any idea on the mind. Hence the production of ideas or sensations, in our minds, can be no reason why we should suppose Bodies or corporeal substances; since that is equally inexplicable with or without the supposition. In short, though there were external Bodies, it is impossible we should ever come to know it; and, if there were none, we should have the same cause to think there were that we now have." *Id. Ibid. p.* 60, 61.

"Try, whether you can conceive it possible for a sound, or figure, or motion, or colour, to exist without the mind, or unperceived.—If you can but conceive it possible for one extended, moveable substance, or, in general, for any one idea to exist otherwise, than in a mind perceiving it; I shall readily give up the cause." *Id. Ibid. p.* 63.

"It is worth while to reflect a little on the motives which induced

duced men to suppose the existence of material substance; that so, having observed the gradual ceasing and expiration of those motives, we may withdraw the assent grounded on them. First, therefore, it was thought that colour, figure, motion, and the rest of the sensible qualities did readily exist without the mind; and for this reason it seemed necessary to suppose some unthinking substratum or substance, wherein they did exist, since they could not be conceived to subsist by themselves. Afterwards, in process of time, men being convinced that colours, sounds, and the rest of the sensible secondary qualities had no existence without the mind; they stripped this substratum of these qualities, leaving only the primary ones, figure, motion, *&c.* which they still conceived to exist without the mind, and consequently to stand in need of a material support. But having shewn above, that none, even of these, can possibly exist otherwise than in a spirit, or mind, which perceives them, it follows, that we have no longer any reason to suppose the being of matter." *Id. Ibid. p.* 118, 119.

For the colours of Bodies: Sir Isaac Newton shews that Bodies appear of this or that colour, as they are disposed to reflect most copiously the rays of light originally endued with such colours. But the particular constitutions whereby they reflect some rays more copiously than others, remain yet to be discovered. However, some of the laws and circumstances thereof he delivers in the following propositions.

1. Those surfaces of transparent Bodies reflect the greatest quantity of light, which have the greatest refracting power, i. e. which intercede mediums, that differ most in their refractive densities: and, in the confines of equally refracting mediums, there is no reflection. 2. The least parts of almost all natural Bodies are in some measure transparent; and the opacity of those Bodies arises from the multitude of reflections caused in their internal parts, &c. 3. Between the parts of opake and coloured Bodies are many spaces, either empty, or replete with mediums of different densities; as water between the tinging corpuscles wherewith a liquor is impregnated, air between the aqueous globules that constitute clouds or mists: and even spaces void both of air and water, between the parts of hard Bodies, are not wholly void of all substance. 4. The parts of the Bodies and their interstices must be less than of some definite bigness, to render them opake and coloured. 5. The transparent parts of bodies, according to their several sizes, reflect rays of one colour, and transmit those of another, for the same reason that thin plates or bubbles do reflect or transmit those rays; and this appears to be the ground of all their colour. 6. The parts of Bodies, on which their colours depend, are denser than the medium which pervades their interstices. 7. The bigness of the component parts of natural Bodies may be conjectured from their colours, on this principle, that transparent corpuscles, of the same thickness and density with a plate, do exhibit the same colour. 8. The cause of reflection is on the impinging of light on the solid or impervious parts of Bodies, as commonly believed. 9. Bodies reflect and refract light, by one and the same power, variously exercised, in various circumstances.

BODY *of a coach*, a word used by joiners and coach-makers. With joiners, it signifies the bare cage or wooden frame of a coach, which the coach-makers are afterwards to line with leather on the outside, and with stuff on the inside: with coach-makers, it signifies the coach thus lined, before it be put on the wheels and on carriage.

BODY is likewise said of the materials which compose a stuff, or some other manufactured work. The Body of a woollen cloth; the Body of a serge; the Body of paper; the Body of velvet. In all those senses, traders say, the Body of this paper is too weak; the Body of this cloth, or of this serge, is good; the Body of this velvet is too loose, or too thin.

BODY *of reserve*, in the military art, a draught or detachment of a number of forces out of an army, who are to engage in case of necessity.

BOG (*Dict.*)—When the ground is drained, it is then, and no sooner, proper to begin the improvement of the soil. First, continue to plant as many potatoes in the dry land as in this season you can, for it is unexceptionable husbandry, equal to a summer-fallow.

Next, fallow all the rest of the ground this very season, and as soon in it as possible: for, besides the benefits of the fallow itself, by the plowings you may save a good deal of expence of levelling the ground, the plowed earth being easily thrown from the high places to the low; and the next plowings will always raise more earth on places where any was taken away. Plow not only all you can this year, but plow up the rest, every inch of it, that the plough can touch, as soon as by the draining it subsides, and becomes so firm, that it can bear the labouring cattle; that, without loss of time, you may get into the clover-husbandry: for ground, yielding grain and grass, from grass-seeds sown alternately, will very probably give more free profit than when it is constantly yielding either the one or the other, if the husbandry for both be equally good.

Where you cannot use the plough, employ the spade, and make your fallow compleat. Then consider which parts are fit for wheat, which for rye, and which want the assistance of dung for the one or for the other; and at any expence put your ground once in good heart, in confidence that, if it were, the method of husbandry I am to direct, will keep it in as good order, or make it better, with small expence of dung, in all time thereafter, though you keep it annually under the sock or scythe: for land in heart and strength is, I am much disposed to think, as much improved by some crops judiciously taken, as weak worn out land is by a summer fallow, at least such a sham fallow as is too often made, without any crop at all, unless it get dung.

When your ground is in all respects in good order, sow wheat on the strongest, and winter rye on the lighest parts of your soil, for the first crop of grain: for the second, sow pease; for they meliorate the ground, when they have proved a good crop, and you may expect it. Immediately after the pease are cut, and cut them high, plow down the stubble, without allowing cattle to eat it; and, after two spring-plowings, sow barley and the great clover, with only a small mixture of rye-grass; because clover is an enricher, and rye-grass impoverishes the ground, and fouls it. After the barley is cut, allow no cattle to enter your inclosure, except in very dry weather, lest they poatch the ground with their feet, and destroy the young clover. If you would keep them out in dry weather as well as wet, and allow the grass to rot among the stubble, by the dressing it would improve the ground, and keeping the roots of the clover-plants warm through winter, your advantage would be greater than though your cattle eat it.

Next year cut it twice, and put cattle upon the fog or eddish. The following year cut it only once, and, when it is beginning to flower, roll it down, plow it in, and harrow the ground, to close the seams, that the swaird may rot the better, and be ready for wheat or winter rye, upon another plowing. If it be not fit for these, it will answer well for barley: and sow pease for the subsequent crop; for two crops of white grain, running, impoverish ground, and make dung necessary. After the pease, sow barley, clover, and rye-grass, and manage as directed; and so go on with this course of husbandry without variation. If you do, I hope your ground will have little need of manure. But, if you find it necessary, and can get time, I advise you to sow it upon the young clover, among the barley stubble in the month of September: fifteen or twenty horse-loads may serve an acre; and will not only encourage the clover, but will incorporate itself with, and meliorate the earth, and so prepare it for succeeding crops; and, if you see cause to use it further, a gentle liming may be profitably and harmlessly repeated upon the young clover every fifth year: for the pease, clover, and tilling down of the clover as directed, will be sufficient dunging to make the lime work; and, it being thus laid upon the surface, there to lie, and incorporate itself with the ground, for the space of two years before it again suffer the plough, the hazard of subsiding below the reach of the plough, which lime is subject to, is prevented. Or you may sow soot, pigeon's dung, or ashes, in lesser quantities, in proportion to the hotness of their different natures, and the hotness or coldness of the quality of the different parts of your soil.

BOHEA, one of the kinds of tea brought from China. *See* TEA *in the Dictionary.*

BOILER.—The Boiler, in the alum works, is a vessel, in which the liquor is evaporated to a consistence, and is made of lead. The general size is about eight feet square, and they contain about twelve tons each.

They make them in this manner: first they lay long pieces of cast iron, twelve inches square, as long as the breadth of the Boiler, and about twelve inches distance from one another. These are placed twenty-four inches above the surface of the fire. On these massy bars of iron they lay, cross-wise, the common flat bars of iron, as close as they can lie together, and then make up the sides with brick work. In the middle of the bottom of this Boiler is laid a trough of lead, wherein they put at first about an hundred pounds weight of the rock. They use Newcastle coals in the boiling; and, if they find the liquor not strong enough, they add more of the rock at times, as it boils. *Phil. Trans.* N°. 142.

BOILERY, or Boilary, in the salt-works, denotes a salt-house, pit, or other place where salt is made.

BOILING (*Dict.*)—The phænomenon of Boiling may be thus accounted for: the minute particles of the fuel being detached from each other, and impelled in orbem, with a great velocity, (i. e. being converted into fire) pass the pores of the containing vessel, and mix with the liquid. By the resistance they here meet withal, their motion is destroyed; i. e. they communicate it wholly to the quiescent water; hence arises, at first, a small intestine motion in the water, and, from the continued action of the first cause, the effect is increased, and the motion of the water continually accelerated: so that the water, by degrees, becomes sensibly agitated. But now the particles of the fire, striking on those in the lowest surface of the water, will not only give them an impulse upwards, contrary to the laws of æquilibrium, but will likewise render them specifically lighter than before, so as to determine them

to

to ascend according to the laws of æquilibrium: and this, either by inflating them into little vesicles, by the attraction of the particles of water round them; or by breaking and separating the little spherules of water, and so increasing the ratio of their surface to their solid content. There will therefore be a constant flux of water from the bottom of the vessel to the top, and consequently a reciprocal flux from the top to the bottom: i. e. the upper and under water will change places; and hence we have the reason of that phænomenon, of the water's being hot at top sooner than at bottom.

Again, an intense heat will diminish the specific gravity of water, so as not only to make it mount in water, but also in air; whence arise the phænomena of vapour and smoak: though the air, inclosed in the interstices of the water, must be allowed a good share in this appearance: for that air, being dilated, and its spring strengthened by the action of the fire, breaks its prison, and ascends through the water into the air; carrying with it some of the contiguous spherules of water, so many as shall hang in its villi, or can adhere immediately to it.

The particles of air in the several interstices of the fluid mass thus expanded, and moving upwards, will meet and coalesce in their passage; by which means great quantities of the water will be heaved up, and let fall again alternately, as the air rises up, and again passes from the water: for the air, after coalition, though it may buoy up a great heap of water, by its elasticity while in the water, yet cannot carry it up together with itself into the atmosphere; since, when once got free from the upper surface of the water in the vessel, it will unbend itself in the atmosphere, and so its spring and force become just equal to that of the common unheated air. Add to this, that, were the spring and motion of the air sufficient to carry up the water with it, yet it would not have that effect, but the water would run off at the extremities of the air; all, except so much as should be either entangled in its villi, or immediately adhere to its surface by attraction: and hence we see the reason of the principal phænomenon of Boiling, viz. the fluctuating of the surface of the water.

Water, only lukewarm, boils very vehemently in the recipient of an air-pump, when the air is exhausted: the reason is obvious; for, the pressure of the atmosphere being taken off from its surface, the air included in the interstices of the water, dilated by a feeble heat, has spring enough to heave up the water, and disengage itself.—When the water ceases Boiling, it is again excited thereto by pouring cold water upon the recipient; and, when it boils the most vehemently, ceases by pouring on hot water; the reason whereof is scarce guessed at.

BOILING *of silk with soap*, is the first preparation in order to dying it. Thread is also boiled in a strong lixivium of ashes, to prepare it for dying.

BOILING, is also a method of trying or essaying the goodness or falseness of a colour or a dye, by Boiling the stuff in water with certain drugs, different according to the kind or quality of the colour to try whether or no it will discharge, and give a tincture to the water.

With this intention, red, crimson silks are boiled, with alum, and scarlets with soap, in a quantity equal to the weight of the silk.

BOLE, in natural history, a kind of earth constituting a distinct genus of fossils, and containing many different species, used principally in medicine. The characters of this genus are, that the earths of it are moderately coherent, ponderous, soft, not stiff or viscid, but in some degree ductile, while moist; composed of fine particles, smooth to the touch, easily breaking between the fingers, readily diffusible in water, and freely and easily subsiding from it. *Hill's Hist. Foss.*

BOLT *of a lock*, is the piece of iron, which, entering the staple, fastens the door; being the part which is moved backwards and forwards by turning the key.

Of these there are two sorts; one shuts of itself by only putting to the door, and is called a spring-Bolt; the other, which only moves when the key opens and shuts it, is called a dormant Bolt. *Moxon, Mech. Exer.*

BOLTERS, or BOULTERS, a kind of sieves for meal, having the bottoms made of woollen, hair, or even wire. *Hought. Collect.*

BOLTING, or BOULTING, the act of separating the flour from the bran, by means of a sieve or bolter.

BOLTING-*mill*, a versatile engine for sifting with more ease and expedition. The cloth round this is called the boulter.

BOMB (*Dict.*)—The shell being filled with gun-powder, the fusee is driven into the vent, or aperture, and fastened with a cement made of quick-lime, ashes, brick-dust, and steel filings, worked together in a glutinous water; or of four parts of pitch, two of colophony, one of turpentine, and one of wax. This tube is filled with a combustible matter, made of two ounces of nitre, one of sulphur, and three of gunpowder-dust, well rammed. To preserve the fusee, they pitch it over, but uncase it, when they put the Bomb into the mortar, and cover it with gunpowder-dust, which, having taken fire by the flash of the powder in the chamber of the mortar, burns all the time the Bomb is in the air; and, the composition in the fusee being spent, it fires the powder in the Bomb, which bursts with great force, blowing up whatever is about it; the great height the Bomb goes in the air, and the force with which it falls, makes it go deep into the earth.

Fig. 6. and 7. *plate* XXXV, in the Dictionary, may serve to give a more exact idea of the Bomb.

Fig. 6. exhibits a Bomb as it appears to the eye; *fig.* 7. its section or profile.

To prove whether it be staunch, after heating it red-hot on the coals, it is exposed to the air, so as it may cool gently; for, since fire dilates iron, if there be any hidden chinks or perforations, they will thus be opened and enlarged; and the rather, because of the spring of the included air continually acting from within. This done, the cavity of the globe is filled with hot water, and the aperture well stopped; and the outer surface washed with cold water and soap: so that, if there be the smallest leak, the air, rarified by the heat, will now perspire, and form bubbles on the surface.

If no defect be thus found in the globe, its cavity is filled with whole gunpowder; a little space, or liberty, is left, that when a fusee or wooden tube, of the figure of a truncated cone, is driven through the aperture, and fastened with a cement made of quick-lime, ashes, brick-dust, and steel filings, worked together in a glutinous water; or, of four parts of pitch, two of colophony, one of turpentine, and one of wax; the powder may not be bruised. This tube is filled with a combustible matter, made of two ounces of nitre, one of sulphur, and three of gunpowder-dust, well rammed.

This fusee, set on fire, burns slowly, till it reach the gunpowder, which goes off at once, bursting the shell to pieces with incredible violence; whence the use of Bombs in besieging towns.

Special care, however, must be taken, that the fusee be so proportioned, as that the gunpowder do not take fire before the shell arrives at the destined place; to prevent which, the fusee is frequently wound round with a wet clammy thread.

A Bomb, thrown out of a mortar eighteen inches one-third diameter, contains twelve pounds of powder in its chamber. Its thickness is two inches all over, except at the breech, where it is two inches five-sixths thick.

The aperture of the touch-hole on the outside should be one inch two-thirds; it contains forty-eight pounds of powder; and, before it is loaded, weighs somewhat above 490 pounds. It has two handles near the touch-hole.

A mortar-piece of twelve inches one-half diameter must have eighteen pounds of powder, for a proper charge; its Bomb must be eleven inches two-thirds diameter, the shell of one inch one-third thick all over, except at the breech, where it should be one inch two-thirds thick. The aperture of its touch-hole, on the outside, one inch one-third; it contains fifteen pounds of powder, and weighs, besides its load, about one hundred and thirty pounds.

Bombs thrown from mortars of twelve inches one-fourth, twelve inches one-third, and so on to twelve inches one-second diameter, observe the same proportion when the mortars are loaded with twelve and eight pounds of powder. The proportion is the same with regard to the Bomb of the common mortar, twelve inches diameter, whose charge is from five to six pounds of powder.

The Bomb thrown by a mortar eight inches one-third diameter, which carries one pound twelve ounces of powder, must be eight inches diameter, ten-twelfths of an inch thick, except at the breech, where it must be one inch one-twelfth thick. The aperture of its touch-hole one inch diameter on the outside; its charge is four pounds of powder, and, before loaded, weighs thirty-five pounds.

The Bomb, thrown by a mortar six inches one-fourth diameter, which carries one pound three-fourths of powder, or rather six inches diameter, five-sixths of an inch thick all over, except at the breech where it is eleven-twelfths of an inch, or an inch thick; its touch-hole is five-sixths of an inch on the outside, its charge three pounds and an half of powder, and weighs, before loaded, about twenty pounds. Those Bombs are commonly made without handles.

In some cases the quantity of powder may be lessened, as some Bombs are only designed to demolish buildings, without setting them on fire, or drop short of an army: for then the intention of the deed is only to make the Bomb burst: consequently there is no occasion for more powder than is necessary to produce this effect. According to M. Belidore's treatise on the Arms and Machines in use before the Invention of Gun-powder, three pounds of powder are sufficient to burst a Bomb of twelve inches diameter: and one pound of powder will have the same effect on a Bomb of eight, from whence we may conclude that eight or ten pounds of powder are sufficient to load a Bomb of eighteen inches diameter, instead of forty-eight pounds, the common charge.

BOMBA'RDING, the act of attacking a city or fortress, by throwing bombs into it, in order to ruin or set on fire the houses and magazines, and do other mischiefs.

BOMBA'ST, in matters of diction, a style too high and pompous for the subject and occasion; or words too big and sounding for the sense and meaning.

BOMBASI'NE, in commerce, a kind of silk-stuff manufactured

tured at Milan, and thence sent into France and other countries.

BOMBYLIUS, in natural history, the name of the common humble-bee, of which we have a great variety of species, many of them very beautiful.

BOMBYLOPHAGES, *Humble-bee-eater*, in natural history, the name of a fly of the tipula or father-long-legs kind, which is larger and stronger than the common kinds; and loving honey, without knowing how to extract it from the flowers, it seizes on the humble-bees, and destroys them, in order to get at the bag of honey which they contain. It is of a blackish colour in the body; its head is of a bright red, and the eyes very large and prominent. It is chiefly found in mountainous places.

BOND, a deed, by which a person obliges himself to perform certain acts; such as to pay a certain sum, or to answer for another, or to serve an apprenticeship with a master.

In England, a Bond is a deed or obligatory instrument in writing, whereby a person binds himself to another, to pay a sum of money, or do some other act, as to make a release, surrender an estate, for quiet enjoyment; to stand to an award, save harmless, perform a will, &c. It contains an obligation with a penalty annexed, and a condition which expressly mentions what money is to be paid, or what other things are to be perfomed, and the limited time for the performance thereof, for which the obligation is peremptorily binding.

It may be made upon parchment or paper, though it is usually on paper, and be either in the first or third person: and the condition may be either in the same deed or in another; and sometimes it is included within, and sometimes indorsed upon the obligation; but it is commonly at the foot of the obligation.

BONITO, in zoology, the name of a fish, of the tunny or trachurus kind, and called by some curvata pinima. It is a large sea fish, with a long, broad, and thick body: its eyes are large, as are also its gills, and the greater part of its body is free from scales.

BONNY, in minerology, a name given by our miners to a bed of ore found in many places in hills, not forming a vein, nor communicating with any other vein, nor terminating in strings, as the true veins do: it is a bed of ore of five or six fathom deep, and two, or somewhat less than that, in thickness, in the largest sort; but there are smaller, to those of a foot long. They have their trains of shoad-stones from them, and often deceive the miners, with the expectation of a rich lead vein. They differ from the squats only in being round beds of ore, whereas they are flat. *Philos. Transf.* N°. 69.

BOOK (*Dict.*)— *Cash* BOOK. This is the first and most important of the auxiliary books. It is so called, because it contains, in debtor and creditor, all the cash that comes in, or goes out, of a merchant's stock. The French call it, also, the Book of cash and of notes (livre de caisse & le bordereau) because, besides an account of the cash received and paid, it contains also notes of the several species of the money, or coin, that comes in, or goes out.

When a merchant does not keep that Book himself, he has it kept by a clerk or book-keeper, whom they stile cashier.

In this Book they write all the sums which are daily received and paid. The receipts on the debtor side, the persons of whom it was received, for what, and on whose account, and in what specie; and the payments on the creditor side, mentioning also the specie, the reason of the payment, to whom, and for whose account they are made.

The better to conceive the nature of this Book, it is to be observed, that in business, where cash happens to be an account which has numerous articles, it is convenient to keep a particular account thereof in a Book distinct from the ledger, and for this reason called the cash Book. This is formed in all respects like the cash accounts in the ledger, with a debtor and creditor side, in which all the cash received and given out is entered, either in a simple stile, or in that of the ledger: but, which way soever the narrative is made, every article must be duly entered on the opposite side of the corresponding account in the ledger, with a reference to the ledger account of cash: for such an account there must also be, into which the sums of the debtor and creditor sides of the particular account must be transferred once a week, or month, as is found most convenient. Thus in the cash Book, the sums being written down against them, say, transferred to the ledger, and mark the folio; and in the ledger account enter the sum, with the date of the transfer, debtor to, and creditor by sundry accounts, as per cash Book. The cash account in the ledger is necessary for the balance of the whole; and the conveniency of the separate account of all the particulars is, that we have them all together in one continued account: whereas, the rule of the ledger being not to allow more than one folio for one account, till that be filled up, the account might hereby lie in several folio's.

BOOK *of Debts or Payments*, is a Book in which is written down the day on which all the sums become due, either to be received or paid, by bills of exchange, notes of hand, merchandizes bought or sold, or otherwise; that, by comparing receipts and payments, one may in time provide the necessary funds for payments, by getting the bills, notes, &c. due, to be paid, or by taking other precautions.

BOOK *of Numero's, or Wares.* This Book is kept, in order to know easily all the merchandizes that are lodged in the warehouse, those that are taken out of it, and those that remain therein. Its form is commonly long and narrow, as of half a sheet of paper folded lengthways. Every page is ruled with transversal and parallel lines, about an inch distant from each other, with two other lines from top to bottom, the one next the margin, and the other next the sums.

Within the oblong squares formed by those lines, they write on the left page the volume of the merchandizes, that is to say, whether it be a bale, a chest, a ton, &c. their quality, as pepper, cloves, honey, soap, &c. and their quantity, or weight; and overagainst it, on the sides of the margin, the numbers which the bales, chests, &c. are marked with, as received into the warehouse.

On the right hand they follow the same method for the discharge of the merchandizes which are sent out of the warehouse, putting, overagainst each article on the left, first, in the margin, the date when the merchandizes were carried out of the warehouse; next, in the oblong squares, the names of those to whom they were sold or sent; and, finally, what quantity of each was sent out, in case the whole were not.

BOOK *of Invoices.* This Book is kept to preserve the journal from erasures, which are unavoidable in drawing up the accounts of invoices of the several merchandizes received, sent out, or sold, wherein one is obliged to enter very minute particulars; it is also designed to render those invoices easier to find, than they can be in the waste Book or journal. The invoices which must be entered here are those of the merchandizes bought, or sent away, for the account of another.

Those of merchandizes which one sells by commission.

Those of such merchandizes as are in partnership, of which others have the management.

Lastly, all the accounts which are not immediately closed, and which one would not open on the ledger.

This Book contains an account, or invoices, of all the goods which a person ships off, either for his own account, or for others in commission, according to the bills of lading, with the whole charges till on board, every invoice following after another, in order as they happen.

BOOK *of Accounts current.* This book is kept in the form of debtor and creditor, like the ledger; it serves to draw up the accounts which are to be sent to correspondents, in order to settle them in concert, before they are balanced in the ledger: it is properly a duplicate of the accounts current, which is kept to have recourse to occasionally.

BOOK *of Commissions, Orders, or Advice.* In this Book are entered all the commissions, orders, and advices, a person receives from his correspondents.

The margin of this Book ought to be very broad, that there be room to write overagainst each article the necessary notes, or remarks, concerning their execution. Some only cross each article, after it has been executed.

BOOK *of Acceptances, or of Draughts.* This Book is designed as a register of all the bills of exchange, which our correspondents advise us by their letters they have drawn upon us.

They are thus registered, to the end that, when the bills are presented, a merchant may know whether he has orders to accept them, or not.

BOOK *of Remittances.* In this Book are registered all the bills of exchange, as they are remitted by the correspondents, to require the payment thereof, when due.

BOOK *of Expences*, is a Book in which is set down a particular account of all the expences, either in their houshold, or for commercial affairs, which, at the end of every month, they cast up, and set down the sum total, either in the waste Book or in the journal, or rather in the cash Book.

This Book, being a separate account of all the expences of living, serves to keep both the profit and loss account, and also the cash Book, more distinct; the greater and more considerable articles are to be placed here particularly, but the several small articles of daily disbursements only in totals; though what denominations, and how general or particular the articles of this Book ought to be made, must be left to every one's choice: all that is necessary to observe here is, that the cash paid out on such accounts must be carefully entered here, and then once a week, or month, be transferred to the cash Book, and to the profit and loss account in the ledger, which is debtor to cash for it.

BOOK *of Copies of Letters.* This Book serves to keep copies of all the letters relating to business, which a merchant writes to his correspondents, that he may have recourse to them upon occasion, and know exactly what he wrote, and what orders he gave to them.

BOOK *of Postage*, is a small register, long and narrow, in which a merchant opens a particular account, to each of his correspondents, of the postage paid for them, which is afterwards cast up, when he thinks proper, and they are entered in the journal and ledger accordingly.

BOOK *of Vessels*, or the ship's Book. This Book is kept by the way

way of debtor and creditor, an account being opened for every ſhip. On the debtor's ſide is ſet down all the expences for victualling, fitting out, wages, &c. and, on the creditor's ſide, all that the ſhip has produced, either for freight or otherwiſe: the total of each is afterwards entered in the journal, making the veſſel debtor and creditor.

BOOK *of Workmen*. This Book is particularly uſed by thoſe traders who have manufactures, and is kept in debtor and creditor, there being an account for every workman that is employed. On the debtor ſide are ſet down the materials which are given to them for manufacturing, and, on the creditor's ſide, the work which they bring home, after it is manufactured.

Bank BOOK. Beſides all the above-mentioned Books, in thoſe cities where there is a public bank, as London, Venice, Hamburgh, Amſterdam, the merchants who keep caſh therein are obliged to keep a bank Book, which is likewiſe by way of debtor and creditor. Herein they ſet down all the ſums which they pay to, or receive from the bank; by which means they can eaſily know, in a very little time, how they ſtand with the bank, that is to ſay, how much caſh they have there.

The ſame may be obſerved with regard to thoſe merchants or other perſons, who keep their caſh at a banker's, which is much practiſed in London.

Month BOOK. This is alſo one of the auxiliary Books kept by ſome merchants. It is numbered in folio's, like the ledger, and divided into ſpaces, on the top of each of which are the names of the twelve months in the year, January, February, &c. allowing a whole folio, or what you pleaſe, to each month; and a different ſet of twelve ſpaces, for every different year. On the left hand page enter the payments to be made to you in that month, and, on the right hand page, the payments you are to make. Make a column likewiſe on the left hand of every page, in which write the day of payment, and after this the name of the debtor or creditor, and draw the ſum into the money columns. This does not differ much from the debt Book above-mentioned.

BOOK *of Rates*. This is a Book eſtabliſhed by parliament, ſhewing at what value goods that pay poundage, ſhall be reckoned at the cuſtom-houſe.

BOOK-*Keeper*, is, or ought to be, a perſon properly qualified to keep ſuch accounts as he is required to do, in a methodical and correct manner. The title is principally given to the chief clerks of merchants, and other eminent traders, and they generally keep the journal and ledger, all the other auxiliary Books being kept by the younger gentlemen clerks, or by others under the Book-keeper.

BOOM, in marine fortification, a chain, cable, &c. ſtretched a-croſs the mouth of harbour, or river, to hinder the enemy's ſhips from coming in.

To lay a BOOM.—Provide a great number of wooden battlings or ſpars of about 20, 30, or 40 feet long, more or leſs, and between 5 and 10 inches diameter: Then moor two boats, having a ſheet anchor in each, in the place near one ſide of the river where it is intended the Boom ſhall begin; bend two cables to theſe anchors, and round them place the ſpars or poles, frapping on each with rattling ſtuff, or better with four inch rope, until the Boom is 7, 8, 9, 10, or more feet diameter (according to the hands employed) the cables being in the middle; next, with iron hoops riveted together, worm the Boom, and drive through the hoop a nail into almoſt every ſpar: after having wrought a good birth from the anchors drop them, and continue the work till it is brought near the other edge of the river, and there drop two anchors more with the cables bent to them: then, over all, laſh the ſpare-yards and top-maſts with the top-chains, ſo far as the channel goes.

To that part of the cable in the channel that makes the Boom, let other cables be faſtened, and theſe bent to anchors laid down the ſtream; over the clinch of theſe cables let battlings or ſpars be wrought for near ten fathoms down the ſtream, that the enemy may not cut theſe cables: theſe will be ſerviceable when the enemy's ſhips come ſtemlings againſt it; for, if he force it in one place, the whole will not be opened by that fracture.

In places where wood is ſcarce, and proper ſpars' are not to to readily had; or in caſes where there is not time ſufficient be prepare them; it may be found ſufficient to laſh two cables together with old ropes, laſhing to them the oars, top-maſts, and yards, and worming the whole about with iron hoops; and let every part be well covered with pitch, and ſmall gravel ſtrewed on it while the pitch is warm. A Boom ſo prepared cannot be eaſily cut.

If on any particular occaſion it ſhould be found convenient and ſafe to open the paſſage, it may be done by tripping the anchors that are on one ſhore and thoſe down the ſtream, whereby the boats may ſwing down the ſtream upon the ebb, and upon the flood the Boom may be relaid, if the enemy appear in ſight, which he muſt do the firſt of the tide, for upon the ebb there is no danger of his coming; becauſe, if the wind be right in, a prudent enemy will not venture againſt the tide, a ſhip then making ſuch wild ſteerage; and, ſhould ſhe ground, ſhe muſt lie there till flood, which may prove fatal to her from the batteries aſhore; and againſt both wind and tide the enemy cannot come in. On the contrary, ſhould the Boom be carried up the flood, and the enemy appear at the beginning of the next flood, the Boom cannot be relayed till the ebb, and before that time the enemy may have accompliſhed his deſign.

If there be good ſtore of timber at hand, then a ſtockado may be made by driving ſeveral rows of piles in the channel before the Boom; or ſhould the depth of water be too great for this work, the trees may be uſefully applied, by making a raft to ride before the Boom by good anchors, obſerving that the cables are ſo made faſt, that the enemy cannot come to cut them: theſe rafts will be of ſingular uſe in putting the enemy into diſorder, by laying rubbiſh upon them to make fires of when the enemy appears, which will put him into ſome conſternation, and perhaps may cauſe him to come to an anchor, and loſe time or his tide; and this may be done each flood, obſerving not to have the ſmoak drive into the works, which might give the enemy too great an advantage.

To lay a BOOM *in a ſtreight Channel*.—Suppoſe the wind, for the moſt part, to blow obliquely acroſs the river or channel on the ſtarboard quarter, going up the river: now, if the Boom be laid directly thwart the channel, the ſhips coming with the tide or flood and a leading gale will run ſtemlings againſt it, and ſo hazard its breaking, by ſtriking with a force that comes direct; whereas, could the Boom be laid obliquely thwart the river, nearly in a line with the wind, ſo as the ſhip muſt take it with her bow, the blow would be diverted by the ſhip's caſting; becauſe, in this poſition the enemy cannot run ſtemlings againſt it; for in ſailing up the river, the ſhip muſt be near before the helm; and to bring her head to the Boom, the helm muſt be put down, and then it is ten to one whether ſhe come to ſo nicely as to take the Boom: not to mention the miſtakes, in a confuſion, committed by the man at the helm, and him upon the cond, nor the ſmoak; for excluſive of all theſe, it may be taken for granted, the ſhip would caſt alongſide the Boom: then the batteries at the end of the Boom on the larboard ſide would take fore and aft, while the oppoſite batteries on the ſtarboard ſide, playing on his broad-ſide with double round and partridge, muſt make a great ſlaughter among his men cutting at the Boom. And, ſhould he not ſwing alongſide the Boom, but lie ſtemling againſt it, then will the batteries on the ſtarboard ſide of the river, which are to be made above the weather end of the Boom, take him fore and aft, while thoſe on the larboard ſide, againſt the leeward end, play on his broad-ſide.

The ſhips within the Boom, which it is to protect, ſhould be moored in a kind of half-moon, with their broad-ſides flanking the Boom. And ſeveral old ſhips, or thoſe the leaſt uſeful, may be ſunk, as ſoon as a ſignal, ſignifying that the Boom will be cut, is made at one of the forts which defend it; for this purpoſe, thoſe ſhips ſhould have large ſcuttles ready cut: and for a further ſecurity, it would be very proper to have a ſmall Boom to divert the enemy, that the ſhips may be ſunk in the channel before he boards them.

As to the reſt of the ſhips, they are left to their commanders judgment; and, if there is no other remedy, the people may get aſhore to windward, if they can, and there make the beſt defence in their power againſt the enemy's boats and fire-ſhips. From duly weighing the whole of theſe circumſtances, it will be found that the chief ſtrength is in the Boom; therefore, if a double, triple, or fourfold Boom was laid, if the materials could be procured, and the value of the ſhipping and cargoes were of ſufficient importance, it would make the place ſo much the ſtronger, and the enterprize of the enemy more hazardous. In ſtretching theſe Booms, the trouble of many anchors may be ſpared, by making all the cables faſt to the firſt, and ſo letting them float in a bight, and by a ſmall anchor ride upon the ebb, to keep clear of one another.

To ſet up a BOOM *in the bend of a River*.—From the point formed by a bend, ſtretch two Booms acroſs the channel, one towards the middle of the oppoſite bight, and the other ſo much higher, as to lie directly thwart the channel, leaving a kind of angular ſpace between them.

Next the point from whence the two Booms ſtretch, erect a proper fort or battery to command the channel both below and above the bend.

On the other ſide the river, erect another fort or battery againſt the bight a little above the end of the lower Boom, and ſo diſpoſed, that its cannon may rake the channel coming up to the Boom, as well as command both the Booms.

A Boom being thus diſpoſed, it is a great chance if a ſhip anſwer her helm ſo timely in bearing or loofing about the point as to take it ſtemlings, and if ſhe ſtrike it with her bow, ſhe caſts; and in either caſe ſhe will be raked fore and aft by one fort, and have her broad-ſide battered by the other.

Let ſome old veſſels be fitted up for fire-ſhips, and placed between the two Booms; from each ſhip let two hauſers be carried aſhore, one on each ſide, and fixed to cramps ſet up; ſo that, as ſoon as paſſed the firſt Boom, theſe ſhips being ſet on fire, and heaved in their way, nothing can hinder the enemy's deſtruction: as ſoon as fire is ſet to the train, the boat may pull aſhore, under covert of the ſhip, without any apparent danger; for ſuch will be the enemy's conſternation,

that

that they will soon leave firing. The hausers may be fastened to cramps below the water line, that they be not burnt, nor in sight of the enemy to cut them. If the fire-ship is clapped aboard the weathermost ship, they may be both heaved together aboard another to leeward.

The ships to be defended may be moored in a half-moon, with their broad-sides so laid, as to batter the enemy when he attempts the Boom: and, if other works than what are here directed be judged necessary, they must be adapted to the situation of the place.

When no strong attacks by land are to be feared, the mooring of ships behind a point is best, on account of laying the Boom: now, should the Boom be forced, which must be upon the flood, a fire-ship, instead of falling on board a ship thus moored, will by the tide be hurried beyond her; and, if the place is any ways favourable to the ships moored there, it will be found impracticable to board a ship thus moored, with such a wind and tide as the enemy must have to break the Boom, unless he expose his boats in carrying out an anchor to warp over, which will be a very dangerous attempt, or some unaccountable accident intervene.

It may be objected, that ships thus moored cannot bring their broad-sides to bear upon the enemy when coming to force the Boom; and that they may be battered by the enemy over the point. To this it may be answered, first, it is no matter whether the broad-sides do or not, for perhaps it might be the best way to get the guns ashore, if there is time, to be there used; and to put the smaller sort only on the lower deck, and turned to flank the Boom. Secondly, the enemy will have but an uncomfortable birth in lying to batter the ships over the point, as they will have to deal with the fire from the fortifications on shore. What is here said, is only to be understood when five or six ships are to be defended; for the wake of a point could not hold any considerable fleet.

BORA'GO, *Borrage*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, of a rotated form; the cup is divided into several segments, and from it there arises a pistil, which is fixed in the manner of a nail to the middle part of the flower, and surrounded with four embryo's, which are afterwards changed into as many seeds. These are of the shape of the head of a snake, and are contained in the cups, which become much inlarged, till they are perfectly ripe.

The common borrage has long held its rank as a cordial of the first class, though perhaps it would not be easy to say on what foundation. Its flowers are of the number of the four cordial ones of the shops, and it has been recommended as a medicine of great efficacy in malignant and pestilential fevers, and against the bites of poisonous animals.

BO'RAK, among Mahometans, a fabulous animal, supposed to be of a middle kind, between an ass and a mule, whereon their prophet was carried in his nocturnal flight from Jerusalem into the heavens.

BO'RAX (*Dict.*)—*Method of refining* BORAX. It is no wonder that all Europe did not fall into the way of purifying Borax for medicinal and other uses at once, since there is no salt in the world in which the process for doing that is so troublesome. The common methods will indeed dissolve it in water, and evaporation will separate it again, but that not in a form fit for sale, or in large and fair crystals. This is only to be done by a process, like that by which it is originally prepared from the water of the mines. When it has been dissolved, and the solution properly evaporated, it is not to be exposed to the cold air in a still place as other salts are in order to the crystalling, but it is to be kept in the hot vessels, and covered close down in them, and the fire is to be continued under them, though only in a gentle degree. By this means we are able to imitate here the sun's heat in the countries where it is produced, and the clay cover, which the people who work it, extend over it, at the time when it is to crystallize; and the effect is the same: the salt shoots into large crystals about the sides of the vessel, and about brass wires, let down from the lid into the liquor.

The Borax is by this means purified from a great deal of its fatty matter, the separating of which renders the operation very offensive, but it is not yet pure; it is yellow and foul even in those crystals. These are to be separated from the liquor, and again dissolved in a lixivium of pot-ashes and lime; and then, on being set to shoot again in the same manner as before, it forms itself into those pure and pellucid crystals which we meet with in the shops.

They, when perfectly formed, as they seldom are indeed, except by a very nicely managed evaporation, are of an octohædral figure, and very pellucid. They are of a very rude and irregular shape, as they generally shoot, and, the process of recrystallizing them not being easily hit upon by those who had not been informed of the manner of it, many have sought a long time in vain to find what was the true figure of the salt.

Borax is of great use in the collecting the particles of any metal over the fire, and running them into a mass; and this, with very little diminution of their weight. Dirt or ashes, though in ever so small a quantity, will certainly hinder some small particles of gold or silver from running together into a mass over the fire; but, if they are so disposed by a very strong fire as to meet into a regulus, a great part of the metal will always adhere to the dirt that is thrown away. The less perfect metals not only suffer the above-mentioned accidents, but, their surfaces being greatly increased, copper and iron turn intirely into scoriæ, and are destroyed, and lead and tin are so in great part. It is therefore very detrimental when these baser metals are mixed in any, even in ever so small a quantity, with gold or silver; for, in the melting, there come upon the surfaces light scoriæ, in which part of the gold or silver is retained, as in the pores of a spunge, and prevented from running into a regulus.

To remedy this mischief, Borax is added, because, as it helps the melting of metals and of all bodies by fire, its bringing the whole mass into a quick fusion gives the metals an opportunity to sink together in a mass to the bottom, and vitrifies the lightest scoriæ, throwing them off to the surface; and this use of this salt is not restrained to gold and silver, but takes place as well in regard to iron as copper.

This salt also causes metals to melt in a much less fire than they otherwise would, and is of very singular use in preserving the less perfect metals while in fusion. It flows over them and covers their surface, while tortured in the fire, as if it were with a kind of very thin glass, which defends them against the combined force of the fire and air, so destructive to the imperfect metals.

The assayers have a custom of rubbing with Borax the insides of vessels, in which the more precious metals are to be melted, which always fills up the small cavities in their sides, that might otherwise take in a part of the metals. When gold is melted with Borax alone, it makes it pale; but this is obviated by adding a small quantity of nitre, or of sal armoniac. Care must be taken, however, not to add both these salts together, because they would cause a detonation.

The above-mentioned use of Borax has caused it to be reckoned, by some writers, among the reducing bodies; that is, such bodies as restore metals, however destroyed, to their pristine form: but this is an error; for Borax does not reduce the destroyed metals, but only the scattered particles of them, while they yet retain their true metallic form. *Cramer's Art of Assaying*.

BORDA'T, a small narrow stuff, which is manufactured in some parts of Egypt, particularly at Cairo, at Alexandria, and at Damieta.

The Bordats of Cairo are sold for about 18 medimns per piece, those of Alexandria for about 24, and those of Damieta for 25 or 26.

BO'RDERS, (*Dict.*)—Borders are of four sorts: those are the most common, that are continued about parterres without any interruption; and wrought with a gentle rising in the middle, like an ass's back, and planted with low shrubs and flowers.

The second sort of Borders are such as are cut into compartments, at convenient distances, by small passages, and being also raised in the middle, as before-mentioned, are likewise set off with shrubs.

The third sort are such as are laid even and flat, without flowers, having only a verge of grass in the middle; being edged with two small paths, raked smooth, and sanded. These are sometimes garnished with flowering shrubs, and flowers of large growth; or with vases and flower-pots placed regularly along the middle of the verge of grass.

The fourth sort are quite plain, and are only sanded, as in the parterres of orangery; and are filled with cases ranged in a regular order along those Borders, which are edged with box on the sides next to the walks; and on the other, with verges and grass-work next the parterre. Sometimes a yew is planted between each case, which makes the Border appear richer, and the parterres handsomer, during the winter season.

Borders are either made straight, circular, or in cants; and are turned into knots, scrolls, voluces, and other compartments.

Florists also make Borders either long walks, or detached; and in these they raise their finest and choicest flowers. These are frequently encompassed with Border-boards painted green, which makes them look exceeding neat.

But, in large parterres, this is not to be expected; since, if they be stocked with flowers succeeding one another in their several seasons, it is sufficient, so that nothing appears bare and naked.

It is usual to discontinue the Borders at the ends next to the house, that the embroidery and rise of the parterre may not be hidden by the shrubs and flowering plants, and that the design may be better judged of.

And sometimes there are branched out of it foliage, palm-leaves, and shells sporting among the sands.

Since the modern taste of gardening has been introduced into England, all the French taste of parterres, scroll Borders, and fret work in box, has been justly banished our gardens; therefore I have only mentioned them here, to expose the taste of those architect-gardeners, who have no idea of the noble

simplicity

fimplicity of an open lawn of grafs, properly bounded by plantations; but, inftead of this, divide that part of the garden, near the houfe, into various forms of Borders edged with box, and fand or gravel-walks leading about them; by which the ground is cut into many angles, fcrolls, &c. which is very hurtful to the eye of a judicious perfon: therefore, where flowers are defired, there may be Borders continued round the extent of the lawn, immediately before the plantations of fhrubs; which, if properly planted with hardy flowers to fucceed each other, will afford a much more pleafing profpect than the ftiff Borders made in fcrolls and compartments, after the French manner, can poffibly do.

Thefe Borders may be made fix or eight feet wide, in proportion to the extent of the garden, and fize of the lawn: for a fmall lawn fhould not have very broad Borders; nor ought a large lawn to be bounded by fmall Borders; fo that a due proportion fhould be always obferved in the laying out of gardens. *Miller's Gard. Dict.*

BO'RING, the act of perforating a folid body, or making a hole throughout its whole length or thicknefs.

Boring of mafts, from top to bottom, is propofed by Dr. Hook as a means of ftrengthening and preferving them; as this would make them dry and harden the better, and prevent their cleaving and cracking: for want hereof, the outfide drying, when the infide does not, the former fhrinks fafter than the latter can keep it company; the confequence of which is eafy to forefee. *Hought. Collect.*

Boring *of Water-pipes*. The method of Boring alder-poles for water-pipes is thus: being furnifhed with poles of a fit fize, horfes, or truffels, are procured of a due height, both to lay the poles, and reft the augre on in Boring; they alfo fet up a lath, whereby to turn the leffer ends of the poles, and adapt them to the cavities of the greater ends of others, in order to make the joint fhut each pair of poles together. The outer or concave part is called the female, and the other, or inner, the male part of the joint. In turning the male part, they make a channel or fmall groove in it, at a proper diftance from the end; and, in the female part, bore a fmall hole to fit over this channel; they then bore through their poles, fticking up great nails at each end, to guide them right; but they commonly bore a pole at both ends; fo that, if it be crooked one way, they can neverthelefs bore it through and not fpoil it. *Neve, Build. Dict.*

A Machine for Boring *Pipes.—Plate* V, *fig.* 9. is a perfpective view of this machine. A, is the water-wheel, on the axis of which there is another wheel B, of a fmaller diameter. This turns the upright wheel or lantern C, on the axis of which is a cog-wheel D, which turns two fmall wheels E and F; the firft E, which is vertical, turns the augre; and the fecond F, which is horizontal, caufes the carriage to advance, by the help of the two arms H and I. The firft, H, draws the wheel G, and the other, I, pufhes it in a contrary direction.

As the augre muft be near twelve feet long, the weight of it muft be fupported, to hinder it from bending, that it may pierce the wood uniformly. L, L, reprefent two fupporters. Thefe fupporters, in order to give no obftruction to the augre, may be made as follows: C, C, *fig.* 7, 8, are two pieces, which muft be faftened to fome of the timber work of the mill; thefe encompafs a fmall plank hung by a cord, at the bottom of which are fixed the pieces *b*, *b*, with joints at the places *e*, *e*; and, that they may not move out of the vertical plane, they are accompanied with tenons *f*, *f*, made in the quarter of a joined circle of the thicknefs of the plank *a*, that they may work freely: on the fide of one of thefe pieces is fixed a fpring *g*, in order to hinder them from uniting, by forceing them to enter below into a mortife made about the thicknefs of the end of a rule; then thefe two pieces make but one bored with a hole, through which the augre is to pafs. See *fig.* 7.

Fig. 6. fhews the cord which is faftened to the plank *a*, and goes on the two pullies *b*, *b*; at the other end of this cord there is hung a weight *e*, refting on the piece N, which is fupported at one end by the piece O, and fixed at the other by a joint to the lever K, which has its center of motion fixed to a piece of wood H; fo that, leaning againft the extremity M of the leaver, the piece N quits the fupport O, the weight finks down, and draws up the piece *a*; then the fides *b*, *b*, *fig.* 8. quit the mortife *d*, and the fpring *g* feparates them; fo that the fupporter does not hinder in the leaft the motion of the augre. *Belidor's Hydraulics.*

Boring in farriery, an operation fometimes practifed for the cure of horfes whofe fhoulders are wrenched. The method is thus: they cut a hole in the fkin through the middle of the fhoulder, and, with the fhank of a tobacco-pipe, blow it as a butcher does a fhoulder of veal; then they run a cold flat iron, like a horfeman's fword-blade, eight or ten inches up, between the fhoulder-blade and the ribs, which they call Boring; after that, they burn him round his fhoulder with a hot iron. *Burd. Gent. Farr.*

Boring, among miners: fee MINEROLOGY in the Dictionary.

BORSE'LLA, in the glafs-works, an inftrument wherewith they extend or contract the glafs at pleafure.

BOSQUE'TS *, (*Dict.*)—Bofquets are groves, or fmall plantations of trees.

* The word is derived from *Bofchetto*, Italian, a diminutive of *Bofco*, a wood or grove.

Thefe fmall compartments in gardens, are formed of trees, fhrubs, or tall large-growing plants, planted in quarters; and are either difpofed regularly in rows, or in a more wild and accidental manner, according to the fancy of the owner: thefe quarters are commonly furrounded with ever-green hedges, and the entrances formed into regular porticoes with yews, which are by far the beft and moft proper trees for this purpofe. In the infide of thefe quarters may be made fome walks, either ftraight or winding; which, if the quarters are large, fhould be fix or eight feet broad, and may be laid with turf, and kept well mowed and rolled, which will render the walking much eafier and pleafanter than if the walks are only the common earth, which in fmaller quarters cannot be otherwife; for, if the trees are clofe, and the walks narrow, fo as to be fhaded and over-hung by the trees, the grafs will not grow.

Thefe quarters may be alfo furrounded with hedges of lime, elm, horn-beam, or Beach; which fhould be kept well fheared, and not fuffered to rife too high; that the heads of the trees may be fully feen over them, and the ftems only hid from the fight, when in the walks on the outfide of the quarters.

In planting of thefe Bofquets you fhould obferve to mix the trees, which produce their leaves of different fhapes, and various fhades of green, and hoary or mealy leaves, fo as to afford an agreeable profpect: befides, there is a great variety of different fruits, which thefe trees produce in autumn; which, although of little or no ufe, that we know of, yet have a very good effect, in affording an agreeable variety for fome time after the leaves are gone; as the euonymus, or fpindle-tree, the opulus, or marfh-elder, the cock-fpur-hawthorn, with many other forts, too numerous to mention in this place. But I would advife never to mix ever-greens with deciduous trees; for, befides the ill effect it hath to the fight, efpecially in winter, they feldom thrive well together; fo that thofe quarters where you intend to have ever-greens, fhould be wholly planted therewith; and in the other parts mix as many varieties of different trees, which caft their leaves, as you can conveniently; and alfo plant fome of the largeft-growing flowers (efpecially near the outfide of the quarters) which will add greatly to the variety, if they have but air enough to grow; but if any of the ever-green trees are mixed with the deciduous, it fhould be only to border the wood.

Thefe Bofquets are proper only for fpacious gardens, being expenfive in their firft making, as alfo in keeping. *Miller's Gard. Dict.*

BOTA'LE *Foramen*, in anatomy, an aperture in the heart of a fœtus, whereby the blood is enabled to circulate, with going into the lungs, or the left ventricle of the heart.

BO'TANIST, a perfon who underftands the nature, hiftory, and diftinction of vegetables, on fettled and certain principles, and can call every plant by a diftinct, proper, and intelligible name. *Linnæi Fundam. Botan.*

BOTT, among bone-lace weavers, a kind of round cufhion of light matter placed on the knee, whereon they work or weave their lace with bobbins, &c. See LACE.

Botts, in zoology, a fpecies of worms which infeft horfes and other cattle; having large heads and little tails; generally found in the ftraight gut, near the fundament. *Ruft. Dict. Skin. Etym.*

The name is alfo given to a fort of grubs which deftroy the grafs in bowling-greens, &c.

BO'TTLING, or Botteling, the operation of putting up liquors in bottles corked, to keep, ripen, and improve.

Cyder requires fpecial precautions in the Bottling, being more apt to fly, and burft the bottle, than other liquors. The beft way to fecure them, is to have the liquor thoroughly fine before it be bottled. For want of this, fome leave the bottles open a while, or open them after two or three days Bottling, to give them vent. If one bottle break through fermentation, it is beft to give them all vent, and cork them up again. Mean cyder is apter to break the bottles than rich. Some foak the corks in fcalding water, to render them more pliant and ferviceable.

Another obfervation is, to lay the bottles fo as that the liquor may always keep the cork wet and fwelled. Something alfo depends on the place where the bottles are fet, which ought to be fuch as expofes them as little as poffible to the alterations and impreffions of the air: the ground is better for this purpofe than a frame, fand better than the bare ground, and a running water, or a fpring often changed, beft of all.

To haften the ripening of bottled liquors, they are fometimes fet in a warm place, or even expofed to the fun, when a few days will bring them to maturity. *Hought. Collect.*

BO'TTOM-*Stone*, a kind of iron-ftone, or ore, in the Staffordfhire mines.

BO'UGIE, in furgery, a kind of large medicated tent, worn in the urethra, for the cure of a gonorrhœa, &c.

The properties requisite in the Bougie, are a sufficient degree of firmness, that it may be introduced with some force; a suppleness and tenacity, that it may conform to the motions of the body without breaking; a lenient suppurative disposition to bring on a discharge without pain; and, lastly, a smoothness of surface, that it may not only be introduced with more ease, but that it may lie easy in the passage till it begins to dissolve.

The best basis of such a Bougie, in my opinion, is diachylon simplex, which may be rendered efficacious, by a great variety of mixtures; but though an addition of certain gums, or of the mucilage plaister, will alone answer the purpose in some disorders of the urethra; yet, as a long use of mercurial applications is almost a specific for venereal ulcers, and has also a powerful effect on every other species of stubborn ulcers, I have chiefly confined my experiments to preparations of mercury.

I have often used white precipitate, red precipitate, calomel, and æthiops mineralis; and, though the precipitates, at least the red precipitate, are properly escharotic powders, yet, when they are mingled in plaister, they lose their corrosive property, in the same manner as elixir of vitriol does by dilution; and, on this account, may be employed with the utmost innocence: however, it may be proper to observe, that the red precipitate ought to be finely levigated, for levigation abates the escharotic quality of it, even when in powder; and in this state I have often carried the proportion of powder from one drachm to three drachms for every ounce of plaister, without producing any mischief, or without discovering any notable difference of operation in the Bougies, so effectually sheathed are the caustical qualities of the mercury by the plaister they are mixed with.

But, though these remedies often work a cure in some stubborn diseases of the urethra, yet a very large quantity of crude quicksilver, added to the plaister, seems to be better calculated for the purpose; as quicksilver, mingled with axungia or plaister, is not only an excellent topical medicine for ulcers, but has also a peculiar discutient quality, which it exerts, even when there is no rupture of the vessels. This operation of the quicksilver, therefore, seems to give it greatly the preference to the other compositions, because it not only acts as favourably upon the surface of the ulcers, but also exerts its other virtues on the fungous or indurated parts of the urethra.

Perhaps we shall discover, hereafter, the proper proportion of quicksilver to the plaister: at present I have allotted half an ounce to every ounce of plaister, which renders it excessively more mercurial than any plaister now in use. The diachylon must be made with oil, and a little pix Burgundica added to it, that it may be sufficiently tenacious: to every ounce of plaister I have usually flung in two drachms of crude antimony, finely levigated, from an opinion that it greatly conduces to the smoothness and good consistence of the Bougie; besides, that it may, possibly, have other virtues. Upon this plan the prescription stands thus:

Diach. cum pice Burgund. ℥ii.
Argent. viv. ℥i.
Antim. crud. pulv. ℥ſs.

The quicksilver, whether it be divided in balsams, sulphur, or honey, must not be put into the plaister till the moment before the Bougies are made; nor must the plaister be boiling-hot at that time, lest, by the heat, the quicksilver should separate from the body it is divided in, and fall down to the bottom in form of globules. When the quicksilver is mingled with the plaister moderately hot, the slips of fine rag must lie ready to dip in the composition. These slips must be of different lengths, from six to nine or ten inches, and about three inches broad; roll them up loosly, and, taking hold of one extremity with the left-hand, let it fall in upon the surface of the plaister, and then draw it out gently; as it is drawn out, it will unrol, and take up a quantity of plaister upon its surface, equal to the thickness of a silver groat; though, to facilitate the unrolling of the rag, it will be proper to assist its motion with the end of a spatula, or any such instrument: the plaister must, however, be so hot, as to soak through and discolour the rag, otherwise it will not make so good a Bougie. Several slips of rags may be dipped in the same composition, one after another, before it becomes too cold; but, to do this more handily, the ladle in which it is melted ought to be broad and flat at the bottom; and the plaister must be kept stirring, that it may preserve an equal consistence.

If the cloth be exactly three inches broad, it will make six Bougies of a moderate size; but their size may be increased or diminished according to the occasion. It is generally adviseable, that the Bougie should be smaller at the end which is introduced through the strictures, than at that which is left out at the penis; for that purpose, many cut off a part of the oblong square I have described, in such a manner as to reduce it almost into the shape of a long right-angled triangle: but, as this way of cutting it weakens the Bougie exceedingly, and it is not at all necessary the Bougie should be taper from one extremity to the other, it is much better to cut off a little slope of about an inch and an half long, from the end that is to be passed into the urethra, which will lessen it where it is requisite to be small, and leave it strong in the other parts where the diminution is not necessary.

The plaister taken up by the cloth, when dipped, will have little bubbles upon its surface, and not be so smooth, as if it had been spread; therefore an iron-spatula, a little warmed, may be passed over the plaister before it be cut into Bougies, which will render it more compact and even. It is a much more exact and speedy method to cut the Bougies off with a knife and ruler, than with sciffars. When they are rolled up, it must be with that side outwards which is covered with plaister; and they must first be rolled up with the finger and thumb as close as possible, before they are rolled upon a board or marble; for, upon this circumstance, the neatness of the Bougie depends: I think too they may be rolled up more neatly by the hand than any kind of machine. Holding the plaister a little before the fire, if it be in winter, will facilitate the rolling, unless it has been just dipped, when it is not necessary. *Sharp's Critical Enquiry.*

BOU'NTY, in commerce, denotes a premium paid by the government to the exporters of certain commodities, on their taking oath, or, in some cases, giving bond, not to re-land the same in England.

Queen Anne's BOUNTY, for augmenting poor livings under 80l. per annum, consists of the produce of the first-fruits and tenths, after the charges and pensions, payable out of the same, are defrayed. A corporation for management of the same was settled, &c. in 1704.

BOURDONNE', in heraldry, is understood of a cross, whose extremities are turned round like the ends of a pilgrim's staff; more frequently called pommeté, globatus.

BOW, in music, denotes a machine that serves to play, or give the sound to viols, violins, and instruments of that kind, by drawing it gently over the strings thereof.

The Bow consists of three parts; the first is the stick, or wood, to which the hair is fastened; the second is composed of about eighty or an hundred horse hairs, or filaments of silk; the third is the nut, a sort of half-wheel, which serves to keep the hairs in due degree of tension. *Playf. Treat. of Music.*

Bow, in trade and manufactures, denotes a flexible instrument, consisting of a piece of steel or iron; to the two ends of which is fastened a cat-gut, used by smiths, watchmakers, and other artificers, for piercing and turning of divers sorts of works.

Bow-*Dye*, a new kind of scarlet-red, superior to madder, but inferior to the true scarlet grain for fixedness and duration.

BO'WER, in gardening, a shady place, under covert of trees, or branches interwoven.

A Bower differs from an arbour, in that the latter is always built long and arched; but a Bower is either round or square at the bottom, and made with a sort of dome or ceiling at the top.

BOX *of a watch*, the outer case or cover.

Box *of a wheel*, the aperture wherein the axis turns.

Box *of a plough*, a name by which the farmers call that cross piece in the head of the plough, through which the spindle of the two wheels passes, and to which are fastened the two crow-staves, serving, by their holes, to regulate the height of the beam, the tow-chain below, the stake which supports the bridle-chain above, and the gallows behind, into which are fixed the wilds with the crooks of iron, for the drawing the whole plough along. This part of the plough is placed crosswise with the beam, and stands much below it, and not far from the ground. *Tull's Husbandry.*

Box-*Tree*, *buxus*, in botany, a genus of trees, whose characters are: the leaves are pennated, and ever-green: it hath male flowers, which are produced at remote distances from the fruit on the same tree: the fruit is shaped like a pottage-pot inverted, and is divided into three cells, containing two seeds in each, which, when ripe, are cast forth by the elasticity of the vessels.

Botanists enumerate seven species of this tree, viz. 1. The Box-tree. 2. The narrow-leaved Box-tree. 3. Striped Box. 4. The gold-edged Box-tree. 5. The dwarf Box. 6. The dwarf striped Box. 7. The silver-edged Box.

The first and second sorts grow in great plenty upon Box-hill, near Darking in Surry, where were formerly large trees of these kinds; but of late they have been pretty much destroyed; yet there are great numbers of these trees remaining, which are of a considerable bigness. The wood of this tree is very useful for turners, engravers, and mathematical-instrument-makers; the wood being so hard, close, and ponderous, as to sink in water; which renders it very valuable for divers utensils.

All the varieties of the trees, or large Box, are proper to intermix in clumps of ever-greens, &c. where they add to the variety of such plantations: these may be propagated by planting the cuttings in autumn in a shady border, observing to keep them watered until they have taken root; when they may be transplanted into nurseries, till they are fit for the purposes intended. The best season for removing these trees is in October; though, indeed, if care be used to take them up with a good ball of earth, they may be transplanted almost at any time, except in the summer: these trees are a very great ornament to cold and barren soils, where few other things will

will grow, they may also be propagated by laying down the branches, or from seeds: the last being the best method to have them grow to be large, the seeds must be sown, soon after they are ripe, in a shady border, which must be duly watered in dry weather.

The dwarf kind of Box is used for bordering of flower-beds, or borders; for which purpose it far exceeds any other plant, it being subject to no injuries from cold or heat, and is of a long duration; is very easily kept handsome, and, by the firmness of its rooting, keeps the mould in the borders from washing into the gravel-walks, more effectually than any plant whatever: this is increased by parting the roots, or planting the slips; but, as it makes so great an increase of itself, and so easily parts, it is hardly worth while to plant the slips that have no roots; but it is now become so common, that it may be purchased from the nurseries at a cheap rate. *Miller's Gard. Dict.*

BRACE, in writing, a term used to signify a certain crooked stroke or figure of a pen, made at the end of two or more lines, in an account which express two or more articles, charged with one and the same sum at the end, which is usually placed at the end, and in the center of the Brace; and expresses, that the sum there specified is the joint price of both the articles mentioned in the lines connected by the Brace.

BRACHIA'LIS, in anatomy, an oblong, thick, and broad muscle, lying immediately on the anterior part of the lower half of the os humeri; the upper part of it is forked, or sloped, and, at the bending of the joint of the elbow, the lower part of it contracts. It is fixed to the surface of the os humeri, by a great number of fleshy fibres, from the lower insertion of the deltoides, almost down to the two fossæ, at the lower extremity of the bone, and from one edge of the fore-side of this lower extremity to the other. The fibres are, for the most part, longitudinal; those nearest the surface of the muscle being longest, the more internal growing gradually shorter.

The lateral fibres are a little oblique; and this obliquity increases, as they descend lower. These lateral fibres are partly fixed in the intermuscular ligaments of the os humeri, of which ligaments, that which lies toward the internal condyle, is longer and broader than that toward the external. The lowest of these fibres are very oblique, and form on each side a kind of small separate fasciculus. In passing over the joint, all these fibres contract in breadth, and afterwards end in a strong flat tendon, inserted in the muscular impression, which is directly below the coronoide apophysis of the ulna.

The sloped or forked extremity of this muscle embraces the large tendon of the deltoides; the internal part of the fork meets the inferior insertion of the coraco-brachialis; and the foreside of the whole muscle is covered by the two fleshy bodies of the biceps. *Winslow's Anatomy.*

BRA'CHMANS, (*Dict.*)—These were a branch of the ancient gymnosophists, or philosophers of India, remarkable for the severity of their lives and manners.

The Greeks usually give them the name gymnosophists; though Clemens, Porphyry, &c. make the Brachmans only a branch of the gymnosophists, whom they divide into two sects, bracmanes and samanæi.

There are some in the Indies who still bear the name, and live in the same manner as the ancient Brachmans: the Portuguese call them bramanes or bramenes; we, usually, bramins. See BRAMINS.

Some say, they derive their name from the patriarch Abraham, whom, in their language, they call Brachma, or Brama. Others deduce it from the name of their god Brachma; which some again take to be the same with Abraham: whence Postel calls them abrachmanes. F. Thomassin fetches the word from the Hebrew, barach, to fly, or escape; because the Brachmans retire into the country, and live in desarts. The same author gives us another derivation, viz. from the Hebrew, barach, benedicere, orare, to bless, pray; in regard this is their principal occupation.

Porphyry observes, that the ancient Brachmans succeeded into the order, by right of family; whereas the Samanæans were elected into it: the former therefore were all of the same family, the latter of various.

The Brachmans were perfectly at liberty, paid no taxes, nor were under the command of any person: they lived on herbs, pulse, and fruits; abstaining from all animals, and thinking it an impiety to touch them. The greatest part of the day and night they spent, in singing hymns in honour of the Deity; praying and fasting continually. The generality of them lived in solitude, without marrying, or possessing any estates.

The Brachmans maintained, that life was a state of conception, and death the moment of birth; that the soul of a philosopher, detained in his body, was in the state of a chrysalis, and displays itself, at the instant of death, like a butterfly, which breaks its shell, and takes its flight. The events of life, according to them, were neither good nor bad; because the same thing which pleases one man, is displeasing to another; nay, the very self-same thing is agreeable and disagreeable, to the same person, at different times.

They granted the world to be finite, to have a beginning and an end. They admitted of a God for a creator, who governed the world; thought the universe formed of the different elements; looked on the heavens as the result of a quintessence; maintained the immortality of the soul, and supposed tribunals of justice among the shades below, &c. Clemens, of Alexandria, erroneously makes the two sects of gymnosophists but one. When they were weary of living, they themselves built up their own funeral pile, lighted it with their own hands, and then ascended it with a grave majestic pace.

Such were these sages whom the Grecian philosophers went so often to consult. Pythagoras is said to have received the doctrine of the metempsychosis from them. We read in Suidas, that they were called brachmanes, from king Brachman, their founder. This sect subsists yet in the East, under the name of bramines, or BRAMINS; which see.

BRACHYTELO'STYLA, in natural history, the name of a genus of crystals, composed of a short hexangular column, terminated at each end by an hexangular pyramid.

BRA'CKET, in building, denotes a kind of wooden stay, in form of a knee or shoulder, serving for the support of shelves, &c. *Neve, Build. Dict.*

BRACTEA'RIUM, in natural history, the name of a genus of fossils of the talc class; the characters of which are: each piece is composed of small plates, in form of spangles; and each of these, naturally thin or fissile, into very thin ones. See *plate* IV. *fig.* 32.

BRAINS *microscopically examined.*—The accurate Mr. Lewenhoeck examined, on several occasions, the Brains of different creatures by his microscope; as that of the Indian hen, the sheep, the ox, the sparrow, &c. He could there always distinguish multitudes of vessels so extremely small, that, if a globule of blood (a million whereof exceed not a grain of sand in bigness) were divided into five hundred parts, those parts would be too large to pass into such vessels. He observed also, that the vessels in the Brain of a sparrow were as large as in that of an ox; and argues from thence, that there is really no other difference between the Brain of a large animal and that of a small one, but only that the one contains a much greater number of these vessels than the other; and that the globules of the fluid, passing through them, are in all animals of the same size. *Baker on the Microscope.*

BRAKE, a name given by husbandmen to a place where female fern grows, and sometimes to the fern itself.

BRAKE is also used for a farrier's instrument, otherwise called barnacles.

BRAKE, in the hempen manufactory, denotes a wooden-toothed implement, wherewith to bruise and break the bun of hemp, and separate it from the rind.

There are two kinds of Brakes used in the dressing of hemp, viz. an open and wide-toothed, or nicked Brake, and a close and streight Brake; the first serving to crush the bun, the latter to beat it forth. When the hemp is braked, they proceed to swingle it. *Hought. Collect.*

BRAKE *of a pump*, signifies the handle wherewith it is wrought.

BRA'MA, in ichthyology. See BREAM.

BRA'MINS, in modern history, a sect of Indian philosophers, formerly called brachmans.

They are priests, and have three principal objects of veneration, the god Fo, his law, and the books which contain their ordinances. They believe that the world is nothing but an illusion, a dream, a deceit; and that bodies, to exist really, ought to cease to be in themselves, and mix themselves with that nothing, which, by its simplicity, makes the perfection of all beings. They make sanctity consist in absolute apathy, to desire nothing, to think of nothing, to perceive nothing, to remove every idea from the mind, even that of virtue, so far, as that it may not disturb the repose of the soul; which is the perfection of holiness, according to the Bramins. This state so much resembles sleep, that a dose of opium appears more likely to sanctify a Bramin, than all his other attempts. This quietism has been attacked in the Indies, and defended with warmth. They are ignorant of their first origin. King Brachman is not their founder. They pretend themselves to have issued from the head of the god Brama, whose brain was not only fertile, but that his feet, hands, arms, stomach, and thighs, also generated beings, though of an inferior class to the Bramins. They have ancient books, which they call sacred, and carefully preserve the language in which they were written. They admit the metempsychosis; assert that the chain of beings descends from the bosom of God, and continually ascends up to it again; like the filament which comes from the belly of the spider, and enters it again.

Their system of religion is various in different parts of the country. On the coast of Coromandel they worship Wistnou, and believe Brama was the first man; that Brama received from Wistnou a power of creating; that he made eight worlds like ours, the government of which he left to eight lieutenants or deputies; that the worlds perish and revive again; that our earth began in water, and shall end in fire; that from the ashes of this present earth a new earth shall be formed, which shall neither have sea, nor vicissitude of seasons. The Bramins make the soul circulate in different bodies. The soul of a man, say they, who was of a quiet gentle disposition, passes into the body of a dove; the soul of a tyrant animates a vulture. In consequence of this doctrine

trine, they hold all animals in great respect; they have founded hospitals for them, and, under a notion of religion, purchase the birds which the Turks take. They are in very great esteem among the Banians throughout all the Indies; but are reverenced in a more especial manner by those which inhabit the coast of Malabar, who carry their veneration to a very extraordinary degree; trusting their brides with them before consummation, to dispose of them according to their holy will, in order to make the bridegrooms happy and prosperous. They are at the head of religion, and explain the dreams of it to the people. The austerity of their lives, and the ostentation of their fasts, promotes the imposture; they are dispersed all over the Indies, but their college is at Banassi. We might proceed farther to expose the extravagances of the philosophy and religion of the Bramins; but it is now unnecessary. Philosophy, in this enlightened age, has made a gigantic progress, and absurdities meet the contempt they deserve.

BRA'NCHERY, in anatomy of vegetables, denotes the vascular parts of divers fruits, as apples, pears, plums, and berries.

BRANCHI'DÆ, in antiquity, priests of Apollo, serving in his temple at Dydima, in Miletus; which was famous for its oracle.

The denomination is taken from branchus or branchides, an epithet given to Apollo as worshipped here; though on what account the title was given, is not agreed on.

BRA'NCHUS, βράγχος, in medicine, a species of catarrh, affecting chiefly the jaws, throat, and aspera arteria.

BRA'NDRITH, among builders, denotes the fence or rail about the mouth of a well.

BRA'NDY (*Dist.*)— The French Brandies, most generally esteemed, are produced up the Loire, or near Cognac, Nantz, and Rochelle. Next to these are the Bourdeaux, or entre deux Meres Brandies; those of Languedoc, and the islands of St. Martin, Oleron, &c.

According to the different species and growth of the grapes, the Brandies always differ; whence there are various kinds of French spirits, having particular flavours; by which the conoisseurs readily distinguish one sort from another; though the vulgar call them all by the name of French Brandy indiscriminately. But an ordinary judgment may easily distinguish Languedoc Brandy from that of the isles, or Bourdeaux from Cognac: nor would there be so great a similarity between the several species of French Brandies as there is, but that only the weakest and lowest-flavoured wines are distilled for their spirit, or such as prove absolutely unfit for any other use: but, when, out of curiosity, or good husbandry, they distil the bottoms, or refuse parcels of the grosser-bodied and full-tasted wines, the Brandy got from them is what we, in England, emphatically call a wine-spirit.

Every kind of grape, therefore, as it affords a wine, so does it also a Brandy of its own peculiar flavour; which is an observation that should be well attended to, when any parcel of French Brandy is proposed to be imitated; for it is ridiculous to expect Cognac Brandy should be perfectly resembled with a quintessence made from Bourdeaux grapes; though the spirit, or subject-matter of the operation, were previously rendered ever so pure or tasteless.

A large quantity of Brandies is made in France during the time of the vintage; for all those poor grapes, that prove unfit for wine, are usually first gathered, pressed, and their juice fermented, and directly distilled. This rids their hands of their poor wines at once, and leaves their casks empty for the reception of better. It is a rule with them to distil no wines that will fetch any manner of price as wine; for in this state the profits upon them are vastly greater than when reduced to Brandies. This large stock of small wines, wherewith they are almost over-run in France, shews the reason of their making such vast quantities of Brandy, more than other countries, which lie warmer, and better for grapes.

But this is not the only fund of their Brandies; for all the wine that pricks, or turns eager upon their hands, is also condemned to the still; and, in short, all that they can neither export, nor consume at home, which amounts to a large quantity; since much of the wine, laid in for their family provision, is so poor, as not to keep the spending.

Their general method of distilling Brandies in France needs no formal description, as not differing from that vulgarly practised among ourselves in working from wash or wines: nor are they one jot more cleanly or exact in the operation. They only observe, more particularly, to throw a little of the natural lee into the still, along with the wine, as finding this gives their spirit the flavour, for which it is generally admired abroad; though not at all by themselves at home, who have a most contemptible opinion of Brandy in general, but especially the high-flavoured kinds; so that, as the distillation of this commodity is usually left to the meanest and most servile hands amongst them, the spirit itself is very little used by any other sort of people throughout the kingdom.

Their notion of proof squares with our's to a tittle, and they stand upon it to a punctilio, as if the whole excellence of the Brandy lay there. And in this form of strong bubble-proof all their fine spirits are constantly found.

But they have one particular expedient for such Brandies as prove foul, feedy, or retain the taste of certain weeds apt to grow among the wines, viz. to draw them over again, with a design to cleanse them of that adventitious flavour: in which operation they leave out the faints, or rather change the receiver, as soon as ever the stream comes proof; then, mixing together all that run off before, they call it by the name of trois-cinque; that is, Brandy consisting of five parts alcohol, and three parts phlegm.

Higher than this the brewers, or common distillers, in France, seldom bring their Brandies; that refined nation having the address to persuade the foreign merchants that the phlegm of French Brandy is a natural part, as essential to it as the body to the soul. The truth is, if people were so disposed, they might easily reduce French Brandies, or the Brandies of any other nations, to half their usual bulk, without impairing their virtues: for, if the essential oil of the wine be the thing required, this is much better preserved in alcohol than in proof spirit. But whether the charge of bringing Brandies into alcohol would exceed that of a double freight, and double stowage, is the merchant's business to consider; or whether it be not proportionably as advantageous to import low wines as Brandies, which, with respect to alcohol, are nothing but a stronger low wine.

They use no manner of art to colour their Brandies, nor to give them any additional flavour; the thing they principally value themselves upon, both in wines and Brandies, being to make them perfectly natural; so that all the colour of their Brandies is acquired from the cask, and the length of time they usually lie therein; which is sometimes twelve or eighteen months, and often two or three years; during which, it is no wonder if they acquire a yellow or brownish cast. Their lying thus long, as it were in a state of slow digestion, wonderfully takes off from that hot, acrid, and foul taste, peculiar to all spirits or Brandies newly distilled; and gives them a coolness and softness not easily to be introduced by art, without great care being had in the first operation. But these fine and grateful Brandies, as they prove after having lain thus long, were at first hot, acrid, foul, and fiery. This fine colour, and an agreeable softness or coolness in the mouth, going along with French Brandies of a good natural flavour, are the things that principally recommend them to the judicious purchaser.

And upon these properties are founded several methods of trying their goodness, or discovering whether they are debased or adulterated by the admixture of coarser spirits. But there is little danger of any such practice in France, as they have no cheaper spirits to debase or adulterate their Brandies withal, especially since the prohibition of melasses spirits in that country: and the same reason, in good measure, holds in favour of the Dutch, who, though generally suspected as great adulterators, yet, in this case, seem but little qualified for it, as, having no treacle spirit, and their malt spirit they despair of rectifying, it being so intolerably fœtid and nauseous, that almost a single gallon would taste through a whole piece of Brandy: all, therefore, that the Dutch seem fitted to do in this case, is to mix Brandies with wine spirits, or the spirit drawn from wine lees, which they have in very great plenty. But even this cannot be very gainful, considering how cheap the Brandies are in Holland; for, paying no duty, they come almost as cheap there as in France itself. The temptation to adulterate French Brandies is much greater in England, where the duties upon them are high; though they are also very much adulterated up and down the continent, and all considerable trading towns and sea-ports. In England, it has been above observed, they use all kinds of spirits to mix with them; malt, melasses, cyder, sugar-spirit, &c. and often do it so dexterously, or so sparingly, as vulgarly to pass undiscovered. The same arts are likewise practised in many other countries: but certain brokers, factors, and under merchants, who deal largely in Brandies, are said to have a particular liquor, which, being added to a glass of any suspected Brandy, will shew, by the colour it makes therewith, whether, and in what proportion, the whole parcel is mixed with a corn spirit. But such proof is erroneous, and not to be trusted. The fact is this: if a few drops of a certain vitriolic solution be let fall into a glass of old French Brandy, it will, if the vitriolic solution were rightly prepared, turn the Brandy of a fine purple, or deep violet colour; by the strength or diluteness of which colour, they judge the Brandy to be either pure, or mixed with a malt spirit, proportionably. The foundation of the thing lies here: old French Brandy, by having long lain in an oaken cask, thus really becomes a dilute tincture of oak, which, upon the addition of the vitriolic solution, necessarily turns of a blue colour, after the manner that ink is made of a tincture of galls and vitriol. But if the Brandy be perfectly pale, or very lately distilled, it will not thus change its colour, upon the addition of the solution, though the Brandy were totally French. And in the same manner a light tincture of oak, extracted with a malt spirit, or any other spirit, will, upon affusion of the same solution, exhibit the same appearance. Hence this kind of proof is nothing more than a way of determining how rich a tincture of oak any common spirit or Brandy is. Calcined vitriol of iron, lightly infused in in a certain dilute, or aqueous mineral acid, gives this solution to great perfection; being, when well made, of a fine yellow colour, and capable of giving, for a season, the finest blue to a spirituous tincture of oak. And here it may not be amiss to mention, that the experiments I formerly made of this kind led me, at the first sight of Dr. Eaton's styptic, to conjecture the manner of its preparation; which, upon a second attempt, I hit to great exactness. I should not mention so small a matter, if the discovery of that famed styptic had not been somewhat unsuccessfully attempted by others; so far, I mean, as concerns the appearance and phænomena, though not, perhaps, the virtues of it. The whole secret is this: to a parcel of old French Brandy add a very minute proportion of calcined green vitriol; and thus there will presently be made a dilute ink, which very slowly deposits a black or dusky cloud, that afterwards rests at the bottom of the glass, and causes the liquor to exhibit all the phænomena, and answer the ends of Dr. Eaton's styptic.

To proceed, it is manifest that the French Brandies naturally receive their colours from the cask. The discovery of which particular might probably be the reason why high-coloured Brandies have of late years sunk in the esteem of many, so as to occasion pale ones to be much ordered; and, for a while, nothing would go down but pale Brandies. Hence, both in France and Holland, they fell to work upon redistilling their old Brandies, to make them of a water whiteness. And to such a length this humour ran, and the difference in price between pale and brown Brandies grew so considerable, that much profit was made in Holland, barely by the re-distillation of Brandies, to render them colourless. This also made very well for France, who had much rather dispose of her new colourless Brandies, for an advanced price, than for a lower, after having kept them in a wasting state, to colour them, many months in the cask: which colour, where not artificially introduced, is a sure sign of age, that is, excellence, on the side of Brandy.

The vulgar method of examining Brandies by the bead-proof may be of good service, in procuring such as will best serve to mix with, and conceal an ordinary spirit; as this proof, when strong, shews they contain a good deal of the essential oil of the grape, which gives an agreeable flavour. But, when intended for other curious or chemical uses, as much labour is often employed to get out this fine-tasted essential oil in France, as the more curious chemists employ to get the fœtid oil out of malt spirits in England: and, indeed, there are many operations where the nidorous odour of either spirit would be very unsuitable, nor is it often proper to use a menstruum to act upon one body, whilst it is already saturated with another. But no judgment can by this kind of proof be formed of Brandies, as to their mixed or adulterated state.

The surest way, for this purpose, is, to acquire the habit of judging from use and practice. The taste and smell, by proper methods, are so far improveable in this particular, as not to be easily imposed upon. Care indeed must be had, not to taste Brandies in too high a state; for this scorches the mouth, and confounds the judgment. Nor should many sorts be tasted soon after one another: for thus a mixture of tastes will be made, the taste of the preceding being not yet gone off the tongue.

The best method is to dilute Brandies well with water, in order to their being smelt and tasted; or rather, to burn away all their inflammable spirit, and afterwards examine the phlegm.

From this history of French Brandies, compared with the doctrine of simple distillation and rectification, it will appear, that many of our English spirits are convertible into Brandies, that shall hardly be distinguished from the foreign, in many respects, provided this operation be neatly performed. And, in particular, how far a cyder spirit, and a crab spirit, may, even from the first extraction, be made to resemble the fine and thin Brandies of France, we would recommend to the practice of those distillers, who have any skill and curiosity this way.

To the same curious persons we would also recommend the discovery of that desideratum, in the business of rectifying French Brandies, which the distillers in France and Holland scarce know how to attempt, though it would be a profitable business in either country. By this rectification is meant the method of clearing Brandies from a certain seedy taste, with which they are frequently impregnated; and, upon which account, they cannot find purchasers, but upon disadvantageous terms. Thus sometimes a cask of French Brandy shall resemble aniseed, or caraway-water, rather than Brandy; so that the proprietor, to get it off, is reduced to the necessity of mixing it among other Brandies, in such small proportions as may render it undiscoverable: whereas, could he but clear it of this flavour, he might readily be reimbursed, with a handsome profit.

The foundation for this kind of rectification is so fully laid under the article RECTIFICATION, that our English distillers, it is hoped, may, from thence, be enabled to effect the thing.

It is a mistake to imagine, that all the Brandies made in France are so good and fine, as we usually taste them upon our keys at London. No; there are many hundreds of pieces made, every year, almost as disagreeable and nauseous as our malt spirit. But the case is, they send the best Brandies, as they do their best wines, to England, where they get the best prices for them. But in Holland, the mart for goods of all sorts, you shall sometimes not be able to pick a good piece of French Brandy out of fifty: the general run of them being either seedy, oily, musty, or otherwise infested with some unnatural and disagreeable flavour. And these are the sorts which, in France, they despair of curing by re-distillation, or bringing towards the state of alcohol, or to what they call three fifths.

These cases require a better method of rectification, than our common one by fixed alkalies: but if due care and skill were employed from the first gathering of the grapes, to the making up of the Brandies; not only such inconveniencies might be prevented, but the Brandies of France might be rendered much finer.

Some prefer Rhenish Brandy to that of France; and, particularly in Holland, it sells for double the price. It is indeed a very fine spirit; but the English know little of it farther, than that a dash thereof serves to fill up a cask of French.

The Spanish Brandies are much coarser than the French, though sometimes made to pass for them in Holland, and other places of great traffic. *Shaw's Essay on Distil.*

The still-bottoms of French Brandy are useful to all the purposes above-mentioned of the still-bottoms of wine-spirit.

BRASS (*Dict.*)—The calamine does not enter the copper under its earthy state, but is first converted by the phlogiston into the form of a metal: Kunkel, it is true, imagined that only the mercurial part of the calamine was added to the copper, without any of the sulphur; but this opinion later chemists seem to have sufficiently refuted. *Vid. Junk, Consp. Chem.*

Brass may be cleansed, first, by rubbing it with a cloth dipped in equal quantities of aqua-fortis and common water; then with an oily cloth, and lastly with a dry one dipped in lapis calaminaris.

Brass is tinged of a gold colour, first, by burning, then dissolving it in aqua-fortis, and, lastly, reducing it to its metalline state. It may be whitened by heating it red-hot, and quenching it in water distilled from sal armoniac and egg-shells. It is silvered, or coloured superficially white, by rubbing it with balls made of silver dissolved in aqua-fortis, with powder of white tartar, sufficient to absorb all the moisture thereof.

BRASS, in the glass trade. Thrice calcined Brass is a preparation which serves the glassmen to give many beautiful colours to their metal. The manner of preparing it is this: place thin plates of Brass on tiles on the leer of the furnace near the occhio; let it stand to be calcined there for four days, and it will become a black powder, sticking together in lumps. Powder this, and sift it fine, and recalcine it four or five days more; it will then not stick together, but remain a loose powder, of a russet colour. This is to be calcined a third time, in the same manner: but great care must be taken, in the third calcination, that it be not over done, nor under done; the way to be certain of making it right, is to try it several times in glass while melting. If it makes it, when well purified, to swell, boil, and rise, it is properly calcined; if not, it requires longer time. This makes, according to the different proportions in which it is used, a sea green, an emerald green, or a turquoise colour. *Neri's Art of Glass, p.* 42.

Brass, by a long calcination alone, and without any mixture, affords a fine blue or green colour for glass; but they have a method of calcining it also with powdered brimstone, so as to make it afford a red, a yellow, or a chalcedony colour, according to the quantity and other variations in the using it; the method of making the calcination is this: cut thin plates of Brass into small pieces with sheers, and lay them stratum super stratum, with alternate beds of powdered sulphur, in a crucible; calcine this twenty-four hours in a strong fire, then powder and sift the whole; and, finally, expose this powder upon tiles, for twelve days, to a reverberating furnace; at the end of this time, powder it fine, and keep it for use. *Neri's Art of Glass, p.* 37.

The glass-makers have also a method of procuring a red powder from Brass, by a more simple calcination, which serves them for many colours. The method of preparing it is this: they put small and thin plates of Brass into the arches of the glass furnaces, and leave them there till they are sufficiently calcined, which the heat in that place. not being enough to melt them, does in great perfection. The calcined matter, powdered, is of a dusky red, and requires no further preparation. *Neri's Art of Glass, p.* 41.

Brass is used to make great guns: some reckon the best method is to put, into the quantity of eleven or twelve thousand weight of metal, ten thousand of rose copper, nine hundred pounds of tin, and six hundred of Brass.

But Mr. Chandler observes, that the best Brass guns are not made with pure copper and calaminaris, but that coarser metals must be mixed therewith, as lead and pot metal, to make it run close and sounder. See FOUNDERY.

What they call Brass wire, or Brass in hoops, is Brass drawn through the wire-drawing iron.

For making the finest statues of Brass, the proportion is one half of copper, and one half of Brass. The Egyptians, whom some think the inventers of this art, used to put two thirds of Brass to one third of copper: rose copper is not so proper for casting statues as that which is hammered.

In common Brass the allay is made with tin, and even with lead, when people would be saving. But the latter ought not to be used in Brass designed for statues. For Brass guns, they put ten or twelve pounds of tin to a hundred of Brass. For bells, they put twenty or twenty-four pounds of tin to the same weight of copper, to which they add two pounds of antimony, to render the sound more soft; and they put but three or four pounds for kitchen furniture.

Corinthian Brass has been famous in all antiquity. L. Mummius having sacked and burnt the city of Corinth, in the 158th Olympiad, or 146 years before Christ, it is pretended, that this precious metal was formed from the immense quantity of gold, silver, and copper with which that city abounded, which, being all melted and mixed together by the fierceness of the fire, composed as it were a new metal. The statues and vessels which were afterwards made of it, by excellent artists, were esteemed of great value: and, though it is commonly the sculptor's hand, which enhances the price of those pieces of workmanship, yet, on this occasion, the matter seemed to vie with, or even to excel above the ordinary perfection of art.

They who have given an accurate account of this metal, distinguish three sorts of it; in one gold was predominant, in the next silver, and in the last gold, silver, and copper were in equal parts. It is very probable, that what was formerly owing to chance, might at present be imitated by art: but, as most things are valued on account of their scarcity, it is but too true, that the ease with which an artist might now make such Brass, would render it less valuable, how like soever it might be to that of Corinth.

Brass is also a colour prepared by the braziers and colourmen to imitate Brass. There are two sorts of it; the red Brass, or bronze, as the French call it, and the yellow or gilt Brass. The latter is made only of copper filings, the smallest and brighest that can be found; with the former, they mix some red ocre finely pulverized. They are both used with varnish. In order to make a fine Brass, that will not take any rust or verdigrise, it must be dried with a chafing-dish of coals, as soon as it is applied.

The finest Brass colour is made with powder-Brass, imported from Germany, diluted into a varnish, made and used after the following manner: the varnish is composed of one pound and four ounces of spirit of wine, two ounces of gum-lac, and two ounces of sandarac: these two last drugs are pulverized separately, and afterwards put to dissolve in spirits of wine, taking care to fill the bottle but half full, otherwise it would burst; in all processes, in which spirit of wine is made to act by means of fire, the vessels must be exactly stopped with a hog's bladder, and but half full. The varnish being made, you mix such quantities as you please of it, with the pulverized Brass, and apply it with a small brush to what you would Brass over. But you must not mix too much at once, because, the varnish being very apt to dry, you would not have time to employ it all soon enough; it is therefore better to make the mixture at several times. After this manner they Brass over figures of plaister, which look as well as if they were of cast Brass.

BRASS *Lumps*, in minerology, a common name given by the miners and diggers of coal, &c. to the globular pyrites. This stone, when kept in the air, often sends forth its efflorescences of salt, in the form of small and slender fibres, perfectly transparent, and sometimes of near an inch long. The place where these stones are exposed to the air, will greatly alter the figures and colours of their efflorescences; if they are laid in a cellar, the shoots will be shorter, and green, like the common copperas; and, if laid in the way of the sun-shine, they will be white and dusty.

Both are the same salt, which is true green vitriol or copperas, and both will, in the same manner, turn a decoction of galls into ink. The white salt is only the green powdered and calcined by the sun's heat. The figure of the fibres of these efflorescences is not easy to be determined; sometimes they seem round, sometimes angular. These, however, are the natural figures of the salts of these stones; and the other shoots into which they form themselves after solution, and bringing them together in a body by water, are rather their accidental forms, though, under a like course of accidents, they generally appear the same. *Philos. Trans.* N°. 110.

BRAWN, in the culinary art, signifies the flesh of a boar, boned, rolled up, or collared, boiled, and, lastly, pickled for a winter's eate.

Brawn is made only of the flitches, without the legs; the oldest boars are chosen for this use, it being a rule that, the older the boar, the more horny the Brawn.

There is also Brawn of pig, which is made by scalding, drawing, and bonding the beast whole, except the head; then cutting it into two collars, soaking it in brine, seasoning, rolling, putting it into a cloth, binding it up, boiling it, and, when boiled, hooping it up in a frame. *Russ. Dict. T.* I. *in voc.*

BRAZEN *Age*, *seculum æreum*, is used by the poets to express the third age of the world.

What Hesiod and the Greeks called the Brazen, the northern nations call the rocky or stony age. *Phil. Trans.* N°. 301.

BRAZEN DISH, among miners, is the standard by which the other dishes are gauged, and is kept in the king's hall. *Hought. Compl. Miner.*

BRA'ZIER, an artificer who makes and sells pans, pots, kettles, and other kitchen utensils and brass ware.

The implements used by Braziers are, a forge, wherein they burn only charcoal to heat their metal: a twibil wherewith to hold their work to the fire; divers sorts of anvils and hammers, wherewith to beat; also pans, ladles, sheers, and punches of divers sorts, soldering irons, borax box, lath for turnings, &c. See BRAZING *in the Dict.*

BRAZIL-WOOD (*Dict.*)—It is differently surnamed, according to the several places from which it is imported: thus there is the Brazil-wood of Fernambuco, or Pernambuco; the Brazil-wood of Japan, that of Lamon, that of Santa Martha, and lastly the brasilet, which is esteemed the worst. This last comes from the Antilles islands.

The Brazil-wood of Japan is otherwise called sapan: there is the large and the small: the large is simply called sapan, and the small sapan bimais.

The tree of the Brazil-wood grows commonly in dry barren places, among rocks. It becomes very thick and tall, and pushes out long branches, whose twigs are furnished with a vast quantity of small leaves, half round, of a fine bright green, pretty much like those of box, but longer, hard, dry, and brittle. Its trunk is seldom straight, but crooked and knotty, almost like the hawthorn. There come, twice a year, at the extremity of the branches, and between the leaves, small bunches of flowers, which are somewhat long, pretty much like those of the lilly of the valley, of a bright red, and an agreeable aromatic smell, very comfortable to the brain, which they strengthen: these are succeeded by a flat red fruit, which contains two small flat seeds, of a most lively red; these seeds are a kind of almonds, of the form of a pumkin seed.

Though the trunk of this tree be very thick, yet it is covered with so gross a bark, that, when the savages have taken it off from the wood, a trunk, which before was as thick as a man's body, remains, as it were, a log not bigger than his leg.

The Brazil-wood is very heavy, very dry, and very hard; it crackles very much in the fire, and emits hardly any smoke, because of its excess in dryness.

None of these different sorts of Brazil-woods have any pith, except that of Japan: that of Fernambuco is reckoned the best. It must be chosen in thick pieces or logs, heavy, compact, very sound, without any part of the inner bark upon it, and without the least rottenness, and such, as after splitting it, from pale becomes reddish; and that, being chewed, it has a sweetish taste like sugar.

This wood is proper for turner's work, and takes a good polish: but its chief use is for dying, where it serves for a red colour. However, by the regulations made in France, the dyers of rich and valuable stuffs are forbidden to use it, because it yields but a spurious colour, which fades very soon; yet the dyers of inferior stuffs are suffered to use it, though it is subject to very great inconveniences.

From the Brazil-wood of Fernambuco, they extract, by means of acids, a kind of carmine: they also make of it a liquid lacca for painting in miniature. And, with a tincture of this wood often repeated, they make that reddish chalk, which is called rosetta; but it is nothing but the white of Roan, to which the Brazil-wood gives the colour of an amaranthus.

BREAD.--Among us, Bread is chiefly divided into white, wheaten, and houshold; differing only in degrees of purity. In the first, all the bran is separated; in the second, only the coarser; in the third, none at all: so that fine Bread is made only of flour; wheaten Bread, of flour, with a mixture of fine bran; and houshold, of the whole substance of the grain, without taking out either the coarse bran, or fine flour.

We also meet with symnel Bread, manchet or roll Bread, and French Bread; which are only so many denominations of the finest or whitest Bread, made of the purest flour; except that in roll Bread there is an addition of milk, and, in French Bread, of eggs and butter also. To which may be added, ginger Bread, made of white Bread, with almonds, liquorice, aniseed, rose water, and sugar; and maslin Bread, panis mixtus, made of wheat and rye, or sometimes of wheat and barley.

For armies the Bread is either baked in the park of provisions in the camp, or in the town nearest the army; for the conveniency of ovens, an army ought always to have at least four days Bread before-hand. In some cases, the distance of the places, from whence Bread is to be had, or the army's march from one country to another, obliges the general to distribute for six or even for eight days; a thing never done without

PLATE VII. *Engraved for the Supplement.* *Facing* Brew-house.

Printed for J. Hinton in Newgate Street.

without absolute necessity, by reason of the abuse which some soldiers make of it, who sell their Bread without regard to future subsistance. For long marches through an enemy's country, they sometimes make bisket instead of Bread.

Horse Bread is made of wheat, oats, and beans; to which sometimes are added aniseed, gentian, liquorice, fenugrec, eggs and ale; and sometimes rye and white wine are used.

For race-horses, three sorts of Bread are usually given with success, for the second, third, and fourth fortnights feeding; they are all made of beans and wheat, worked with barm; the difference consisting chiefly in the proportion of the two former. In the first kind, three times the quantity of beans is used to one of wheat; in the second, equal quantities of both; in the third, three times the quantity of wheat to one of beans.

The process of making houshold Bread, amongst us, is thus: to a peck of meal they add a handful of salt, a pint of yeast, and three quarts of water, cold in summer, hot in winter, and temperate between the two; the whole, being kneaded in a bowl or trough by the fire in winter, from it in summer, will rise in about an hour; they then mould it into loaves, and put it into the oven to bake. *Haught. Collect.*

For leavened Bread, part of the flour intended for it, being made into dough with warm water and a little salt, is laid in the rest of the flour an hour or more, in which time it rises to three times the bulk; then they mix and knead the whole with more water, till it be brought into a stiff dough; which, being formed into loaves, is baked in the oven: though the more usual way is to take a piece of dough kneaded, and leave it in the tub till next time, when they break it small, and mix it with the meal, adding some yeast. *Haught. Collect.*

For French Bread, they take half a bushel of fine flour, ten eggs, and a pound and a half of fresh butter, into which they put as much yeast, with manchet; and, tempering the whole mass with new milk, pretty hot, let it lie half an hour to rise; which done, they make it into loaves or rolls, and wash it over with an egg beaten with milk: care is taken the oven be not too hot. *Rust. Dict.*

BREAM, *brama*, in ichthyology, a river fish of the leather-mouthed kind, esteemed a species of carp, and called by the generality of authors cyprinus latus.

It is a very broad and thin fish; the head is small, the back of it broad and flat, and the back rising from the head and tail toward the middle, like that of a hog; the side lines are turned into a sort of arched figures near their origin at the gills, and run much nearer the belly than the back. When the fish is full grown, its sides are of a yellowish hue, and its belly reddish; the scales are large, and striated downwards; the mouth is very small for the size of the fish, and has no teeth. It lives in ponds, and rivers of slow current, and sometimes grows to more than two feet in length, and is not accounted a delicate fish. *Willughby, Hist. Pisc. Gesner de Pisc.*

This is but a coarse fish for the table, but it affords great sport to the angler. The method of taking it is this: procure about a quart of large worms, put them into some fresh moss, well washed and dried; let this be changed every three days, and let then be put, at the bottom of the vessel, some good black mould, with some fennel chopped small amongst it. This will clean them perfectly; and, in about three weeks, they will be fit for use. The lines must be silk alone, or silk and hair, and the floats large goose or swans quills; a plummet must be prepared of a piece of lead, of the shape of a pear, with a ring at the small end; the lead must be fastened to the line, and the line hook to the lead; about ten or twelve inches space will be enough between the lead and the hook; and the lead must be heavy enough to sink the float. The hook to be baited with a strong and vigorous worm, which will draw it up and down at the bottom, and provoke the Bream to bite more greedily. It will be best to fit up three or four rods in this manner, and set them all at once. Find the exact depth of the water, if possible, that the float may just lie even with the surface, directly over the lead; then provide the following ground bait.

Take a peck of sweet gross ground malt, boil it a little, strain it through a bag, and take it to the water side; throw in this malt by handfuls, squeezed hard together, that the water may not separate it before it gets to the bottom; it should be thrown in about a yard above the place where the hook is to be. This is to be done about nine o'clock at night, and, about three in the morning, go again to the place, approaching cautiously, so as to keep out of sight of any fish that may be at the top of the water, while the rest are feeding at the bottom; then throw in the line, with the hook nicely baited, and the others at about a yard distance above and below the first, and one another; let the rods lie on the ground, and, when one is taken, there is no occasion to run up hastily; but the fish may be left to tire himself a little, and then be taken up.

BREAST-PLATE, in the manage, denotes a leathern strap running from one side of the saddle, cross the horse's breast, to the other; intended to keep the saddle from slipping backwards, in mounting up rising grounds. It is otherwise called tee; sometimes the poitrail.

BREAST-PLATE, among artificers, denotes a drill-plate, against which to set the blunted end of the drill. *Moxon's Mechan. Exercises.*

BREEDING *of fish.* The necessary qualities for a pond, in order to its serving well for the Breeding of fish, are very different from those which are to make it serve for feeding them; insomuch that some particular ponds serve only for one of these uses, and others for the other; and scarce ever the same pond is found to serve for both. In general, it is much more rare to find a good Breeding pond than a good feeding one. The best indications for a Breeding pond are these: that there be a good quantity of rushes and grass about its sides, with gravelly shoals, such as horse-ponds usually have: when a pond has this property, and takes to the Breeding of fish, it is amazing what a progress will be made in a little time. The spawn of fish is prodigious in quantity, and, where it succeeds, one is able to produce many millions: thus, in one of these Breeding ponds, two or three melters, and as many spawners, will, in a very little time, stock the whole country. When these ponds are not meant intirely for Breeding, but the owner would have the fish grow to some size in them, the method is to thin the numbers, because they otherwise starve one another, and to put in other fish that will prey upon the young, and then devour them in the quickest manner. Eels and pearch are the most useful on this account; for they prey not only upon the spawn itself, but on the young fry, from the first hatching to the time that they are of a considerable size. Some fish are observed to breed indifferently in all sorts of waters, and that in considerable plenty; of this nature are the roach, pike, and pearch. See the article FISH.

BRE'NTA, in zoology, the name of a fowl of the goose-kind, known among us by that of the brent-goose, and, by some, supposed to differ from the barnacle no other way than in sex; but this is erroneous. It is somewhat larger than the barnacle, and is longer-bodied; the head, neck, and upper part of the breast, are black; the neck, however, is ornamented on each side with a sort of chain of white. Its back is of a brownish grey, but somewhat blackish towards the tail; the feathers immediately over the tail are white; it is white also on the belly, and of a brownish grey on the breast. *Ray's Ornith.* See *Plate* IV. *fig.* 34.

BRETE'SSE, in heraldry, a term used to express a line in some coat of arms, of the same nature with what is usually called the crenelle, or embattled line; except that this last is only embattled on one side, and the Bretesse or crenelle on both sides. Some authors seem, however, to have understood the terms Bretesse and crenelle as synonymous words, and, when they would express such a line, they call it, if embattled on both sides, contre-Bretesse. *Nisbet's Heraldry.*

BREW-HOUSE, a building adapted to the brewing, &c. of malt liquors.

In order to erect a large or public Brew-house to the best advantage, several circumstances should be carefully observed. 1. That three sides in four, of the upper part, or second floor, be built with wooden battons about three inches broad, and two thick, that a sufficient quantity of air may be admitted to the backs or coolers. 2. That the coppers be erected of a proper height above the mashing-stage, that the hot water may be conveyed by means of cocks into the mash-tuns, and the worts into the coolers. 3. That the fire-places of the coppers be very near each other, that one stoker, or person who looks after the fire, may attend all. 4. That the yard for coals be as near as possible to the fire-places of the copper. 5. That the malt be ground near the mash-tuns, and the mill erected high enough that the malt may be conveyed from the mill immediately into the mash-tuns by means of a square wooden spout or gutter. 6. That the upper backs be not erected above thirty-three feet above the reservoir of water, that being the greatest height water can be raised by means of a common single pump. 7. That the pumps which raise the water or liquor, as the brewers call it, out of the reservoir into the water-backs, and also those which raise the worts out of the jack-back into the coppers, be placed so that they may be worked by the horse-mill, which grinds the malt.

Explanation of *Plate* VII. being a section of that part of a large Brewhouse, which contains the coppers, mash-tuns, &c.

a a a a, the coppers.

1 1 1 1, copper-pumps, which throw the wort out of the coppers into the boiling-backs.

2 2 2 2, boiling-backs.

3 3, cocks to supply the coppers with water.

4 4 4 4, cocks which convey the water out of the coppers into the mash-tuns. The water is carried from these cocks through a wooden trunk to the bottom of the mash-tun, above which is a false bottom full of small holes, through which the water rises and wets the malt in the mash-tun.

5 5 5, mash-tuns.

6 6 6 6 6, men mashing, or stirring with utensils, called oars, the malt and water in the mash-tun.

7, an utensil called an oar, used in mashing.

8 8 8, the mashing-stage, or floor on which the mash-tuns are placed.

9, 9 9, 9, Cocks for letting the wort, or, as brewers call it, the goods, out of the mash-tuns, into the under backs.

10, 10, 10, Under backs, which receive the goods from the mash-tuns.

11, The jack-back. This back is placed something lower than the under backs, and has a communication with them all; and out of this back the wort is pumped into the coppers.

12, 12, Two wort-pumps, by which the wort is pumped out of the jack-back into the coppers. These pumps, as well as those which raise the water from the reservoir into the upper backs, and which could not be shewn in the figure, are worked by the horse-mill which grinds the malt.

13, The miller, or person who grinds the malt.

14, A boiling-curb. Its use is to prevent the wort from boiling over the copper.

15, The master-brewer.

16, A gutter for conveying the wort out of the wort-backs into the cooling-backs.

17, Pipes which carry the wort from the wort-pumps into the coppers.

BREWING (*Dict.*)—*Method of* BREWING *Butt-beer*, or *Porter*. When the water just breaks or boils, they let in a quantity of cold to keep it from scalding, which they let run off by a great brass-cock down a wooden trunk, fixed to the side of the mash-tun, and up through a false bottom into the malt: then mash with wooden oars half an hour; by this time the water in the copper is scalding hot, which they likewise let run into the malt, and mash half an hour longer. This they cap and cover with fresh malt, and let it stand two hours; then spend away by a cock-stream into the under back, where it lies a little while until a second liquor is ready to boil, but not boil, with which they mash again to have a sufficient length of wort that they boil at once, or twice, according to the bigness of their utensils. Others will make a third mash, and boil a second copper of wort. The first wort is allowed an hour and a half's boiling with three pounds of hops to each barrel. The second wort two hours with the same hops, and so on. Some calling the first hop-wort; the second, mash-wort; the third, neighbour-wort, and the fourth, blue. Which last, being a most small sort, is sometimes allowed six or seven hours boiling with the same used hops. When in a right temper, they let down the worts out of the backs into the tun from their grosser contents, where they cooly ferment it with yeast, till a fine curled head rises and just falls again, which sometimes requires twenty-four, sometimes forty-eight hours, as the weather is hot or cold to perform this operation. Then they cleanse it off into barrels.

Uses of sap in BREWING.—The sap or juice of trees not only improves malt liquor, but renders it much cheaper. The sycamore is the best tree for tapping for this purpose; it yields a great quantity, and that without any other trouble than boring a hole properly, and placing a vessel under it. One bushel of malt brewed with this juice will make as good beer as four bushels in the ordinary way. The best way of procuring the sap is this: take a large augre, and with it bore two holes on the opposite sides of the tree, each so deep as to the pith. Each hole is to be bored sloping upwards, and the best place for it is immediately under a large arm of the tree near the ground; and, if the arm be pierced through with the augre in the way to the tree, it will be so much the better: in this manner, there needs no spiggot or stone to keep open the hole, or to direct the course of the liquor, for it will of itself run down into a vessel placed to receive it; and one tree will thus, in a few days, yield a sufficient quantity of liquor to brew with.

In order to preserve the sap in a proper condition for Brewing, what is first gathered must be insolated by a constant exposition of it to the sun, in proper glasses, till the rest be obtained; otherwise the first will contract an acidity that will spoil it. When a sufficient quantity of the sap is thus collected, as much rye-bread must be put into it, cut thin and well toasted, but not burnt, as will serve to ferment it; when it works well, the bread is to be taken out, and, at a convenient time, it is to be bottled up, and will thus afford a pleasant liquor, of considerable strength, without malt or any other addition. Some people add sage to this liquor, baking it in their crusts of rye bread, till thoroughly dry, and then adding it with the bread to the working liquor. If a few cloves be tied up in a rag, and put into the vessels into which the sap is received from the tree, they will preserve it the year round, without any fermentation: they are very apt to give a taste to the liquor; but, if it be so contrived that they are taken out before they give this taste, the liquor will keep well without any flavour of them. The adding a few drops of oil of sulphur will have the same effect; and so will the fuming with sulphur itself. A little spirit of wine, poured on the top of the juice in every bottle, will also be very instrumental in the preserving it.

Many people, instead of adding malt, and Brewing the sap of the sycamore or birch into ale, use raisins, and make a sort of wine of it; and some add sugar. Some have used the rye toasts with very good success, though they were not put into the liquor, but only hung over it, at such a distance as to give warmth and motion to the surface. Common ale-yeast has been tried by some to ferment the juice of the birch; but it usually spoils it, turning the liquor into a very bad small beer. The Flemish wheat ferment would probably in time excel the bottled juice of the birch or sycamore; but it would require a considerable time for it. Cinnamon is worthy to be tried in the stead of cloves, as of an infinitely more agreeable flavour. Honey has no effect on cyder at all; for it will not mix with it, though boiled in it, to make mead; but, after a time, the cyder lets fall the honey, and becomes simple cyder again: it is a question whether it would mix with these juices; but, if it will, it will probably make a great improvement in them. The tops and young leaves of birch, boiled in the sap, are said by some to preserve it. *Philos. Transact.* N°. 146.

BREWING *for Distillation*, implies the extracting a tincture from some vegetable substance, or making a solution of it by hot water, fitted for vinous fermentation.

Such a fermentable tincture or solution is obtainable from any vegetable whatever, under proper management and regulation; but, the more readily and perfectly the subject dissolves, the better it is disposed for fermentation, and the production of spirits. Thus sugar, honey, treacle, manna, and other inspissated vegetable juices, which totally unite with water, into a clear and uniform solution, are more immediate, more perfect, and better adapted subjects of fermentation, than roots, fruits, or herbs in substance, the grains, or even malt itself; all which dissolve but very imperfectly in hot water.

Yet malt, for its cheapness, is generally preferred in England; and brewed for this purpose, much after the common manner of Brewing for beer; only the worst malt is generally chose for distillation; and the tincture, without the addition of hops, and the trouble of boiling, is directly cooled, and fermented.

To brew with malt for distillation in the most advantageous manner, it is requisite, 1. That the subject be well prepared. 2. That the water be suitable and duly applied, and, 3. That some certain additions be used, or alterations made, according to the season of the year, or the intention of the operator.

By an exact regulation in these respects, all the fermentable parts of the subject will be brought into the tincture, and thus become fit for fermentation.

The due preparation of the subject consists in its being justly malted, and well ground. When the grain is not sufficiently malted, it is apt to prove hard and flinty, so that the water can have but little power to dissolve its substance; and, if it be too much malted, a part of the fermentable matter is lost in the operation.

The harder and more flinty the malt, the finer it ought to be ground; and perhaps in all cases, when designed for distillation, it ought to be reduced to a kind of coarse meal. For it is found by experience, that, if it be ground thus fine, good part of the trouble, the expence, and the time usually consumed in Brewing, may be saved, and a greater yield of spirit procured. For thus the whole substance of the malt may all along remain mixed among the tincture, and be fermented and distilled along with it: which is a particular that deserves the attention of the malt-stiller; as he principally consults dispatch, and making the most of his subject, without sollicitously regarding the purity and perfection of the spirit.

The secret depends upon thoroughly mixing, or briskly agitating and throwing the meal about, first in cold, and then in hot water; and repeating this brisk agitation after the fermentation is over: when the thick turbid wash being immediately committed to the still, already hot and dewy with working; there is no danger of burning, unless by accident, even without the farther trouble of stirring: which in this case is found needless, though the quantity be almost ever so large, provided the requisite care and cleanliness be used. And thus the business of Brewing and fermenting may very commodiously be performed together, or reduced to one single operation.

There are some also, who, the better to prepare their malt, sprinkle it, before grinding, with an aqueous solution of nitre, or common salt: for the same purpose others use lime-water; which seems not so well adapted, if the design, besides preventing the avolation of the finer flour in the grinding, be to promote the fermentation, increase the quantity of spirit, or add to its pungent, acid vinosity.

The best or most profitable water for the purpose of Brewing, is that of rain; as being not only very thin, soft, and thence well fitted to extract the tincture of the malt, but also abounding in fermentable parts; whereby it quickens the operation, and adds something to the yield of the spirit. Next to this is that of rivers or lakes, especially such as wash any large tract of a fertile country, or receive the sullage of populous towns; especially if taken up near the place where great Brewing or distilling works are constantly carried on.

But where neither of these waters are commodiously procurable, or only a hard, aluminous, or vitriolic spring-water is to be had; this may be made fitter for the purpose, either by laying a chalk bottom, for it to run upon; or by adding ſome particular preparation to a parcel of it, after it is pumped. A prudent uſe of quick-lime and fixed alkali will in ſuch caſe be of ſervice, and precipitate the offending mineral matter. There are alſo other ſimple preparations, and ſome compoſitions made with the liquor of calcined flints, &c. that anſwer this end ſtill better; but they come too dear to be uſed in that quantity they are here required

Whatever water is made choice of, it muſt ſtand in a hot ſtate upon the prepared malt; eſpecially if a clear tincture be deſigned: but a known and very conſiderable inconvenience attends its being applied too hot, or near to a ſtate of boiling, or even ſcalding, with regard to the hand.

To ſave time in this caſe, and prevent running the malt into clods or lumps, the beſt way is to put a certain meaſured quantity of cold water to the malt firſt, and ſtir that very well in with it, ſo as to form a kind of thin uniform paſte; after which the remaining quantity of water required may be added, in a ſtate of boiling, without the leaſt danger of making what, in the language of diſtillers, is termed a pudding. And thus the proper or preciſe degree of heat, neceſſary to extract the full virtue of the malt, with all advantages, may be very expeditiouſly hit, or aſſigned, to a great exactneſs; as the heat of boiling water is a ſtandard, which may at once be let down to any deſired point of warmth, by a proper addition of cold water; due allowance being made for the ſeaſon of the year, and the temperature of the air. And this little obvious improvement, applied to the method juſt above hinted, for reducing Brewing and fermentation to a ſingle operation, will render it practicable to conſiderable advantage.

The quantity of the water employed muſt be ſuited to that of the malt: the rule is, that a clear tincture, or turbid mixture, be made ſo dilute and thin, as to ferment with eaſe and expedition, yet not needleſsly increaſe the bulk of the whole. Too little water makes a viſcous, clammy, tincture or mixture, ſcarce at all diſpoſed to ferment, before it is let down lower with water; nor can the water ſo clogged extract all the ſoluble parts of the malt: on the other hand, when the tincture is too thin and aqueous, it takes up too much room, and adds to the trouble and expence of all the parts of the operation. A due medium therefore is here to be choſe: and, in general, the goodneſs or richneſs of the malt-ſtillers waſh ſhould be much the ſame as of the weakeſt French wines, or that ordinarily deſigned by the brewers of London for ten ſhilling beer. But, if a more exact ſtandard is required, recourſe muſt be had to the eſſay-inſtrument, water-poiſe, hydroſtatical balance, or other methods of trying the ſtrength of ſolutions, and finding their ſpecific gravity or tenacity: which afford a ſurer rule than that obtained by weighing the malt and meaſuring the water, becauſe of the different goodneſs of different parcels of malt, and the accidents of the operation. But, if a fine ſpirit be the thing in view, it is much better to make the waſh too weak, than in the leaſt too rich.

Under the right application of the water, muſt alſo be conſidered the proper manner of agitating the maſs; ſo that all the parts of the aqueous fluid may come fully and frequently in contact with all the ſoluble particles of the ſubject: and when once the water is thus well ſaturated, by ſtanding the proper time, it is to be drawn off, and freſh poured on: and the agitation repeated, till at length the whole virtue, or ſaccharine ſweetneſs of the malt, is extracted and nothing but a fixed huſky matter remains behind, uncapable of being farther diſſolved by the action of hot or boiling water; or of being advantageouſly waſhed, or rinſed by the bare affuſion of cold. This artificial and external agitation is requiſite, as well in the ordinary way of Brewing, as the ſhorter above-mentioned; and may to advantage be repeated more than once in both caſes, towards the beginning of the operation, and at each affuſion of freſh water; but eſpecially in the ſhort method which has a great dependence thereon.

The difference of ſeaſons is found to require ſome alteration in the direction and management of the buſineſs of Brewing: thus it is particularly found neceſſary to uſe the water colder in the ſummer, than in winter; to cool the tincture ſuddenly in cloſe ſultry weather, leſt it ſhould turn eager; and to check the too forward diſpoſition which malt has to ferment, when the air is hot, by a ſuitable addition of unmalted meal; which, being much leſs diſpoſed to fermentation than malt, thus helps to reſtrain and moderate its impetuoſity, ſo as to render the operation ſuitable and effectual to the production of ſpirit, that might otherwiſe, in great meaſure, be diſſipated and thrown off by an over-haſty and violent fermentation; eſpecially when the warm air is ſuffered freely to come at the fermenting liquor. Others, for the ſame purpoſe, uſe rye-meal; but this gives the ſpirit a moſt diſagreeable and nauſeous flavour, not eaſily to be got off or altered to advantage, by any known method of rectification.

It has likewiſe been thought of ſervice, in general, or at ſome particular ſeaſons eſpecially, to acidulate the water employed in Brewing, with a ſmall proportion of ſome vegetable, or light mineral acid; which is ſuppoſed to curb and regulate the fermentation of the tincture, improve the acid vinoſity of the ſpirit, and occaſion ſome ſmall increaſe of its quantity; and, with the ſame view, common ſalt, nitre, and tartar have likewiſe been employed in the manner hinted above.

The particular intention of the operator may render various other additions neceſſary: thus ſome, to improve the tincture, and diſpoſe it to yield more ſpirit, or to give it a particular flavour, add ſtrong and pungent aromatics in the Brewing; chuſing the cheapeſt for this purpoſe, ſuch as gran. paradiſ. cort. winteran. ginger, &c. But, in the common way, it is to be feared theſe additions do not effectually anſwer the intention; becauſe a particular encheireſis is requiſite to make the practice advantageous. Upon this foundation ſtands a very inſtructive method, uſed abroad for preparing geneva ab origine, by mixing the bruiſed berries of the Juniper among the malt, and Brewing them together; whence they procure a compound tincture, which, by fermentation and diſtillation, affords a ſpirit much more intimately and homogeneouſly impregnated with the fine eſſence of the berry, than that prepared in the common way of diſtillers.

The inconveniences that attend the Brewing directly with malt, are very conſiderable; the malt being of a very large bulk in proportion to the ſoluble, ſaccharine, or truly fermentable parts it affords; whence numerous large veſſels, much labour, and conſequently great expences are required to conduct and manage ſuch a buſineſs in the large way. The remedy here, as in all other caſes, may be much eaſier ſtarted than effectually applied. However, the foundation for it ſeems to reſt in practically reducing the perplexed buſineſs of the malt-ſtiller to the ſimple buſineſs of the fine-ſtiller; or, in other words, in reducing malt to a treacle. The thing in itſelf may be done to perfection; but how, in the large way, it will anſwer as to expence, muſt be left to thoſe who think it worth their care to conſider. The experiment is no more than this; when a parcel of wort, brewed in the common manner, is become fine by ſtanding, let it be decanted clear, and directly boiled in a common copper, till it begins to inſpiſſate or change a little towards a brown or duſky colour: at which time it muſt be directly emptied, into a balneum mariæ, where it may be exhaled to the full conſiſtence of treacle; which is a proper form to preſerve it in, till occaſion calls for it.

If the operation were finiſhed in the copper, the matter would be in great danger of burning, or unavoidably contracting an empyreuma, that could ſcarce ever be got off again; whence the whole might come to be abſolutely unfit for the purpoſe: or, if it eſcaped this accident, it would ſtill, through the unſuitableneſs and violence of the heat, or fire, now acting immediately upon the containing veſſel, be greatly indiſpoſed to ferment; ſo as, if it fermented at all, not to yield one fourth of the ſpirit the wort itſelf would otherwiſe have afforded.

But if the operation be dextrouſly and carefully performed, which perhaps is not quite ſo eaſy a thing as it may at firſt ſeem, the ſaccharine matter, though of as full a body, will be abundantly paler than treacle, a little more glutinous, very ſweet, pleaſant, and finely bitter, though no hops were uſed in the preparation. In this ſtate it will keep long, without any alteration; and remain capable at all times of being brought back by water to a wort again, that will ferment fully, and yield a ſpirit after the manner of treacle.

If upon full experience this method ſhall be found advantageouſly practicable in large, plentiful years, convenient ſituations, proper helps, &c. may be pitched upon for ſetting up a new trade of treacle-making, for the diſtillers at leaſt; if it ſhall not be found farther practicable to turn this new treacle into potable liquors or ſugars: which might poſſibly, under due regulation, lay the foundations of a work not unlike the ſugar-works of our plantations, though manageable with abundantly leſs trouble and expence.

When once the fermentable parts of vegetables are thus concentrated, and brought together into a ſmall compaſs, the buſineſs of Brewing becomes very facile; as being now no more than mixing, diſſolving, or ſufficiently diluting the inſpiſſated juice with lukewarm water: whence the ſolution, either alone, or with additions, is now perfectly fitted for fermentation. See FERMENTATION in the Dictionary and Supplement.

BRICKS (*Dict.*)— Bricks, among us, are various, acquiring various forms, dimenſions, uſes, method of making, place where, &c. Thoſe from their form, are compaſs Bricks, of a circular form, uſed in ſteyning of walls. 2. Concave or hollow Bricks, on one ſide flat, like a common Brick, on the other, hollowed. They are uſed for the conveyance of water. 3. Feather-edged Bricks, which are like the common ſtatute Bricks, only thinner on one edge, than the other, and are uſed for penning up the Brick-pannels in timber-building. 4. Triangular Bricks.

Thoſe from their dimenſions are, the great and ſmall, or ſtatute, and didoron, tetradoron, and pentadoron.

Great Bricks, are twelve inches long, ſix broad, and three thick; the weight of one is about fifteen pounds, ſo that a hundred will weigh fifteen hundred pounds, and a thouſand of them fifteen thouſand pounds.

Thoſe from cuſtom, are, ſtatute and cogging Bricks.

Statute Bricks, are thoſe whoſe dimenſions are conformable to the ſtatute, viz. nine inches in length, four and a half in breadth, and two and a quarter in thickneſs.

Cogging Bricks are uſed for making the indented work under the coping of walls built with great Bricks.

Thoſe from the method of making, are place and ſtock Bricks. Place Bricks, are ſuch as are made in a place prepared on purpoſe for them, near the building they are to be uſed in. Theſe are uſually ſmall common Bricks, and ought to be nine inches long, four and a half broad, and two and a half thick. Stock Bricks are thoſe made in a mould, and burnt in a kiln. Theſe are alſo Dutch, or Flemiſh Bricks, which are uſed in paving yards, or ſtables, and for ſoap-boilers fats and ciſterns.

Thore from their uſe, are buttreſs or pilaſter, coping and paving Bricks. Buttreſs or pilaſter Bricks, are of the ſame dimenſions with the great Bricks, only they have a notch at one end of half the breadth of the Brick. Their uſe is to bind the work at the pilaſters of fence-walls which are built of great Bricks. Coping Bricks are formed on purpoſe for coping-walls; paving Bricks, or tiles, are of ſeveral ſizes in ſeveral counties and places.

Thoſe from accident, are clinkers, ſamel, or ſandal. Clinkers are ſuch Bricks as are glazed by the heat of the fire, in making. Samel or ſandal Bricks, are ſuch as lie outmoſt in a kiln or clamp, and conſequently are ſoft and uſeleſs, as not being thoroughly burnt.

Manner of making Stock BRICKS.— They chuſe a piece of earth, called haſle-mold, or ſtiff loam, with a mixture conſiſting of a little ſand and a great deal of earth, without any clay.

Some little time before Chriſtmas they begin to dig as deep as the earth allows, laying it as level as poſſible, and end before Candlemas, that it may lie to mellow; that is, that the hard lumps may fall to pieces, which they will do either by the help of rain or froſt; when it is thus dug, they let it lie till Lady-day or Eaſter, when they have commonly fair weather. Then they water the earth well, and temper it with a narrow ſpade about five inches broad, with which they dig it down, and then temper it with their feet till it is in good caſe to make a Brick, that is, like a piece of dough, ſuch as will juſt ſtick in the mold or frame when lifted up, and not fall off of itſelf: they then bring to the earth a table ſtanding upon four legs, about three feet high, five feet and a half long, and three feet and a half over, and load it with as much as it will well bear at the right-hand end about half way; at the other end are boards nailed about nine inches high to lay ſand in, and in the middle they faſten with nails a piece of board, which they call a ſtock; this ſtock is about half an inch thick, and juſt big enough for the mold to ſlip down upon: the mold or frame is made of beech, becauſe the earth will ſlip eaſieſt from it. This mold, frame, or voider is made of the bigneſs of the Brick, only half an inch deeper, to give way for the ſtock aforeſaid; and it muſt be ſhod with a thin iron of half a quarter of an inch thick, both at the top and bottom, and this keeps it from breaking and wearing out: they alſo have upon the table, before the mold or frame, a little trough, that will hold about three or four quarts of water, and in it a ſtrike to run over the mold to make the Bricks ſmooth. This ſtrike is uſually made of fir, nine inches long, an inch and a half broad, and half an inch thick: they have alſo, on a little form juſt by the ſand-bin, about thirty little pieces of board twelve inches long, ſix inches over, and half an inch thick, called pallat-boards. When they are thus prepared with utenſils, one man ſtrews ſand on the table and moulds the earth upon it; then rubbing the ſtock and inſide of the mold with ſand, with the earth he forms a Brick, ſtrikes it, and lays it upon the pallat; then comes a little boy, and takes away three of theſe Bricks and pallats, and lays them upon a hackſtead, a raiſed place like a balk in a field, or a border in a garden; which is a piece of ground five or ſix rods long, two feet over, with a gutter on each ſide about a foot deep, and as wide a top; which is made by digging half a foot deep, and the earth that comes thence raiſes the hackſtead: this hackſtead muſt be well beaten, that it may be ſmooth, level, and hard, and upon it the boy lays his Bricks edgeways, the thickneſs of the pallats one from another, on each ſide of the hackſtead a row, and ſo that the heads of each row may be two or three inches aſunder, when they are pretty hard, which in dry weather will be in a day; then the boy lays another courſe croſsways, till they come to be ten courſes high, when they are covered with ſtraw till they are hard and dry, which uſually is in three weeks or a month, and then they burn them. One perſon, without a man to temper, or boy to carry them away, but to temper and lay them himſelf, will make a thouſand in a ſummer's day, viz. about fourteen or fifteen hours; but with a man to temper, and a boy to carry them, and lay them as above, he will make two thouſand, and an extraordinary man three thouſand in a day; and the uſual price for this tempering, making, and laying, is four ſhillings per thouſand, of which the maker has one half, and the temperer and the boy the other.

The Bricks being thus prepared, they are next burnt; for the method of which, ſee BRICKS, in the Dictionary. *Hought. Collect.*

Manner of making Place BRICKS.— Theſe are generally made in the eaſtern parts of Suſſex, and are ſo called, becauſe there is a place hard by, where they ſtrike or mold their Bricks, which is a level ſmooth piece of ground, prepared for the bearer-off (i. e. him who carries the Bricks from the ſtriker) to lay them down ſingly in rows (which are by them called ricks) as ſoon as they are molded; where they are let lie until they are a little dried, viz. until they are ſtiff enough to be turned on their edges, and dreſſed (i. e. until their inequalities are cut off) and, when they are dried, they carry them to the hacks (or places where they are rowed up like a wall of two Bricks thick, with ſome ſmall intervals between them, to let in the wind and air to dry them.) When the hack is filled, they cover them with ſtraw on the top, till they are dry enough to be carried to the kiln to be burnt.

Worlidge, and others after him, have laboured to excite Brick-makers to try their ſkill in making a new ſort of Brick, or a compoſition of clay and ſand, whereof to form window-frames, chimney-pieces, door-caſes, and the like. It is to be made in pieces faſhioned in moulds, which, when burnt, may be ſet together with a fine red cement, and ſeem as one intire piece, by which may be imitated all manner of ſtone work.

The thing ſhould ſeem feaſible by the earthen pipes made fine, thin, and durable, to carry water under ground at Portſmouth, and by the earthen backs and grates for chimneys, formerly made by Sir John Winter, of a great bigneſs and thickneſs.

In reality, much might be done towards making chimney-pieces, ſtone-mouldings, architraves, faſcias for fronts of buildings, and the like, if men of this profeſſion had a little tincture of chemiſtry, which would enable them to contrive ſome good compoſition of earth, and a proper way to manage it in the moulding, burning, &c. Might not even a compoſition, ſomething like common crockers earth, in ſome meaſure, anſwer the deſign? It is apparent, into whatever form the crockers put their earth, it retains it after drying and burning, although the crocks be very thin. If chimney-pieces, thus made in moulds, and dried and burnt, were not found ſmooth enough, they might be poliſhed with ſand and water: or, were care taken, when they were half dry, in the air, to have them poliſhed with an inſtrument of copper or iron, and then leave them till they were dry enough to burn, it is likely they would not want much poliſhing afterwards. The work might even be glazed, as potters do their fine earthen ware, either white, or of any other colour; or it might be veined in imitation of marble, or be painted with figures of various colours, which would be much cheaper, and perhaps equally durable, and as beautiful as marble itſelf. *Neve, Builder's Dictionary.*

BRICKS, or BRIQUES, in heraldry, are figures or bearings in arms, reſembling a building of Bricks; being of a ſquare form, like billets and tablets, from which they only differ in this, that they ſhew their thickneſs, which the others do not. *Coat. Dict. Herald.*

BRICKLAYER, an artificer whoſe buſineſs is to build with bricks, or make brick-work. See the articles BRICKS and BRICKLAYING.

Bricklayers work or buſineſs, in London, includes tiling, walling, chimney-work, and paving with bricks and tiles. In the country, it alſo includes the maſons and plaiſterers buſineſs. *Neve, Build. Dict.*

There is ſome diſpute, as to the point of priority, between the white maſon, or hewer of ſtone, and the red maſon, or hewer of bricks: ſcripture, it ſeems, favours the latter, making mention of making bricks, before any account of hewing or digging of ſtones. *Moxon's Mechan. Exerc.* See the article MASON.

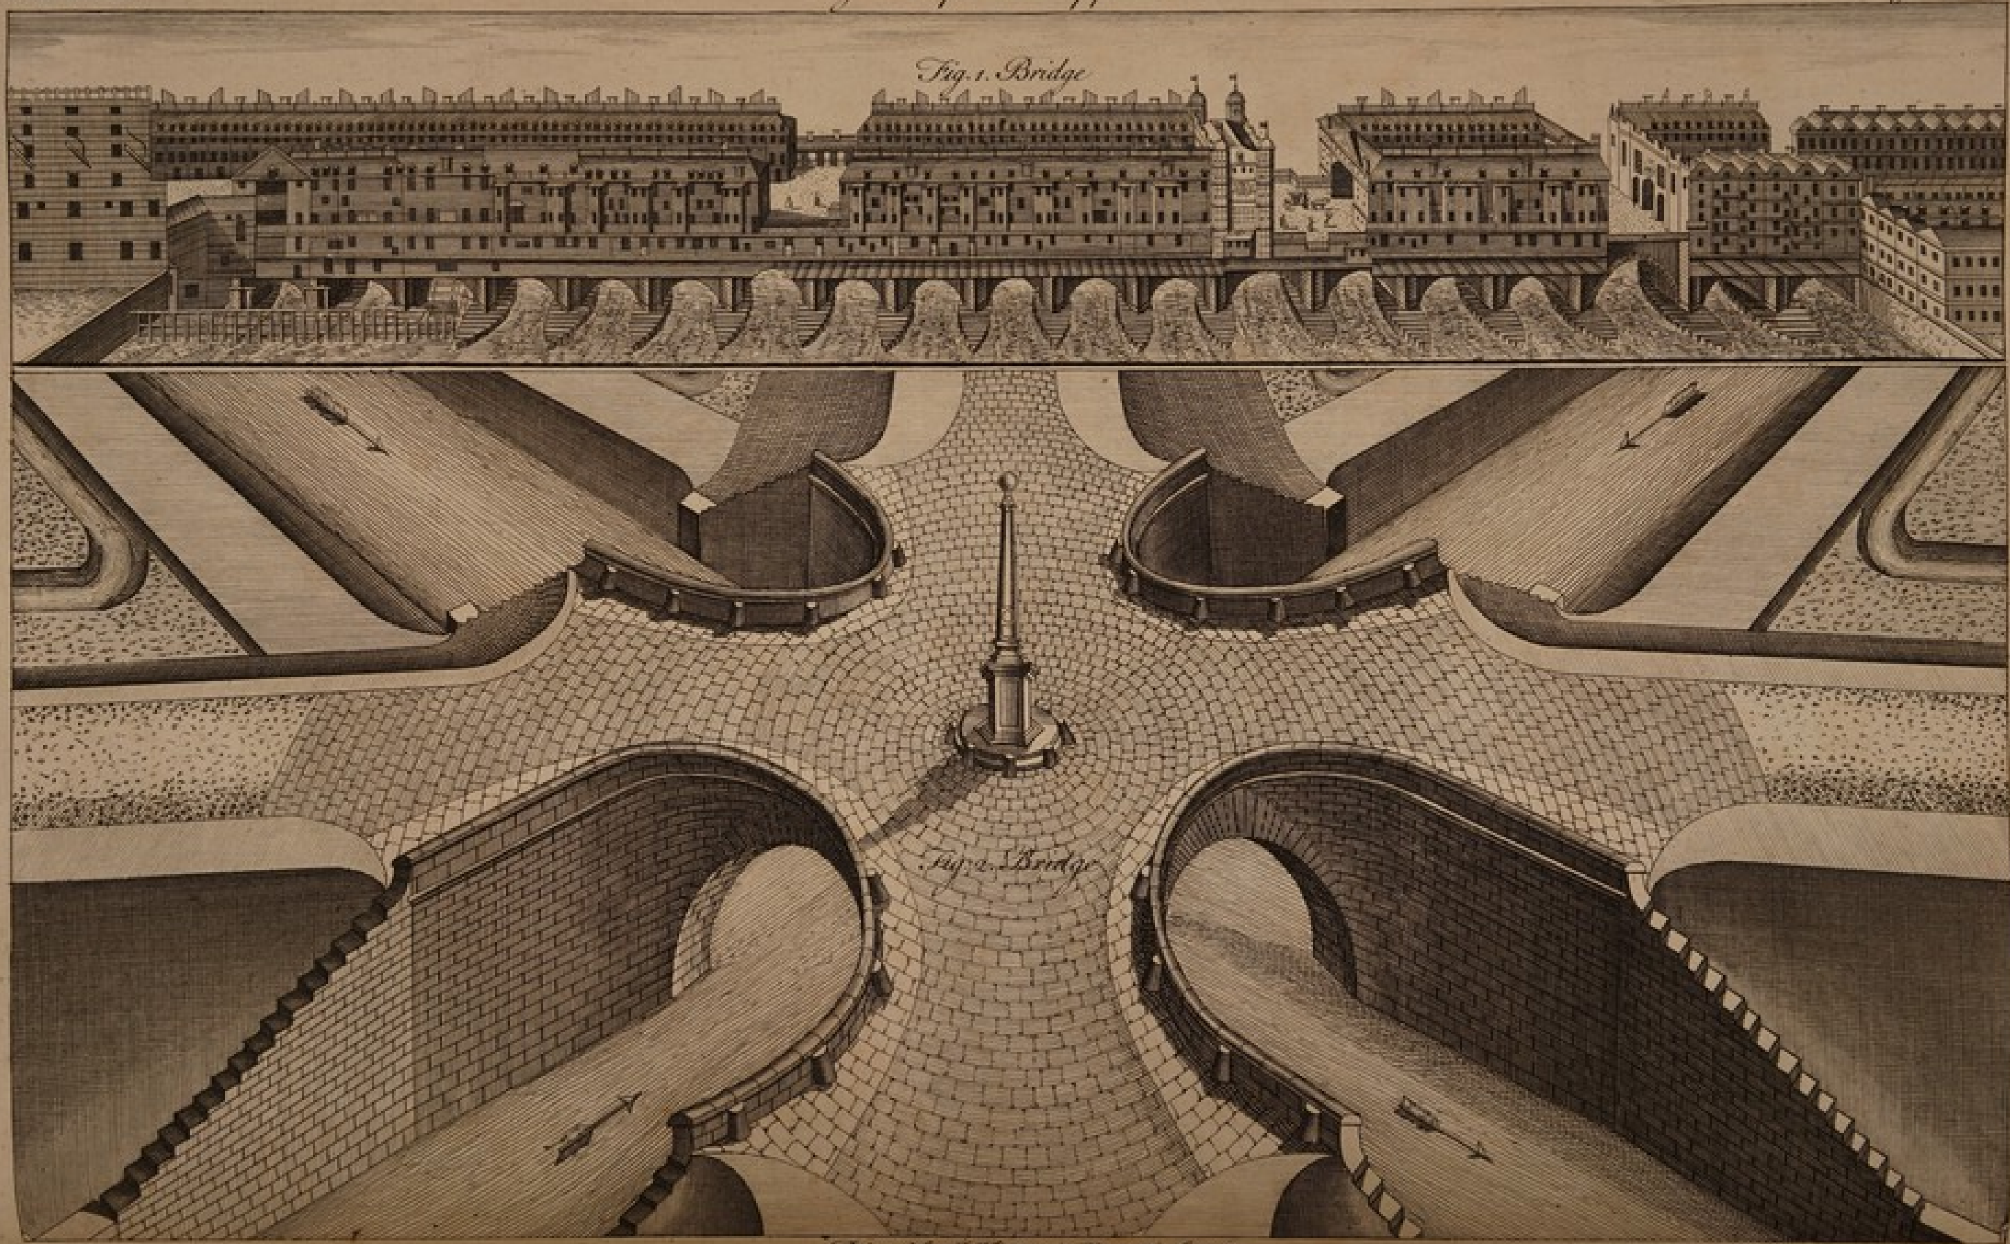
The materials uſed by Bricklayers, are bricks, tiles, mortar, laths, nails, and tile-pins.

Their tools are, a brick trowel, wherewith to take up mortar; a brick ax, to cut bricks to the determined ſhape; a ſaw, for ſawing bricks; a rub-ſtone, on which to rub them; alſo a ſquare, wherewith to lay the bed or bottom, and face or ſurface of the brick, to ſee whether they be at right-angles; a bevel, by which to cut the under ſides of bricks to the angles required; a ſmall trammel of iron, wherewith to mark the bricks; a float-ſtone, with which to rub a moulding of brick to the pattern deſcribed; a banker, to cut the bricks on; line-pins, to lay the rows or courſes by; plumb-rule, whereby to carry their work upright; level, to conduct its horizontal; ſquare, to ſet it off at right-angles; ten feet rod, wherewith to take dimenſions; jointer, wherewith to run the long joints; rammer, wherewith to beat the foundation; crow and pick-ax, wherewith to dig through walls. *Moxon, Ib. cit. p.* 245 *& ſeq.*

The London Bricklayers make a regular company, which was incorporated in 1568, and conſiſts of a maſter, two wardens, twenty aſſiſtants, and ſeventy-eight on the livery. *New View of London.*

Tilers and Bricklayers were incorporated, 10 Elizabeth, under the name of maſter and wardens, of the ſociety of freemen of the myſtery and art of tilers and Bricklayers.

PLATE VIII. *Engraved for the Supplement.* *Facing* Bridge



Printed for J. Hinton in Newgate Street.

The universal call for this trade is so well known to every one, that little need be said of it.

This, however, is to be observed, that it is mostly an out-door business, much exposed to the weather, by which they are often hindered from working.

As to the work itself, it is not very difficult to be learned, nor laborious (for they have labourers to do their heavy work) but handy and ingenious in contriving. With respect to the masters, most of them live handsomely: and some, who employ many hands, and undertake large works, commonly called master-builders, obtain good estates; but then they are such, who not only have money at command, but take great pains to qualify themselves for projecting, drawing plans, surveying and estimating buildings.

BRICKLAYING, the art of building edifices with bricks.

The following directions, with regard to the best method of laying bricks, have been recommended by experienced workmen.

1. Take care to procure good strong mortar. See the article MORTAR, *Dict. and Sup.*

2. If your bricks are laid in winter, let them be kept and laid as dry as possible. If they are laid in summer-time, it will quit cost, to employ boys to wet them; because, being wetted, they will unite much better with the mortar, than if they were laid dry, and will render the work much stronger.

But if it shall be objected, that, if the building be large, it will be a great deal of trouble to wet all the bricks, by dipping them in water; and also that it will make the workmen's fingers sore in laying them.

To prevent these inconveniences, water may be thrown on each course of bricks after they have been laid; as is said to have been done by the order of the ingenious Mr. Robert Hook, the surveyor at the building of the Physicians-college in Warwick-lane.

3. If bricks are laid in the summer-time, do not fail to cover them, to prevent their drying too fast; for, if the mortar dry too hastily, it doth not cement so firmly to the bricks as when it dries leisurely.

4. If the bricks are laid in the winter-time, take care to cover them well, to defend them from rain, snow, and frost; the last of which is a mortal enemy to all mortar, especially to all such as has taken wet just before the frost seizes it.

5. Take care that bricks be not laid joint in joint on the middle of walls, but as seldom as may be; but let there be good bond made there, as well as on the outsides: for some workmen, in working a brick and half wall, lay the header on one side of the wall, perpendicular on the other side of the wall; and so all along through; which, indeed, necessarily follows, from the unadvised setting up of the quoin at a toothing; for it is common to tooth in the stretching-course two inches with the stretcher only; and the header on the other side to be perpendicular over the header on this side; which causes the headers to lie joint in joint in the middle of the work.

Whereas, if the header on one side of the wall were toothed as much as the stretcher on the other side, it would be a stronger toothing, and the joints of the headers on one side would be in the middle of the headers of the course they lie upon on the other side.

All that can be pretended in excuse of this ill practice in working thus, is this: that the header will not hang two inches over the bricks underneath it.

This, indeed, is an objection: but yet the inconveniency may be avoided without much difficulty, viz. as follows: by having a piece of wood of the thickness of a course of bricks, and two inches broad, and laying it on the last toothing-course, to bear it; or a brick-bat, put upon the last toothing, will bear it till the next quoin is set upon it, and then the bat may be taken away.

6. The same inconvenience at an upright quoin in a brick and half wall; where it is usual to lay a closer next the header, on both sides of the walls; and, in so doing, it is joint in joint all the length of the wall, except, by chance, a three-quarter bat happen to be laid.

In order to avoid this inconveniency, and by that means to make the wall much firmer, lay a closer on one side; but lay a three-quarter bat on the stretching-course, and join a header next to the header at the quoin, in the heading-course.

7. Also, in two brick-walls, it will be the best way in stretching-courses, in which stretching is laid on both sides the walls next the line, to lay also stretching in the middle of the wall, and the closers next to each stretching-course which lies next the line.

BRIDGE (*Dict.*)— The ancients built many stupendous structures of this kind: and the remains of several of them over the Tyber are still to be seen at Rome.

The emperor Adrian caused the first to be built, which is the Pont Ælius, at present called Pont St. Angelo, or Angel's Bridge, the finest of all those that are at this day at Rome. It was called the Bridge Angelo, on account of an angel pretended to have been seen at the entrance of it. It was garnished on the upper part with a covering of brass, supported by forty pillars of the same.

The second was the Triumphal Bridge, of which the ruins are still to be seen in the river Tyber. Over this Bridge the emperors and consuls used to pass, when they had a triumph decreed them; which was at that time adorned with all imaginable art.

The third was the Pons Janiculensis, at present called Sixtus's-Bridge; because pope Sixtus IV. caused it to be rebuilt in the year 1475. This Bridge was antiently built of marble.

The fourth was that called Pons Cæstius; at present, St. Bartholomew's-Bridge; which was re-edified in the time of the emperor Vespasian.

The fifth was that named Fabricius, or Tarpeius; at present called Ponte Caspi, or Quatro Capi.

The sixth was the Senatorian, or Palatine Bridge, now called Sancta Maria.

The seventh was the Pons Horatius, or Sublicius; one of the finest Bridges of Rome, and of which the ruins are still to be seen in the Tyber, and which has not yet been re-edified.

An Italian author in his works concerning the antiquities of the city of Rome, has given a full account of the elevation, &c. of this celebrated structure.

The figure of it seems extraordinary and fantastical: to see a second Bridge raised over a first, and, in a like work, columns and other ornaments of architecture over that; so that it appeared more like a triumphal arch, or portico, than a Bridge. This Bridge was demolished in the reign of the emperor Otho, but rebuilt by Antoninus Pius.

The eighth and last was that without the city of Rome, and about two miles distant; which was called Milvius, in the Flaminian Way.

Besides these Roman Bridges, we have modern ones, which are not without their merit.

Among those of France, may be reckoned those of Avignon, of Saint Esprit, and of Lyons upon the Rhone. The first of these is demolished; there remaining only some arches on the side of Avignon.

The second is still subsisting, and may be said to be one of the finest Bridges in the universe. One thing particular in these three Bridges, is, that their plan is not in a straight line, especially those of Avignon and Saint Esprit.

The angle is little sensible in that of Lyons, but nevertheless perceivable; and is on the upper side of the stream.

But, as for the two preceding, it is certain, that they have an angle, or a sort of bending, the convexity of which opposes the waters of the Rhone, as though being by this disposition centered, and are bouted, the better to resist the weight and current of the waters.

The Bridge of Avignon was composed of eighteen arches, in length one thousand three hundred and forty paces, making about five hundred fathoms. It was begun in the year 1176, and finished in 1188.

The schism between Benedict and Boniface was fatal to it in the year 1385; but a greater calamity happened to it in the year 1602, by the negligence of repairing one arch fallen down, which caused the fall of three others. In fine, in the year 1670, the cold was so violent, that the Rhone was frozen so as to bear waggons with the heaviest loads for several weeks; and, upon the thaw happening, such mountains of ice dashed against the piers, as shook them, and caused several arches to fall down.

But, nevertheless, the third pile on Avignon side, with the chapel of St. Nicholas built upon it, has always borne up against all accidents.

Pont Saint Esprit is finer and more bold than that of Lyons, or Avignon: it consists of nineteen great arches, besides seven smaller ones. It has arches from fifteen to twenty fathoms, opening, rather more than less, which make the length of the Bridge upwards of four hundred fathoms.

The Bridge of Lyons, upon the Rhone, has twenty arches. It is observed farther of these Bridges, that they are defended by towers to secure the passages.

Among the fine Bridges of France, are reckoned the Pont Royal of the Thuilleries, that of Tolouse upon the Garonne, and one arch of Pont-Neuf at Paris.

But the most famous Bridge in France is that of four arches built on the section of two navigable canals, and may be looked upon as a very great improvement in architecture.

This famous Bridge is situated on the section of the canals of Calais and Ardres, on the new road between Calais and St. Omer. By its ingenious contrivance it has centered to a single point the navigation of four different canals, the passage of a great road, and the communication of the four principal parts of the country, which, before the building of it, were separated, and could not be joined without making several Bridges, whereas this alone answers the end. The eight banks of these canals, besides the use in drawing of the boats, serve likewise for the conveniency of carriages to and from the adjacent parts, and one may perceive twelve different ways leading to the center of the Bridge which facilitates the commerce and the carriage of provisions to the neighbouring towns, as well as for carrying manure, &c. to the lands; whereas, before, the farmers were obliged to transport their

grain,

grain, and to be at annual expences and great losses, by loading and unloading their commodities at different places.

The invention of this Bridge is owing to M. Barbier, engineer of Bridges and causeys, who contrived it in 1747, when he was impowered by the generality of Picardy for carrying on works of this kind.

The court having approved of his plan, the execution of it was committed in 1750 to M. Bessara, engineer in the same generality, who brought it to its present perfection. See a perspective view of this celebrated Bridge, *Plate* VIII. *fig*. 2.

This Bridge is formed of four circular arches, over which rises a vault, and over the center a semi-spheroid vault, one and twenty feet high, which is penetrated with the four arches for the passage of boats, &c.

England can boast of several fine Bridges, particularly that over the Thames at Westminster; a full account of which we have given under the article BRIDGE, in the Dictionary.

London-Bridge was begun in the reign of Henry II, in the year 1176, and finished in the reign of king John, in the year 1209. Since that time, it has been divers times burnt, and ruined by ice, and as often repaired, or re-built. The king and the city contributed to the charge. This Bridge is made of hewn stone: it has nineteen arches of a hundred and twenty-five fathoms, Paris measure, or eight hundred feet long, and thirty or twenty-eight feet and one eighth broad. Some say sixty or fifty-seven feet one quarter; for the London foot is fourteen sixteenths of that of Paris. In height, on the two sides of the Bridge, are built two rows of stately houses; and a considerable fund is settled for the maintaining it. This Bridge is continually assaulted by the flux and reflux of the tide. Large vessels, which come up to the Thames, do not go above the Bridge; but small ones pass through it. Its piers are perfectly well guarded by starlings. See a perspective view of this structure, *Plate* VIII. *fig*. 1.

When any one projects a Bridge, he ought to begin,

1. With making an exact local plan; which plan shall precisely lay down the extent of the water, the sands, if it has any, the banks, or brinks of the river, and the ways or streets that abut upon this Bridge.

2. He must project upon this plan the Bridge designed, whether of masonry, or carpentry; with the number of arches, and quantity of piles, bays, or joists. He must always lay down the Bridge over the river upon the square, and never slanting.

3. He must, upon this plan, trace a line which shall cut the Bridge in the middle, and there found the depth of the water from fathom to fathom, or from two to two, or from three to three, according as there shall be occasion.

This founding is to be made either by a pole, divided into feet, at the end of which is a leaden weight, according as the current of the water shall require.

If this shall not be sufficient, he must make use of a cannon-ball, put into a little bag, tied to the end of a cord, which has been before divided into feet and fathoms.

He must make use of these, or other methods, which shall be found to be most proper, according to the rapidity of the water that is to be surmounted.

All this is to be done by means of a boat, which may be conducted in different manners; either by a cable, which is carried a-cross the river, or by other cords made fast to trees, or stakes on the bank, or to stakes drove down for that purpose; round which the cable that is to hold it is to be many times turned, and slackened, according as occasion requires, to guide the boat more to one side than the other.

4. The foundings of the water being made, and set down on the plan, they serve for making a profile of the river, which marks or sets out the depth of the water that has been found; and the line under the water, whether it be sandy or rocky, to which attention must be given, marking the difference on the profile.

Upon this profile is marked by a line the depth of the water, at the lowest it is at any time of the year, which the Bridge-masters of great and navigable rivers will acquaint you with; and the peasants or inhabitants of the neighbouring places to small rivers will inform as to the height of those inundations, which have happened in their memory.

These may also be drawn in the profile, which shall shew the a mean of the height of the waters.

All these lines being drawn by a perfect level, parallel the one to the other, may be washed with a water colour.

5. The profile being thus raised, a founding-iron may be made, of a convenient length, for founding below the depth of the water, the ballast, or sand; and no certainty can be attained till this is done, and the depth of the water be known: and, in order to this, there are two methods used, either by a founding instrument of iron, made on purpose, having a large ring at its head for a crowning, cross which there goes the arm of a borer, larger or smaller, in order to turn it with; and having at the top a head to be driven down, to make it enter till it comes to a firm bottom below the sands.

This founding-iron is made pointed and barbed at the end with four angles; so that being bored or forced through the sand or part of the rock, or solid ground, that it meets with below the sand, by being turned several times, in order to bring up in the hollows of the barbs some small quantities of the solid ground it meets with, and thus being drawn up, the quality of it is to be entered down in the memorial that is provided for this purpose, in order to know what kind of ground the bottom is.

There are instruments for founding of another sort, which have a little pocket in the form of a snail-shell at the end in the shape of a borer, which receives nothing but sand in turning one way, and the earth under the sand by turning it the other.

These founding instruments must be all of one piece, that they may be as strong as possible; sometimes they are adjusted according to the hardness or easiness of the ground to be penetrated; sometimes they are of no use, especially when the sand is too gross, and meets with flints that the founder cannot remove.

In this case, they make use of a stake of oak made round, of the straightest piece of a tree of three, four, five, or six inches diameter; which having determined to what depth of the earth they would found, they arm with a lardoir, or pointed iron at the end, for removing the flints; with a ferrel at the head, to be able to resist the strokes of a beetle with two or three helves, with which the founder is driven down.

All this requires a great deal of pains, care, and expence too; but the satisfaction of doing the work well, and making a faithful relation of it on the profile, of the depth of the sand or gravel that is to be piled, or which ought to be removed for the foundation of the piles, in order to settle the dams necessary, will make amends for them; and, so long as a person is ignorant of the depth, he can neither project a Bridge, nor know how to compute the expence, since he cannot tell what timber it will take up, nor what precautions ought to be taken for securing the work.

6. When a knowledge of the consistence of the ground has been obtained, as whether sand, earth, rock, &c. then a person may proceed with safety upon the profile he has made, to lay down the projection of the Bridge, whether of masonry or carpentry; then the length and thickness of the piers and piles may be known, according as the foundation must be more or less in depth.

7. This being done, and the height of the highest inundations being known by the information of the oldest neighbouring inhabitants, marks are to be made at this height; and supposing three feet upwards to be the intradosse, or inward face of the arches of the Bridge that one would lay down a projection of, and also the bays, joists, beams, &c. of a wooden Bridge, which is the same: the work may be so regulated, that it may be known to what height the greatest inundation will rise, and to what depth the foundation of the piles, &c. must be carried.

8. The next thing to be done, is to provide the materials which are to be employed in the work.

For a stone Bridge. It ought to be considered from whence the free-stone may be had, its distance, the easiness or difficulty of cutting it, its carriage, its nature, as to its being strong or weak, in regard to the effort it is to sustain, being pressed by the reins of the arches, if it will be able to sustain the weight; for there are some stones so tender, especially having been but lately taken out of the quarry, as one may say bleeding, that they will crack, split, or shiver to pieces.

As to the lime, it is to be considered from whence that is to be had, its nature, and when it takes hold, whether as soon as it is used, or a long time after; the wages of workmen, the cheapness and conveniency of having provisions, the conveniency of the place, and number of the workmen required to finish the work in a certain time, before the rains of autumn, which make rivers overflow; and many precautions are necessary to be taken, that cannot well be enumerated.

For a Bridge of carpentry. The builder must inform himself from whence the timber must be had: if it be found and good; the time for procuring it; the charge of it, as to what it will cost, laid down at the place; what quantity must be fashioned for piles, and what for centers, scaffolding, &c. that all the materials may be ready in time, to begin the work without hindrance, and to be able to finish it before the contrary seasons for the compleating of the Bridge commence. See PLANS *of Bridges*.

BRIGA'DE-*Major*, in the military art, an officer chosen from among the most ingenious and expert captains. Brigade-majors are to wait, at proper times, to receive the word and orders which they carry first to their brigadier, and afterwards to the adjutants of regiments at the head of the Brigade, where they regulate together the guards, parties, detachments, and convoys, and appoint them the hour and place of rendezvous at the head of the Brigade, where the Brigade-major takes and marches them to the place of the general rendezvous. A major of Brigade ought to keep a roll of the colonels, lieutenant-colonels, majors, and adjutants, belonging to the Brigade. When a detachment is to be made, the major-

major-general of the day regulates with the Brigade-majors, how many men and officers each Brigade shall furnish; and they again with the adjutants of the regiments, how many each battalion is to send, which the adjutants divide among the companies. The complements each regiment is to furnish, are taken by the adjutant at the head of each regiment, at the hour appointed, who delivers them to the Brigade-major at the head of the Brigade, who again delivers them to the major-general of the day, and he remits them to the officer who is to command the detachment. *Vide Bland's Milit. Discipl.*

BRI'MSTONE-*Marble*, a preparation of brimstone in imitation of marble.

To do this, you must provide yourself with a flat and smooth piece of marble; on this make a border or wall, to encompass either a square or oval table, which may be done either with wax or clay. Then having provided several sorts of colours, as white-lead, vermilion, lac, orpiment, masticot, smalt, Prussian blue, &c. melt on a slow fire some Brimstone, in several glazed pipkins; put one particular sort of colour into each, and stir it well together; then, having before oiled the marble all over within the wall, with one colour quickly drop spots on it, of a larger and less size; after this, take another colour and do as before, and so on, till the stone is covered with spots of all the colours you design to use. When this is done, you are next to consider what colour the mass or ground of your table is to be; if of a grey colour, then take fine sifted ashes, and mix it up with melted Brimstone; or, if red, with English red oker; if white, with white-lead; if black, with lamp or ivory-black. Your Brimstone for the ground must be pretty hot, that the coloured drops of the stone may unite and incorporate with it. When the ground is poured even all over, you are next, if judged necessary, to put a thin wainscot board upon it: this must be done while the Brimstone is hot, making also the board hot, which ought to be thoroughly dry, in order to cause the Brimstone to stick the better to it. When the whole is cold, take it up, and polish it with a cloth and oil, and it will look very beautiful. *Smith's Laboratory.*

BRIMSTONE *Medals, Figures*, &c. are cast in the following manner: melt half a pound of Brimstone over a gentle fire; with this mix half a pound of fine vermilion, and, when you have cleared the top, take it off the fire, stir it well together, and it will dissolve like oil; then cast it into the mould, which must first be anointed with oil. When cool, the figure may be taken out; and, in case it should change to a yellowish colour, you need only wipe it over with aqua-fortis, and it will look like the finest coral.

BRINE-*Pans*, the pits wherein the salt water is retained, and suffered to stand, to bear the action of the sun, whereby it is converted into salt.

There are divers sorts of salt-pans, as the water-pan, second-pan, sun-pan; the water being transferred orderly from one to another. *Coll. Disc. of Salt and Fish.*

BRINE-*Pit*, in salt-making, the salt spring from whence the water to be boiled into salt is taken. There are of these springs in many places; that at Namptwich in Cheshire is alone sufficient, according to the account of the people of the place, to yield salt for the whole kingdom; but it is under the government of certain lords and regulators, who, that the market may not be overstocked, will not suffer more than a certain quantity of the salt to be made yearly. *Ray's Engl. Words.* See the article PIT.

Leach-BRINE, a name given to what drops from the corned salt in draining and drying, which they preserve and boil again; being stronger than any Brine in the pit. *Hought Collect.*

BRI'STLE, the strongest hair standing on the back of a hog, or a wild boar.

Hog Bristles are put to several uses, particularly in making several sorts of brushes: they are commonly sent in barrels or hogsheads, in parcels of several sizes, which are sold by weight. Wild boar's bristles are much stronger than hog's, and are much more valued, but then they are also much dearer. Shoemakers, harness-makers, sadlers, and others, use them, putting one of them as a needle or awl at the end of their thread, to sew their work.

There is a great deal of this commodity imported from Muscovy and Livonia, by the way of Hamburgh and Holland; whence it is sent away in small parcels tied in the middle, and put in little deal boxes about a foot long, and two or three inches broad: it is commonly sold by weight.

Bristle, both of hogs and wild boars, is part of the ironmongers trade in France, who buy it by wholesale, and sell it by retail, to such workmen as make it into brushes, &c. or have occasion for it in their own way of business.

BRITA'NNICA, in the materia medica of the ancients, the name of a plant described as having leaves of a dark colour, very large, and in shape resembling those of the common wild dock, but somewhat hairy, and of an astringent taste; the root small and slender, and the stalk not large. This is the description of Dioscorides, who attributes to its inspissated juice great virtues, as an astringent, and a remedy for ulcers of the mouth and tonsils; and Pliny acquaints us of its prodigious efficacy in a distemper attending the army of Germanicus, who, when they had crossed the Rhine, encamped in a place where there was only one spring of water, the drinking of which affected them in a terrible manner in their mouths, and made their teeth drop out; and that the physicians, who called the disease stomacace and scelotyrbe, were at length directed to a remedy by the Frisians who were in their camp, which was the herb Britannica.

The virtues attributed to this plant are observed by the later physicians to agree very well with those of the hydrolapathum majus, or great water dock, a plant produced very abundantly with us, but at present neglected in the practice of physic; and Muntingius, who has written professedly of the Britannica of the ancients, is persuaded that this is the true and genuine plant. He by no means countenances the opinion of its having its name from the island of Britain, but deduces it from a very expressive phrase in the Frisian language, in which brit signifies to consolidate, tan a tooth, and ica loose; so that it plainly had its name from its virtues of fastening the teeth, when loosened in the mouth by distemperature. Every part of the herb is powerfully astringent, and the root, which is its most efficacious part, is very serviceable in hæmorrhages of all kinds, and in whatever disorders the cold astringents are required in. It is said also to be very useful in nervous complaints; and is very powerful in the cure of quinsies, inflammations of the tonsils, and almost all the disorders of the mouth and throat, and is by some esteemed a specific in the scurvy.

Its leaves are styptic, and bitter to the taste, and strike a strong red upon blue paper; the root has the same effect, but in a more remiss degree. The bark of it is of a flesh colour, and streaked, and the heart of a pale yellow. Experience confirms its efficacy in some disorders of the mouth; the chewing it in a morning having been found an effectual remedy for the bleeding of the gums. *Muntingius de vera Herba Britan.*

BRIZE-*Vents*, or BRISE-*Vents*, a kind of shelters used by gardeners, who have not walls on the north side, to keep the cold winds from damaging their melon beds.

BROAD-SIDE, in the sea language, a discharge of all the guns on one side of a ship at the same time.

BROCATE'LLE, a slight stuff made with cotton, or coarse silk, in imitation of brocades. There are some all of silk, and others also of wool. That which was manufactured at Venice was always the most valued.

They also give the name of Brocatelle to another sort of slight stuff, which is otherwise called ligature, or mezeline.

There is also a kind of marble, called Brocatelle.

BRO'CCOLI, among gardeners, the shoot of a sort of cabbage. There are several sorts of it, the Roman, the Neapolitan, and the black; but the Roman is far the best, and is therefore the only sort now in use.

The seeds of this should be sown about the middle of May, in a loose moist soil, when the young plants have eight leaves: they are to be transplanted, and set three inches distant; and, when they have grown there till the middle of July, they will be fit to plant out for standing. They must be now set in some well-sheltered ground, but not under the drip of trees, and at a foot and an half distance from one another. The soil should be light, and, about the beginning of December, they will begin to shew their heads, which look somewhat like a cauliflower; from this time they will continue eatable to the end of March. When the heads divide, and begin to run up, they are to be cut, with about four inches of the stem to them; and, when these are cut off, about a month's time furnishes a fresh crop from the same stock. They are to be stripped of their outward skin, and boiled; and, when perfectly fine, they are very little inferior to asparagus. The best way to have them fine, is to get fresh seed every year from Italy; for they are very apt to degenerate. *Miller's Gard. Dict.*

BRO'KER *(Dict.)*—The Broker's profession is very necessary in commerce, and renders it more easy, especially in towns of great trade, there to have persons of a good understanding, well known and esteemed amongst the merchants, workmen, and tradesmen, to give them notice where they may meet with the merchandizes they may have occasion for, or with the materials proper for their several works, or for their manufactures, and to find for those who have manufactured any wares, or who would sell them, persons ready or willing to buy or barter them.

We may distinguish, as it were, two sorts of Brokers; the one who may be called simply Brokers of merchandizes, and the other Brokers of manufactures, workmen, and tradesmen.

Their functions are alike; that is to say, they all contrive to make people buy, sell, or barter, for the sake of their commission, or brokerage; but the object of their functions is, in some manner, different, the former facilitating between merchants the sale of the merchandizes which they have bought by wholesale, or which the foreign merchants bring to market; and the latter applying themselves only to procure to the manufacturers, workmen, and artificers, the materials proper for their several manufactories, or works; or to afford them opportunities and means for selling the stuffs, and other merchandizes, they have worked.

Stock BROKERS are those who are employed to buy and sell shares in the joint stock of a company, or corporation.

As the practice of stock-jobbing has been carried to such an excess, as became not only ruinous to a great number of private families, but even affected, or at least might soon affect, even the public credit of the nation, the legislature thought fit to put a stop to it, or, at least, to bring it within certain bounds, and under some regulation; and, therefore, the following act was passed:

By statute 7 George II. cap. 8. sect. 1. All contracts, upon which any premium shall be given for liberty to put upon, deliver, accept, or refuse, any public stock, or securities, and all wagers, puts, and refusals, relating to the present or future price of stocks, or securities, shall be void; and all premiums upon such contracts, or wagers, shall be restored to the person who shall pay the same, who shall be at liberty, within six months from the making such contracts, or laying such wager, to sue for the same, with double cost; and it shall be sufficient therein for the plaintiff to alledge, that the defendant is indebted to the plaintiff, or has received to the plaintiff's use the money, or premium, so paid, whereby the plaintiff's action accrued, according to the form of this statute, without setting forth the special matter.

Sect. 2. Persons who, by this act, shall be liable to be sued, shall also be obliged to answer, upon oath, such bill as shall be preferred in equity, for discovering any such contract, or wager, and the premium given.

Sect. 3. Provided that the plaintiffs, relators, or informers, in such bill, give security to answer cost.

Sect. 4. Every person who shall make any such contracts, upon which any premium shall be given, for liberty to put upon, deliver, accept, or refuse, any public stock, or securities, or any contracts in the nature of puts and refusals, or shall lay any such wager (except such who shall, bona fide, sue, and, with effect, prosecute, for the recovery of the premium paid by them; and except such who shall voluntarily, before suit commenced, repay, or tender such premium, as they shall have received; and also except such who shall discover such transactions in any court of equity) shall forfeit 500 l. and all persons negotiating, or writing, such contracts, shall likewise forfeit 500 l. which penalties may be recovered by action of debt, or information, in any of his majesty's courts of record at Westminster, one moiety to his majesty, and the other moiety to them who shall sue for the same.

Sect. 5. No money, or other consideration, shall be voluntarily given, or received, for compounding any difference for the not delivering, or receiving, any public stock, or securities; but all such contracts shall be specifically executed; and all persons, who shall voluntarily compound such difference, shall forfeit 100 l. one moiety to his majesty, and the other moiety to them who shall sue for the same.

Sect. 6. No person, who shall sell stock, to be delivered and paid for, on a certain day, and which shall be refused, or neglected to be paid for, shall be obliged to transfer the same; but it shall be lawful to such persons to sell such stock to any other, and to receive, or recover from the person, who first contracted for the same, the damage which shall be sustained.

Sect. 7. It shall be lawful for any person, who shall buy stock, to be accepted and paid for on a future day, and which shall be refused, or neglected to be transferred, to buy the like quantity of such stock of any other person, at the current market-price, and to recover and receive, from the person who first contracted to deliver the same, the damage sustained.

Sect. 8. All contracts which shall be made for the buying, or transferring, of stock, whereof the person, on whose behalf the contract shall be made to transfer the same, shall not, at the time of making such contract, be actually possessed in his own name, or in the name of trustees, shall be void; and every person on whose behalf, and with whose consent, any contract shall be made to sell stock, whereof such person shall not be actually possessed in his own name, or in the name of trustees, shall forfeit 500 l. and every broker, or agent, who shall negociate such contract, and shall know that the person on whose behalf such contract shall be made, is not possessed of such stock, shall forfeit 100 l.

Sect. 9. Every person, receiving brokerage in the buying or disposing of stocks, shall keep a Broker's book, in which he shall enter all contracts that he shall make, on the day of making such contract, with the names of the principal parties; and such Broker, who shall not keep such book, or shall wilfully omit to enter any such contract, shall forfeit 50 l.

This act was made perpetual, 10 George II. cap. 8.

Piece-BROKERS, a sort of petty dealers in drapery, who sell fragments or remnants of cloths, stuffs, silks, and the like, at under-price.

BRO'KERAGE, or brokage, the fee or commission paid to a broker for his trouble in negociating business between person and person.

BROKERAGE. Thus they call at Bourdeaux a duty which is raised on all sorts of merchandizes, of what nature soever they be, which are either imported, or exported, by sea, in that city; except, however, those merchandizes, on which new duties are laid; on these Brokerage is raised, when it is said in the decrees, edicts, or declarations, that those merchandizes shall pay no other duties, but those laid upon them in the said decrees, edicts, or declarations.

BRO'NTLÆ, among naturalists, a kind of figure stones, commonly hemispherical, and divided by five pointed zones.

The word is formed from the Greek βροντη, thunder, alluding to the popular tradition, that those stones fall in thunder-showers; whence they are also denominated thunder-stones, sometimes polar stones, fairy-stones, and also ombriæ, by naturalists.

BRO'NZE, a factitious metal, chiefly used for the casting of statues and figures.

The word is French, where it is used more extensively, so as to include all the compositions of brass or copper, as for guns, bells, pots, or the like.

It is formed from the Italian Bronze, which signifies the same. Copper medals are frequently called medals of Bronze.

The composition of Bronze is different; for the finest statues, the mixture is half copper and half brass, or latten. The Egyptians, whom some make the inventors of the art, used two-thirds brass, and one-third copper.

BRONZE also denotes a colour prepared by the colour-men of Paris, wherewith to imitate Bronze.

There are two sorts, the red Bronze, and the yellow or golden. The latter is made solely of copper-dust, the finest and brightest that can be had; in the former is added a little quantity of red oker, well pulverized. They are both applied with varnish. To prevent their turning greenish, the work must be dried over a chafing-dish, as soon as bronzed.

BROO'DING, the act of an hen, or other bird, sitting on a number of eggs, to keep them warm, till they hatch or produce young ones.

BROOM, a medicinal plant, growing plenteously on heathy grounds, and producing a yellow flower; reputed to be nephritic, hepatic, and splenetic; and, as such, used to bring away gravel, and against cachexies and dropsies.

It roots deep, and, shedding no leaves, is continually sucking the moisture from the earth. The best method of destroying it, is the burning the land, then plowing it deep, and manuring it very well with dung and ashes; the spreading on the land chalk or marle, or the manuring it with urine. If the ground be designed for pasture-land, it is best to cut it close to the ground in May, when the sap is strong in it. By this artifice, the roots are destroyed; whereas, in the common way of pulling up the young plants, some strings will be left, and the least of these will grow. Foddering of cattle upon broomy land is one very good way of destroying the Broom, their urine killing the roots, and their treading the land making it less proper for the roots of this plant; for the Broom is never observed to grow in trodden places. This troublesome and pernicious plant is not, however, without its use to the farmer; for, when well laid, it will make an excellent and lasting kind of thatch for barns.

BROOM-*Gall*, in natural history, a name given by authors to a remarkable species of galls found on the genista vulgaris, or common Broom.

BROWN, a dusky kind of a colour, inclining somewhat towards redness.

Dyers distinguish divers shades and gradations of Brown, a sad Brown, London Brown, clove Brown, purple Brown, walnut-tree Brown, &c.

Spanish Brown is a dull red colour, used by house-painters, chiefly for priming, as being cheap and easy to work.

BRUSH, an assemblage of hairs or hog's bristles, fastened in the holes of a wooden handle or board, pierced for that purpose, serving to cleanse divers bodies by rubbing therewith.

Sherman's BRUSH is made of wild boar's bristles, and serves to lay the wool or nap of cloths, after sheering it for the last time.

The manner of making Brushes, is by folding the hair or bristle in two, and bringing it, by means of a packthread, which is engaged in the fold, through the holes wherewith the wood is pierced all over, being afterwards fastened thereon with glue. When the holes are thus filled, they cut the ends of the hair, to make the surface even.

BRUSH, among painters, a large and coarse kind of pencil, made of hog's bristles, wherewith to lay the colours on their large pieces.

BRUSHES for painters are of divers shapes and sizes, some round, others flat; the latter chiefly used for drawing lines, and in imitating olive and walnut work.

Plaisterers have three kinds of implements wherewith they apply their plaister and white-wash on walls, viz. stock-brushes, round Brushes, and pencils. *Moxon, Mechan. Exerc.* See the article PLAISTERING.

Wire BRUSHES are used by silver-smiths and gilders, for scrubbing silver, copper, or brass pieces, in order to the gilding them.

BRUSH *Iron-ore* signifies a kind of ore full of striæ, resembling the hair of a brush.

BRUTE, an animal destitute of the faculty and use of reason.

The common opinion of the untaught and unprejudiced part of mankind seems to be, that the brutes have sense, imagination,

nation, memory, and passion, but that they are void of understanding and reason; that is, in the language of philosophers, they have the inferior faculties of the soul, but not the superior. Nor will the distinction appear groundless to those who attend to the difference between the objects of the mind, and its acts about those objects; as also to the difference between the confused and distinct comprehension of any thing. How great a difference therefore is there between the faculties of Brutes, and those of even a child, who can speak, reckon, and perform the operations of arithmetic? Some philosophers gravely tell us, that Brutes want speech to express themselves; and assign this as a cause of their seeming want of understanding. But will not a parrot, brought up in a nursery with children, learn to pronounce words sooner than they; but will he, therefore, also learn to express his thoughts, reckon, &c? Ought we, therefore, to say, that Brutes cannot speak? It is true, Brutes do many things, from some principle incomprehensible to us, although there are instances of a like principle in man; but it does not follow, that this principle is understanding and reason. A bee does not make honey, nor does an infant suck from reason. The like may be said of many other actions of Brutes, as building their nests, &c. What the true principle of such actions is, may, perhaps, be beyond the power of human faculties to comprehend. But, whatever it be, it is far from putting Brutes on a level with man. The difference is immense; and those who, in other respects, admit of insensible gradations from one order of beings to another, must own there is a vast chasm between man and the most perfect Brutes. Mr. *Buffon's Hist. Natur.*

BU'BALUS, *the buffalo*, a sort of wild bull, very common in many parts of Europe, and in the pope's territories, kept tame, for the sake of the milk of the female, of which the famous cheeses, called case de cavallo, are made. They are also commonly employed in the affairs of husbandry, and have, for this purpose, a brass or iron ring put through their noses, and, by means of a rope, or thong of leather, put through this, they are managed at pleasure; though, if ever so well tamed, they usually keep something of their native fierceness.

The buffalo is about the bigness of an English calf six months old, and pretty much like our English bull, excepting that it hath very short horns, and a bunch or rising on its back between the shoulders. See *plate* XIII. *fig.* 3. *Edwards's Hist. Birds.*

BU'BBLES (*Dict.*)—The black spots at the top of the water-bubble, and, in the middle of the object glasses, compressed together, are always surrounded by a multitude of concentric rings of all sorts of colours; and, as the colour in every ring is the same quite round its circumference, and different in different rings, so it is manifest (from the spherical figure both of the object-glasses and of the Bubbles of water, and from the uniform gravity of the particles of the water subsiding gradually on all sides from the top to the bottom) that the thicknesses, both of the plate of air between the glasses and of the water-bubble, are also the same in every part of the same ring, and different in different rings; which shews that the particular colour of any ring depends upon a particular thickness of the plate of air, or shell of water, where the incident light of the open air is reflected to the eye. Rings of colours do also appear by light transmitted through the water-bubble, and through the object-glasses, held between the eye and the light; but their colours are different from those that appear in the same places, by reflected light.

These are the general appearances of the rings in the open air; but, when homogeneal light is cast by a prism upon the object-glasses in a dark room, the colour of all the rings, seen by light reflected from the glasses, is the same as of the light thrown upon them; and in the intervals between the coloured rings other dark rings appear like the spot in the middle; through all which the incident light is transmitted, and forms other intermediate rings of the same colour upon a white paper held behind the glasses, as represented in *plate* XI. *fig.* 1. It is also to be observed, that the diameters, breadth, and intervals of rings of homogeneal lights, of different colours, are all different; those made by homogeneal red being the largest, and by homogeneal violet the least; and those of intermediate prismatic colours are of intermediate sizes. And from hence the origin of the different-coloured rings in the open air is manifest; namely, that the air between the glasses, according to its various thickness, is disposed in some places to reflect and in others to transmit the light of any one colour; and in the same place to reflect that of one colour where it transmits that of another. The appearances are the same when water is between the object-glasses, only the rings are smaller.

BUBBLES, a cant term, given to a kind of projects for raising money on imaginary grounds, much practised in France and England about the years 1719, 1720, and 1721.

The pretence of these schemes was the raising a capital for retrieving, setting on foot, or carrying on, some promising and useful branch of trade, manufacture, and machinery, or the like. To this end, proposals were made out, shewing the advantages to be derived from the undertaking, and inviting persons to be engaged in it. The sum necessary to manage the affair, together with the profits expected from it, were divided into shares, or subscriptions, to be purchased by any disposed to adventure therein.

BU'BO, in zoology, a name used by some for the owl in general, but, by the more accurate naturalists, appropriated to the great horn-owl, called also, in some places, the eagle-owl. Some authors have described three species of this bird; but they seem to be only varieties of the same species, according to the difference of age, sex, and other accidents.

BUCARDI'TES, *or bucardia*, in natural history, a name given by many authors to a stone, in some degree resembling the figure of an ox's heart.

It is usually of the substance of the coarser stones, and is no other than a quantity of the matter of such stones received, while moist, into the cavity of a large cockle; the cardo or hinge of this shell making a long and large dent in the formed mass, which gives it a heart-like shape.

BUCA'RDIUM, in natural history, a name given by authors to a kind of heart-shell, resembling an ox's heart in shape; it is of the genus of the cordiformes, or heart-shells, and differs from the other kind, in being of a more globular figure.

BU'CCINUM, *the trumpet-shell*, in natural history, the name of a large genus of shells, the characters of which are these; they are univalve shells of the form of a trumpet, according to old pictures, with a wide belly and a large broad and elongated mouth. They have a distinct and regular tail, usually long, though sometimes short; they have a crooked beak, and the clavicle is often elevated, though sometimes depressed and contabulated. See *Plate* V. *fig.* 11, 12, 13.

The family of the Buccina, when examined ever so strictly, is very large; but according to the general custom of authors, of confounding together several genera under the name, it is usually made to appear much larger then it really is. Lister has made it comprehend a vast number of shells, by confounding with it the families of the murex and purpura.

It is not indeed peculiar to this author to have confounded these genera; those who went before him have done the same: and Pliny has comprised the Buccinum, murex, and purpura under the general name ceryx.

To avoid the general confusion, which arises from not distinguishing the families of the Buccinum, murex, purpura, and vis, or screw-shell, it will be proper to observe that there are regular characters, which distinguish them all one from another; the characters are these:

The Buccinum differs from the purpura, in that it has a very long mouth of an oval figure, and has an elevated head; whereas the purpura has a round mouth, and a head somewhat flatted. The tail of the purpura is also usually furrowed, and is shorter than that of the Buccinum.

The Buccinum differs also from the murex in having a longer tail, by the smoothness and variety of colours of its coat, and by having a larger mouth less furnished with teeth; the murex having a smaller and longer shaped mouth, its surface covered with points or spires, and several teeth.

It is easier to distinguish the Buccinum from the screw-shell, as this is always more long and slender than the Buccinum; it has also a flat mouth and has rarely any tail. These are all very large families in nature, and it is highly necessary for the naturalists to be well acquainted with them. The most singular species of the Buccinum class is one that hath its mouth turned the contrary way to all other shells: this has been thence called by authors the unique and the sans pareil. Aldrovand is of opinion that the Buccina may be ranked among the bivalve shells; because they have an operculum, or shelly substance, fixed to the end of their body, which occasionally stops up the aperture of the mouth; but, if this were a sufficient reason, we should have many more genera to add to the bivalves, particularly the snails of several kinds.

The Buccina generate in warm months, and some species of them have been frequently remaining in pairs together, upon the rocks deserted by the tide on that occasion. These have been thence supposed to be of a different genus, and have been called buccina litoralia; they are usually found in copulation early in the morning.

BUCK, a male horned beast of venery or chace, whose female is denominated a doe.

A Buck the first year is called a fawn, the second a prickat, the third a sorel, the fourth a sore, the fifth a Buck of the first head, and the sixth a great Buck. *Cos. Gent. Recr.*

Buck, is also applied to the male of the hare and rabbit kind. Hares commonly go to Buck in January, February, and March, and sometimes all the warm months; sometimes they seek the Buck seven or eight miles from the place where they sit. *Cox. Libat.*

BUCKING, an operation performed on linen cloth and yarn, to render them somewhat white, by working them with lye made with ashes.

BUCKING *of cloth* is the first step or degree of whitening it.

To drive a buck of yarn, they first cover the bottom of the Bucking-tub with fine ashes of the ash-tree, then spread the yarn thereon, then cover it again with ashes, and thus stratum super stratum, till the yarn is all in, when they cover the whole with a Bucking-cloth, and lay on it more ashes and pour in warm water, till the tub be full, and let it stand all night

night. Next morning they let the lye run into another veſſel, and, as it waſtes, fill up the tub with warm water from a kettle, and, as this waſtes, fill it up with the lye that runs from the Bucking-tub; ſtill obſerving to make the lye hotter and hotter, till it boils. Thus are both the tub and kettle to be ſupplied for at leaſt four hours, which is called driving a buck of yarn. *Hought. Collect.*

BU'CKLE, in matters of trade, a little metalline machine, whereby to retain and keep faſt certain parts of the habit, as well as of the harneſs of horſes, &c.

Buckles are of divers ſorts, as ſhoe and garter Buckles; ſome round, others ſquare, or oval, or cut, each of which have their reſpective artificers by whom they are made.

The like may be ſaid of the great variety of Buckles belonging to the pack and hackney ſaddles, ſuch as ſets, black or oiled Buckles, ſanguine Buckles, crupper Buckles, breaſt-plate Buckles, and ſurcingle Buckles: and to theſe may be added divers other Buckles, made promiſcuouſly with the former, as the heſter Buckle, plain and knobbed, for the white bridles, and the open and plain crown Buckles for the black; and ſo the Poland Buckle, the peaſe Buckle, chaſed Buckles, Dutch and Iriſh Buckles, which are braſs, and made by the copperſmith. *Plot. Nat. Hiſt. Staffordſhire.*

BU'CKRAM, a ſort of coarſe cloth, made of hemp gummed, calendered, and dyed ſeveral colours.

Buckrams are ſold wholeſale by the dozen of ſmall pieces, or remnants, each about four ells long, and broad according to the pieces from which they were cut. Sometimes they uſe new pieces of linen cloth to make Buckrams of; but moſt commonly old ſheets, and old pieces of ſails. They make a great many at Paris, and they get, alſo, vaſt quantities from Normandy, particularly from Caen, Roan, and Alencon.

BU'CKTHORN, *rhamnus*, a hedge tree or buſh, whoſe branches are full of long ſtiff thorns, and yellowiſh green leaves about as big as the ſloe-tree, more neatly ſerrated about the edges. The flowers grow ſeveral together, being ſmall, four-leaved, and yellow, which are ſucceeded by little round black berries yielding, when ripe, a purpliſh bitter juice, and having three or four angular ſeeds. It grows in woods and hedges, and flowers in June, the berries being ripe about the latter end of September. See *Plate* IX. *fig.* 2. where *u* is the plant, *f* the flower, *g* the berry, *b* the ſeed.

The juice of the berries purges ſerous watery humours pretty briſkly, and is good againſt the dropſy, gout, jaundice, and ſcurvy, and very ſerviceable againſt the itch, and all manner of eruptions on the ſkin.

The berries of which are ordered by the College of Phyſicians for medicinal uſe; but particularly for making a ſyrup, which was formerly in great uſe; but of late the perſons who ſupply the markets, have gathered ſeveral other ſorts of berries, which they have either mixed with thoſe of the Buckthorn, or have wholly ſubſtituted them in their place. Theſe are the berries of the frangula, cornus fœmina, &c. which mixture hath ſpoiled the ſyrup, and rendered it leſs eſteemed. But whoever purchaſes the Buckthorn berries, may diſtinguiſh whether they are right or not, by opening them, and obſerving the number of ſeeds in each; for theſe have commonly four, whereas the frangula has but two, and the cornus fœmina but one; as alſo by bruiſing of the berries on white paper, the juice giving a green tincture.

By the chymical analyſis, the berries yield a great deal of acid phlegm and oil, and a little fixed ſalt and earth. They are purgative, and very good to remove ſerous humours in chronical diſeaſes; by which it relieves thoſe that have the gout, palſy, cachexy, ſciatica, and rheumatiſm. Take a drachm, or a drachm and a half of its berries, powdered and mixed with a little conſerve of orange flowers. They boil fifteen or twenty berries in common broth, adding half a drachm of cream of tartar; ſtrain it through a cloth, and give it the patient to drink; ſome mix with it two drachms of tincture of ſteel, or boil half an ounce of iron ruſt in a rag tied up in a knot, for the green ſickneſs. The moſt common uſe of theſe berries is to make a ſyrup of them. The doſe is from one ounce to two, and even to three, when neceſſary; but it is proper to eat ſome pottage after taking it. *Martyn's Tournefort.*

Syrup of BUCKTHORN-*berries. Syrupus de Spina Cervina.*

The College Diſpenſatory orders it to be thus made:

Take of the juice of freſh ripe Buckthorn berries one gallon, cinnamon, ginger, and nutmegs, each one ounce, the fineſt ſugar ſeven pounds; let the juice ſtand for ſeveral days to ſettle; then ſtrain it, and infuſe the ſpices in part of it; boil the reſt, and, towards the end of the time, add that part of it in which the ſpices were infuſed, being firſt ſtrained; let the whole be reduced by boiling to four pints, to which add the ſugar, and make a ſyrup of them.

The Edinburgh Diſpenſatory directs it in the following manner:

Take of the clarified juice of ripe Buckthorn berries, three quarts; brown ſugar four pounds; and with a gentle fire boil them to a ſyrup; and, while it is yet warm, mix therewith a drachm of the diſtilled oil of cloves, received upon a little ſugar.

To add the corrector here, in the form of a chymical oil, ſaves the trouble of ſteeping the ſpices ordered for that purpoſe in the London Diſpenſatory, and anſwers the end more certainly.

Sydenham obſerves, that ſyrup of Buckthorn alone evacuates water plentifully and little elſe, without diſturbing the blood, or rendering the urine high-coloured, as other purgatives generally do, and has only one bad quality, as occaſioning great thirſt during the operation. But if it be given, even in the greateſt doſe, to ſuch as are difficult to purge, it will neither give any motions, nor carry off enough of water.

Of Buckthorn berries are made three ſeveral ſorts of colours; being gathered green, and kept dry, they are called ſap-berries; which, being ſteeped in allum-water, give a fair yellow colour, uſed by painters, bookbinders, and leather-dreſſers; who alſo make a green colour, called ſap-green, taken from the berries when they are black. Theſe being bruiſed, and put into a braſs kettle, and there ſuffered to remain three or four days, with ſome beaten alum put to them, they are afterwards preſſed, and the liquor uſually put into bladders, and hung up till it be dry; this is afterwards diſſolved in water or wine, but canary is the beſt, to preſerve the colour from ſtarving. The third is of a purpliſh colour, made of the berries, ſuffered to grow upon the buſhes till the middle or end of November, when they are ready to fall of themſelves.

BUCK-WHEAT, *fagopyrum*, in botany, a genus of plants, whoſe characters are:—the flowers are ſpecious, growing in a ſpike, or branched from the wings of the leaves: the cup of the flower is divided into five parts, which reſemble the petals of a flower: the ſeeds are black, and three-cornered.

Buck-wheat is cultivated in many parts of England, and is a great improvement to dry barren lands. The beſt ſeaſon for ſowing the ſeed is in May: one buſhel will ſow an acre. The ground ſhould be plowed and dreſſed in the ſame manner as for barley; and, if the ſoil is not very lean, it will yield a very great increaſe, as fifty or ſixty buſhels upon an acre, and is excellent food for hogs, poultry, &c. The flour of it is very white, and makes a very good ſort of pancake, if mixed with a little wheat flour. The ſtraw is good fodder for cattle; and the grain, given to horſes amongſt their oats, will make them thrive; but it muſt be broken in a mill, otherwiſe it is apt to paſs through the cattle whole.

It is commonly late in the ſeaſon before it is ripe; but there is no great danger of the ſeeds failing, nor of ſuffering by wet after it is mown: it muſt lie ſeveral days to dry, that the ſtalks (which are hard) may wither before it is houſed.

Buck-wheat is ſometimes ſown very thick, and ſuffered to grow until it is near flowering, and is then plowed in, which makes a very good lay for wheat or rye: but ſome people eſteem it the better way to feed cattle with it, eſpecially milch-cows, which, they ſay, will cauſe them to give a great deal of milk, and make both the butter and cheeſe very good. This will alſo afford food for cattle in the drieſt time, when all other graſs is burnt up. *Miller's Gard. Dict.*

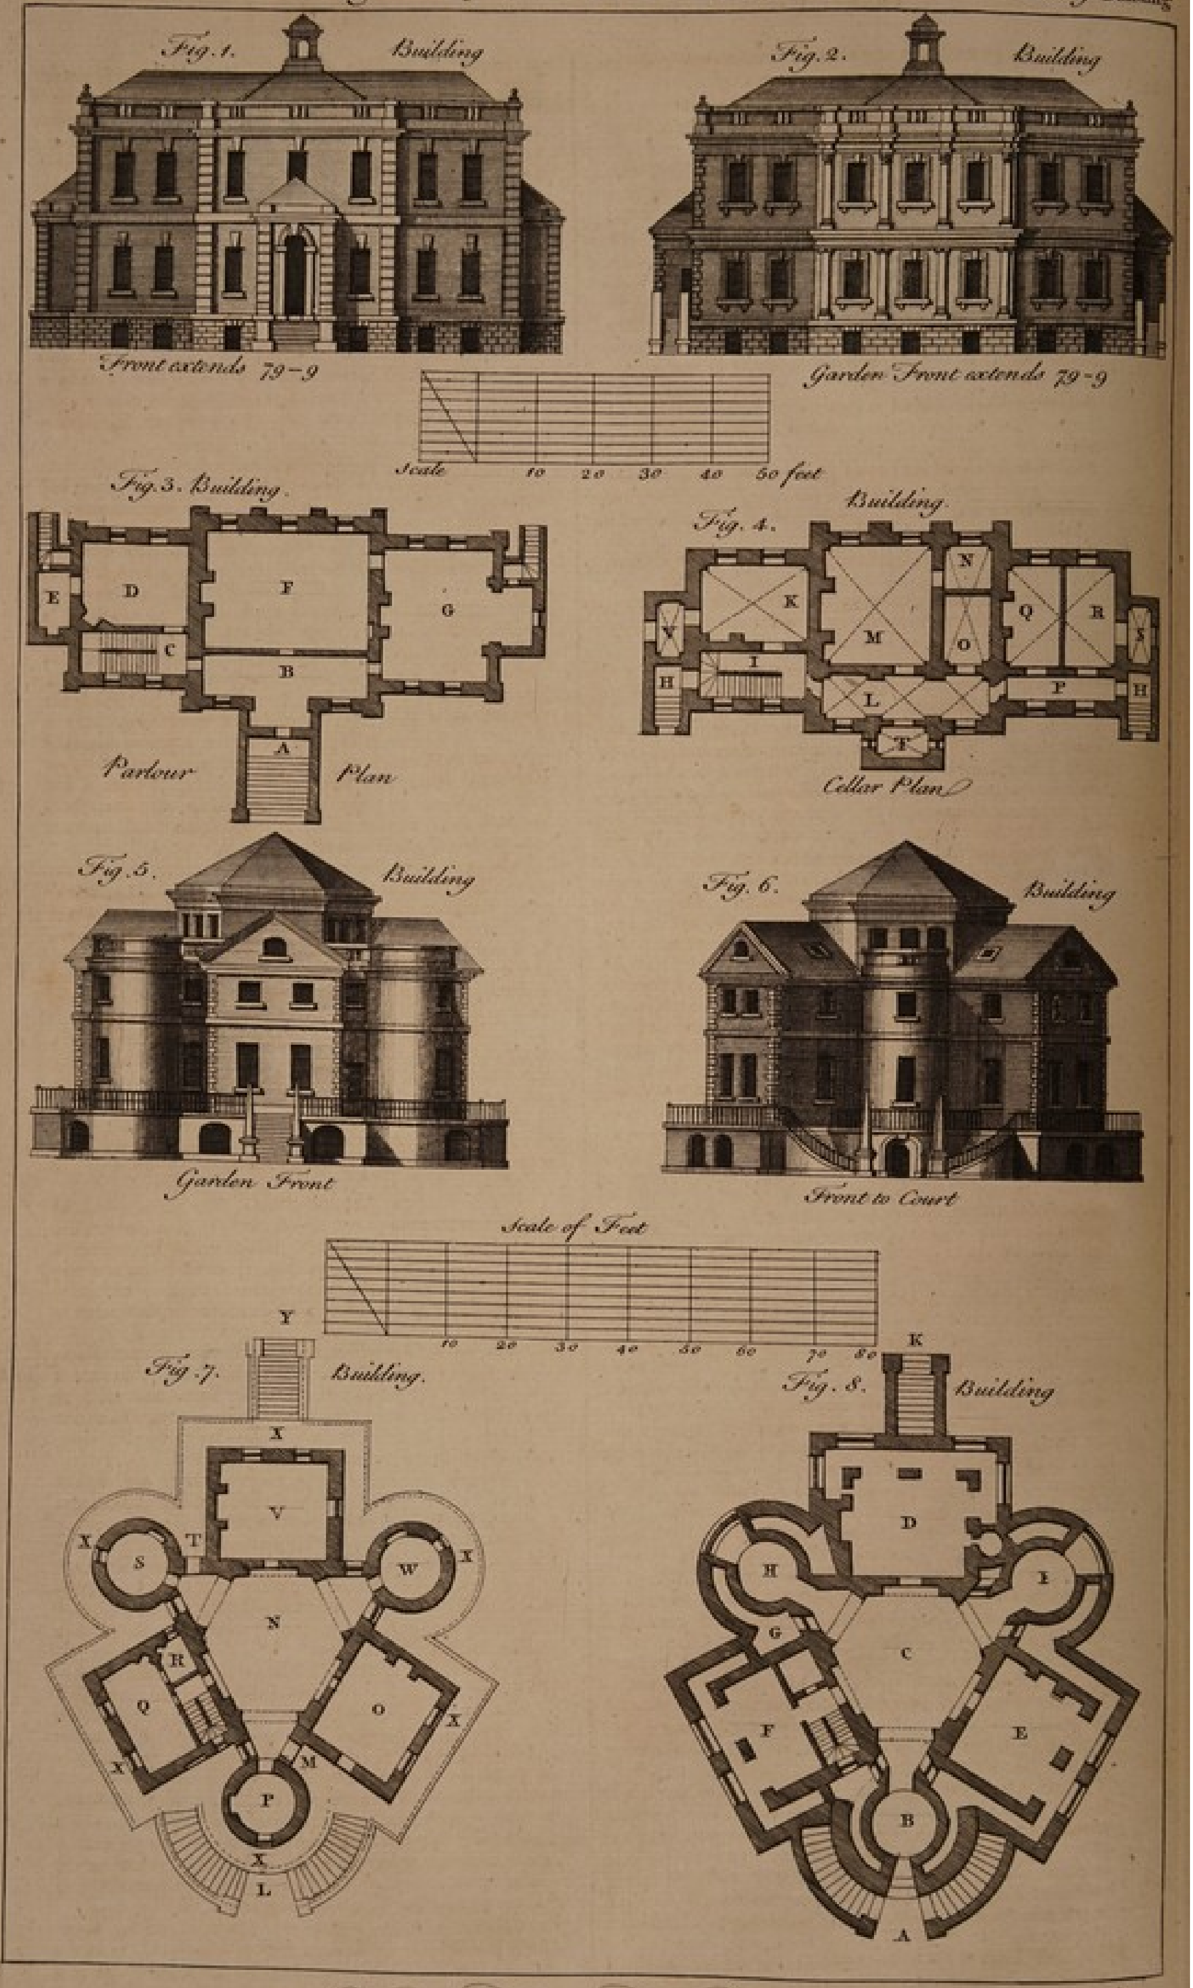
BU'DDLE, in minerology, a name given by the Engliſh dreſſers of the ores of metals to a ſort of frame made to receive the ore after its firſt ſeparation from its groſſeſt foulneſs.

The ore is firſt beaten to powder in wooden troughs, through which there runs a continual ſtream of water, which carries ſuch of it as is fine enough to paſs a grating, which is placed at one end of the trough; this falls into a long ſquare receiver of wood, called the launder; the heavieſt and pureſt of the ore, falling at the head of the launder, is taken out ſeparately, and requires little more care or trouble; but the other parts, which ſpread over the middle and lower end of the launder, is thrown into the Buddle, which is a long ſquare frame of boards, about four feet deep, ſix long, and three wide; in this there ſtands a man bare-footed, with a trambling ſhovel in his hand, to caſt up the ore about an inch thick, upon a ſquare board placed before him as high as his middle; this is termed the Buddle-head; and the man dexterouſly, with one edge of his ſhovel, cuts and divides it longways, in reſpect of himſelf, about half an inch aſunder, in theſe little cuts; the water, coming gently from an edge of an upper plain board, carries away the filth and lighter parts of the prepared ore firſt, and then the metalline part immediately after, all falling down into the Buddle, where, with his bare feet, he ſtrokes it and ſmooths it, that the water and other heterogeneous matter may the ſooner paſs off from it.

When the Buddle by this means grows full, the ore is taken out; that at the head part, being the fineſt and pureſt, is taken out ſeparate from the reſt, as from the launder. The reſt is again trampled in the ſame Buddle; but the head, or, as it is called, the forehead of this Buddle, and of the launder, are mixed together, and carried to another Buddle, and trampled as at firſt. The forehead of this laſt Buddle, that is, that part of the ore which has fallen at the head, is carried to what they call a drawing Buddle, whoſe difference from the reſt is only this, that it has no tye, but only a plain ſloping board, on which it is once more waſhed with the trambling ſhovel. Tin ore, when it is taken from this, is called black-tin, and this is found to be compleatly ready for the blowing-houſe. *Philoſ. Tranſ.* N°. 69.

BU'DDLING *of calamine*, denotes the operation of cleanſing it from

Printed for J. Hinton in Newgate Street.



Printed for J. Hinton in Newgate Street from filth, by washing and picking it, preparatory to the baking it in the oven. *Phil. Transf.* N°. 198.

BUDDLING-*dish*, a small shallow vessel, like the basons of a pair of scales, for the washing of ores of metals by the hand. *Shaw's Lett.*

BUG'LOSSUM, bugloss, in botany, a physical plant, which, from a long, thick, brown root, sends forth large, rough, hairy leaves, less prickly than borrage, half a foot long, narrow, and sharp-pointed. The stalks arise to the height of two or three feet; full of short stiff hairs, on which grow long narrow leaves, set on without foot-stalks. The flowers grow several together, at the top of the branches, in long rough calyces, of a single leaf, cut into five round partitions, of a purple colour at their first appearing, and turning to a bright blue as they stand, and are succeeded by four-cornered rough seeds.

Bugloss is usually planted in gardens, and flowers in June and July. The leaves, flowers, and sometimes the root, are used.

Bugloss is much of the nature of borrage, being accounted cordial, and good to exhilarate the spirits, and drive away melancholy; and is useful against hypochondriac and hysteric disorders.

The flowers are amongst the number of the four cordial flowers. *Miller's Bot. Off.*

The roots are very glutinous, and gives a deep tincture of red to blue paper; the flowers give it but very little, and the leaves hardly any at all: so that probably the sal ammoniac in this plant is involved in a glutinous juice, in which the earth and sulphur are predominant. The Bugloss moistens, cools, and gives great relief to melancholy persons; it is good to dissipate the defluxions of the breast, and an obstinate cough. The juice is drank from three ounces to six. The ptisan is taken by glass-fulls. The roots and leaves are used in cooling broths, and this plant cools no otherwise than by restoring the motion of the blood, which stagnates and heats the parts wherein its circulation is retarded. Bugloss flowers are used after the manner of tea. A conserve is made of the flowers. The syrup made with the juice of the leaves of Bugloss gives great relief to melancholy persons: this juice is employed in the simple Byzantine syrup, and the compound one of Mesue. It enters also as an ingredient in Fernelius's syrup of spleen-wort. *Martyn's Tournefort.*

BUGLOSSUM *Silvestre*, wild bugloss.—This is a much less plant than the garden kind, growing not above a foot high, with a small whitish root, which dies yearly: the leaves are long and narrow, but broader, and roundish-pointed at the end, rough and prickly, like borrage. The stalks are thick, succulent, and prickly, cloathed with narrow and sharp-pointed leaves, set on without foot-stalks. The flowers grow on the tops of the stalks, in shape like the flowers of garden bugloss, but less, and of a light blue colour; the seeds are also like the seeds of that. It grows by hedges and way-sides, and among the corn; and flowers in May.

This wild Bugloss is but seldom used, though it is said to have the same virtue with the garden, but in a lower degree, and, for want of that, may serve to supply its place. *Miller's Bot. Off.*

BU'GULA, bugle, in botany, a plant having a small stringy root, sending forth several stalks of different forms; some roundish, and lying along, and creeping on the ground, sending out fibrous roots from the joints; the others, which grow erect, and bear the flowers, are square, beset with but few leaves, standing in pairs opposite to one another; the lower on long foot-stalks, the upper on very short ones; they are oblong, somewhat crenated about the edges, an inch and half long, and an inch broad, of a dull green colour, and oftentimes with a dash of purple: The stalks are eight or nine inches high, having the flowers growing at the top, in loose spikes, whorle fashion, with two small brownish leaves under each whorle. They are of a blue colour, and labiated, but have the galea so small, that it is hardly discernible. When the flowers are past, they are succeeded by small longish seeds, in fine pointed calyces. It grows in woods and hedges, and flowers in May.

Bugle is a noted vulnerary plant, and used inwardly and outwardly for all kinds of bruises, wounds, and contusions, as likewise for sores and ulcers, for spitting of blood, and hæmorrhages from any part. It is also aperitive and diuretic, and good to open obstructions of the kidneys, and provoke urine. *Miller's Bot. Off.*

This plant is bitter, detersive, and gives a faint red colour to blue paper. It is employed in vulnerary potions, ptisans, and apozems; the dysentery, fluor albus, and diseases of the throat, ulcers and thrushes in the mouth. The clarified juice of Bugle has the same virtues; it is used in plaisters; Camerarius and Dodonæus prescribed it for obstructions of the liver. It contains some sal ammoniac involved in sulphur. *Martyn's Tournefort.*

BU'ILDING (*Dict.*)—In the distribution of lodging-rooms, in a building, it is a popular and ancient fault, especially among the Italians, to cast the partitions so, as, when the doors are all open, a man may see through the whole house; grounded on the ambition of shewing a stranger all the furniture at once: an intolerable hardship on all the chambers, except the inmost, where none can arrive but through all the rest, unless the walls be extreme thick for secret passages: nor will this serve the turn, without at least three doors to each chamber; a thing inexcusable, except in hot countries: besides its being a weakening to the Building, and the necessity it occasions of making as many common great rooms as there are stories, which devours a great deal of room, better employed in places of retreat; and must likewise be dark, as running through the middle of the house.

In the compartition, the architect will have occasion for frequent shifts; through which his own sagacity, more than any rules, must conduct him. Thus he will be frequently put to struggle with scarcity of ground; sometimes to damn one room for the benefit of the rest, as to hide a buttery under a stair-case, &c. at other times, to make those the most beautiful which are most in sight: and to leave the rest, like a painter, in the shadow, &c.

For the covering of the Building; this is the last in the execution, but the first in the intention: for who would build, but to shelter? In the covering, or roof, there are two extremes to be avoided, the making it too heavy or too light: the first will press too much on the underwork; the latter has a more secret inconvenience; for the cover is not only a bare defence, but a band or ligature to the whole Building, and therefore requires a reasonable weight. Indeed, of the two extremes, a house top-heavy is the worst. Care is likewise to be taken, the pressure be equal on each side; and Palladio wishes, that the whole burden might not be laid on the outward walls, but that the inner likewise bear their share.—The Italians are very curious in the proportion and gracefulness of the pent or slopiness of the roof; dividing the whole breadth into nine parts, whereof two serve for the height of the highest top or ridge from the lowest: but, in this point, regard must be had to the quality of the region; for, as Palladio insinuates, those climates which fear the falling of much snow, ought to have more inclining pentices than others.

The strength of a Building is sometimes much impaired by the erecting it, by reason of the master not having prepared either sufficient materials, or money, before he set about Building. For, when Buildings are erected by fits and pauses, by doing first one piece, and then another, the work dries, and sinks unequally; by which means the wall becomes full of chinks and crevices: and therefore this way of Building by fits is condemned by all authors.

As for beauty: let not the front look a-slant upon a stranger, but accost him right at his entrance. Uniformity and proportion are very pleasing to the eye. And it is observable, that free-stone, like a fair complexion, grows old, whilst bricks keep their beauty longest.

Let the offices keep their due distance from the mansion-house; those are too familiar which presume to be of the same pile with it.

The same may be said of stables and barns; without which, a house is like a city without works: it can never hold out long. It is not only very inconvenient, but rather a blemish than a beauty to a Building, to see the barns and stables too near the house; because cattle, poultry, and such-like, must be kept near them; which will be an annoyance to an house.

Gardens ought also to be disposed in their proper place. When God planted a garden eastward, he made to grow out of the ground every tree pleasant to the sight, and good for food. Sure (says Dr. Fuller) he knew better what was proper to a garden, than those who now-a-days only feed their eyes, and starve their taste and smell.

Mr. Worlidge advises, that the garden join to one, if not more sides of the house. For what can be more pleasant and beautiful, for the most part of the year, than to look out of the parlour and chamber-windows into gardens?

For beauty, says he, let there be also courts or yards, kept from cattle, poultry, &c. and planted with trees, to shade, defend, and refresh your house: and the walls also planted with vines, and other wall-fruit: all which will add pleasure and beauty to your habitation.

Thus much for the principal or essential part of a Building.—For the accessories, or ornaments, they are fetched from painting and sculpture. The chief things to be regarded in the first, are, that no room have too much, which will occasion a surfeit; except in galleries, or the like: that the best pieces be placed where there are the fewest lights: rooms with several windows are enemies to painters, nor can any pictures be seen in perfection, unless illumined, like nature, with a single light: that in the disposition regard be had to the posture of the painter in working, which is the most natural for the posture of the spectator; and that they be accommodated to the intentions of the room they are used in.

For sculpture it must be observed, that it be not too abundant; especially at the first approach of a Building, or at the entrance, where a Doric ornament is much preferable to a Corinthian one: that the niches, if they contain figures of white stone, be not coloured in their concavity too black, but rather dusky; the sight being displeased with too sudden departures from one extreme to another. That fine sculptures have

have the advantage of nearness, and coarser of distance; and that, in placing of figures aloft, they be reclined a little forwards: because, the visual ray, extended to the head of the figure, is longer than that reaching to its feet, which will of necessity make that part appear further off: so that, to reduce it to an erect posture, it must be made to stoop a little forward. M. le Clerc, however, will not allow of this resupination, but will have every part in its just perpendicular.

As to the stone and stucco, used in Buildings, which are fresh and white at first, and are commonly supposed to be discoloured with the air, moisture, smoak, &c. the true cause thereof is, that they become covered with a minute species of plants, which alter their colour. A sort of lichens yellowish, brownish, or greenish, which commonly grow on the barks of trees, do grow also on stones, mortar, plaister, and even on the slates of houses, being propagated by little light seeds, dispersed by the wind, rain, &c. The best preservative, known, is a coat of lime. *Build. Dict.*

Explanation of *Plate* X.

Fig. 1, 2, 3, 4, The cellar and parlour plans with the two elevations of a house, seventy-nine feet nine inches front, and are divided as follows.

Fig. 3. A, Front steps.

B, Hall or passage fourteen feet wide in the middle, and eight feet at each end.

C, Stairs eighteen feet by seven feet six inches.

D, Parlour eighteen feet by fourteen feet.

E, Closet nine feet by six feet.

F, Great drawing-room twenty-eight feet three inches by twenty feet.

G, Dining-room twenty-two feet by eighteen feet, with a recess for a side-board ten feet by eight feet.

This story is fourteen feet high in the clear, and that over it thirteen feet, which may be divided into three bed-chambers; the room over D must be equal to that below, next to which take eight feet four inches from the room over F, and divide it into two closets, which will be each nine feet nine inches by eight feet; that to the front (by making a door through the wall) will be a dressing closet for the room over D, and the other will be dark, which may open to the passage; then the room over F will be nineteen feet eleven inches by twenty feet, its chimney being cut off by the dressing closet; fix one at the back of that in the room over G, then take, from the garden front of the room over G, seven feet four inches, and divide it into two dressing closets, which will be each eight feet ten inches by seven feet: and the room over G will be eighteen feet by fourteen feet eight inches; the chimney may be fixed in the angle at the side of that which may be made in the dressing closet; the chimney for the room over G may be fixed in the angle of the Building.

N. B. The plan of the great room F is a diagonal proportion, its length being equal to the diagonal or hypothenuse of a square, whose side is equal to the width of the room.

The cellar plan, *fig.* 4.

Let the height of the lower offices be nine feet in the clear; the parlour floor is five feet six inches above the surface of the earth, from which, take one foot four inches for the thickness of the vaulted arch with joist and board, and four feet two inches remains, which is the height of its sofeta, above the surface, and shews that the floor of the offices must be sunk four feet ten inches below to make the clear of the story nine feet; the plan is divided as follows:

H H, Steps leading down to the offices.

I, Passage and stairs seventeen feet six inches by seven feet three inches.

K, House-keeper's room seventeen feet six inches by thirteen feet six inches.

L, Passage seven feet three inches wide.

M, Kitchen nineteen feet three inches by eighteen feet.

N, Larder eight feet six inches by eight feet.

O, Cellar ten feet eleven inches by eight feet.

P, Passage four feet wide.

Q, Butler's pantry seventeen feet two inches by eight feet seven inches.

R, Cellar ditto.

S, Ditto nine feet six inches by five feet six inches.

T, Ditto nine feet by five feet.

V, House-keepers ditto nine feet six inches by five feet.

CAUTION.

Observe, in the laying out groined vaults, to place the buttments as near as possible to push against each other, more especially when the spand is large, otherwise they will be in great danger of falling, let the workman do his part ever so well; for example, see the buttment between L and M, if that was a large spand, it must unavoidably push out the wall. I laid it down thus, as an example in executing the work: omit the pier L, and groin single from the buttments of the two angles in the kitchen M, &c. because where strength or conveniency is absolutely necessary (especially in the baser parts of a Building) nice regularity must give way.

Estimate to this Building.

This Building contains twenty-five square one-half, measuring but one of the sheds, and computing them both to be equal to so much of the other plan; for the same reason all the outside steps are throwed into the plans of the porch; the whole may be built in a moderate well finished manner, sixty-four pounds per square, which amounts to one-thousand six-hundred thirty-two pounds.

Fig. 5, 6, 7, 8, The ground and parlour plans of design for a Building formed by an equilateral triangle, whose sides B H I B, or P S W P, are forty-four feet, which are the extreme points of the angle, and are the centers of the circular closets, &c. the dimensions of the several rooms are as follows:

Fig. 8. A, Foot of steps, which leads up to the terras.

B, Porch or entrance into the lower offices, nine feet six inches diameter, and its floor two feet below the surface of the earth.

C, Servants hexagon hall, twenty-one feet six inches diameter, lighted by four windows from the terras.

D, Kitchen seventeen feet six inches by fifteen feet six inches in the clear of the walls, which bears the upper stories.

E, House-keeper's room ditto.

F, Cellar seventeen feet six inches by eight feet nine inches in the clear, between the stairs and wall which bears the upper stories.

G, Little cellar six feet six inches by six feet six inches.

H, Butler's pantry nine feet six inches diameter.

I, Larder ditto.

K, Steps to the garden.

N. B. The walls of this story are two feet six inches thick, and the void space between them two feet three inches.

Parlour plan. *Fig.* 7.

L, Foot of the steps.

M, Door of entrance from the terras.

N, Hexagon hall twenty-two feet diameter, two stories high.

O, Parlour eighteen feet by sixteen feet.

P, Closet ten feet diameter.

Q, Study eighteen feet by nine feet.

R, Closet seven feet by six feet.

S, Closet ten feet diameter.

T, Door to the terras.

V, Dining-room eighteen feet by sixteen feet.

W, Closet ten feet diameter.

XXXXXX, Terras five feet wide, inclosed by iron rails.

Y, Garden steps.

The terras is eight feet above the surface of the earth, from whence the floor of the hall rises six inches, and the floor of the offices is two feet below the surface; so the whole height from the office floors to the floor of the hall is ten feet six inches, from which deduct one foot for the thickness of the floor, and nine feet six inches remains for the height in the clear of the office story. The parlour story is fourteen feet high in the clear, and the story over it eight feet, and trussed galleries in the hall for a communication between the upper rooms; there are garrets in the roof, and a billiard room over the hall with a coved ceiling.

Estimate to this Building.

The whole plan, including steps and terras, contains forty-one square and one-half, and may be built one with the other in a good manner for thirty-five pounds per square, which amounts to one thousand four hundred and fifty-two pounds ten shillings. *Halfpenny's Architecture.*

BUL, in the Hebrew calendar, the eighth month of the ecclesiastical, and second of the civil year, since called Marshevan; it answers to our October, and is composed of nine and twenty days.

BULBOCASTA'NUM, *earth-nut*, in botany, the name of a genus of plants, the characters of which are these: the flower is umbelliferous, and of a rosaceous kind, being composed of several leaves, arranged in a circular form. The cup finally becomes a fruit, composed of two small seeds, which are sometimes smooth, sometimes striated on their gibbose sides, and smooth on their flat ones. To which it is to be added, that the roots are tuberous and fleshy.

Mr. Miller has enumerated six species of this plant, and Tournefort four.

They are all very hardy plants in respect to cold; so may easily be propagated by sowing of their seeds on a moist shady border, soon after they are ripe, (for, if they are kept out of the ground till spring, they seldom succeed so well as when they are sown in autumn.) When the plants appear in the spring, they must be carefully cleared from weeds; and, where they are too near, they should be thinned, so as to leave them three or four inches asunder; after this they will require no other culture, but to keep them clear from weeds, for they do not bear transplanting; so must be sown where they are to remain. The autumn following the roots will be fit for use, and will continue good all the winter, till they shoot up their stems in the spring for seed; after which time they are tough, and not fit for eating.

BU'LLET (*Dict.*)—Bullets shot into the water undergo a refraction; several experiments concerning which are given by Mr. Carre.

BULLETS are usually piled up in the form of a pyramid. See a representation of a pile of Bullets, *plate* XXXV. *fig.* 18. in the Dictionary.

BULLET-*moulds* consist of two concave hemispheres, with an handle whereby to hold them; and between the hemispheres is is a hole, called a gate, at which to pour in the melted metal. The chaps, or hemispheres of Bullet-moulds, are first punched, being blood-red-hot, with a round-ended punch, of the shape, and nearly of the size, of the intended Bullets. To cleanse the insides, they make use of a Bullet-bore.

BULLET-*bore* is a steel shank, having a globe at one end, wherewith to bore the inside of the mould clean, of the size intended. *Moxon, Mechan. Exerc.*

BU'LLION (*Dict.*)—When gold and silver are in their purity, they are so soft and flexible, that they cannot well be brought into any fashion for use, without being first reduced and hardened with an allay of some other baser metal.

To prevent the abuses which some might be tempted to commit, in the making of such allays, the legislators of civilized countries have ordained, that there shall be no more than a certain proportion of a baser metal to a particular quantity of pure gold or silver, in order to make them of the fineness of what is called the standard gold or silver of such peculiar state or nation.

According to the laws of England, all sorts of wrought plate, in general, ought to be made to the legal standard; and the price of our standard gold and silver is the common rule whereby to set value on their Bullion, whether the same be in ingots, bars, dust, or in foreign specie: whence it is easy to conceive, that the value of Bullion cannot be exactly known, without being assayed, that the exact quantity of pure metal therein contained may be determined; and, consequently, whether it be above or below the standard.

BU'NIAS, *navew gentle*, in botany.—The leaves of this plant, which lie on the ground, are long and large, deeply cut in, and in shape like a turnep-leaf, but less, and very little hairy. The stalks grow to be two or three feet high, beset with smaller leaves, smooth as well as the stalk, and little or nothing jagged, especially those which grow higher upon the branches, which are round and broad at bottom, and encompass the stalk, ending in a narrow point of a bluish-green colour. The flowers grow many together, on the tops of the stalks, made of four bright yellow leaves, and are succeeded by long cylindrical pods, containing small, round, black seed; the root is white, longer and slenderer than a turnep, but much like it in taste. It is sown in gardens, and flowers in April; the root is used in food, and the seed in physic.

The seed is commended by the antients as good against all kinds of poisons, and the bites of venomous creatures, to provoke urine, and the menses. Matthiolus extols it against all kinds of infectious distempers, to expel malignity, and chear the heart, as also to drive out the small pox and measles. *Miller's Bot. Off.*

BUPHTHA'LMUM, *ox-eye*, in botany, by some called cachlan, sends forth tender and somewhat slender stalks, with leaves like those of fennel, and yellow flowers, larger than those of the anthemis, and resembling an eye; whence it took its name. It grows in fields, and about cities and towns. The bruised flowers, with cerate, discuss œdematous tumors and hardnesses. They say, that Buphthalmum, drank after coming out of the bath, restores, after some time using it, a good complexion, to those who are discoloured with the yellow jaundice. *Dioscorides, lib.* 3. *cap.* 156.

Ox-eye is a plant that has a great many shrubby branches, whereon grow fine winged leaves, like yarrow, but shorter, stiffer, and somewhat white and hoary: each stalk is terminated by one pretty large corymbiferous flower, of a deep yellow colour, like a marigold, but that the middle thrum is larger in proportion, and the petala are much shorter and firmer. The root is small and fibrous. It grows wild in some parts of the north of England, and flowers in June or July. It is seldom or never used: but that which is called the ox-eye in the shops is the bellis major. *Miller's Bot. Off.*

BURLE'SQUE (*Dict.*)—Some who are fond of discovering traces of every thing in antiquity, ascribe the invention of Burlesque to Homer, whose Batrachomyomachia, say they, is only some parts of the Iliad and Odyssey travestied and turned into ridicule, by an application of the combats of kings and heroes to the battle of the frogs and mice: but it is not certain Homer was the author of this poem. Suidas gives the honour of it to Pigres, or Tigres, brother to the famous Artemisia; and, in an ancient MS. of this in the French king's library, the name of this Carian is wrote at the beginning of it. Stephen Nunnesius, and other learned moderns, are of opinion Homer was not the author of it. But antiquity decides in favour of Homer. Martial expressly ascribes it to him in this Epigram:

> Perlege Mæonio cantatas carmine ranas,
> Et frontem nugis solvere disce meis.

Statius is of the same opinion; and a basso relievo, representing Homer with two rats, done by Archelaus, which was dug up near Rome, in the gardens of the emperor Claudius, seems to confirm the opinion of the ancients on this head.

BU'RNING *of Land* (*Dict.*)—This is a very great means of improvement of lands, and is not only at this time used in many parts of this and other kingdoms, but it has been practised from the earliest times of husbandry that we have any account of. Virgil very expressly mentions, and greatly recommends it, and all the old writers of husbandry say much in its praise.

It does not take effect, however, in all sorts of ground. It is not proper for rich soils, nor for stony or chalky ones; nor is it a practice often to be repeated on any land, especially where the surface is shallow; nor must corn be sown too long upon the land afterwards; for Burning exhausts the good juices of the land, in some degree, as well as the bad ones. It is most profitably used to such lands as have lain a long time uncultivated, and over-run with rank weeds, such as sowre grass, fern, heath, furze, and the like. Some lands, when corn is sown upon them, run it up into straw, and make the ears but poor and light; these are, beyond all others, improved by Burning. The usual method of plowing up for this is with a breast-plough, which a man pushes before him, and cuts the turf off the surface, turning it over when he has cut it to about eighteen or twenty inches long. The common way is only to pare it about half an inch thick; but, if it be very full of weeds, with stubborn roots, it is better to go deeper.

If the season proves dry, the turf needs no more turning, but dries, as it lies. If it be wet, it is necessary to set it on edge, and keep it hollow till such time as the wind and air have sufficiently dried it. It is then to be piled up in little heaps, about the quantity of two wheel-barrows full in each heap; and, if there be much roots and a good head upon it, there needs no farther care but setting it on fire, and the whole heap will be reduced to ashes; but if it be earthy and too dead to burn out by itself, there must be a heap of furze or heath laid under every parcel.

When the heaps are reduced to ashes, they are left upon the place till some rain comes to wet them; otherwise, in the spreading, they would all blow away. When they are wetted, the farmer takes the opportunity of a calm day, and spreads them as equally as possible over the whole land, cutting away the earth a little under the heaps, to abate its over great fertility there. After this, the land is to be plowed but very shallow, and the corn is to be sown upon it only in half the quantity that it is upon other land, and the later this is sown the better. If it be wheat, the best time is the latter end of October; for, if sown sooner, it is apt to grow too rank. The beginning of May is the proper time for cutting the turf off from these lands, because there is then time sufficient to get the land in order for sowing at the proper season. The whole charge of cutting, carrying, and Burning the turf, is generally about twenty-four shillings an acre.

The turf is not to be burnt to white ashes, for this wastes a great part of its salt; it is only to be burnt so as to crumble all to pieces, and be in a condition to spread well upon the land; and it is better that the heaps of it should burn slowly and gradually than furiously.

Some farmers stub up furze, heath, and the like, and, covering heaps of them with the parings of the earth, set fire to them; others burn the stubble of the corn fields, and others the stalks of all sorts of weeds, and add half a peck of unslaked lime to every bushel of ashes. They cover the lime with the ashes, and leave the heaps in this manner till there comes some rain to slake the lime; and, after this, they spread the mixture carefully over the field. There is one great advantage attending this sort of manure, which is, that it does not breed weeds like the common way with dung, but only fills the ears of the corn, not running them up into stalk; but it is proper to add some dung to these lands at the time of plowing them up for a second or third of crop corn. *Mortimer's Husbandry.*

BU'RNISHER, which some also call polisher. An instrument to burnish with. It is made of the finest steel, and is of several figures, according to the matter that is to be burnished: it ought to be well smoothed with the file, and afterwards polished on the wheel, till it be as bright as a looking-glass. They temper it afterwards as strongly as they can; the harder and better polished it is, the better it serves for its several uses. To burnish gold, silver, and other metals, and gilded works, the Burnisher must be of pure steel, made round, sometimes with one, and sometimes with two handles; when it has but one, the other end is fastened with a moving ring to the working boards, on which the workman works. The Burnisher for gilt works is made of a wolf's or dog's tooth, or with a piece of blood-stone fastened to a wooden handle.

BURNISHER, is also a tool used by the engravers of copper-plates: it is an instrument of steel, about six inches long, on one side of the figure of a heart, the point of which is something long, made round, not very thick, and not sharp. At the other end it has a kind of a darts head of iron, with three angles, sharp on the three sides. They call it a grater. See ENGRAVING.

The lock-smiths have three sorts of Burnishers: some that are crooked, to polish the rings of the keys; some straight, to polish the iron; and some half-round, to tin over. Other artificers who work and polish iron, as the gun-smiths, sword-cutlers, &c. have also several Burnishers or polishers, some like those of the lock-smiths, others like those of the engravers, and some that are peculiar to themselves, but little differing from the others.

BU'RSA *Pastoris*, *shepherds-purse*, in botany, a plant whose lower leaves lie flat on the ground, in a round compass, three or four inches long, narrow, and cut into several gashes, a little hairy. The stalk is slender, about a foot high, branched towards the top, beset with a few whole leaves, which are sharp-pointed, and set close on, without foot-stalks. The flowers are small, white, and four-leaved, and are succeeded by three square seed-vessels, in the shape of a purse, containing a very small reddish seed. The root is whitish, woody, and full of fibres, of but little taste. It grows every-where among rubbish, banks, and walls, and flowers all the summer. *Miller's Bot. Off.*

It is of an herby taste, a little saltish, and detersive; the juice of its leaves gives a faint red colour to blue paper, which gives us reason to imagine, that, in this plant, the sal ammoniac, which is natural in the salt of the earth, predominates over the other principles; this sal ammoniac is dissolved in a considerable quantity of phlegm, and is tempered by a good deal of earth, and a little sulphur.

This plant does not yield much acid, by a chemical analysis; almost all that is extracted from it is salt, besides a small quantity of earth.

There are but few plants which yield more concrete volatile salt, fixed lixivial salt, and earth. These principles, mixed together, render the shepherds-purse proper to dissolve the blood, when it is thickened by foreign acids, which hinder it from passing, with its ordinary velocity, from the arteries into the veins; to which we may refer the greatest part of defluxions. Besides, the earth, which is in this plant, easily imbibes the serosities, which occasion a relaxation of the fibres; thus, by the consent of all authors, it is vulnerary and astringent; it is also believed to be febrifugous and lenitive. The juice of its leaves drank, from four ounces to six, is an excellent remedy in all losses of blood, and in defluxions attended with an inflammation. They boil a handful of it in lean broth, and employ it in ptisans, clysters, and cataplasms Its distilled water has little or no virtue; it is nothing but the phlegm separated from the other principles.

It is found almost all the year; for it propagates itself by seed towards the end of summer. *Martyn's Tournefort.*

BUSS, a small sea vessel used by us and the Dutch in the herring-fishery. They call it in Dutch haering-buys; these vessels are commonly from forty-eight to sixty tons burthen, and sometimes more. They have two small sheds or cabbins, one at the head, and the other at the stern: that at the head serves for a kitchen.

Each Buss has a master, an assistant, a mate, and seamen in proportion to the vessel's bigness. The master commands in chief, and, without his express order, the nets cannot be cast or taken up. The assistant has the command after him, and the mate next, whose duty it is to see the seamen manage the rigging in a proper manner; to mind those who draw in the nets, and those who kill, gut, and cure the herrings, as they are taken out of the sea. The seamen generally engage for a whole voyage in the lump.

The provisions which they take on board the Busses, consist commonly of bisket, oatmeal, and dried, or salt fish; the crew being content for the rest with what fresh fish they catch.

BU'TCHER, one who kills, cuts up, and sells meat, either in the shambles, where it should only be sold, or at particular shops in the market.

The practical part of this trade, or killing, may claim its rise with almost the beginning of time itself; and that of selling was also very early.

When Rome flourished, they were three collected companies under strict regulations, which bore even the modern distinction of beef-Butchers, hog-Butchers, and slaughter-men, with some little difference.

Ours now are divided into carcase-Butchers, who buy live goods at market, have them killed, and sell the carcases whole, ready for cutting up; some indeed halve and quarter them.

The next are the great retailers, who themselves buy their goods alive, kill them, and dispose them in joints, or pieces, for sale. Some of these chiefly sell beef, others only veal, others mutton and lamb, others pork, and many of them all sorts. There are, also, small retailers, who buy their meat of the carcase-Butchers, and sell it by piece-meal.

Hog-Butchers, are such as deal in swine only; and some of these are also called bacon-men, who cure hog-meat for bacon, which is a very considerable business in and about London; but, in the country, most people cure it themselves.

How necessary and populous the trade of a Butcher is, we see daily. The buying in live stock requires experience, which gives judgment; the killing part is very slavish, dirty, wet work; the shop-keeping part ought to be accompanied with a good deal of cleanliness, besides the art of setting off their meat.

They commonly have with an apprentice five or ten pounds, and give a journeyman ten or twelve pounds a year, and his board; but the slaughtermen are paid by the head; some of whom will earn four or five shillings in a day, or night, for they have no set hours of working.

They were a company in the city of London, before the year 1180; but not incorporated till 1605, in the reign of king James I. Livery fine forty shillings.

Their hall is in Pudding-lane, near the Monument; and their court-day on the first Wednesday of the month.

Arms. Azure, two axes saltier-ways, or, headed proper; between two bulls-heads couped argent, armed or, on a chief of the fourth a boar's-head erased gules, between two garbs of the fifth.

Motto. *Omnia subjecisti sub pedibus: oves et boves.* Thou hast brought all things under foot: sheep and oxen.

BU'TEO, in zoology; see BUZZARD.

BU'TTER (*Dict.*) — *A new way to make the best of* BUTTER *from St. Foyne.*

—The following essay is extracted from a letter, which has been sent us by a gentleman, who has contributed his assistance from the country, where he cultivates a large estate of his own, and communicates to others such improvements as he makes, with a generous openness of spirit and freedom, rarely to be met with among us. This seed of St. Foyne, being much larger than clover, must be sowed in a much greater quantity. Four bushels to an acre will be better than three, which is the least you can venture to sow; observe the directions given for clover, as to manuring while the turf is tender, and the earth is frozen; but, as to the time of letting it grow, that may, if you please, be five years, for so long it will continue in its prime perfection; and, running into a large knotty root, does so enrich the ground it grows on, that, after it has borne St. Foyne five years, it will afford three excellent crops of what corn you please, and so improve itself, by alternate burdens of grass and corn, till it arrives at the utmost perfection which land is capable of reaching. Nothing is so sweet, nothing so innocent, as this St. Foyne; but, above all, it is observed to increase milk, in quantity and quality, beyond any grass yet known in the whole world; and it is for this reason that I advise you to keep cows upon it, and make you a five-years dairy. But, when I say a dairy, imagine not that I mean such a dairy as is commonly kept in England. Would you know what kind of dairy? I will hasten to inform you, and conclude my letter with this particular. The worst acre of an hundred, which quantity of land is most suitable to this purpose, improved by this grass, will very well maintain four cows from the first of April to the end of November, and afford besides a sufficient store of hay, to make good part of their subsistence the four winter months following: you must buy then about four hundred milch-cows, but take care you chuse them with judgment. I have bought your largest sort of runts from Wales, for less than fifty shillings a cow, with a good calf by her side, which I always disposed of as soon as I could. You will observe, that I make too good an use of the milk to afford the calf his share of it: I generally keep these cows above twelve months, and then, selling them, sometimes for four pounds a-piece, I stock myself with such that are new milched. I observe this rule every year, and the trouble is sufficiently rewarded by the advantage it brings me; for, besides the profit I make by selling dearer than I buy, I avoid the inconvenience of having any thing to do with bulls, and the consequences; so that I always preserve my cows in their full milk, and find it no uncommon thing for one of these milch-cows to be milked twice a day, and afford a gallon and an half at a meal. Four hundred of these cows will cost a thousand pounds; and you will find, that, coming from a poor pasture to a rich, they will prosper and increase both in milk and size. In eight convenient places about your hundred acres let there be built eight thatched sheds, a little rising in the middle to carry off the water; the height may be ten feet, and the breadth thirty; each of these sheds should be a hundred and twenty-five feet long, and, under the highest part, directly in the middle, you must raise a slight partition, lathed and plaistered, which serves to support the ridge of the roof, while the two sides are sustained by square wooden posts, about eight feet high, and placed at proper distances. On either side of the partition wall let there be fixed a kind of rack, like those in stables, which is to run the whole length of the shed, and must be placed as high as a cow can reach her fodder from. The shed must next be divided into stalls, like those for stone-horses, and each stall will be about five feet broad; the length of these stalls must be exactly fitted to that of a cow, that a cross bar, being placed at the outward end, may keep the beast from running backwards: thus every shed will hold fifty cows, five and twenty on each side of the partition: to every one of these sheds you must appoint a man, whose business it will be to clear the place, and carry off the dung; as also to mow the St. Foyne every day, and give it to the cows in the rack before-mentioned: this man beginning at one end of his proportion of ground, and going gradually on to the other, the first place will always be fit to mow again by that time he has gone through his whole division. Your cows are thus fed at discretion, with neither too much nor too little; they are not pestered with the scorching heats, nor troubled with the stinging fly, which, in open pastures, often makes them whisk about, and trample down more grass than they eat. At each end of every shed you must build a slight room of brick, thirty feet square, and ten feet high, which is to be divided, cross-

cross-way of the shed, into two partitions, each fifteen feet broad, and thirty feet long; that, which joins the cow-house, must be paved with tiles, and is to serve for a dairy; the the other must be floored and windowed, and is to be a lodging-room for the dairy-maids. Every shed will require five maids, that is, to every ten cows one dairy-maid; fewer might serve, but it is better to exceed, than fall short, in this particular. Thus each dairy will have two or three maids belonging to it, whose lodging will be the room adjoining, and whose care is to extend to the shed on both sides the partition, to the five and twenty cows which are the nearest to their station. All along both sides of the partition, at about a foot above the ground, let there be fixed, close to the wall, a strong pipe of lead, a little less than an inch diameter; both which pipes, being somewhat raised exactly in the middle of the shed, must have a gentle and almost an invisible descent from that rising to the dairies, through the wall of which their nether ends are to be brought, and there wrought into one another, that whatever descends through them, into either of the dairies, may have issue but at one mouth. This mouth of the pipes must be made very small, and neatly fitted into the hollow end of a strong wooden axle-tree; which, whilst it is turning swiftly round the mouth of the pipe, may by no means strain it by the motion, but receive, into its own hollow, the milk which descends through the leaden pipes, without spilling any, and passes so far through a wheel, or vessel like a barrel, only much larger in its circumference. The axle-tree, which this vessel is to turn upon, is bored very full of round holes, through which it delivers the milk into the vessel, as fast as it receives it from the pipe.

The vessel must be capable of containing, at least, three times the quantity of milk, which it is designed to receive; and there must be six wings, or thin pieces of wood, glued on edge-ways to the wooden axle-tree, whose length and breadth must be so contrived, as to leave a free space of six inches at at either end of the axle-tree, and a foot between their edges length-ways, and the smooth inside of the vessel; in the most convenient part of which must be contrived a door, to open and shut down upon occasion, as closely as if there was none. This door will perform its work very neatly, if you line the inside and edges with some kind of cloth, which is commonly used in the pressing of cheese. The other solid end of the axle-tree must extend itself about five feet longer; and the whole length may be supported by square wooden posts, and turn in their tops, which are to be made hollow, and kept greased for that purpose. This end of the axle-tree is to be fastened into a wheel, exactly like those which are used in many places for roasting of meat. The diameter of this last wheel must be within six inches of the height of the dairy, and two or three large dogs, being put into it at a time, will turn it with extraordinary swiftness: the dogs are easily taught, and will at last take delight in the exercise. I have brought up a large buck to the practice of this labour, and it is wonderful to see the force with which he runs round an hour or two together, and turns a wheel of ten feet diameter; but you must make your wheel as light, as it can possibly hold together. I have but one thing more to say, and I finish this direction: pretty near that side of every stall in your shed, to which the maid must come to milk the cow that belongs to it, let a hole, as small as will serve the occasion, be contrived by your plumber, in the uppermost part of the leaden pipe, to shut and open with a little screw, which screw, for fear of losing it, may be fastened by a little iron chain to the body of the pipe. I have endeavoured, in the description of all this, to make my meaning as plain as possible; if you do not comprehend it at first, you will after two or three times reading and considering it.

May BUTTER, *butyrum majale*, is a medicine in some repute among good women for strains, aches, and wounds. It is made of butter churned at that time, and exposed to the sun during the whole month, till, by repeated fusions, it be brought to a whiteness. Helmont calls it magistery of grass. Quincey affirms it is no better than plain lard.

Butter of stone, a kind of mineral drug found on the highest mountains and hardest rocks of Siberia, being drawn by the sun's heat, in the way of transudation from the dry substance of the stones themselves, and adhering to the surface thereof like a sort of calx, which, having received its full coction, is scraped off by the inhabitants under the name of camine massa. The Russians ascribe many virtues to it. It is much used for the dysentery and venereal diseases; but its operation is so violent, however corrected by other ingredients, that none but the Russians dare use it.

Butter-bur, petasitis, an officinal plant, both in figure and virtues resembling master-wort; it is reputed an alexipharmic and detergent, and used in many compositions, especially of the first of those intentions.

BUTTERFLY, *papilio*, in zoology, a large class of insects, which derive their origin from caterpillars.

Metamorphosis of BUTTERFLIES.—There is something very surprising in the metamorphoses of these and several other insects. Towards the end of the summer, and sometimes sooner, the caterpillars, when satiated with verdure, and, having changed their skins several times, cease to eat, and employ themselves in building a retreat, wherein they are to quit the life and form of a caterpillar, to give birth to the form of the Butterfly they contain within them. A few days are sufficient to conduct some into a new state of existence. Others continue whole months and years in their sepulchres. There are some species which plunge themselves into a small depth in the earth, after they are satiated with their food. In that situation they begin their efforts, and rend their robe, which, with the head, the paws, and entrails, shrink back, like dried parchment; and there remains a substance that resembles a bean, or a kind of covering of a brown colour, with an oval form, the most pointed part of which terminates in several moving rings, whose dimensions are gradually diminished. This is called the chrysalis, and incloses the embryo of the Butterfly, with such fluids as are proper to nourish and complete its growth. When the creature has acquired its perfect form, and is invited by a genial warmth to quit the scene of its confinement, it bursts the large extremity of its inclosure, which always corresponds with its head, and is weak enough to be opened at the first effort.

Some caterpillars, instead of sinking themselves into the earth, prepare a lodgment under the protection of roofs, in the cavities of walls, and even in the heart of the wood. All of them have sufficient abilities to secure themselves a safe retreat, for the time they are to continue in the state of aurelia's.

There are others who suspend themselves, with great dexterity, to the roofs of houses, or the first stake that occurs in their way, and they proceed in the following manner: the caterpillar extracts, from her own substance, a glutinous fluid, which lengthens, and acquires a due consistency, in proportion as she advances her head from one place to another: and when she has glued, and interlaced, several threads on some smooth place, to which she intends to fix herself, she insinuates her hinder paws into a complication of the tissue, by means of the minute claws in which they terminate. In this manner she accomplishes her first fastening; after which she rears her head, and fixes a new thread on the lateral wood that corresponds with her fifth ring, and then, with a gentle deflection of her head, she draws this thread in the form of a bow, around her back, and then fastens it to the opposite side. She frequently repeats these motions, in order to conduct the thread from the left to the right, and from the right to the left. When this second band, which sustains the animal above the middle of her body, has been sufficiently doubled and fortified, she rests upon it, and then agitates her body, till it is entirely covered with sweat. She then bursts her skin, which gradually shrinks to the side where her paws are implicated in the wood. These paws are, likewise, dissipated like the rest of her spoils; but all this is not sufficient to disengage the chrysalis; because, instead of the paws, by which it was detained, the extremity of it has shot out little points, whose heads terminate like that of a mushroom, or nails; and, as they are extended beyond the threads, they are sufficient, with the band that traverses the back, to fasten it, till the proper season, when the papilio is to be discharged from her confinement.

Some caterpillars involve their bodies in a texture of thread and glue, and then roll themselves over a bed of sand, by which means they collect an incrustation of small grains, and build themselves, in this manner, a monument of stone.

There are others who build in wood, and crumble into small particles the substance of a willow, or some other plant to which they have habituated themselves. They afterwards pulverize the whole, and form it, with an intermixture of glue, into a paste, in which they wrap themselves up. This composition dries over the chrysalis it surrounds, and which assumes much the same figure, so that it resembles a mummy, which corresponds with the body it incloses, and which serves it as a defence. If you press them a little, they will discover some signs of life, though their outward appearance indicates no such thing.

The caterpillars we are most acquainted with, are found in great numbers upon elms, apple-trees, and bushes. The papilio that proceeds from these, chuses some beautiful leaf, on which she fixes her eggs in autumn, and soon after dies, glued and extended on her beloved family. The sun, whose rays have still some power, warms her eggs, out of which, before the winter-season, a multitude of little caterpillars spring, who, without ever having seen their mother, and without the least model and instructions, immediately, with a kind of emulation, betake themselves to spinning, and, with their threads, industriously weave themselves beds, and a spacious habitation; where they shelter themselves from the severity of the season, distributed into different apartments, without eating, and frequently without stirring abroad. There is only one little opening at the bottom of this mansion, through which the family, sometimes, takes the air, towards noon, in a fine sunshine, and sometimes in the night, when the weather is settled. When you would open their retreat, you must employ a little strength to break the tissue that forms it, which is, generally, as firm as parchment, and not to be penetrated by rain, wind, or cold. There you will find the whole family reposing on a soft and thick down, and surrounded with several folds of the web they have spun, which

at

at once supplies them with their quilts, their curtains, and their tent.

How is it possible to be unaffected with this little miracle of nature! Open one of these aurelia's, and it will seem to present you with nothing but a kind of putrefaction, containing the elements of a better state of existence, and composing the nutrimental juices which contribute to the growth of a more perfect animal. The time for its enlargement, at last, arrives, and the creature then forces its way through the prison that contained it. The head disengages itself through the aperture, the horns lengthen, the legs and wings are extended, and, at last, the Butterfly takes its flight through the air, retaining no similitude of its former condition. The caterpillar, which is changed into a nymph, and the Butterfly that proceeds from it, are two animals entirely different.

The first was altogether terrestrial, and crawled heavily along the ground. The second is agility itself, and is so far from limiting its motions to the earth, that, in some measure, it disdains to repose on its lap. The first was all shaggy, and frequently of an hideous aspect; the other is arrayed in colours of the most beautiful glow. The former, stupidly, confines itself to a gross food; whereas this ranges from flower to flower, regales itself with honey and dews, and perpetually varies its pleasure. This new animal enjoys all nature in full liberty, and is, itself, one of her amiable embellishments.

The arrangement of Butterflies into genera and classes are, in a great measure, taken from these several parts, and from the great uses which they make of them. The general distinction is, that which divides them into the day and night kinds: we have, among the birds, some few that fly abroad only by night; but these bear only a small proportion in number to the day-fliers: on the contrary, the number of Butterflies which we see fluttering about the fields and gardens, are scarce so many as those which fly abroad only by night. We often meet with this, even in our houses, flying about the candles, and the hedges swarm with them: in the day-time we find them hid under the leaves of plants, and often, as it were, in a torpid state. In this condition they remain till evening, but they are so cunning in hiding themselves at this time, that it is difficult to see one even in places where there are great numbers. The way to discover them, is to beat and disturb the bushes, or shake the branches of trees in places where they are suspected to be, and they will often be driven out in swarms. In this case they never fly far, but settle again on the first tree or bush they come to; and, in summer, if any one goes out into the fields or gardens, with a candle, in a calm and still night, there will numbers of different kinds of them, almost immediately, gather about it. These are called, by naturalists, night Butterflies, phalènæ, and moths.

The several kinds of Butterflies, that have those various inclinations, have also external characters by which they may be distinguished; all those which have buttoned antennæ, or club antennæ, are of the diurnal kind, and are never seen flying about candles in the night. There are other forms of the antennæ also, which are peculiar to the day Butterflies; and the night ones are distinguished by their having the plumose, the prismatic, or the conic ones.

Those which fly about our candles are always of one of these three kinds. It is not, indeed, to be wholly affirmed, that no one of these kinds is ever seen flying by day-light, since, in woods and thickets, we often see them fluttering about without having been disturbed; but all that are thus caught flying are males, and are that time seeking after the females, to couple with them, these being all fixed immoveably under the leaves and on the branches of trees.

The common kinds that we see fly about from flower to flower, are all of the day kind: a few species of the phalenæ sometimes flutter about the thistle flowers, and seem to suck them; but these are seldom seen; and among the moths, or night kinds, as we call them, there are a great many that never fly about by night any more than by day, and, indeed, make no use of their wings at all.

It is also a singular observation, that the moths which fly about our candles, whether in the house, or abroad in the gardens, are all males; the females never do it. The male of a glow-worm flies in the same manner at the candle, thinking it the light of his female; and it is possible, that the female moths may, in the night, yield a light that affects the eyes of the male of the same species, though it be insensible to our view.

The great general distinctions of the Butterflies into day and night kinds being made, it is necessary to have recourse to numbers of other sub-distinctions, in order to arrange them in any method; and these can, by no means, be taken from them in their prior state of caterpillars, many of them being in that state alike in all their general characters, though of different genera in their flying state.

As the antennæ serve for distinctions of the Butterflies into classes, so do their trunks into genera; but these are only capable of distinguishing a few, the flat and the round being their principal distinction. Mr. Reaumur has observed, that the day Butterflies have all these trunks, but that many of the night kinds want them. The wings, however, give the greatest variety of generical characters among these animals. The shape of these, and the manner in which these creatures carry them, when walking, and at rest, serve as great and essential distinctions.

Class 1. contains those Butterflies whose antennæ are terminated by buttons, and whose wings, when at rest, are placed in a perpendicular direction to the thing the creature sits upon, the under edges of which embrace the lower part of the body, and whose six legs are all employed in sustaining the body, and in walking. The black-spotted white Butterfly, produced from the beautiful cabbage caterpillar, is one of the Butterflies of this class.

Class 2. contains the Butterflies of the same characters with the former in all respects, except that they use only four of their legs in sustaining the body, and in walking. The two anterior legs in the flies of this class are held in a bent posture, and are furnished with a downy part at their ends, and seem to serve as a sort of arms. These Butterflies, in general, are produced from the prickly caterpillars. The solitary nettle kind gives us an instance in its Butterfly.

Class 3. contains those Butterflies which agree in all respects with the former, except that their two anterior legs, which they use as arms, and never in walking, are not terminated by downy ends, but are fashioned like the other legs, at the extremity, only so small, that it requires a microscope to distinguish them. There is an instance of this class in a common grey and yellow Butterfly, that is found in pastures among the grass in June, July, and August.

Class 4. contains those Butterflies which have buttoned antennæ, as the others, and which carry their wings, when at rest, in a perpendicular direction to the thing they sit upon; but, as the former have the inferior edge of their wings bent round the upper part of their body, so in these the inferior edge is bent upwards in both pair of wings, and embraces and covers the upper part of the body. However obvious this distinction may be, there is another yet more plain in this, that all of this class have one of the jags of the wing so far extended beyond the rest of the verge, that it forms a kind of tail; and they are called the tailed Butterflies. These use all their six legs in walking.

Class 5. contains those Butterflies which have six real legs, which they use as such, and their horns terminated by buttons as the others; but whose wings, when they repose, are not elevated perpendicularly to the thing they sit on, as in the four preceding classes, but are held in an horizontal direction, or, at the utmost, never meet in an angle over the back. We have an instance of this class in a Butterfly bred from a smooth caterpillar of the marshmallow.

Class 6. contains those Butterflies which have club antennæ, that is, such antennæ as gradually increase in thickness from their origin to their extremity. These are that class of Butterflies which are always upon the wing, and buz about flowers without ever settling upon them. They dart their trunks into the flower while they sustain themselves in the air, and have a way of holding themselves in poise, like a kite or other bird of prey; but, when they are busy about the flowers, they have their wings in continual motion, and make a humming noise, like the humble-bees.

Class 7. In the last class are comprehended those Butterflies whose antennæ are long at their origin, smaller afterwards, and finally terminated by an oval head; and which differ from the club antennæ in having no pencils of hairs at the end. This class is not very numerous, and the most frequent instance we have of it is in a painted kind, which we frequently find on blades of grass, in meadows, in July. This flies little in the day time, but is usually found fixed to a plant, as the moths are. *Reamur's Hist. Insect.*

BUTTERFLY-*shell*, in natural history, the English name for a beautiful species of the volutæ. See *plate* VI. *fig.* 32.

The volutæ are the most beautiful shells of the whole body of sea productions. See VOLUTA.

BUTTON.—The form and use of a Button are too familiar to need a description. The matter whereof they are made is various; as metal, thread, silk, mohair, &c.

Method of making common BUTTONS.—Common Buttons are usually made of mohair; some indeed are made with silk, and others with thread; but the latter are a very inferior sort. In order to make a Button, the mohair must be previously wound on a bobbin. The mould is then fixed to the board by means of a bodkin thrust through the hole in the middle of it; and the workman wraps the mohair round the mould in three, four, or six columns, according to the nature of the button.

Wrought BUTTONS.—The first part of the process, in making these Buttons, is the same as the preceding; viz. the mould is covered with mohair in three, four, or six columns as before; after which they are stitched by various kinds of stitches, so as to represent different figures.

Horse-hair BUTTONS.—The moulds of these Buttons are covered with a kind of stuff composed of silk and hair; the warp being Belladine silk, and the shoot horse-hair. This stuff is wove with two selvedges in the same manner, and in the same loom, as ribbands; for the method of which see ribband WEAVING. The stuff is cut into square pieces proportionable to the size of the Button; these pieces are wrapped round the moulds, and their selvedges stitched together, which forms the under part of the Button.

Cleansing of BUTTONS.— A Button is not finished when it comes from the maker's hand; the superfluous hairs and hubs of silk must be taken off, and the Button rendered glossy and beautiful, which they perform in the following manner:

A quantity of Buttons are put into a kind of iron sieve, called by workmen a singing-box. Then a little spirit of wine being poured into a shallow iron dish, and set on fire, the workman moves and shakes the singing-box, containing the Buttons, briskly over the flame of the spirit, by which means all the hairs, hubs of silk, &c. are burnt off, without damaging the bottom. Great care must be taken that the Buttons in the singing-box be kept constantly in motion; for, if they are suffered to rest over the flame, they will immediately burn.

When all the loose hairs, &c. are burnt off by the flame, the Buttons are taken out of the singing-box, and put, with a proper quantity of crumbs of bread, into a leather bag, about three feet long, of a conical shape, the apex or small end being closed up. The operator then takes one end of the bag in one hand, and the other in the other, and shakes them briskly, and with a particular jerk; by which means they are rendered very glossy and fit for use.

Gold-twist BUTTONS.— The mould of these Buttons is first covered with silk in the same manner as common Buttons. The mould being overlaid with silk, it is covered with a thin plate of gold or silver, and then wrought over in different forms with purle and gemp. The former is a kind of thread composed of silk and gold wire twisted together: and the latter capillary tubes of gold or silver, about a tenth of an inch long. These are joined together by means of a needle filled with silk, thrust through their apertures, in the same manner as beads or bugles.

The manner of making metal BUTTONS.— The metal to be used is first cast into a small ingot, and then flatted into thin plates, or leaves, of the thickness intended, at the flatting mill; after which, it is cut into little round pieces of a diameter proportionable to the wooden mould they are to cover: this cutting is performed with a sharp punch, on a leaden block or table.— Each piece of metal thus cut, and taken off from the plate, is reduced to the form of a Button, by beating it successively in several spherical cavities, with a round piece of iron in form of a puncheon; still beginning with the flattest cavity, and proceeding to the more spherical, till the plate have got all the relievo required: and, the better to manage so thin a plate, they form ten, twelve, or even twenty-four, to the cavities at once; and also neal the metal to make it more ductile.

The inside thus formed, they give an impression to the outside, with the same iron puncheon in a kind of mould, like the minter's coins engraven en creux, or indentedly, and fastened to a block or bench, by means of the same kind of press used in coining. The cavity of this mould, wherein the impression is to be made, is of a diameter and depth suitable to the sort of Button to be struck in it; each kind requiring a particular mould. Between the puncheon and the plate is placed some lead, called by workmen a hob, which contributes to the better taking off all the strokes of the engraving; the lead, by reason of its softness, easily giving way to the parts that have relievo; and as easily insinuating itself into the trace, or engraving of the indentures.

The plate, thus prepared, makes the upper part or shell of the Button.— The lower part is formed of another plate, made after the same manner, but flatter, and without any impression. To this last is soldered a little eye made of wire of the same metal, for the Button to be fastened by.

The two plates are soldered together, with soft solder: and then turned in a lathe.— Ordinarily, indeed, they content themselves to cover the naked mould with the shell; and in this case, for the fastening, they pass a thread or gut a-cross through the middle of the mould; and the cavity between the top of the mould and the cap they fill with cement, in order to render the Button firm and solid; for the cement, entering all the cavities formed by the relievo of the other side, sustains it, prevents its flattening, and preserves its bosse or design.

Button-MOULD; see the article *Button*-MOULD.

BUTTON, among gardeners, denotes a flower or cluster of leaves not yet expanded.

Buttons are a kind of ova, out of which arise either leaves alone, or intermixed with flowers. Leaf Buttons are smaller and more pointed than flower Buttons, which are bigger and rounder. Among trees which bear kernel fruit, each Button produces several flowers; and, among stone fruit-trees, each Button yields but one flower.

BUTTON, *in fencing*, signifies the end or tip of a foil, being made roundish, and usually covered with leather, to prevent making contusions in the body.

BUTTON, *in building*, denotes a slight fastening for a door or window, made to turn on a nail.

BUTTON *of the reins of a bridle*, is a ring of leather with the reins put through it, running all along the length of the reins.

BUTTON *Antennæ*, a name given by naturalists to those antennæ or horns, as they are called, of butterflies, which are slender and terminated at the top by a sort of Button, in form of an olive, or part of one.

BY'SSUS, or BYSSUM, βύσσος, a fine sort of thready matter produced in India, Egypt, and about Elis in Achaia, of which the richest apparel was intirely made, especially that wore by the priests both Jewish and Egyptian.

Authors usually distinguish two sorts of Byssus, that of Elis, and that of Judea, which was the finest. Of this latter were the priestly ornaments made. Bonfrerius notes, that there must have been two sorts of Byssus, one finer than the ordinary, by reason there are two Hebrew words used in scripture to denote Byssus, one of which is always used in speaking of the habit of the priests, and the other that of the Levites.

BYSSUS, in botany, a word used to express a genus of mosses the most imperfect of the whole class of vegetables. The characters of this genus are: the mosses of it are composed of simple and uniform parts, and always appear in form of excrescences, either of a woolly or of a dusty matter. It seems properly a genus of vegetables of a middle kind, between the mushrooms and the mosses, but most approaching to the latter, in that the several species of it are of a longer duration, and want that fleshy texture which distinguishes the fungus class, and in that they never produce heads, nor have any thing of the figure or texture of fungi.

BU'ZZARD, *buteo*, a bird of the long-winged hawk kind, of the size of a pheasant, or small pullet. Its head is large and flat, and its beak short, crooked, and of a bluish black, and covered above with a yellow skin down to the nostrils. Its back and wings are of a reddish or yellowish brown, tending to black, or, as some call it, a rusty black, sometimes variegated with white spots near the shoulders. Its breast and belly are of a yellowish white, but on the breast there are several oblong rusty-coloured spots. Its thighs are covered with yellowish white feathers, with transverse streaks of a ferrugineous colour; between its eyes and nostrils there are several black bristles. The tail is not forked; the legs are short, thick, strong, scaly, and of a yellowish colour. It feeds on moles, field mice, and other such animals; sometimes on small birds, and sometimes will seize on rabbits. In want of better food, it will also sometimes live on beetles, worms, and the like. Its eggs are white, more or less sprinkled with irregular red spots. In age, or by some other accidents, the head and back in this species are sometimes found grey. *Ray's Ornithology.*

C.

CAABA, a square stone edifice in the temple of Mecca, supposed to have been built by Abraham and his son Ishmael; being the part principally reverenced by the Mahometans, and to which they always direct themselves in prayer.

The word is Arabic, Caaba, and caabah, a denomination which some will have given to this building, on account of its height, which surpasses that of the other buildings in Mecca; but others, with more probability, derive the name from the quadrangular form of this structure.

The length of the Caaba is about twenty-four cubits, its breadth twenty-three, and height twenty-seven cubits; the door, which is on the east side, being four cubits from the ground, and the floor level with the bottom of the door. In the corner next this door, is the famous black stone, which is set in silver, and exceedingly respected by the Mahometans. The pilgrims kiss it with great devotion, and it is by some called the right hand of God on earth. It is fabled to be one of the precious stones of Paradise, which fell down to the earth with Adam, and, being taken up again at the deluge, was brought back by the angel Gabriel to Abraham, when he was building the Caaba. It was at first whiter than milk, but grew black long ago; some say by the touch of a menstruous woman, others by the sins of mankind, others by the numerous kisses of the devotees. On the north side of the Caaba, within a semicircular inclosure, lies the white stone, said to be the sepulchre of Ishmael, which receives the rain water that falls off the Caaba, by a spout formerly of wood, but now of gold. The Caaba has a double roof, supported within by three octangular pillars of aloes wood, between which, on a bar of iron, hang some silver lamps. The outside is covered with rich black damask, adorned with an embroidered border of gold, which is changed every year, and was formerly sent by the caliphs, afterwards by the sultans of Egypt, but now provided by the Turkish emperors. At a small distance from the Caaba, on the east side is the station or place of Abraham, where there is another stone wherein they pretend to shew the footsteps of that patriarch, supposed to have been made when he stood on it in building the Caaba, where it served him for a scaffold, with this peculiar advantage, that it rose and fell of itself, as he had occasion.

CAAMI'NI, in botany, a name given by the Spaniards and others to the finest sort of the Paraguay tea. It is the leaves of a shrub which grows on the mountains of Maracaya, and is used in Chili and Peru as the tea is with us. The mountains, where the trees which produce this valuable leaf grow naturally, are far from the inhabited parts of Paraguay; but the people of the place know so well the value and use of it, that they constantly furnish themselves with great quantities of it from the spot. They used to go out on these expeditions many thousands together, and their country is left to the insults of their enemies the mean time, and many of them perish with the fatigue.

To remedy these inconveniences, they have of late planted the trees about their habitations; but the leaves of these cultivated trees have not the fine flavour or the virtues of the wild ones.

The king of Spain has permitted the Indians of Paraguay to bring to the town of Santfoy twelve thousand arobes of the leaves of this tree every year; but they are not able to procure so much of the wild leaves annually; about half the quantity is the utmost they bring of this; the other half is made up of the leaves of the trees in their own plantations, and this sells at a lower price, and is called pabos. The arobe is about twenty-five pounds weight; the general price is four piastres for the arobe, and the money is always divided equally among the people of the colony. *Observ. sur les Coutumes de l'Amerique.*

CAB, or KAB, a Hebrew measure of capacity, equal to the sixth part of the seah, or an eighteenth of the epha.

The Cab of wine contained two English pints; the Cab of corn 2 5/6 pints, corn measure.

CA'BALA *Vein*, in natural history, a name given by our Sussex miners to one kind of the iron ore commonly wrought in that country. It is a stony ore, of a brownish colour, with a blush of red, which is more or less conspicuous in different parts of the same masses.

CA'BBAGE, *brassica*, in botany, a genus of plants, whose characters are: the flower consists of four leaves, and is of the cruciform kind; the pistil which arises from the cup, becomes at length a long cylindrical pod, divided into two cells, which are filled with roundish seeds, by an intermediate membrane. Tournefort has enumerated twenty-five, and Mr. Miller twenty-two species of Cabbage.

All the common sorts of Cabbages are largely cultivated about London. The common white, red, flat, and long-sided ones, are chiefly for winter use. The seeds of these sorts must therefore be sown in the middle of March, in beds of good fresh earth; and in April, when the young plants will have about eight leaves a piece, they are to be prickled out into shady borders, about three inches square; and, about the middle of May, they must be transplanted to the places where they are to remain: and this is commonly between cauliflowers or artichokes, at about two feet distance in the rows. They must be watered at times, and the earth must be houghed up about their roots, and kept clear from weeds.

These Cabbages will be fit for use soon after Michaelmas, and will continue till February, if not destroyed by bad weather; to prevent which, the gardeners about London pull up their Cabbages about November, and trench the ground in ridges, laying their Cabbages against the ridges, as close as possible on one side, burying their stems in the ground; and in this manner they let them remain till after Christmas, when they cut them for market.

The Russian Cabbage is small, and not much cultivated now. It is to be raised as the others, but may be planted nearer, as not so large. It is fit for use in July.

The early Battersea and sugar loaf Cabbages are sown for summer use, and are commonly called Michaelmas Cabbages. The season for sowing these is the beginning of July, in an open spot of ground. It is common to sow spinage in the same beds with these, houghing it up from about their stalks in spring; in May and June these begin to turn their leaves for cabbaging, and may be brought to it much sooner then naturally they would, by tying them about with an ozier band.

The Savoy Cabbages are for winter use, and are to be sown about the beginning of April; they are to be treated as the common Cabbage, and planted out at two feet distance, in an open place.

The bore-cole may be cultivated in the same manner, but must be planted only at one foot distance; these are not fit to cut till the frosts have nipped them.

The method of getting good Cabbage seed is this: chuse out some fair plants in October, pull them up, and hang them up three days, with the root upward, in a shady place; then plant them under a warm hedge, burying the whole stalk and half the Cabbage in the earth; cover them with culm, if the winter be severe, and in spring they will shoot out many branches. When these begin to pod, the ends of the upper ones should be cut off, to give strength to the other pods. The seed must be preserved from the birds, by planting some lime twigs about the plants, where the catching one or two will intimidate the rest. When ripe, it must be threshed out, and kept for use. *Miller's Gard. Dict.*

The Cabbage removes, as it is said, the consequences of hard drinking; and it has been well known to be a custom among many at this time, as well as among the antient Egyptians of old, to eat raw or boiled Cabbage, as a preservative against the effects of wine. This seems to have sprung from the opinion of the great antipathy of the plants to one another; it having been affirmed, that the vine and Cabbage will by no means grow together; and some of the moderns have endeavoured to account for this, from the nature of these two plants, by saying, that they are both so fond of nutritive juice, as greedily to suck up all the juices of the earth, and by that means, when planted near, to starve one another. But we have no reason to have recourse to these suppositions, since there is not the least truth in the observation, but the vine and Cabbage grow as well together as any two plants in the world. *Ephemerid. German.*

CA'BBALA (*Dict.*)—This oral tradition has obtained so much credit among Christians that some have put its authority on a level with holy writ; amongst these is the famous Johannes Picus, whom a zealous attachment to the Romish religion carried beyond his reason. He imagined the cabbalistical books he had purchased, at no small expence, authentic, thought them the work of Esdras, and that they contained the doctrine of the ancient Jewish church. He thought he saw

in

in them the myftery of the Trinity, the incarnation, the redemption of mankind, the paffion, death, and refurrection of Jefus Chrift, purgatory, baptifm, the abolition of the old covenant, and, in fhort, all the opinions maintained and received by the Romifh church: but his notions were exploded, his thefes were fuppreffed, and thirteen of his propofitions condemned as heretical. The original of the Cabbala is very obfcure. Some tell us the angel Raziel, the inftructor of Adam, gave him the Cabbala, a book containing the celeftial fciences, which on his expulfion from paradife he took away from him, but, moved by the intreaties of Adam, Raziel returned to him again. Others fay Adam did not receive this book till after his fall. They tell us that Adam, on his humble fupplication to God for comfort in his unhappy ftate, received this book from Raziel to which they attribute all the pretended power of magic. They add that this book was handed down from father to fon, and at laft fell into the hands of Solomon, whom it taught to build the temple by the means of the worm Zamir, without the help of any inftrument of iron. Ifaac Ben Abraham publifhed a book to prove this, but the book was condemned to the flames by the Jews of his own tribe.

The learned are fo much divided in their opinions concerning the origin of the Cabbala, that it is almoft impoffible to determine any thing certainly about it. Morus and Van Helmont are the firft who have wrote on this fubject, with defign of clearing up the point: but in this they have fucceeded very ill, having afcribed falfe principles to the Cabbala, which is proved by Wachterus, in Judaifm detected, page 2. To avoid falling into the fame error we fhall extract, what we advance on this fubject, from thofe authors who have wrote with the moft perfpicuity and order on it. R. Ifaac Lorica and R. Abraham Irira among the moderns are moft eminent. The firft wrote the Drufchim, which contains a metaphyfical introduction to the Cabbala; the fecond wrote a book intitled Schaar Hafcamaim, that is the Gate of the Heavens; thefe books are wrote with much clearnefs, and explain the foundation of the cabbaliftical philofophy, which depends on the following principles.

1. From nothing nothing can be produced; and on this one principle depends the whole of the cabbaliftical philofophy. The cabbaliftical philofophers were no ftrangers to the term creation, but they underftood the word in a very different light from the Chriftian notion, which is, that God from nothing created all things. They did not borrow this principle from the Jewifh church but the heathen philofophers, who, looked upon it equally abfurd to affert any exiftence was produced from nothing, as to fay a thing is and is not. Spinofa has urged this argument ftrongly in favour of his opinion; Epicurus among the ancients advanced this doctrine againft Heraclitus and the Stoics. But the fuppofition of a pre-exiftent omnipotent caufe at once deftroys the force of it.

2. In confequence of the firft, no fubftance can have proceeded from nothing.

3. Even matter, therefore, could not have proceeded from nothing.

4. Matter, becaufe of the vilenefs of its nature, owes not its original to itfelf. The reafon Irira advances, in fupport of this principle, is, that matter in itfelf is without form, and is only one degree removed from non-exiftence.

5. From whence it follows, that there is not in nature any fuch thing as matter properly fo called.

The philofophical reafon the cabbalifts bring to maintain this principle is, the intention of the efficient caufe to make a work like unto himfelf; now, the firft caufe being a fpiritual fubftance, the productions muft have been fpiritual rather than corporeal fubftances; becaufe the former moft refemble the nature of the efficient caufe. This reafon they infift on very ftrenuoufly, and argue, that it is as great an abfurdity to fay God created material fubftances, which are different from his own nature and effence, as to fay God created darknefs, fin, and death; for, fay they, matter is nothing but a privation of fpirit, as darknefs of light, fin of fanctity, and death of life.

6. From whence it follows that whatever exifts is fpirit.

7. This fpirit is uncreated, eternal, intellectual, fenfible, having in itfelf the principle of motion, infinite, independent, and neceffarily felf-exiftent.

8. This fpirit is confequently the enfoph or infinite God.

9. It follows therefore, that whatever exifts, muft be an emanation from this infinite fpirit. As the cabbalifts did not admit of a creation in fuch a manner as the Chriftians receive the doctrine of it, fo they were obliged either to admit of a pre-exifting matter, or maintain that the univerfe proceeded from God by way of emanation: the firft opinion they dared not embrace, becaufe it was contrary to their tenets to admit of a material caufe exclufive of God, and therefore fell into the doctrine of emanations, which they received from the orientals who were taught it by Zoroafter, as appears from cabbaliftical writers.

10. The nearer things are in their emanation from the divine fource of all, fo much are they more noble and divine; the more diftant they are, fo much lefs do they partake of the divine nature and perfection.

11. The world is diftinct from God as the effect from its caufe, not as a tranfient but a permanent effect. The world, therefore, being an emanation from God, is to be confidered as God himfelf, who, being incomprehenfible in his effence, has chofen to manifeft himfelf in his emanations.

Thefe are the principal doctrines of the Cabbala, from whence they have deduced a multitude of extravagant whims, which we do not think it neceffary to trouble our reader with.

CA'BINET, a piece of joiner's workmanfhip. It is a kind of prefs or cheft, with feveral doors and drawers, to lock up the moft precious things, or only to ferve as an ornament in chambers, galleries, or other apartments.

There are common Cabinets of oak, or of chefnut; varnifhed Cabinets of China and Japan; Cabinets of inlaid work; fome of ebony, and other fcarce and precious woods.

The Cabinets of Germany were formerly in great repute in France, where they were very much efteemed, on account of feveral mechanical rarities and curiofities, which they were filled with in the infide. They are very much valued in foreign countries, and the Dutch carry fome ftill into the Eaft; but they are almoft intirely out of date in France, as well as the Cabinets of ebony, which came from Venice.

Cabinet, in a garden, is a conveniency which differs from an arbour, in this, that an arbour or fummer-houfe is of a great length, and arched over head, in the form of a gallery; but a Cabinet is either fquare, circular, or in cants, making a kind of falon to be fet at the ends or in the middle of a long arbour.

Cabinet *of natural hiftory*, a building containing all the curiofities of nature, digefted in a proper manner.

Such a building might indeed be called, with more propriety, a mufæum or repofitory; Cabinet here, therefore, muft be underftood in a larger fenfe than the common acceptation of the word, as herein are exhibited to our view the animal, vegetable, and mineral kingdoms at once: in fhort, an epitome of nature.

It is not certain whether the ancients ever formed any collections of this kind, or erected any ftructures for the reception and difpofition of them. But it is not improbable, that Ariftotle, fupported by the generofity and magnificence of Alexander the Great, built fomething of this kind, at leaft with regard to animals; becaufe the obfervations he has left us, are undoubtedly the refult of anatomical obfervations, and the remarks he has made on the various fpecies of animals fhew our knowledge, even fince the revival of letters, to be vaftly inferior to his, in this refpect.

The knowledge of natural hiftory improves, as collections of this kind are made more perfect; and our own age has firft fet on foot eftablifhments that deferve the name of Cabinets of natural hiftory.

That in the garden of the king of France is reckoned one of the richeft in Europe; a fketch of it may not be difagreeable. In the animal kingdom are feen human fkeletons of all ages, a numerous collection of bones remarkable for fiffures, fractures, deformities, and difeafes. Several preparations of anatomy injected and dried: feparate parts preferved in fpirits. Some fine pieces of anatomy reprefented in wax, wood, &c. Some pieces of mummies and ftony concretions extracted from human bodies, a large quantity of habiliments, arms, and inftruments ufed by the favages, &c. brought from America and other parts of the world.

Among the quadrupeds a great number of fkeletons and other pieces of ofteology, parts of the beafts preferved in fpirits, fome fkins ftuffed to refemble the life, &c.

Fine fkeletons of the largeft and moft uncommon birds, others preferved in fpirits, others ftuffed, &c.

A numerous collection of fea and river fifh dried, others preferved in fpirits.

A vaft number of different fpecies of lizards, ferpents, &c. collected in all parts of the world.

A very great feries of fhell and cruftaceous animals, &c.

And laftly a prodigious number of infects both of land and water; amongft others, a papilionaceous feries almoft complete, and a vaft collection of falfe marine plants of all fpecies.

In the vegetable kingdom are complete herbals furnifhed by Meff. Tournefort and Vaillant with numerous feries of roots, barks of trees, feeds, and fruits of plants; a collection of gums, refins, balms, and other juices of vegetables almoft complete.

In the mineral kingdom are collections of earths, common and figured ftones, petrifications, incruftations, ftalactites; a fine feries of pebbles, fine ftones, rough and polifhed, ranged in plates and vafes, &c. precious ftones, cryftals, all forts of falts and bitumens, mineral and foffile fubftances; a collection of the minerals found in France and all the parts of Europe, efpecially in the northern parts of the world, and principally America.

All thefe collections are ranged in a methodical order, and diftributed in a manner moft proper for the ftudy of natural hiftory. Every individual is marked with its proper title. The whole is placed under glaffes with tickets, or difpofed in the moft convenient manner for obfervation.

To form a Cabinet of natural hiftory, it is not enough to collect

lect without choice, and heap together all the objects we meet with in natural history, without taste or order; we must know how to distinguish what ought to be rejected, what admitted. Order and relative distribution constitute the principal beauty of these collections, the ends of which are instruction and entertainment; and, without the merit of order and distribution, of what use is a great collection? What will it signify, whom will it improve, to amass in sumptuous buildings, at great pains and expence, a multitude of productions, which are presented to us in confusion, and without any regard to the nature of the things themselves, or the principles of natural philosophy? I should be apt to say to such naturalists as these, Send back to the sea your shells; restore to the earth its roots, seeds, and plants; cleanse your apartments of this heap of dead bodies, of birds, fishes, and insects: if you only make a chaos wherein I see nothing distinct, you know not how to display the riches of nature; let men of so low a genius hew the stone, but leave to others the direction of the structure.

M. d'Aubenton, who is demonstrator and keeper of the king of France's cabinet, has given some excellent directions for the distribution and arrangement of such collections.

The disposition most proper for the study of natural history, says he, is a methodical order, which distributes whatever it contains into classes, genera and species. Thus the animal, vegetable, and mineral kingdoms will have their separate apartments. The same order should subsist between the genera and the species. The individuals of the same species should be placed near, under, and round about it, never distant from it. Thus you will see the species in their genera, and the genera in their classes. Such an arrangement as this must tend greatly to the improvement of natural history; every thing becomes instructive; at one cast of the eye, we not only have a real knowledge of the object we apply ourselves to, but discover also the affinity it has with those that surround it. The resemblances indicate the genius, the differences mark the species. By following nature thus in all the variety of her productions, we pass insensibly from one kingdom to another; the gradations prepare us, by little and little, for the great change, which is not sensible in the whole, but by comparing the two extremes.

England may be complimented on the possession of Sir Hans Sloane's collection, and there is no room to doubt but it will be disposed in the most elegant and methodical manner; because the noble and learned personages, concerned in that affair, are most eminent for capacity and genius.

CABINET, is sometimes particularly used for a place at the end of a gallery, wherein are preserved the paintings of the best masters, conveniently ranged, and accompanied with busts, and figures of marble and bronze, with other curiosities.

CA'BLE (*Dict.*)—In the manufacture of Cables, after the ropes are made, they use sticks, which they pass first between the ropes, of which they make the strands, and afterwards between the strands, of which they make the Cable; to the end that they may all twist the better, and be more regularly wound together: and also to prevent them from twining, or entangling, they hang to the end of each strand, and of each rope, a weight of lead, or stone.

When the Cable is made, and twisted as it ought to be, they untwist three or four turns, that the rest may better remain in their proper position.

Cables that are too much twisted, burst very easily; and, when they are spun off, that is to say, not sufficiently twisted, they break.

The number of threads, of which a Cable ought to be composed, is always proportionable to its length and thickness; and it is by the number of threads that compose it, and make its diameter and circumference, that one may judge of its weight, and, consequently, make an estimate of its value, which is an expeditious way of computing the worth of cordage. See ROPE-*making*.

CA'BLING, in architecture, the figure of a staff, or reed, either plain or carved, in resemblance of a rope, or a rush, wherewith a third part of the flutings of a column are sometimes filled up; hence called cabled flutings.

CABO'CHED, in heraldry; a deer's, leopard's, or bull's head, is said to be Caboched, when it is borne full-faced, without any part of the neck. *Coats, Dict. Herald.*

CA'CAO (*Dict.*)—See *Plate* IX. *fig.* 4. where *n* is a young shoot of this tree, *o* its flower, *p* ripe fruit, *q* ripe fruit open, *r* kernel, *s* kernel open, *t* kernel dissected.

In order to cultivate this plant in Europe, by way of curiosity, it will be necessary to have the nuts planted into boxes of earth (in the countries where they grow) soon after they are ripe; because, if the nuts are sent over, they will lose their growing quality before they arrive. These boxes should be placed in a shady situation, and must be frequently watered, in order to forward the vegetation of the nuts. In about a fortnight after the nuts are planted, the plants will begin to appear above ground; when they should carefully be watered in dry weather, and protected from the violent heat of the sun, which is very injurious to these plants, especially while they are young: they should also be kept very clear from weeds, which, if suffered to grow in the boxes, will soon overbear the plants, and destroy them. When the plants are grown strong enough to transport, they should be shipped, and placed where they may be screened from strong winds, salt water, and the violent heat of the sun. During their passage, they must be frequently refreshed with water; but it must not be given them in great quantities, lest it rot the tender fibres of their roots, which will destroy the plants; and, when they come into a cool latitude, they must be carefully protected from the cold, when they will not require so frequently to be watered; for, in a moderate degree of heat, if they have gentle waterings twice a week, it will be sufficient.

When the plants arrive in England, they should be carefully taken out of the boxes, and each transplanted into a separate pot, filled with light rich earth, and plunged into a moderate hot-bed of tanners bark; being careful to cover the glasses in the heat of the day, to screen the plants from the sun: they must also be frequently watered; but it must be done with caution, not to rot their roots. In this hot-bed the plants may remain till Michaelmas, when they must be removed into the bark-stove, and plunged into the tan, in the warmest part of the stove. During the winter season, the plants must be frequently refreshed with water; but it must be given to them in small quantities: yet in summer they will require a more plentiful share. These plants are too tender to live in the open air in this country, even in the hottest season of the year, therefore must constantly remain in the bark-stove; observing, in very warm weather, to let in a large share of fresh air to them, and in winter to keep them very warm. As the plants increase in bulk, they should be shifted into larger pots, in doing of which, there must be particular care taken not to tear or bruise their roots, which often kills the plants; nor must they be placed in pots too large, because that is a slow but sure death to them. The leaves of these plants must be frequently washed, to clear them from filth; which they are subject to contract by remaining constantly in the house; and this becomes an harbour for small insects, which will infest the plants, and destroy them, if they are not timely washed off. If these rules are duly observed, the plants will thrive very well, and may produce flowers in this climate; but it will be very difficult to obtain fruit from them; for, being of a very tender nature, they are subject to many accidents in a cold country.

CACAO *preserved*, or *sweet-meats of Cacao*. They are made in the Antilles, are excellent, and far excel all the sweet-meats made in Europe.

The Cacao which one would preserve, must be gathered some time before it be quite ripe; the maturity of this fruit is known by its pods beginning to turn yellow; they must be chosen, therefore, some days before they begin to take that colour.

The nuts, which are then delicate and tender, are put to soak in fresh clear water, which must be changed every morning and every night during five or six days; after which they lard them with very thin bits of lemon-peel and cinnamon; then they make a syrup of the finest sugar, but very thin, wherein they put the nuts: after it is taken from the fire, and sufficiently clarified, they leave them in that syrup 24 hours. When they are taken out of it, and well dried, they make another syrup, but thicker, in which they leave them again a whole day. Lastly, after they have thus passed them through five or six syrups, they make another, of a greater consistency than the former, wherein they put musk, ambergrise, or other perfumes, people like them; and in this last syrup the nuts are kept for use.

When they would have them dry, they take them out of the last syrup; and, having drained them well, they plunge them into another syrup, very strong of sugar, and well clarified, and put them immediately into a stove, where they are candied.

F. Labat, from whom this account is taken, observes, that this sort of sweet-meats requires a great deal of care, and consumes a prodigious quantity of sugar: he adds, that the confectioners of the French islands seldom make any, and cannot undertake it, or make it as it should be, under a crown the pound. *Labat Nouveaux Voyages aux Isles de l'Amerique.*

CACHE'XIA (*Dict.*)—Dr. James, for the illustration of the subject, has endeavoured to explain how a Cachexy may be, and generally is produced.

Suppose, says he, a person, of any constitution whatever, has his stomach and organs of digestion impaired by any accident; and that this person takes one or more hearty meals of any aliment which is superior to the force of the digestive organs; and that, moreover, he uses little or no exercise: upon this occasion it is not likely, that the aliment should be digested and assimilated, so as to produce good blood; but, in proportion as the aliment is more or less dissolved, the partially dissolved portions will stagnate in the first, or more remote series of vessels, that is, in the larger or smaller vessels; and will cause various disorders, according to the uses and importance of the parts which they obstruct.

Suppose the aliment so little dissolved, that the largest particles which the lacteals can possibly admit, are by these conveyed to the receptacle of the chyle, and from thence to the mass of blood; with which, circulating till they arrive at the lungs, they either pass not at all, or with difficulty, through the minute vessels of that organ, on account of their bulk; hence difficulty of breathing and palpitations arise: and, as the blood should be farther elaborated, and receive its red colour in the lungs, this

this impediment will, in some degree, prevent them both: hence the blood will be pale, and the particles of which it consists, will not be so perfectly mixed and united together, as to form a fluid adapted to the exigencies of the animal œconomy. For this reason, the watery particles readily separate from the rest, and loiter, or stagnate, in different parts, where they cause soft tumors, as under the eyes, and in the parts remote from the heart. As these large particles must, moreover, stagnate in the glands, and obstruct them, the secretions of their respective fluids must be impaired. For this reason, many of the aqueous particles, which should either be separated for expulsion, or applied to particular uses, are retained in the mass of blood; the bile, also, a fluid of the utmost importance in digestion, as well as the pancreatic juice, becomes defective, inert, and languid; and all the solids are farther relaxed, and, amongst them, the organs of digestion; whence every subsequent meal lays a new foundation for an increase of the disorder, and all its symptoms.

I must add, that, when women have acquired such a habit, the watery particles of the blood loiter, or stagnate; and the other particles are too large to pass through the minute uterine vessels, and form the catamenia.

From what has been said, the reasons are evident, why the eating chalk, cinders, dirt, unfermented, farinaceous vegetables, as oatmeal, and other indigestable substances, induce a chlorosis.

I cannot conceive it possible to adapt a method of cure to such a disorder as has been described, more likely to succeed, than that which consists in supplying the organs of digestion with aliments the most easy of digestion, and which approach the nearest to the nature of the sound and healthful juices; in due and prudent evacuations of the first organs of digestion; in corroborating these organs, and supplying the deficiencies of bile, by aromatics, bitters, and, at last, by steel; in directing proper exercise; and in expelling the matter stagnating in the glands, and other parts, by the proper emunctories, when once sufficiently resolved, in the manner specified above. *James, Dict. Med.*

Juncter, in his Conspic. Med. has given us the following method of cure: the general method must be by correction of the vitiated humours; a reseration of the viscera; an evacuation of the humors, when thus prepared for it; and, finally, a restitution of the due tone to the solids.

For the first fortnight, the patient should be treated with resolvents and digestives; such as *tartarum vitriolatum*, and absorbents saturated with acids; as crabs-eyes with lemon-juice; and with aperient decoctions of the woods of guaiacum and sassafras; as the roots of pimpernel, and the like; and, either during this time, or afterwards, evacuants are to be given; such as sena, jalap, and dwarf-elder. When the improper treatment of a fever has been the occasion of the malady, the mild alexipharmics are to be given at times; and, when an obstruction of the menses is in the case, the time they are to be expected is to be carefully regarded, and emmenagogues and baths for the feet are to be ordered at those periods. When obstructions of the hæmorrhoidal discharges are the cause, then, after the first fortnight, leaches should be applied to the hæmorrhoidal veins; and, if the disease has arisen from long continued hæmorrhages, then analeptics are to be trusted to, with very gentle correctives, for fear of exciting new commotions in the blood; and, in these cases, bleeding in the arm is sometimes found necessary.

CACHU'NDE, the name of a medicine highly celebrated among the Chinese and Indians; but, as the describers of aromatics, and the later authors, has made no mention of it, Zacutus Lusitanus gives us the following method of preparing it, which, he says, was with great difficulty obtained of celebrated physicians, who had the health of the East-Indian viceroys, and other princes, for many years, committed to their care.

Take, says he, of the terra cimlia, or any other proper earth, two pounds; of amber, one pound; of musk and ambergrise, each, three ounces; of the best aloes-wood, by the Portuguese called calambac, ten ounces; of prepared pearls, three ounces; of prepared rubies, emeralds, granats, jacinths, each four ounces; of red sanders, four pounds; of yellow sanders, three ounces; of mastich, sweet flag, galangal, cinnamon, aloes washed with juice of roses, the best rhubarb, Indian mirobalans, Belloni mirobalans, wormwood, red coral, and Armenian bole, each two ounces; and of calcined ivory, three pounds and a half. The ingredients to be pounded must be reduced to a very fine powder; and, after having sprinkled them with ordoriferous wines and balsams, and water distilled from the flowers of the cinnamon-tree, they must be dried in a shade, and mixed up with a sufficient quantity of the finest white sugar; then, with a mucilage of gum tragacanth and gum arabic, the whole is to be reduced to a very tenacious, viscid mass, which is of a pretty red colour.

Of this mass various figures are formed, which the merchants convey to several parts of the world, but principally to Lisbon, the most celebrated emporium of the whole earth. The Indian princes, and the grandees of China, use this antidote in the following manner: in the day-time they keep a small portion of it, about the bulk of a lentil, in their mouths; from this portion, a sweet and fragrant liquor gradually and insensibly drops from the fauces to the stomach, and gives the breath so agreeable a flavour, that all who come near them are sensible of it. This medicine is truly worthy to be used by kings and grandees, for the preservation of the natural heat; for it preserves and defends the body from corruption, prevents the bad consequences of a pestilential air, removes melancholy and flatulencies, and wonderfully relieves those who labour under melancholy disorders. It removes palpitations of the heart, cures the cardialgia, the apoplexy, and the epilepsy. It refreshes the animal and vital spirits, invigorates all the faculties, strengthens the stomach, and resists poisons of every kind. It corroborates the brain, and is the most sovereign remedy in the world against a stinking breath. It proves an incentive to venery, for which intention it is much used by both sexes in the Indies. In short, it is a truly royal medicine; for it protracts life, puts death at a distance, and is consequently sold at a high price. Whoever use it, cannot help admiring the happy effects produced by it. *Zacutus Lusitanus de Medicor. Princip. Hist. Lib.* 1. *Observat.* 37.

CADE'NE, one of the sorts of carpets which the Europeans import from the Levant; they are the worst sort of all, and are sold by the piece from one to two piasters per carpet.

CÆCI'LIA, in zoology, the name of the slow-worm, or blind-worm, called by the Greeks typhlinus. It is a small species of serpent, which has such extremely small eyes, that it has been usually supposed to have none at all. It is distinguished from all our snakes by its smallness, and by the shape of its tail, which runs out a great way beyond the anus, and yet is blunt, and considerably thick at the end. The colours vary much in the different sexes, and probably often also in the same sex; the common colour is a dusky greenish yellow on the back, the sides are variegated with streaks of black and white: it resembles the viper in its manner of producing its young, which are put forth alive.

CÆ'MENT-*Pots*, in assaying, are vessels made for the cementation of metals with salts, and the ingredients of the strong acid menstrua, where the force of those menstrua, and a strong fire, are required together.

The pots are cylindrical vessels, made of potters clay, with tiles adapted to them, and may be conveniently turned by the potters. The size of these vessels must be proportioned to the quantity of cæment to be put in them. It is not prudent, however, to make them of more than eight or ten inches broad, because, when they are larger, the fire acts but difficultly and unequally upon them, especially on that part of the matter near the center.

It is to be observed, in making these vessels also, that all kinds of clay contract and take up a smaller space in the drying and baking; the purer clay will contract one tenth part of their diameter, but, the more sand, or other dry powder, there is in the mixture, the less it contracts. If a vessel, therefore, of any determinate size is to be made of clay without any admixture, it must be made one tenth larger than the expected size; if of clay with these admixtures, experience alone can shew what must be the excess in size, when moist. *Cramer, Art. Ass.*

CÆRU'LEUS, in zoology, a name given by authors to a bird of the thrush or black-bird kind, and somewhat resembling that species of black-bird commonly called the solitary sparrow. It loves rocks and old buildings, and is thence called by some petrocossyphus, or the stone black-bird; and, from its colours, is called by the Germans blauvogel; it is of the size of a starling; its breast, back, and neck, are of a very fine deep blue; it lives among the mountains; it sings very sweetly, and in winter loses its fine blue colour, and becomes black.

CÆSALPI'NA, in botany, a plant so called by father Plumier, who discovered it in America, in honour to Andreas Cæsalpinus, who was an eminent botanist, and one of the first writers on a method of classing plants.

The characters are: it hath a flower of an anomalous figure, consisting of one leaf, which is divided into four unequal parts; the upper part is large, and hollowed like a spoon. From the bottom of the flower arises the pointal, amongst many incurved stamina, which afterwards becomes a pod, including oblong seeds.

CA'FFA, cotton cloths, painted with several colours, and of divers designs. They are manufactured in the East-Indies, and sold at Bengal. The length and breadth are not the same in all the pieces.

CAFFA'RD. They give the name of Caffard-damasks to several sorts of stuffs, in some of which the warp is of silk, or ferret, and the woof of thread; in others, both the warp and the woof are of thread, and some are intirely of wool.

CAFFI'LA, a company of merchants, or travellers, or rather a company composed of both, who join together, in order to go with more security through the dominions of the Grand Mogul, and through other countries on the continent of the East-Indies.

CAFFILA, signifies, also, in the several ports which the Portuguese still hold on the coast of the kingdom of Guzerat, or Cambaya, a small fleet of merchant-ships, which sail from those ports to Surat, or come back from thence, under the convoy of a man of war, which the king of Portugal keeps there for that purpose.

CAGE, an inclosure made with wire, wicker, or other matter interwoven latticewise, for the detention of wild beasts or birds.

CAGE, in carpentry, signifies an outwork of timber, inclosing another within it.

CAJOU, *Cashew*, or *Cassu*, an American fruit, shaped like a pear, having the large end next the stalk, and, at the small end, a nut, in shape and size, resembling a hare's kidney, which is the seed of the plant.

The Cajou is the fruit of the acajou, a tree frequent in Jamaica and the Caribbee Islands. The nut or seed, called in English the cashew-nut, and sometimes the apple-bean, bears a near affinity in figure, as well as in virtues, to the anacardium, or Malacca bean, of which some make it a species, under the denomination of anacardium occidentale.

Clusius describes the Cajou as resembling a goose egg, both for size and figure, of a yellow colour, and sweet; full of a liquor like that of a citron: both the fruit and nut are eaten in Jamaica with great pleasure; as the former grows bigger, the nut diminishes. Between the rind and shell of the latter is a spongy substance full of a caustic oil, used against tetters, but which must be discharged by roasting the nut in embers, before the kernel is eaten. The thin ash-coloured skin wherewith the kernel is covered, is used as an exciter to venery.

CALABA, Indian mastich-tree in botany, a genus of trees, whose characters are: it has a rosaceous flower, consisting of several petals which are placed in a circular order; from whose flower-cup arises the pointal, which afterwards becomes a spherical fleshy fruit, including a nut of the same form.

This tree grows to a great magnitude in the warm parts of America, where it is a native. From the trunk and branches there issues out a clear gum, somewhat like the mastich, from whence it received its name, the gum being used in those countries as mastich.

At present, this tree is pretty rare in England, it being so tender as not to bear the open air; so that it must be preserved in stoves, with the most tender exotic plants. It is propagated by the nuts, which are frequently brought from America; these should be planted in small pots filled with fresh light earth; and plunged into an hot bed of tanners bark, observing to water the pots frequently, to forward the vegetation of the nuts, which, having hard shells, are pretty long before they break their covers, unless they have a good share of heat and moisture. When the plants are come up about two inches high, they should be carefully transplanted, each into a separate small pot, filled with fresh light earth, and plunged into a moderate hot-bed of tanners-bark, observing to water and shade them until they have taken new root; after which time they should have air admitted to them, in proportion to the heat of the weather, and the bed in which they are placed; and they must be frequently watered in warm weather. In this bed they may remain during the summer-season; but at Michaelmas they should be removed into the bark-stove, and placed in a warm situation. During the winter-season these plants will require water pretty often; but it should not be given to them in large quantities, especially in cold weather, lest it rot the fibres of their roots. As the plants advance, they must be shifted into larger pots, and treated in the same manner as directed for the coffee-tree, with which management this plant will thrive very well; and, as the leaves of these plants are long, strong, and of a shining green colour, they make a pretty appearance in the stove, with other tender exotic plants. *Miller's Gard. Dict.*

CALABASH, in commerce, a light kind of vessel made of the shell of a gourd, emptied and dried, serving for a case to put divers kinds of goods in, as pitch, rosin, and the like.

The word, is in Spanish, calabaça, which signifies the same.

The Indians also, both in the north and south sea, put the pearls they have fished in Calabashes, and the Negroes on the coast of Africa do the same by their gold dust.

CALAE, CALAEM, or CALAEMUM, denotes a species of Indian tin, which by force of fire is transmutable into ceruss, like that made of our lead.

CALAMBAC, or CALAMBA, a resinous or fragrant wood brought from the East-Indies. It is usually called lignum aloes, or aloes wood.

There are three kinds of this wood, distinguished by the names of Calambac, common lignum aloes, and calambour.

1. The Calambac, or finest aloes wood, is the most resinous of all the woods we are acquainted with. It is of a light spongy texture, very porous, and its pores so filled up with a soft and fragrant resin, that the whole may be pressed and dented by the fingers like wax, or moulded about by chewing in the mouth in the manner of mastich. This kind laid on the fire melts in great part like resin, and burns away in a few moments with a bright flame and perfumed smell. Its scent, while in the mass, is very agreeable. This is so variable in its colour, that some have divided it into three kinds; the one variegated with black and purple, the second with the same black, but with yellowish instead of purple, and the third yellow alone like the yolk of an egg. This last is the least scented of the three; these differences however are very trivial; the substance being in them all the very same in every respect except the colour, and that often altering very considerably in the keeping. This is brought from Cochin China.

2. The lignum aloes vulgare is the second in value. This is of a more dense and compact texture, and consequently less resinous than the other: There is some of it however that is spongy, and has the holes filled up with the right resinous matter, and all of it, when good, has veins of the same resin in it. We meet with it in small fragments, which have been cut and split from larger. These are of a tolerable dense texture in the more solid pieces, and of a dusky brown colour, variegated with resinous blackish veins. It is in this state very heavy, and less fragrant than in those pieces which shew a multitude of little holes filled up with the same blackish matter that forms the veins in others. The woody part of these last pieces is somewhat darker than the others, and is not unfrequently purplish, or even blackish. The smell of the common aloes wood is very agreeable, but not so strongly perfumed as the former. Its taste is somewhat bitter and acrid, but very aromatic. Laid on the fire, or held on a hot iron, it does not melt away like the Calambac; but it exsudates a large quantity of a fine fragrant resin, which smells extremely sweet, while it burns. This wood is also brought from Cochin China, sometimes also from Sumatra. It is but rarely found in our shops however, and the former, or Calambac, scarce ever at all. It bears so large a price upon the spot, that nobody ventures to bring it away.

3. The calambour, or, as some write it calambouc, a word approaching much nearer to Calambac, than the substances expressed by them do to one another. This is the wood that is most common in our shops, though it has of all the others least title to be so, as it has the least virtue, and contains the least resin of any. It is a light and friable wood, of a dusky and often mottled colour, between a dusky green black and a deep brown. It is less firm and solid than most of the officinal woods. Its smell is fragrant and agreeable, but much less sweet than that of either of the others; and its taste bitterish, but not so much acrid or aromatic as the others. We meet with this very frequent and in large logs, and these sometimes intire, sometimes only the heart of the tree, the cortical part being separated. This is brought from the island of Timor, and some other places, and is the aloes wood used by the cabinet-makers and inlayers, but is very improperly used under the name of lignum aloes in the shops.

The Indians use the Calambac, by way of incense, burning small pieces of it in the temples of their gods; and sometimes their great people burn it in their houses in times of feasting. It is esteemed a cordial, taken internally, and they sometimes give it in disorders of the stomach and bowels, and to destroy worms. It has also the credit of being a great thing for preserving and strengthening the memory. A very fragrant oil may be procured from it by distillation, which is recommended in paralytic cases, from five to fifteen drops. It is at present however but little used, and would scarce be met with any where in the shops, but that it is an ingredient in some of the old compositions.

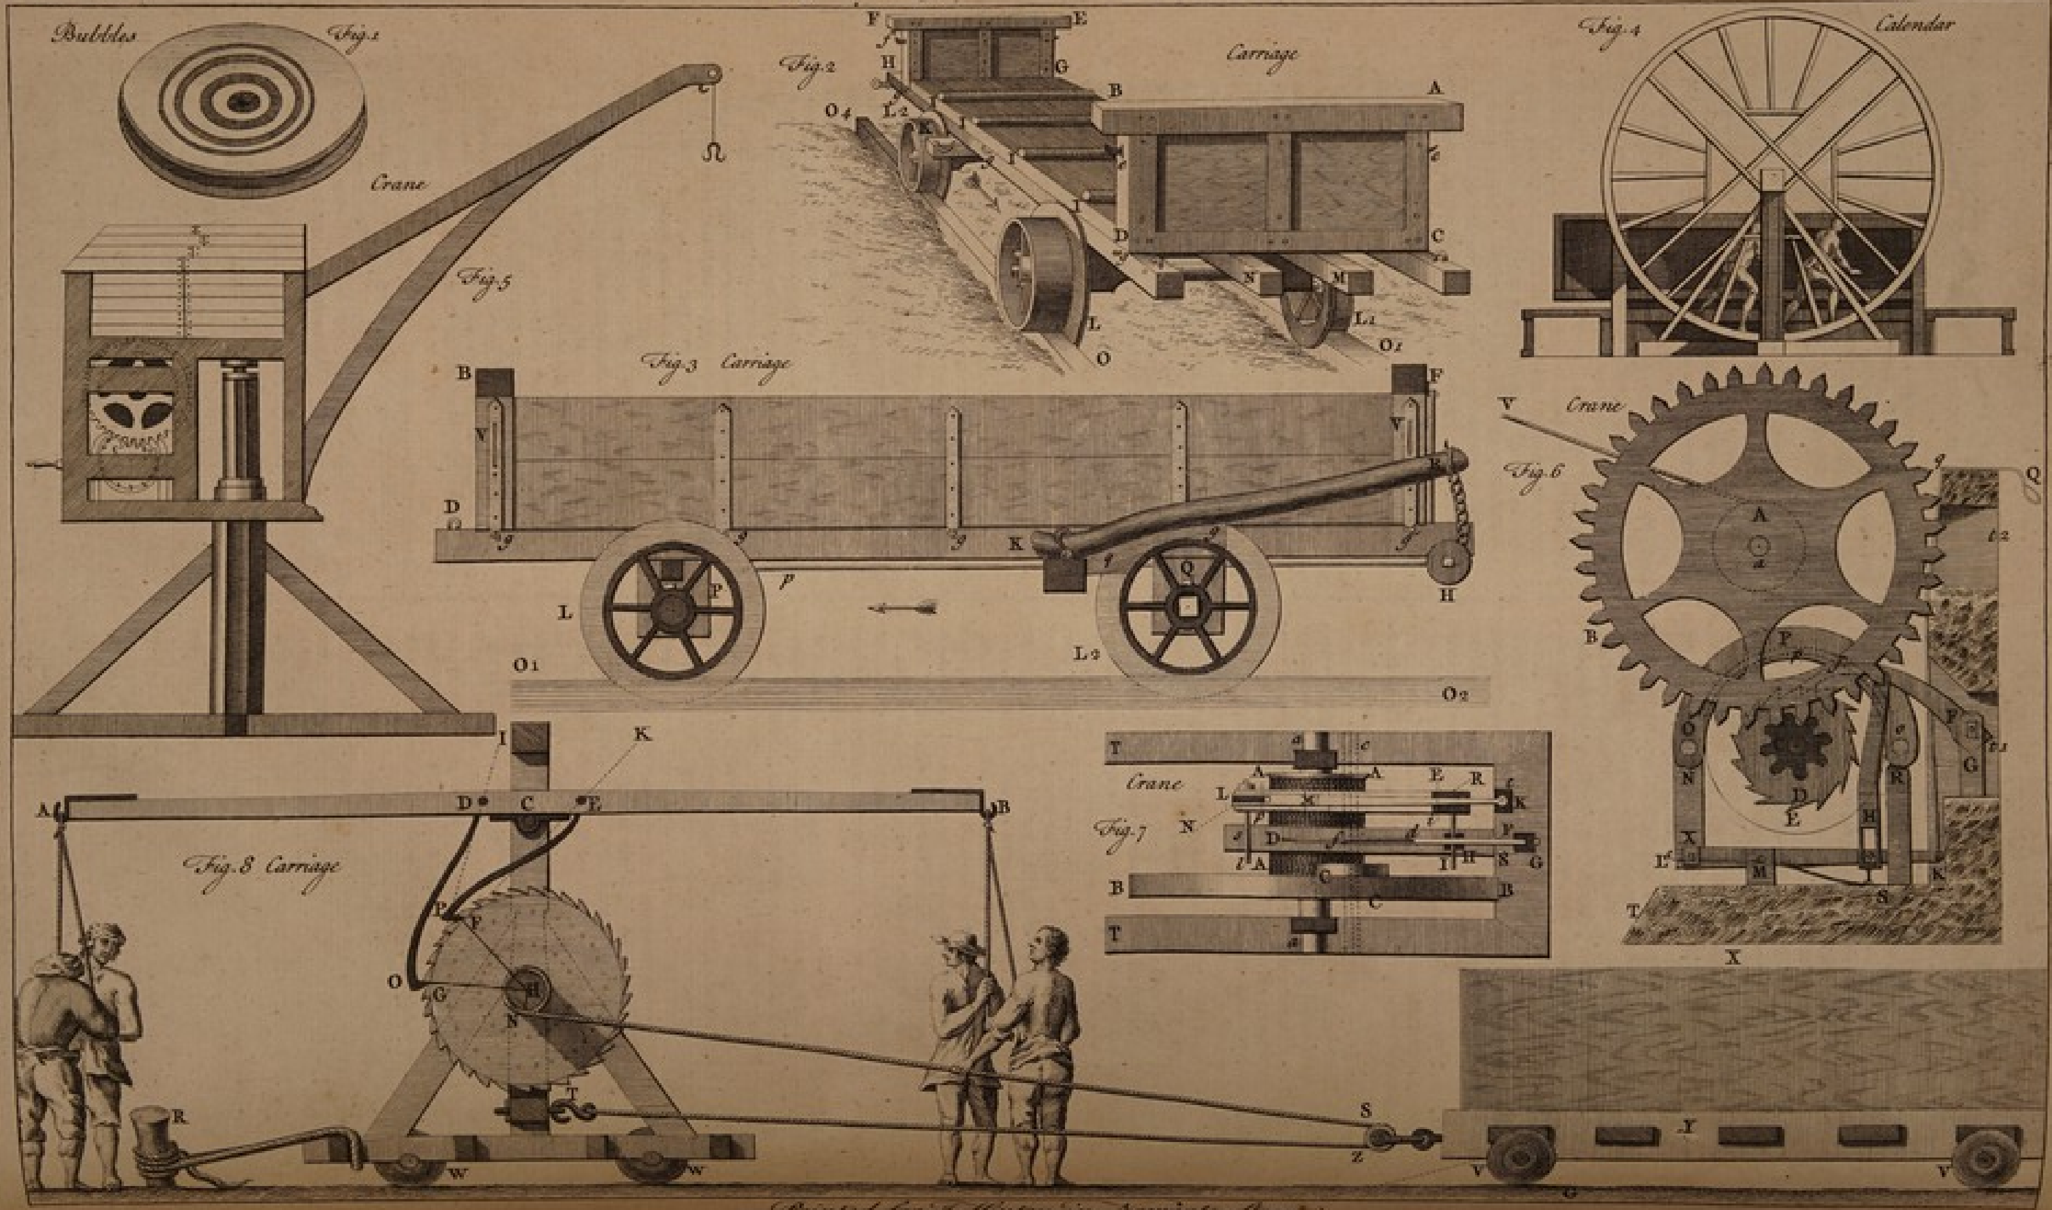
We are told in the Philosophical Transactions, that the tree, while growing, abounds with a milky juice of so acrid and caustic a nature, that, if it gets into the eyes, it will occasion blindness, and, if it only fall on any part of the skin, it will raise blisters. If this be a fact, perhaps, there would be required some caution in the internal use of the true resinous wood of this name; but, as to the common one we meet with, there does not seem to be much to be dreaded from that.

CALAMANCO, a woollen stuff manufactured in Brabant, in Flanders, particularly at Antwerp, Lisle, Tournay, Turcoin, Roubaix, and Lannoy. There are, also, a great many made in England. In France, they are of different breadths; some of $\frac{1}{12}$, others of $\frac{2}{3}$, of $\frac{7}{12}$, of $\frac{1}{2}$, or of $\frac{5}{12}$, of an ell, all Paris measure. As for the length of the pieces, there is nothing settled; the weavers make them longer or shorter, according as they please, or as they are commissioned by the merchants. This stuff has a fine gloss upon it, and is checkered in the warp, whence the checks appear only on the right side. It is commonly wove wholly of wool; there are some however, wherein the warp is mixed with silk, and others with goat's hair. There are Calamancoes of all colours, and diversly wrought; some are quite plain; others have broad stripes, adorned with flowers; some with plain broad stripes; some with narrow stripes; and others watered. This, also, is no inconsiderable branch of the woollen manufacture of England, both for home wear and foreign exportation. See WOOLLEN *Manufacture*.

CALAMITIS, is used for a species of artificial cadmia found adhering to the sticks, ladles, and other utensils wherewith they stir the copper when in fusion in the furnace.

CALAMITA *Alba*, in natural history, the name of an earth dug in Spain and Italy, of a hard texture, a white colour, and styptic taste; they pretend that this attracts flesh in the same manner as the magnet does iron, and thence call it magnes carneus.

CALAMUS *Scriptorius*, or *Arundo Scriptoria*. The ancients wrote on parchment or Ægyptian paper, with a reed made in the shape of a pen, and thence called Calamus scriptorius. We mention parchment or Ægyptian paper, because our paper is of modern invention. The Arabians, Persians, Turks, Greeks, and



Printed for J. Hinton in Newgate Street.

and Armenians use it even at this day; and, though the Greek be a much finer character than ours, write it with great dispatch and elegance.

CALA'SH, or CALESH, a small light kind of chariot, or chair, with very low wheels, used chiefly for taking the air in parks and gardens.

In the Philosophical Transactions, we have a description of a new sort of Calash, going on two wheels, not hung on traces, yet easier than the common coaches, over which it has this further advantage, that, whereas a common coach will overturn, if one wheel go on a surface a foot and a half higher than that of the other, this will admit of a difference of above 3 feet, without danger of overturning. Add, that it would turn over and over, that is, after being turned so as that the spokes are parallel to the horizon, and one wheel flat over the head of him that rides in it, and the other flat under him, it will turn once more, by which the wheels are placed in statu quo, without any disorder to the horse, or rider.

CALCA'NEUM (*Dict.*) The body of the os calcis has six sides, one posterior, one anterior, one superior, one inferior, and two lateral.

The posterior side is broad, unequally convex, and, as it were, divided into two portions; one superior, small, and polished; the other inferior, much larger, unequal, and rough, which, in children, is an epiphysis, and may be named the tuberosity of the os calcis. The lower part of it is bent downward, and terminates in two turbercles, or obtuse points, which belong rather to the inferior than to the posterior side of the bone.

The upper side may be divided into two parts, one posterior and unequal, having a small depression; the other anterior, convex, and cartilaginous, proportioned to the great inferior cavity of the astragalus. This side is turned obliquely forward, and by this obliquity becomes part of the foreside, the remaining part of which is lost in the anterior apophysis.

The lower side is narrow, and behind it lie the two tubercles, of which the internal is the biggest. They both serve for the insertion of the aponeurosis in the soal of the foot, but principally the biggest.

The two lateral sides are continued over the anterior apophysis. The external is gently convex and unequal, covered only by the common integuments and ligaments. The internal is hollowed and depressed.

The great or interior apophysis lies in the same direction with the body, being a continuation thereof. It has five sides or remarkable parts, and, were it not for the body, it would have a sixth.

The upper side has an irregular and unequal depression, which, together with that in the apophysis of the astragalus, forms a considerable fossula. At its anterior extremity, there is a small cartilaginous surface, answering to one of those in the apophysis of the astragalus.

The anterior side of the apophysis is broad, oblique, cartilaginous, partly convex, and partly concave, and articulated with a little surface of the os cuboides. This is the foreside of the whole os calcis, when considered without any division.

The outside of the apophysis is very rough, being a continuation of the outer side of the body, with a tubercle or eminence at the place where these two sides meet, which, however, is not found in all subjects. On the lower part of this tubercle, is a cartilaginous surface, for the passage of the tendon of the peronæus longus: sometimes we see only some small vestiges of this eminence, and often none at all. We sometimes meet with another small cartilaginous surface lower down, and more forward, near the anterior extremity of the apophysis, for the passage of the same tendon. The lower side is a tuberosity, continued from the side of the body, and designed for the insertion of muscles.

The lateral apophysis is almost common to the body, and to the great anterior apophysis, and increases the cavity on the inside of the os calcis. On its upper part, it has a very smooth cartilaginous surface, articulated with one of the inferior surfaces of the astragalus. This apophysis is very low down, and its inferior part is smooth for the passage of tendons.

The os calcis has four cartilages, of which three are superior, one large, and two small, for its triple articulation with the astragalus; the fourth is anterior, for the os cuboides. To these must be added a small thin cartilage, of a kind of ligamentary substance, under the tubercle on the outside of this bone. *Winslow's Anat.*

Factitious CALCE'DONY, in chemistry.—As the agate jasper, and Calcedony have a great affinity, the same process may serve to imitate these three kinds of precious stones. Dissolve one ounce of silver in aqua-fortis. Then take of lime, pewter, cinnabar, bole armeni, crocus martis, crude antimony, minium, orpiment, white arsenic, and æs ustum, of each half an ounce: reduce these ingredients to a fine powder, and pour a sufficient quantity of aqua-fortis upon it, drop by drop, very softly, for it will make a considerable effervescence; when the effervescence is over, pour more aqua-fortis on it, and put the vessel in a digestion of a moderate heat: after a few days draw off the aqua-fortis by distillation, and the powder will remain of a greenish red, which must be reduced by levigation to an impalpable powder. Then to twelve ounces of crystal fritte add two ounces of this powder, at four different times, one half ounce each time; stir this mixture carefully, while in fusion, over a proper heat. At the end of twenty-four hours the operation will be performed.

CALDA'RIUM, in the antient baths, denoted a brazen vessel or cistern, placed in the hypocaustum full of hot water, to be drawn thence into the piscina or bath, to give it the necessary degree of heat.

CA'LENDAR, in mechanics (*Dict.*)—The Calendar is composed of two thick cylinders, or rollers, of very hard and polished wood, round which, the stuffs which are to be calendered are rolled very smooth.

These rollers are placed cross-ways, between two very thick boards, of polished wood, which are longer than they are broad; some call them tables.

The undermost board, which serves as a base for the whole machine, is fixed, and placed level, on a solid foundation of brick-work. The uppermost board is moveable, though loaded with large stones, cemented together, weighing twenty-thousand pounds, or more.

A cable wound round the tree, or axis, of a large wheel, something like that of a crane to raise stones, and tied with strong rings to this uppermost board, serves to move it, sometimes one way, sometimes another, according as the men that walk in the wheel set it a going. It is this alternate motion, together with the prodigious weight of the uppermost board of the Calendar, that renders the stuffs smooth and glossy, or gives them the waves, by making the cylinders, on which they are put, roll with great force over the undermost board.

When they would put a roller from under the Calendar, to put on another, they only incline the undermost board of the machine. See a section of the Calendar *plate* XI, *fig.* 4.

The dressing alone, with the many turns they make the stuffs and linens undergo in the Calendar, gives the waves, or waters them, as the workmen call it. It is a mistake to think (as some, and those not a few, modern authors, have asserted) that they use rollers with a shallow indenture, or ingraving, cut into them.

There is at Paris a very extraordinary Calendar, called, by way of eminence, the royal Calendar. It was made by the order of the late Monsieur Colbert, minister and secretary of state, and superintendant of the arts and manufactures of that kingdom.

The undermost table of this Calendar is a block of very well polished marble, and the uppermost is lined underneath with a copper-plate, all of a piece, and extremely well polished, wherein it differs from the other Calendars, whose tables, or boards, are commonly of wood only.

There are some Calendars without wheels, which are moved by a horse, tied to a wooden bar, which turns sometimes to the right, and sometimes to the left, a great pole, placed upright, at the top of which, about a kind of drum, is wound a cable, the two ends of which, being fastened to the two ends of the uppermost board of the Calendar, set it a going. The Calendars moved by horses are not reckoned so good as those with wheels, the latter having a more uniform and certain motion.

At Paris, none but the principal master-dyers have the liberty of keeping Calendars at their own houses; at Amiens, and other places, every one may have them who pleases.

Astronomical CALENDAR, an instrument engraved upon copper-plates, printed on paper, and pasted on board, with a brass slider which carries a hair, and shews, by inspection, the sun's meridian altitude, right ascension, declination, rising, setting, amplitude, &c. to a greater exactness than our common globes will shew.

Reformed or *corrected* CALENDAR, that which, setting aside all apparatus of golden numbers, epacts, and dominical letters, determines the equinox with the paschal full moon, and the moveable feasts depending thereon, by astronomical computation, according to the Rudolphine tables.

This Calendar was introduced among the protestant states of Germany, in the year 1700, when eleven days were at once thrown out of the month of February: so that, in 1700, February had but eighteen days: by this means, the corrected stile agrees with the Gregorian. This alteration in the form of the year they admitted for a time, in expectation that, the real quantity of the tropical year being at length more accurately determined by observation, the Romanists would agree with them, on some more convenient intercalation.

Construction of a CALENDAR, or *Almanack*. 1°. Compute the sun's and moon's place for each day of the year, or take them from Ephemerides. 2°. Find the dominical letter, and, by means thereof, distribute the Calendar into weeks. 3°. Compute the time of Easter, and thence fix the other moveable feasts. 4°. Add the immoveable feasts, with the names of the martyrs. 5°. To every day add the sun's and moon's place, with the rising and setting of each luminary; the length of day and night; the crepuscula, and the aspects of the planets. 6°. Add, in proper places, the chief places of the moon; and the sun's entrance into the cardinal points; i. e. the solstices and equinoxes; together with the rising and the setting, especially heliacal, of the planets, and chief fixed stars. Means for each whereof will be found under the proper heads. The duration of the crepuscula, or the end of the evening, and beginning of the morning twilight, together with the sun's rising and

and setting, and the length of days, may be transferred from the Calendars of one year into those of another: the differences in the several years being too small to be of any consideration in civil life.

Hence, it appears, that the construction of a Calendar has nothing in it of mystery, or difficulty, if tables of the heavenly motions be at hand.

Gelalean CALENDAR, is a correction of the Persian Calendar, made by order of Sultan Gelaleddan, in the 467th year of the Hegira, and in the 1389th of the Christian æra.

CA'LENDS (*Dict.*) — To find the day of the Calends answering to any day of the month we are in, see how many days there are yet remaining of the month, and to that number add two; for example, suppose it the twenty-fourth of June, it is then the eighth of the Calends of July, for June contains thirty days; twenty-four taken from thirty, there remains six, to which two being added makes the sum eight.

The Calends of January were the most considerable, being particularly consecrated to Juno, and the god Janus. On this day, the magistrates entered upon their offices, and feasts were kept every-where, and presents exchanged between them, in token of friendship; for they believed, if they diverted themselves well in the beginning, they should pass the whole year so.

On the Calends of March, they took their leases, &c. in regard the year, as fixed by Romulus, commenced on that day: Hence, the Calends of March was a fatal day to debtors, because their leases expired on that day, which made Horace call them tristes calendas.

The Roman writers themselves were at a loss for the reason of this absurd and whimsical manner of computing the days of the month; yet, it is still kept up in the Roman Chancery, and, by some authors, out of a vain affectation of learning, prefering it to the common more natural and easy manner.

CA'LENTER, a name given by the Persians to their treasurer, and receiver of the rents of their provinces. He oversees the king's revenues, receives and gives an account to the council, or by the king's order to the cham, who is governor of the province.

CALF, *vitulus*, in zoology. There are two ways of breeding Calves that are intended to be reared; the one is to let the Calf run with its dam all the year round: this is the method in the cheap breeding countries, and is generally allowed to make the best cattle. The other way is to take them from the dam after they have sucked about a fortnight; they are then to be taught to drink fleet milk, which is to be made but just warm for them, it being very dangerous to give it them too hot.

The best time of weaning Calves is from January to May; they should have milk for twelve weeks after, and, a fortnight before that is left off, water should be mixed with the milk in larger and larger quantities. When the Calf has fed on milk about a month, little whisps of hay should be placed all about him in cleft sticks to induce him to eat. In the beginning of April, they should be turned out to grass; only, for a few days, they should be taken in for the night, and have milk and water given them; the same may also be given them in a pail, sometimes in the field, till they are so able to feed themselves that they do not regard it. The grass they are turned into must not be too rank, but short and sweet, that they may like it, and yet get it with some labour.

Calves should be always weaned at grass, for, if it be done with hay and water, they often grow big-bellied on it, and are apt to rot. When those among the males are selected, which are to be kept as bulls, the rest should be gelded for oxen: the sooner the better. Twenty days old is a very good time, or any thing between that age and ten days. About London, almost all the Calves are fatted for the butcher. The reason of this is, that there is a good market for them, and the lands here are not so profitable to breed upon as in cheaper countries. The way to make the Calves fat and fine is, the keeping them very clean, giving them fresh litter every day, and hanging a large chalk-stone in some corner where they can easily get at it to lick it, but where it is out of the way of being fouled by their dung and urine. The coops are to be so placed as not to have too much sun upon them, and so high above the ground that the urine may run off. They also bleed them once when they are a month old, and a second time before they kill them; this is a great addition to the beauty and whiteness of their flesh; the bleeding is by some repeated much oftener, but this is sufficient.

Calves are very apt to be loose in their bowels; this wastes and very much injures them. The remedy is, to give them chalk scraped into milk, pouring it down with a horn; if this does not succeed, they give them bole armenic in large doses, and use the cold bath every morning. If a cow will not let a strange Calf suck her, the common method is to rub both her nose and the Calf's with a little brandy: this generally reconciles them after a few smellings. *Mortimer's Husbandry.*

CALF'S *skins*, in the leather manufacture, are prepared and dressed by the tanners, skinners, and curriers, who sell them for the use of the shoe-makers, sadlers, bookbinders, and other artificers, who employ them in their several manufactures.

Calf-skins, dressed in sumac, denote the skin of this animal curried black on the hair side, and dyed of an orange colour on the flesh side, by means of sumac, chiefly used in the making of belts.

The English Calf-skin is much valued abroad, and the commerce thereof very considerable in France and other countries; where divers attempts have been made to imitate it, but hitherto in vain. Mr. Colbert, to whom France owes a great number of arts and establishments of this kind, set on foot a company of undertakers in 1665, who set up a manufactory of this kind, under the denomination of bonnets tanneurs; but, after an hundred thousand livres sunk in the undertaking, they were forced to desist.

CA'LIBER, or CALIPER-*rule*, is an instrument, wherein a right line is so divided, as that, the first part being equal to the diameter of an iron or leaden ball of one pound weight, the other parts are to the first, as the diameters of balls of two, three, four, &c. pounds are to the diameter of a ball of one pound. The Caliber is used by engineers, from the weight of the ball given, to determine its diameter, or Caliber; or vice versa.

The Caliber, in general, consists of two thin pieces of brass, six inches long, joined by a rivet, so as to move quite round each other; the head, or one end of the piece, is cut circular; and one half of its circumference is divided into every second degree. On the other half are divisions, from one to ten; each, again, subdivided into four: the use of which divisions and subdivisions is, that, when the diameter of a bullet, &c. not exceeding ten inches, is taken, the diameter of the semicircle will, among the divisions, give the length of that diameter taken between the points of the Calibers, in inches and fourth parts.

The degrees on the head serve to take the quantity of an angle; the method of which is obvious. If the angle be inward, apply the outward edges to the planes that form the angle; the degrees, cut by the diameter of the semicircle, shew the quantity of the angle sought. For an outward angle, open the branches till the points be outwards, and, applying the streight edges to the planes that form the angle, the degrees cut by the diameter of the semi-circle shew the angle required, reckoning from 180, towards the right-hand.

On one branch of the Calibers, on the same side, are, first, six inches; and each of these subdivided into ten parts. Secondly, a scale of unequal divisions, beginning at two, and ending at ten; each subdivided into four parts. Thirdly, two other scales of lines, shewing, when the diameter of the bore of a piece is taken with the points of the Calibers outwards, the name of the piece, whether iron or brass; i. e. the weight of the bullet it carries; or that it is such or such a pounder from one to forty-two pounds.

On the other branch of the Calibers, on the same side, is a line of cords to about three inches radius; and a line of lines on both branches, as on the sector; with a table of the names of the several pieces of ordnance. On the same face is a hand graved, and a right line drawn from the finger towards the center of the rivet: shewing, by its cutting certain divisions made on the circle, the weight of iron shot, when the diameter is taken with the points of the Calibers. Lastly, on the circle, or head on the same side, are graved several geometrical figures inscribed in each other, with numbers; as a cube, whose side is supposed one foot; a pyramid on the same base and altitude, and the proportions of their weight, &c. a sphere inscribed in a cube; a cylinder, cone, circle, square, &c.

CALIBER, also signifies an instrument, or rule, used by carpenters, and bricklayers, to see whether their work be well squared. It is nothing but a piece of board, notched, or cut triangularly in the middle.

CALIBER. The gunsmiths use several sorts of tools to which they give that name, some of which are of wood, and others of steel.

The Calibers of wood are properly models, after which they cause to be cut, out of walnut-tree, ash-tree, or maple-tree wood, the stocks on which they mount guns or pistols, or other fire-arms. They are nothing but very thin pieces of wood, cut in the figure of the gun, pistol, &c. that is to be mounted upon them: so that there are as many of those Calibers as there are several sorts of fire-arms, as fusees, muskets, pistols, &c.

The steel Calibers in the gunsmith's business are of two sorts, some double, and the others simple. The simple one is a kind of file, without either a handle or a tail, with holes of several diameters bored into it, at some distance from each other. They serve to make and fine the lower parts of screws. The double Caliber differs from the simple one in this only, that it is composed of two files, placed the one over the other, and joined or fastened together with a screw at each end, by means of which they are put closer to, or further from each other, at pleasure. The undermost handle has a handle also of steel, a little incurvated within: these last Calibers serve to turn, as it were, by a turning-wheel, the nuts, or knobs, of the plates that are put between them.

CALI'CO, or CALLICO, a kind of linen manufacture, made of cotton, chiefly in the East-Indies. There is a great trade in the province of Bengal in this commodity, which is transported in prodigious quantities into Persia, Turkey, Arabia, Muscovy,

PLATE XII.

Engraved for the SUPPLEMENT.

Facing Calico-printing

Printed for J. Hinton in Newgate Street.

Muscovy, and all over Europe. Some of them are painted with flowers of various colours; and the women in the Indies make veils and scarfs of them, and, of some, coverlets for beds, and handkerchiefs. They make another sort of this manufacture, which they never dye, and hath a stripe of gold and silver quite through the piece; and at each end, from the breadth of one inch to twelve or fifteen, they fix a tissue of gold, silver, and silk, intermixed with flowers; both sides are alike. They make, also, other sorts of cotton cloths at Brampour, because there is no other province in all the Indies which has greater quantities of cotton.

At Seconge they are said to make the best sorts of Calicoes; in all other parts the colours are neither so lively nor lasting, but wear out with often washing; whereas those made at Seconge grow the fairer, the more you wash them. This is said to arise from a peculiar virtue of the river that runs by the city, when the rain falls; for the workmen, having made such prints upon their cottons as the foreign merchants give them, by several patterns, dip them into the river often, and that so fixes the colours, that they will always hold. There is also made at Seconge a sort of Calico, so fine, that, when a man puts it on, his skin shall appear as plainly through it as if he was quite naked; but the merchants are not permitted to transport it, for the governor is obliged to send it all to the Great Mogul's seraglio, and the principal lords of the court, to make the sultanesses and noblemen's wives shifts and garments for hot weather.

The city of Baroche, also, is very famous for trade, on account of the river, which has a peculiar quality to whiten their Calicoes, and which are, therefore, brought from all parts of the Mogul's territories thither for that end.

This manufacture is brought into this nation by the East-India company, which is re-exported by private merchants to other parts of Europe and America.

CALICO-*printing*, the art of staining Calicoes, &c. of various colours.

Method of printing CALICOES.—Before the operation of printing is performed, the cloth is carried to the printing-house in order to be properly prepared, which is done in the following manner: It is first laid to soak in water, and then well washed, and beat out; after which, it is put into a copper of water, rendered a little acid, by a proper quantity of spirit of vitriol, or juice of lemons; in this menstruum it is kept in a midding degree of heat (but not suffered to boil) till it has sufficiently imbibed the acid particles of the menstruum. It is then taken out, and well washed; and, in order to free it entirely from the acid, it is scalded in a menstruum composed of water and cow-dung; and then cleared again by washing, beating, &c. After which, it is thoroughly dried, and calendared.

The intention of this previous preparation, is to free the cloth from the alkaline particles it has acquired in the making, &c. for it is absolutely necessary, that the cloth should be entirely free from all alkaline or acid particles.

The pattern intended to be printed on the Calico, is drawn in water-colours on paper, and then cut on blocks, either of pear-tree or holley. But it must be observed, that no more of the pattern is cut on one block, than is of one colour. That is, if there are three different reds in the pattern, only that part of the drawing is cut on the block which is of the same colour. Whence it follows, that, as many different colours as there are in the pattern, so many different blocks will be necessary to print it. The colours used are black, two purples, and three reds; for, withregard to the yellows, blues, and greens, they are pencilled in.

The Calico is printed on a table about six feet long, and two feet broad, covered with a woollen blanket, on which the cloth is spread. On the left side of the table stands a shallow tub, containing the colour to be used; in this tub is a float or sieve, composed of a broad ashen hoop, and the bottom a sheepskin, upon which is a piece of superfine broad-cloth. The colour in which this sieve floats, is well stiffened with gum arabic or seneca, to prevent its splashing.

The sieve being furnished by a boy with a proper quantity of colour, the printer dips his block into it, with his right hand, and places it on the cloth, striking it with an oval mallet of lignum vitæ, with his left hand.

When he has printed the whole piece with one colour, it is printed over again in the same manner with another block, on which the parts of the pattern to be printed of another colour are cut. And in the same manner the whole is printed with the several colours intended.

In the printing-house there is a large fire to set the colours, to prevent their running.

After printing, it is carried to the stove-room, and hardened, but not suffered to be quite dry; and then put into a dye of madder, in which it is kept till the dye just begins to boil. After it is taken from the dye, it is well washed, beat, &c. and then put into a copper of water mixed with bran. It is then carried back to the printing-house, in order to have the blues, yellows, and greens, pencilled in. After which it is again washed, and sent to the whitsters to be bleached. For the method of which, see the article BLEACHING, in the Dictionary.

Explanation of *Plate* XII, representing part of the inside of a Calico printing-house.

1 1, Two tables covered with blankets on which the Calico is printed.

a a, The Calico on the tables.

2 2, Two printers at work; the first of which is going to dip his print in the colour, and the second has just placed his print on the Calico.

3 3, Tubs containing the colour.

4 4, Blocks on which the pattern is cut.

5 5, Stools that support the tubs of colour.

6 6, Boys which stir the colour in the tubs, and keep a proper quantity in them.

7, Blocks, or prints, placed on a shelf in the printing-room; one of which, marked *b*, is placed with its face outward.

8 8, Pieces of Calico printed and hung up to set the colour.

9 9, Women pencilling the yellow, and blue colours.

The colours with which the Calico is printed, except those which are pencilled in, are all composed of madder-dye, and a proper quantity of a fixed alkaline salt; this mixture turns black upon the Calico, but, when put into the copper of madder dye, turns of a beautiful red or purple colour; and, the greater quantity of alkaline salt there is in the mixture, the deeper the colour is after it comes out of the dye. Hence we see the reason why the cloth must be deprived of all its alkaline or acid particles; for the madder-dye will not strike on any part of the cloth but where it is previously prepared by the salt: and, the ground being intended to be white, it is necessary that none of the alkaline menstruum touch it; and, with regard to the slight tinge which the ground of the cloth receives from the madder-dye, it is entirely discharged in the bleaching.

The beautiful yellow colour which is pencilled in, is extracted from iron by stale small beer, and the blues from indigo and turnsole by the help of urine. With regard to the green, it is compounded of the blue and yellow; the parts intended to be green being first covered with a blue, and afterwards with a yellow.

It appears highly probable that the Indians, for making the fine, bright, and durable colours wherewith their Calicoes and chinches are stained, use metalline solutions; for, some stained Calicoes having been kept for forty or fifty years, the bright colours have been observed to eat out the cloth, exactly in the same manner as the corrosive and acid spirits, which dissolves metals, are found to do: whence, to imitate their richest and noblest colours, we are directed to use proper metalline solutions.

But it would be a farther step towards perfection, not only in this art, but also in the art of painting, to prepare the finest colours without employing either acid or alkaline salts; which usually subject colours to change, or else are apt to prey upon the cloth or canvas, as we see in verdigrease, the blue and green crystals of copper, &c. Whence we are directed, 1, to search for menstruums that are neither acid, alkaline, or saline; 2, for such metalline calxes, precipitates, or powders as will not lose their colours by being well washed, to get out their salts; 3, to prepare certain metalline matters by calcination, or the bare assistance of the fire; and, 4, to look out for native colours, wherein no saline matter abounds.

It may be worth the trying, whether certain metals are not soluble by triture, with the purest oils employed in painting, and such as contain neither acid nor alkaline salts; or whether mere water, the white of eggs, saliva, gum-water, &c. may not, by the same means, be made to dissolve them; so as that the metalline particles may be left behind upon Calicoes, cloths &c. when the aqueous or mucilaginous matter is dried, or washed away from them. But no great effect can be rationally expected in such attempts, unless the triture be long continued, and mills, or other well adapted engines, be used for the purpose: for we find, in all instances, that metals must be reduced to very fine particles before they will tinge or colour.

CA'LIN, a kind of metal, finer than lead, but inferior to tin. It is very common in China, Cochinchina, Japan, Siam, &c. It is commonly used in the East-Indies for covering the roofs of houses, as we do lead in Europe; they likewise make of it several pieces of furniture. The tea boxes which comes from China are made of Calin. They also make coffee-pots of it, some of which are even brought into Europe.

It is a mixture of tin and lead, and some other mineral, as zink, &c. rather than a metal of a new kind.

CA'LVINISTS, those who follow the opinions of John Calvin, one of the principal reformers of the church, in the 16th century.

Calvin was born at Noyon, in Picardy, in the year 1509: he first studied the civil law; afterwards retiring to Basil, he turned his thoughts to the study of divinity, and published there his Institutions, which he dedicated to Francis I. He was made professor of divinity at Geneva, in the year 1536. The year following, he prevailed with the people to subscribe a confession of faith, and to renounce the Pope's authority: but, carrying the matter a little farther than was agreeable to the

the government, he was obliged to retire from Geneva; upon which he set up a French church at Strasburgh in Germany, and was himself the first minister of it: but, the town of Geneva inviting him to return, he came back thither in September 1541. The first thing he did, was to settle a form of discipline and consistorial jurisdiction, with a power to inflict censures, even to excommunication; and he gained himself many enemies, by his inflexible severity, in maintaining the rights and jurisdiction of his consistory: he was a person of great parts, indefatigable industry, and considerable learning. He died in the 56th year of his age, in 1564.

The principal opinions of the Calvinists are drawn from the writings of Calvin, contained in the forty articles of their Christian faith, which they presented to the French king, in their catechisms and ecclesiastical discipline.

The Calvinists are great advocates for the absoluteness of God's decrees; and hold, that election and reprobation depend on the mere will of God, without any regard to the merit or demerit of mankind; that he affords to the elect an irremissible grace, a faith which they cannot lose, which takes away the freedom of will, and necessitates all their actions to virtue.

In short, they believe that God foreknew a determinate number whom he pitched upon to be the persons in whom he would manifest his glory; that, having thus foreknown them, he predestinated them to be holy; in order to which he gives them an irresistible grace, which makes it impossible for them to be otherwise.

This last is the principal point in which Calvin's heterodoxy differed from that of Luther, who always believed the real presence in the sacrament.

The Calvinists reduce the number of the sacraments to two; reject evangelical councils, and monastic vows; defend imputative righteousness, and dispute against the received notion of justification.

CA'LUMET, among travellers, a mystic kind of pipe used by the American savages as the ensign of peace, and for religious fumigation.

The Calumet is a sort of tobacco pipe, made of red, black, or white marble. The shank is decorated with rounds of feathers and locks of hair, or porcupines quills: in it they smoke in honour of the sun.

The Calumet is the symbol and security of traffic; by it they pronounce life and death, peace and war: they also ascribed to it a power of raising the souls of the dead.

CALX *antimonii*, a name given in the late London Dispensatory to the preparation of antimony, called before antimonium diaphoreticum. This is made by mixing antimony with three times its weight of nitre, throwing it into a hot crucible; and, when removed from the fire, washing it both from its salts and from such parts as have not been well calcined; the washing is to be continued till the water come away tasteless, and the finer part is separated for use by pouring off the water turbid, and leaving the coarse particles behind, taking only the sediment of this water. *Pemberton's Lond. Dispens.*

CALX *vivа*, quick-lime, that on which no water has been cast since burning, in opposition to Calx extincta, that slaked by the effusion of water.

CA'MERA *lucida*, a contrivance of Dr. Hooke, for making the image of any thing appear on a wall in a light room, either by day or night.

Opposite to the place or wall, where the appearance is to be, make a hole of at least a foot in diameter, or if there be a high window with a casement of this dimension in it, this will do much better without such hole, or casement opened. At a convenient distance to prevent its being perceived by the company in the room, place the object or picture intended to be represented, but in an inverted situation. If the picture be transparent, reflect the sun's rays by means of a looking-glass, so that they may pass through it towards the place of representation; and, to prevent any rays from passing aside it, let the picture be encompassed with some board, or cloth. If the object be a statue, or a living creature, it must be much enlightened by casting the sun's rays on it, either by reflection, refraction, or both. Between this object and the place of representation put a broad convex glass ground to such a convexity as that it may represent the object distinctly in such place. The nearer this is situate to the object, the more will the image be magnified on the wall, and the further the less; such diversity depending on the difference of the spheres of the glasses. If the object cannot be conveniently inverted, there must be two large glasses of proper spheres, situate at suitable distances, easily found by trial, to make the representations erect. This whole apparatus of object, glasses, &c. with the persons employed in the management of them, are to be placed without the window or hole, so that they may not be perceived by the spectators in the room, and the operation itself will be easily performed. *Philosophical Trans.* N°. 38.

CA'MLET, or as some spell it CAMBLET, a plain stuff, composed of a warp and woof, and which is manufactured on a loom with two treddles, as linens and stamines are.

The Camlets are either longer or shorter, broader or narrower, according to their several kinds and qualities, and the places where they are manufactured. There are Camlets of all sorts: some of goats hair, both in the warp and woof; and others, in which the warp is of hair, and the woof half hair and half silk; others again, wherein both the warp and woof are of wool; and, lastly, some of which the warp is of wool, and the woof of thread.

Some are dyed in thread; that is to say, that the materials both of the warp and of the woof were dyed before they were wove, or wrought on the loom: others are dyed in the piece; others are marbled, or mixed; some are striped, some waved, or watered, and some figured.

Camlets are proper for several uses, according to their different kinds and qualities. Some serve to make garments, both of men and women, some for bed curtains, and other houshold furniture.

Figured Camlets are those of a single colour, on which have been stamped, or imprinted, various figures, flowers, foliages, &c. This is performed with hot irons, which are a kind of moulds, that are passed under a press at the same time with the stuff. The figured Camlets come only from Amiens and Flanders. The trade of them was formerly pretty considerable; at present there are but few of them sold, which serve commonly for church ornaments, or for making some houshold furniture.

Waved Camlets are those on which a kind of waves have been impressed, as on tabbies, by making them pass several times under the calendar.

Water Camlets are such, which, being taken from the loom, undergo a certain preparation with water, after which they are put into the hot press, that renders them smooth and glossy.

CAMP (*Dict.*— The origin of Camps is of a very great antiquity; we read of them among the Hebrews, who observed a strict discipline, and an outward decency and purity; insomuch that they were not allowed to ease nature, within the limits of the Camp; this promoted cleanness, and contributed to the preservation of their health.

The Greeks had also their Camps, as we read in Homer, fortified with gates and ditches; though not so particularly described, as to be able from thence to give the reader a clear idea thereof. Among the Greeks, the Lacedemonians were reckoned the most dexterous at encampments: these made their Camps of a round figure, looking upon that as the most perfect and defensible form of any other. We are not however to imagine that they thought this form so essential to a Camp, as never to be dispensed with, when the circumstance of the place required it. Greek writers furnish us with almost as many different encampments, as historical relations, and the Latins likewise; it seldom happening that the circumstances of these are the same. Thus a general, when he is about to encamp, has always new occasion to exercise his genius, and it is the part of a skilful officer to contrive such new encampments as are suitable to time and place, and other circumstances. The Lacedemonians, indeed, are said to have been prescribed a constant method of building towers and encamping, by their lawgiver, who thought a spherical figure the best fitted for defence, which was contrary to the custom of the Romans, whose Camps were quadrangular: but all forms of that sort were rejected by Lycurgus, the angles being neither fit for service or defensible, unless guarded by a river, mountain, wall, or some such fortification. It is further observable of the Lacedemonians, that they frequently moved their Camps, being accustomed vigorously to prosecute all their enterprizes, impatient of delays.

When the Greeks were in danger of having their Camp attacked, it was usual to fortify it with a trench and rampire, or wall, on the sides whereof they erected turrets, not unlike those upon the walls of cities, out of which they annoyed their enemies with missive weapons. Homer has described their works, *Iliad*, η. 136.

The manner of living in Camps depended upon the disposition of their generals, some of which allowed their soldiers in all sorts of excess and debauchery; others obliged them to the strictest rules of temperance and sobriety; a remarkable instance whereof we have in Philip of Macedon, who, as Polynæus report, condemned two of his soldiers to banishment for no other offence, than because he had found them with a singing-woman in his Camp. But the Grecian discipline was not always so severe and rigid, for their lawgiver allowed them greater liberty in the Camp than at other times, to invite them to serve with delight in the war; for, whilst they were in the field, their exercises were more moderate than at home, their fare not so hard, nor so strict a hand kept over them by their governors; so that they were the only people in the world to whom war gave repose. *Xenophon de Repub. Laced. Potter's Græc. Ant. Mountfaucon's Ant.*

The Camps of the Romans were generally of an exact square form, or else oblong; though this, without doubt, was often accommodated to the situation of the place. Frontinus says, that Pyrrhus king of Epirus taught the Romans first to encamp; for, upon having defeated him and forced his Camp, they considered the form of it, and from thence modeled their own. But this is a mistake; for, when Pyrrhus first saw the Roman Camp, he was astonished at the form and disposition of of it, and said thus to Megaces: 'Hæc Barbarorum Castra non Barbara videntur. The Camps of the Barbarians have no Barbarian face.' In short, the art of encamping was known at Rome in the time of their kings; for they then fortified their Camps with towers and palisadoes. Indeed, in the infancy of Rome, Camps were not very common, nor can it be supposed they should, when the regal dominion was so small, hardly extending itself beyond the territory of the city.

When the war was carried on at any considerable distance, their Camps were often made of freestone, as appears from Trajan's column. These Camps, thus built, were often the origin of cities, but especially the Camps called stativa, which were a sort of standing Camps, where armies lay for some time, or where they passed the winter, and which, for that reason, were called stativa hiberna. Of this sort there were many upon the Rhine, to hinder the passage of the Germans into Gaul. Besides these stativa hiberna, there were also stativa æstiva, in which they passed the summer under tents. Within these Camps they pitched their tents, some whereof were made of gold and silk; some were of a square form, and others round, terminating at the top in a cone. *Mountfaucon's Ant.*

The Turks, and some other nations of Asia, who generally make war in plain, open countries, surround their Camp with an inclosure formed by their waggons, baggage, &c.

The present practice of European nations is very different from this: they make the safety of a Camp consist in such a disposition as may render it most easy for the horse and foot to be drawn out with the greatest expedition, to face and fight the enemy.

Therefore, as the order of battle, fixed on by the general, ought to be looked on as the best disposition in which an army can engage, it follows, that an army ought to encamp in such a manner, as to be best able to form themselves in such a manner, upon occasion, if the ground permits.

The order of battle, therefore, absolutely determines the form of the encampment; which is agreeable to the remark of the marquis de Santa-Crux on this subject, viz. An army ought to encamp according to the order of its march, and march according to the order in which it is to fight.

As troops engage by battalions and squadrons, the tents must be erected in the same order, and the soldiers ranged in the Camp in the same manner they are in line of battle.

From whence it follows, that the extent of the particular Camps of the several battalions and squadrons, from right to left, must be equal to the front which these troops take up in the line of battle; and that there must be the same spaces between their respective Camps, as was observed in their march.

By this disposition, the extent of the front of every Camp, from right to left, is equal to the front of the line of battle; and, an army being thus drawn up in line of battle, every battalion and squadron may pitch their tents behind them; after which, the troops may either go into the Camp, or march out, and engage in a moment, as it were, at the word of command.

If the front of the Camp be longer than the line of battle, the troops, in forming themselves at the head of the Camp, must leave great spaces between each other, if they would cover it; if, on the contrary, the front of the Camp be shorter than the line of battle, the troops will not have room to form themselves at the distances ordered by the general. To avoid both these inconveniencies, the front of the Camp must be proportional to the line of battle.

There is no certain rule laid down either by custom or authors, who have wrote on the military art, relating to the distances to be observed between the parts of an army; as between battalion and battalion, squadron and squadron, &c.

M. de Bombelles observes, that this cannot be determined exactly, because the extent of the Camp of every battalion in front depends on the space wherein the general would have his army encamp. Yet he imagines, in ordinary ground, one hundred and twenty paces may be allowed for the front of a battalion, including its interval; ninety paces he allows for the encampment; and, consequently, thirty remain for the interval.

Other authors do not make intervals between battalions, but allow thirty paces between regiment and regiment; but they do not support this method by any good reason, and it seems only their intention to divide an army by regiments. Though this division appears most agreeable to the present custom, yet it must not be looked on as general, not having been always observed. M. Rozand, lieutenant-colonel and engineer in the troops of Bavaria, who published a very good treatise of Fortification in 1733, asserts, that he had always seen forty or fifty paces allowed for a squadron to encamp, and as much for the space, or interval; that he has even seen one hundred paces allowed for the front of the Camp of every battalion, and as much for its interval. This practice, which is agreeable to the principles before laid down, may be looked on as an invariable rule, if the general chuses to give battle with intervals equal to the fronts of the different troops of his army. But, however, he determines, his order of battle in the Camp of every respective corps and its interval must be proportional to the front.

It follows from the principles laid down, with regard to the extent, or front of the Camp, that there ought to be, before every corps, battalion, and squadron, an open ground for forming the army in order of battle.

Wherefore, if we are obliged to encamp in disadvantageous posts, the first thing we are to attend to, is to lay out the ground in such a manner, that the troops may have an easy communication, and move without any obstacle.

The order of battle being commonly a right line, on the side next the enemy, and the same line, too, if the ground permit, the colours and standards are placed in it. This is the principal line; or, to express ourselves in terms of military fortification, this is the master-line of the Camp, on which all the rest depend.

After having explained the principles in which the front of a Camp is formed, let us proceed to speak of its depth. This is determined by the depth of the Camps of the battalions and squadrons, which we may reckon at twenty-four fathoms.

The second line must have the same space before it as the first, quite clear, to draw the troops up in line of battle.

The distance from the head of the Camp, or first line, to the second, is commonly three or four hundred paces, sometimes five hundred, if the ground be spacious enough; but the distance never should be less than two hundred paces; because, otherwise, the rear of the Camp of the first line would interfere with the front of the Camp of the second line.

In case of an attack, it is extremely beneficial to have a large space of clear ground before the Camp; because the troops of the second line may march out through their intervals, and have opportunity of forming themselves behind those of the first, in order to support them; and this is an advantage which ought never to be neglected, when it can be procured.

It sometimes happens, an intrenchment is made before the front of a camp; in this case, there should be no obstacle to the communication of the troops between the Camp and the intrenchments.

In countries such as Hungary, and the provinces bordering upon the Danube, where the Germans make war upon the Turks, the officers in general make use of tents: but, in Flanders, Italy, &c. which are often the seat of war, there are many villages and houses, wherein the principal officers, as lieutenant-generals, and field-marshals, have quarters. The quarter-masters of the army appoint each a house in the villages contained within the extent of the Camp. Brigadiers even may lodge in a house, according to military law, if there be one at the rear of their brigade; but inferior officers, as colonels, and all below them, must encamp at the rear of their respective corps.

Care is always taken to lodge or dispose the general officers on the side of the army which they command: that is, those who command the right, on the right; those who command the left, on the left; and those who command the center, on the center. *M. le Blond's Essay on Encampment.*

Where the grounds are equally dry, those Camps are always most healthful, which are pitched on the banks of large rivers; because, in the hot season, situations of this kind have a stream of fresh air from the water, serving to carry off the moist and putrid exhalations. On the other hand, next to marshes, the worst encampments are on low grounds, close beset with trees; for then the air is not only moist and hurtful in itself, but, by stagnating, becomes more susceptible of corruption. However, let the situation be ever so good, Camps are frequently rendered infectious by the putrid effluvia of rotten straw, and the privies of the army; more especially, if the bloody-flux prevails; in which case, the best method of preventing a general infection, is, to leave the ground, with the privies, foul straw, and other filth of the Camp, behind. This is to be frequently done, if consistent with the military operations; but, when these render it improper to change the ground often, the privies should be made deeper than usual, and once a day a thick layer of earth thrown into them, till the pits are near full, and then they are to be well covered, and supplied by others. It may also be a proper caution, to order the pits to be made either in the front or rear, as the then stationary winds may best carry off their effluvia from the Camp. Moreover, it will be necessary to change the straw frequently, as being not only apt to rot, but to retain the infectious steams of the sick. But, if fresh straw cannot be procured, more care must be taken in airing the tents, as well as the straw. *Pringle, Observ. on the Diseases of the Army.*

CAMPAIGN (*Dict.*)—The beginning of every Campaign is considerably more unhealthy than if the men were to remain in quarters. After the first fortnight or three weeks encampment, the sickness decreases daily; the most infirm being by that time in the hospitals, the rest more hardened, and the weather growing daily warmer. This healthy state continues through the summer, unless the men get wet cloaths, or wet beds; in which case a greater or lesser degree of the dysentery will appear, in proportion to the preceding heats. But the most sickly part of the Campaign begins about the middle or end of August, whilst the days are still hot, but the nights are cool and damp, with fogs and dews: then, if not sooner, the dysentery prevails; and, though its violence be over by the beginning of October, yet the remitting fever, gaining

ground,

ground, continues throughout the rest of the Campaign, and never intirely ceases, even in winter quarters, till the frost begin.

At the beginning of a Campaign, the sickness is so uniform, that the number may be nearly predicted; but, for the rest of the season, as the diseases are then of a contagious nature, and depend so much upon the heat of summer, it is impossible to foresee how many may fall sick from the beginning to the end of autumn. It is also observed, that the last fortnight of a Campaign, if protracted till the beginning of November, is attended with more sickness than the first two months of the encampment; so that it is better to take the field a fortnight sooner, in order to return into winter quarters so much the earlier.

As to winter expeditions, though severe in appearance, they are attended with little sickness, if the men have strong shoes, good quarters, fuel, and provisions.

Long marches in summer are not without danger, unless made in the night, or so early in the morning, as to be over before the heat of the day. *Pringle, Observ. on the Diseases of the Army.*

CAMPA'NULA, *bell-flower*, in botany, a genus of plants whose characters are: the flower consists of one leaf; is shaped like a bell, and is, before blown, of a pentagonal figure; and, when fully opened, is cut into five segments at the top: the seed-vessel is, for the most part, divided into three cells, each having an hole at the bottom, by which the seed is emitted.

Boerhaave has enumerated thirty-four, Tournfort eighty-seven, and Miller thirty species of this plant.

This plant is propagated either by sowing the seeds in March, in a bed of light undunged soil, or by parting the roots; the latter method, being the most expeditious, is commonly practised; for every plant, taken from the roots in September or March, will grow, if rightly managed.

The peach-leaved bell-flowers may be raised from seeds, in the same manner, or be increased, by parting their roots in Autumn, which is the most expeditious method.

The Canterbury bells are biennial, seldom lasting longer than the second year: these, therefore, are only raised by sowing their seeds; the best season for which is in the beginning of April; and in June the plants will be fit to transplant.

The Canary Campanula is one of the most beautiful plants of the green-house, it producing its flowers in the depth of winter; and continues them through the months of December, January, and February. This plant is propagated by parting its roots, the season for which is in June, when the stems are quite decayed; and, in doing of it, great care should be taken not to break or bruise their roots, which would endanger their decaying. The soil in which these roots should be planted, must be one third fresh earth, a third part sand, and the rest lime-rubbish: this should be well mixed and screened, and, if laid together half a year before it is used, that it may incorporate, it will be the better.

When you plant the roots, give them a little water to settle the earth about them; but, afterwards, let your waterings be very sparingly done, and but seldom repeated, until their stems begin to advance; after which, they must have it a little freely: for want of this caution, many of these, and other flowers-roots, which are kept in pots, are destroyed; for it is impossible to suppose, that a root, which is entirely at rest, and destitute of leaves, should be capable of discharging any quantity of moisture: therefore let this caution be constantly observed. The stems of the flower will begin to appear in August; and, if the roots are strong, will rise to eight or nine feet in height; and in November, or sooner, will begin to shew its beautiful flame-coloured flowers. When these stems begin to advance, we should remove the plants into shelter, to guard them from morning frosts, or great rains; and, as the weather grows colder, they must be removed into a good green-house, where they should have as much free air as possible, in open, mild weather. This plant will require the same proportion of heat as is allotted for the ficoides, and will thrive in the same house, better than amongst orange-trees, &c.

CANA'DIAN, *Philosophy*. We are indebted, for what we know of the savages of Canada, to the baron de Hontan, who resided amongst them near ten years. He tells us, that in some conversations with them, which he relates on the subject of religion, he did not always get the better in the dispute. It is, indeed, surprising, a Huron should use all the subtilty of logic, to combat the Christian religion, and be as perfect in every trick of the schools, as if he had studied Scotus. It has been suspected, the baron had a mind to throw a ridicule on the religion he had been brought up in, and has put arguments in the mouth of a savage, he dared not make use of himself.

Those who have neither seen nor read any authentic account of these savages, have conceited they were covered with hair; lived in the woods, like wild beasts; had no society, and bore but the figure of man: whereas these savages have really no hair on their bodies, excepting on their head and eyebrows, which many take pains to pull off: if accidentally a hair grows any where else, they are careful to pluck it out, even by the roots. They are born as white as Europeans, but their going naked, daubing themselves with oil, and painting themselves with different colours, which the sun at last imprints on their skin, spoils their complexion; they are large men, superior in stature to us; their features are regular; their nose aquiline; are in general well-shaped; and it is a rarity to see any among them lame, blind, or deformed.

At first sight, a man would scarce entertain a favourable opinion of these savages: they have a fierce look; a rough deportment; and, in meeting each other, they are so silent, and shew so little emotion, that it would be difficult for an European, ignorant of their customs, to believe this their manner of civility, and the ceremony in fashion among them. They make a great jest of our compliments, using but few outward demonstrations of kindness; but are, however, good, affable, and exercise to strangers, and the unhappy, a charitable hospitality, that may shame all the nations of Europe; and an evenness of mind, which is neither altered by prosperity nor adversity. This is in a great measure owing to their want of those vicious resentments, which luxury and abundance have introduced among us.

The following are principal points of their religion and philosophy.

1. All the savages maintain there is a God; his existence they prove by the formation of the universe, which manifests the almighty power of its author; from whence it follows, say they, that man is not the work of chance, but of a principle superior in wisdom and knowledge, which they call the great mind. This great mind contains all, appears in all, acts in all, and gives motion to all things. In short, all we see, all we conceive, is this God, who subsists, without bounds, and without body, ought not to be represented by any figure whatever, and therefore they adore him in all his works. This is so true, that, when they see any thing remarkably fine, curious, or surprising, especially the sun and stars, they break out in this exclamation: Oh! great mind, we see thee every-where!

2. They say the soul is immortal, because, if it were not, all men would be equally happy in this life; for God, being infinitely perfect and wise, could not have created some for happiness, and others for misery; they maintain, that God, for certain reasons, above our comprehension, wills, that a certain number of beings should suffer in this world, that he may recompense them in the next; and therefore cannot bear to hear Christians say, such a one was unhappy, because he was killed, or burnt; asserting that what we call unhappiness, is only in our own ideas; because nothing is done, but by the will of this infinitely perfect being, whose conduct can neither be uncertain nor capricious.

3. The supreme mind has given men reason to enable them to discern good from evil, and to follow the rules of justice and wisdom.

4. Tranquillity of the soul is highly pleasing to the supreme mind; that, on the contrary, he detests the tumult of the passions, which makes men wicked.

5. Life is a sleep, death an awakening, which gives us intelligence of things visible and invisible.

6. The reason of man not being capable of lifting itself up to the knowledge of things above the earth, it is needless and troublesome to dive into invisible things.

7. After death, our souls go into a certain place, in which we cannot tell whether the good are happy, or evil unhappy; because we know not whether our ideas of happiness and misery coincide with those of the supreme spirit or mind.

CA'NAL, (*Dict.*)—An artificial Canal is a place dug to receive the waters of the sea, one or more rivers, &c. Rivers not only contribute to the natural riches of the country, by watering the soil through which they pass, but make a kind of artificial riches in every province through which they flow, by rendering the convenience of merchandizes easy. The more their course is extended in any state, and the more they communicate with each other, so much more the parts of that state are connected together, and mutually disposed to enrich each other. If nature has not done every thing to the highest perfection for man, man is to improve nature to the best advantage; and the Dutch, or, if we may credit travellers, the Chinese, who possess a country of prodigiously larger extent, have shewn how far human industry may go in making Canals and rivers navigable; and their labours have been sufficiently recompensed.

But the benefit of Canals was apprehended in very early ages of the world. Herodotus relates, that the Cnidians, a people of Cacia, in Asia minor, undertook to cut the isthmus, which almost joins Cnidos to the continent, but that they were diverted by an oracle. Several kings of Ægypt have attempted to make a communication between the Red-sea and the Mediterranean. Cleopatra had the same design. Solyman II, emperor of the Turks, employed five thousand men to no purpose, in the same attempt. The Greeks and Romans projected a Canal cross the isthmus of Corinth, which joins Morea and Achaia, to make a communication between the Ionian sea and the Archipelago. King Demetrius, Julius Cæsar, Caligula, and Nero, made vain attempts at the same thing. Under the reign of Nero, Lucius Verus, one of the generals of the Roman army in Gaul, undertook to join the Sone and the Moselle, by a Canal, to make a communication between the Mediterranean sea and German ocean, by the Rhone, the Sone, the

the Moselle, and the Rhine; which he could not execute. Charlemagne formed a design of uniting the Danube and the Rhine, by making a communication between the Ocean and the Black-sea, by a Canal from the river Almutz, which discharges itself into the Danube, to the river Reditz. He employed a vast number of hands, but different obstacles, which succeeded each other, made him lay aside this project. Bernard proposes, in his treatise on the Junction of the Seas, a communication between the sea of Provence and the ocean towards the coasts of Normandy, by uniting the Ouche to the Armanson, and so to go through France by the Rhone, the Sone, the Ouche, the Armanson, the Yonne, and the Seine.

There are several great Canals in France; as that of Briare, begun under Henry IV. and finished under Lewis XIII. by the care of cardinal Richlieu, which made a communication between the Loire and the Seine, by the Loing. It is eleven leagues in length, from Briare to Montargis. It enters the Loire below Briare, and, at Cepoi, ends in the Loing. The waters of this Canal are kept up by forty-two sluices: these serve to carry up and down rafts of wood, and boats made of a proper length and depth for this navigation; a certain toll is paid at every sluice, to defray the expence of keeping the Canal in order, and to reimburse the proprietors.

The Canal of Orleans was undertaken in 1675, for the communication of the Seine and Loire; it has twenty sluices; Philip of Orleans, regent of France, finished it in the minority of Lewis XV. It bears the name of a town through which it does not pass; beginning at Combleuse, a mile and a half from Orleans.

The project of the Canal of Picardy, for joining the rivers Somme and Oise, was carried into execution under the ministry of the cardinals Richlieu and Mazarin; and finished under the administration of M. de Colbert.

But one of the greatest and most stupendous works of this kind is the Canal of Languedoc, which forms a junction of two seas. This great and useful plan was proposed in the reigns of Francis I, Henry IV, and Lewis XIII; but not begun till the reign of Lewis XIV, wherein it was finished. It begins with a reservoir of four thousand paces in circumference, and eighty feet deep, which receives the waters of the black mountain; these descend to Nauroufe, in a basin four hundred yards long, and two hundred yards broad, lined with free-stone. Here is the point of separation, where the waters distribute themselves to the right and left, in a Canal sixty-four leagues long, into which many lesser rivers discharge themselves; and this is kept up from one space to another by one hundred and four sluices. The eight sluices, in the neighbourhood of Besiers, make a very fine shew; they form a cascade three hundred yards long, with an inclination of twenty-two yards.

This Canal is conducted in several places by aqueducts and bridges of an incredible height, which admit other rivers under their arches. In others, its way is cut through a rock, sometimes above, sometimes under ground, for the length of one thousand paces. It joins the Garonne at one end, near Toulouse; the other, crossing the Aude twice, passes between Agde and Besiers, and ends in the great lake which extends to Port Cette.

This Canal may stand in competition with the greatest attempts of the Romans; it was projected in 1666; Francis Requet demonstrated the practicability of it by many experiments made on the spot, and finished it before his death, which happened in 1680.

We have but one remarkable Canal, and that made by other people, and suffered to decay by ourselves. By this I mean that ancient Canal from the river Nyne, a little below Peterborough, to the river Witham, three miles below Lincoln, called by the modern inhabitants Caudike; which may be ranked among the monuments of the Roman grandeur, though it is now most of it filled up. It was forty miles long; and, so far as appears from the ruins, must have been very broad and deep; some authors take it for a Danish work. Morton will have it made under the emperor Domitian. Urns and medals have been discovered on the banks of this Canal, which seem to confirm that opinion. *Morton, Nat. Hist. Northampt.*

The great Canal of China is one of the wonders of art, made about eight hundred years ago; it runs from north to south quite cross the empire, beginning at the city of Canton. By it all kinds of foreign merchandize, entered at that city, are carried directly to Pekin, a distance of eight hundred and twenty-five miles. Its breadth and depth are sufficient to carry barks of considerable burthen, which are managed by sails and masts, as well as towed by hand. On this Canal the emperor is said to employ ten thousand ships, abating one for a reason very peculiar. It passes through, or by, forty-one large cities; there are in it seventy-five vast locks and sluices, to keep up the water, and pass the barks and ships where the ground will not admit of a sufficient depth of channel, besides several thousand draw and other bridges.

F. Magaillaine assures us, there is a passage from one end of China to the other, the space of six hundred French leagues, always, either by Canals or rivers, except a single day's journey by land, necessary to cross a mountain; an advantage which this Jesuit, who made the voyage himself, observes, is not to be found in any other state of the universe.

CANA'RY-*birds*, a species of singing-birds, greenish in colour, formerly brought only from the Canary-islands, but of late chiefly from Germany and Switzerland; which last, called also German birds, are preferred to the former.

Canary-birds are distinguished by different names, at different times and ages: such as are about three years old, are called runts; those above two are named eriffs; those of the first year, under the care of the old ones, are termed branchers; those that are new-flown, and cannot feed themselves, pushers; and those brought up by hand, nestlings.

Canary-birds are various in their notes, some having a sweet song, others a lavish note, others a long song, which is best, as having greatest variety of notes. Some prefer those that whisk and chew like a tit-lark; others are for those which begin like a sky-lark, continuing their song with a long yet sweet note; others chuse those which begin their song with the sky-lark, and then run on the notes of the nightingale; others, again, prefer a loud note and lavish, regarding little more than the noise.

CA'NCER (*Dict.*)—*To prevent* CANCERS. When there is danger of an approaching Cancer, the acrimony of the blood is, if possible, to be corrected by the use of both internal and external remedies, and a strict regimen in regard to diet is to be observed. Broths and soups, made of the flesh of young animals, and with proper herbs boiled in them, as scorzonera, and the others of that tribe, are very beneficial in these cases; the most wholesome drink is either fair water, or a decoction of China-root, or sarsaparilla, or the like; and, when the pains are violent from the schirrus, which is now threatening to become a Cancer, white poppy-seeds may be added in considerable quantities to the decoction; and it may be sweetened with a proper quantity of syrup of diacodium. Two or three times a day also should be taken a dose of Gascoin's powder, salt of wormwood, native cinnabar, crude, and diaphoretic antimony, adding to each dose, as there shall be occasion, half a grain of laudanum, to assuage the violence of the pain: great benefit is also sometimes received in this case, by taking either the powder or juice of millepedes, with sperma ceti.

Purges also of the mercurial kind do great service, as do also bleeding and cupping frequently in the spring and autumn. A thin plate of lead, well impregnated with quicksilver, may also be very conveniently worn on the part, and with great advantage; for this method cannot but weaken the sense of pain, and may often prevent a Cancer.

If the application of the plate of lead shall prove insufficient, plaisters and ointments, composed of such ingredients as are known to assuage pains, may also be applied; the following are of this kind, and are frequently found of service: take, of the unguentum diapompholygos, two ounces; of opium, half a scruple; mix these into an ointment, and frequently rub the part affected with it; or take, of an amalgama of quicksilver and lead, two ounces; mix this with a sufficient quantity of ointment of roses, or any the like unguent; then spread a part of it on a linen rag, and apply it in the manner of a plaister to the part; or take, litharge vinegar, an ounce; expressed oil of henbane-seeds, poppy-seeds, and the infused oil of roses, of each two ounces; mix them, by a long and continued stirring together, into an ointment, adding, toward the end of the operation, purified opium, from six to ten grains, as the urgency of the symptoms may require: this is to be spread in like manner on linen rags, and applied at times to the part.

If the daubings of these ointments is disliked, a refrigerant plaister may be used in their stead; such is the lead plaister of Mynsycht, the plaister of red lead, or pompholyx, or the excellent plaister made by the following prescription: take of the fresh and depurated juices of henbane, garden poppy, and water hemlock, of each four ounces; boil these to a thickness over a gentle fire, adding, toward the end of the boiling, eight ounces of white wax, and one ounce of oil of roses, and make the whole into a plaister; or take, sugar of lead, of ceruse, the amalgamation of quicksilver and lead, and of the expressed oil of henbane-seed, and infused oil of roses, of each two ounces; make these into a plaister. If the pains are very violent, a small quantity of opium may be added to either of these plaisters. *Heister's Surgery.*

CANCER, in the military art, denotes a long, ponderous beam, used for beating down walls, not unlike the manner of a ram.

CA'NCEROUS, or CANCEROSE, something that belongs to, or partakes of the nature and qualities of a cancer.

CA'NDLE *, a cotton or linen wick, loosely twisted, and covered with tallow, wax, or sperma ceti, in a cylindrical figure; which, being lighted at the end, serves to illumine a place in the absence of the sun.

* The word *Candle* comes from the Latin *candela*, and that from *candor* of *candeo*, I burn; whence also the middle-age Greek *κανδηλα*.

A tallow Candle, to be good, must be half sheep's tallow, half bullocks; that of hogs making them gutter, give an ill smell, and a thick black smoak.

Tallow Candles are of two kinds; the one dipped, the other moulded: the first, which are those in ordinary use, are of an old standing; the latter are said to be the invention of the Sieur le Brez, at Paris. The manufacture of the two kinds is very dif-

different, excepting in what relates to the melting of the tallow, and making the wick, which is the fame in both.

Method of making CANDLES. The tallows, being weighed and mixed in their due proportion, are cut or hacked into pieces, to facilitate their melting, and thrown into a pot, or boiler, having a cavity of fome depth running round the top, to prevent its boiling over. Being thus perfectly melted and fkimmed, a certain quantity of water is thrown in, proportioned to the quantity of tallow, which ferves to precipitate the impurities of the tallow, which had efcaped the fkimmer, to the bottom of the veffel. The tallow, however, intended for the three firft dips, muft have no water; in regard the dry wick, imbibing the water readily, makes the Candles fplit and crackle in the burning. The melted tallow is now emptied through a fierce into a tub, having a tap for letting it out, as occafion requires. The tallow thus prepared, may be ufed, after having ftood three hours, and will continue fit for ufe twenty-four hours in fummer, and fifteen in winter.

—*For the wicks*, they are made of fpun-cotton, which the chandlers buy in fkeins, and wind off three or four together, according to the intended thicknefs of the wick, into bottoms or clues, whence they are cut out with an inftrument contrived for that purpofe, into pieces of the length of the Candle required; then put on the fticks, or broches, or elfe placed in the moulds, as the Candles are intended to be either dipped or moulded.

Making of dipped CANDLES. The liquid tallow is drawn off, from the tub above-mentioned, into a veffel called the mould, fink, or abyfs, of an angular form, perfectly like a prifm, except that it is not equilateral; the fide on which it opens being only ten inches high; and the others, which make its depth, fifteen. On the angle, formed by the two great fides, it is fupported by two feet, and placed on a kind of bench, in form of a trough, to catch the droppings, as the Candles are taken out each dip. At a convenient diftance from this, is feated the workman, who takes two fticks, or broches, at a time, ftrung with the proper number of wicks, viz. fixteen, if the Candles are to be of eight in the pound; twelve, if of fix in the pound, &c. and, holding them equi-diftant, by means of the fecond and third finger of each hand, which he puts between them, he immerges the wicks two or three times for the firft lay; and, holding them fome time over the opening of the veffel, to let them drain, hangs them on a rack, where they continue to drain and grow dry. When dry, they are dipped a fecond time, then a third, as before; only for the third lay, they are immerged but twice, in all the reft, thrice. This operation is repeated more or lefs times, according to the intended thicknefs of the Candle. With this laft dip they neck them; i. e. plunge them below that part of the wick where the other lays ended.

It muft be obferved, that during the operation, the tallow is ftirred from time to time, and the ftock fupplied with frefh tallow. When the Candles are finifhed, their peaked ends, or bottoms, are taken off, not with any cutting inftrument, but by paffing them over a kind of flat brazen plate, heated to a proper pitch, by a fire underneath, which melts down as much as is requifite.

Method of making mould-CANDLES. Thefe Candles are made in moulds of different matters; brafs, tin, and lead, are the moft ordinary. Tin is the beft, and lead is the worft. Each Candle has its mould, confifting of three pieces, the neck, fhaft, and foot: the fhaft is a hollow metal cylinder, of the diameter and length of the Candle propofed; at the extremity of this is the neck, which is a little metallic cavity, in form of a dome, having a moulding within-fide, and pierced in the middle with a hole big enough for the wick to pafs through. At the other extremity is the foot, in form of a little tunnel, through which the liquid tallow runs into the mould. The neck is foldered to to the fhaft, but the foot is moveable, being applied when the wick is to be put in, and taken off again when the Candle is cold. A little beneath the place where the foot is applied to the fhaft, is a kind ftring of metal, which ferves to fupport that part of the mould, and to prevent the fhaft from entering too deep in the table to be mentioned hereafter. Laftly, in the hook of the foot is a leaf of the fame metal, foldered within-fide, which, advancing into the center, ferves to keep up the wick; which is here hooked on precifely in the middle of the mould. The wick is introduced into the fhaft of the mould, by a piece of wire, which, being thruft through the aperture of the hook, till it comes out at the neck, the wick is tied to it; fo that in drawing it back, the wick comes along with it, leaving only enough at the top for the neck; the other end is faftened to the hook, which thus keeps it perpendicular. The moulds, in this condition, are difpofed in a table pierced full of holes, the diameter of each being about an inch: thefe holes receive the moulds inverted, as far as the ftring in the foot. Being thus placed perpendicularly, they are filled with melted tallow, (prepared as before) drawn out of the tap into a tin-pot, and thence poured into the foot. After the moulds have ftood long enough to cool, for the tallow to have arrived at its confiftence, the Candle is taken out, by taking off the foot, which brings the Candle along with it. Thofe who aim at perfection in this work, bleach or whiten their Candles, by faftening them on rods or broches, and hanging them out to the dew, and earlieft rays of the fun, for eight or ten days: care being taken to fkreen them in the day time from the too intenfe heat of the fun; and in the night from rain, by waxed cloths.

Wax CANDLES, are made of a cotton or flaxen wick, flightly twifted, and covered with white or yellow wax.—Of thefe there are feveral kinds; fome called tapers, ufed to illumine churches, proceffions, funeral ceremonies, &c. and others ufed on ordinary occafions.

For the firft kind, their figure is conical, ftill diminifhing from the bottom, which has a hole to receive the hook of the candleftick, the top of which ends in a point: the latter kind are cylindrical. The firft are either made with a ladle, or with the hand.

Manner of making wax CANDLES *with the ladle*. The wicks being twifted and cut of the proper length, a dozen of them are tied by the neck, at equal diftances, round an iron circle, fufpended directly over a large bafon of copper tinned, and full of melted wax; a large ladle-ful of this wax is poured gently, by inclination, on the tops of the wicks, one after another; fo that, running down, the whole wick is thus covered: the furplus returning into the bafon, where it is kept warm by a pan of coals underneath it. They thus continue to pour on the wax, till the candle arrives at its deftined bignefs: ftill obferving, that the three firft ladles be poured on at the top of the wick, the fourth at the height of three fourths, the fifth at one half, and the fixth at one fourth; by which means the candle arrives at its pyramidal form. The candles are then taken down hot, and laid afide of each other, in a feather bed folded in two, to preferve their warmth, and keep the wax foft: they are then taken and rolled, one by one, on an even table, ufually of walnut-tree, with a long fquare inftrument of box, fmooth at bottom. The candle being thus rolled and fmoothed, its big end is cut off, and a conical hole made in it.

Manner of making wax CANDLES *by the hand*. The wick being difpofed, as in the former, they begin to foften the wax, by working it feveral times in hot water, contained in a brafs caldron tinned, very narrow and deep. A piece of the wax is then taken out, and difpofed, by little and little round the wick, which is hung on a hook in the wall, by the extremity oppofite to the neck; fo that they begin with the big end, diminifhing ftill, as they defcend towards the neck. In other refpects, the method is the fame here as in the former cafe, only that they are not laid in the bed, but are rolled on the table juft as they are formed. It muft be obferved, however, that, in the former cafe, water is always ufed to moiften the feveral inftruments, to prevent the wax from fticking; and, in the latter, lard, or oil of olives, for the hands, table, &c.

Cylindrical wax CANDLES, are either formed on the table or drawn. The firft kind are made of feveral threads of cotton, loofely fpun, and twifted together, covered with the ladle, and rolled as the conical ones, but not pierced.

Wax CANDLES *drawn*, are fo called, becaufe actually drawn, in the manner of wire, by means of two large rollers, or cylinders of wood, turned by a handle, which, turning backwards and forwards feveral times, pafs the wick through melted wax, contained in a brafs bafon; and at the fame time through the holes of an inftrument, like that ufed for drawing wire, faftened at one fide of the bafon: fo that, by little and little, the candle acquires any bulk at pleafure, according to the different holes of the inftrument through which it paffes: by this method, may four or five hundred ells length be drawn running. The invention of this was brought from Venice by Pierre Blefimare, of Paris, about the middle of the laft century.

CANICULAR year, annus canicularis, denotes the Egyptian natural year, which was computed from one heliacal rifing of Canicula to the next.

This is called annus canarius, and annus cynicus; by the Egyptians themfelves the Sothic year, from Soth a denomination given by them to Sirius. Some alfo call it the heliacal year.

The Canicular year confifted ordinarily of three hundred and fixty-five days, and every fourth year of three hundred and fixty-fix days, by which it was accommodated to the civil year. The reafon of their choice of Canicula before the other ftars, to compute their time by, was not only the fuperior brightnefs of that ftar, but becaufe its heliacal rifing was in Egypt a time of fingular note, as falling on the greateft augmentation of the Nile, the reputed father of Egypt. Ephef-tion adds, that, from the afpect of Canicula, its habit and colour the Egyptians drew prognoftics concerning the rife of the Nile; and, according to Florus, predicted the future ftate of the year. So that the firft rifing of this ftar was yearly obferved with great attention.

CANKER, in medicine; fee APHTHÆ, *Dict.* and *Sup.*

CANKER *in trees*, a term ufed by our farmers to exprefs a wound or blemifh in the trunk of a tree, which does not heal up by nature, but will increafe and damage, if not indanger the whole tree. Thefe wounds are fometimes occafioned by accidents, as blows, or by the branches of one tree galling another by the motion they are put into by the winds; if this latter be the cafe, the offending branch muft be cut off, or drawn another way, or elfe all remedies are vain.

The

The wound muſt be cut and enlarged every way to the quick, and all the decayed wood muſt be taken clean out; then the whole internal ſurface of the wound muſt be rubbed over with tar mingled with oil, and after this it muſt be filled up with clay and horſe-dung mixed together, or with horſe-dung alone, which many eſteem beſt of all; in this caſe the dung muſt be bound over with a rag; hog's dung is by many preferred to horſe-dung for this purpoſe, and it is proper to add to this application the keeping of the roots cool and moiſt, by laying fern and nettles about them. If the Canker be only in one of the boughs of the tree, the ſhorteſt way is to cut off the bough at once; if that be a large one, it ſhould be cut off at ſome diſtance from the body of the tree; but, if a ſmall one, it ſhould be cut off cloſe. The adding a coat of dung, and pond or river mud, about the roots of trees, if they are ſubject to this from their ſtanding in a dry barren land, as is often the caſe, is a very good cure. *Mortimer's Huſbandry.*

CA'NNABIS, hemp in botany, a genus of plants whoſe characters are: it hath digitated (or fingered) leaves which grow oppoſite to one another: the flowers have no viſible petals; it is male and female, in different plants. This plant is propagated in the rich fenny parts of Lincolnſhire in great quantities, for its bark, which is uſed for cordage, cloth, &c. and the ſeeds afford an oil, which is uſed in medicine.

Hemp is always ſown on a deep, moiſt, rich ſoil, ſuch as is found in Holland, in Lincolnſhire, and the fens in the iſles of Ely, where it is cultivated to great advantage, as it might in many other parts of England, where there is the like ſoil; but it will not thrive on clay, or ſtiff cold land: it is eſteemed very good to deſtroy weeds, but it will greatly impoveriſh the land, ſo that this crop muſt not be repeated on the ſame ground.

The land on which hemp is deſigned to be ſown, ſhould be well plowed, and made very fine by harrowing; about the middle of April is a good ſeaſon for ſowing the ſeed: three buſhels will ſow an acre: in the choice of the ſeed, the heavieſt and brighteſt-coloured ſhould be preferred, and particular care ſhould be had to the kernel of the ſeed, ſo that ſome of them ſhould be cracked to ſee if they have the germ or future plant perfect: for in ſome places the male plants are drawn out too ſoon from the female, that is, before they have impregnated the female plants with the farina; in which caſe, though the ſeeds produced by theſe female plants may ſeem fair to the eye, yet they will not grow, as is well known to the inhabitants of Bickar, Swineſhead, and Dunnington, three pariſhes in the fens of Lincolnſhire, where hemp is cultivated in great abundance, who have dearly bought their experience.

When the plants are come up, they ſhould be hoed out in the ſame manner as is practiſed for turnips, leaving the plants a foot or ſixteen inches apart; obſerve alſo to cut all the weeds, which, if well performed, and in dry weather, will deſtroy them. This crop will require a ſecond hoeing about a month after the firſt, in order to deſtroy the weeds: if this be well performed, it will require no further care; for the hemp will ſoon after cover the ground, and prevent the growth of the weeds.

The firſt ſeaſon for pulling the hemp is uſually about the middle of Auguſt, when they begin to pull what they call the fimble-hemp, which is the male plant; but it would be much the better method to defer this for a fortnight or three weeks longer, until theſe male plants have fully ſhed their duſt, without which the ſeeds will prove abortive, produce nothing if ſown the next year, nor will thoſe concerned in the oil-mills give any thing for them, there being only empty huſks without any kernels to produce the oil.

The ſecond pulling is a little after Michaelmas, when the ſeeds are ripe: this is uſually called karle-hemp: it is the female plants, which were left at the time when the male were pulled. This karle-hemp is bound in bundles of a yard in compaſs, according to the ſtatute meaſure, which are laid in the ſun for a few days to dry; and then it is ſtacked up or houſed to keep it dry, till the ſeed can be threſhed out. An acre of hemp, on a rich ſoil, will produce near three quarters of ſeed, which, together with the unwrought hemp, is worth from ſix to eight pounds.

Of late years the inhabitants of the Britiſh colonies in North America have cultivated this uſeful plant, and a bounty was granted by parliament for the hemp, which was imported from thence; but whether the inhabitants of thoſe colonies grew tired of cultivating it, or the bounty was not regularly paid, I cannot ſay; but, whatever has been the cauſe, the quantity imported has by no means anſwered the expectation of the public, which is greatly to be lamented; becauſe, as this commodity is ſo eſſential to the marine, which ſhould be the principal object of this kingdom, the being furniſhed with it from our own plantations will not only ſave the ready money paid for it, but ſecure to the country an ample ſupply at all times without being obliged to our neighbours for it. *Miller's Gard. Dict.*

The ſociety for improving agriculture at Edinburgh has given us the following directions for propagating and dreſſing hemp:

1. Hemp, as well as flax, requires good ſeed; which ought to be renewed from time to time. The beſt is had from Riga or Narva. Hemp-ſeed is not ſo apt to degenerate as flax-ſeed is, and by change of ſoil it will much recover its vigour.

2. Hemp requires a deep, fat, brown ſoil, and may be ſowed on ground newly dunged; nay, if it is not ſufficiently rich and fat, it ought to be dunged over again. It muſt have the ſame plowings and harrowings as flax. Moiſt grounds, or ſuch as breed ruſhes, are altogether improper for hemp, till fully drained.

3. A boll of hemp-ſeed will ſuffice to ſow an acre of land, and ſo proportionally. The ſame ſeaſon of the year wherein you ſow flax, you ought alſo to ſow hemp; and your ground muſt be laid level and flat: when it is once ſown, and well covered with earth, ſo that the birds cannot come at it, you need have no further care of it, until it is ripe and fit to pull.

4. The male hemp is conſtantly ripe five or ſix weeks ſooner than the female. The way to know them is this: the male bears a bloſſom, but no ſeed; the female bears a ſeed. The way to know when the male is ripe, and fit for pulling, is by obſerving when the ſtalk as well as leaf is growing yellow; then that ſort of hemp is ripe: or if, in a fair morning, upon ſhaking of the ſtalks, you perceive much duſt to fall off from the bloſſom, the male hemp is fit for pulling.

5. You muſt obſerve the ſame caution in the pulling of your hemp as in your flax; for there are in hemp, as well as flax, diverſities of degrees of coarſeneſs and fineneſs: therefore, in pulling the male hemp, you muſt take care to ſort the coarſeſt together, the middle ſort likewiſe together, and ſo the fineſt by itſelf. Beware, in pulling it, that you do not break the ſtalks of your female hemp; for, by the breaking of the ſtalks, your ſeed, as well as hemp, will ſuffer. You muſt ſtill, as you have a ſufficient quantity of hemp, make ſmall ſheaves of it about the thickneſs of your thigh; tie them in the middle, and let them dry; for it is a certain rule, that hemp or flax ought never to be watered or graſſed until it is perfectly dry. If you deſign to water your male hemp the ſame ſeaſon that you pull it, you muſt tie it up in ſheaves, about the bigneſs of your waiſt, with three ſtrong ſtrings; one at each end, and one in the middle. It ought to be ſo moderately tied, that you need not fear its burſting; but at the ſame time not ſo hard but that the water may conveniently penetrate to all parts of it. In the tying up your ſheaves, you muſt ſet the one half of your roots one way, and the other half the other way, that all the ſheaves may be of equal thickneſs. If you forbear the watering that ſeaſon, you need not in ſuch caſe tie your hemp into big ſheaves; but when it is ſufficiently dry, ſo as to be out of danger of heating, you ought to put it in a dry barn, or ſtack it in the barn-yard, laying always the roots outward, as you would do corn; and there leave it till the ſeaſon offers for watering it. But all this while you muſt carefully obſerve to keep all your ſorts of hemp apart from each other.

6. When you come to water your hemp, you muſt make bundles or ſheaves, as already obſerved. It is needleſs to enlarge on the watering part, in regard it differs in nothing from what is ſaid under the article FLAX. Your pits for hemp ought to be deep and wide, becauſe of the great length which good hemp grows to. You muſt in all things obſerve the directions given in relation to the watering of flax; and, by trying the ſame experiments directed to make in reference to it, you will diſcover when your ſeveral ſorts of hemp may be fully watered.

7. When your hemp is well watered, you muſt take it up; and, having waſhed away the filth that clings to it, you muſt graſs it in the ſame manner as flax, obſerving the like rules and directions, as to each quality and ſort of hemp. This is ſtill to be underſtood, in caſe you deſign it for cloth: but, if you deſign it for cordage or nets, there will be no occaſion for graſſing it; but only, after it is taken out of the water, you may again ſtook it till it is dry; then put it into a dry barn, where you ought to let it ſweat for ſix weeks or two months, that it may work the more kindly. Note likewiſe, that male hemp is generally fitter for cloth than female, becauſe it is finer.

8. As for your male hemp, you will diſcover when it is ripe and fit for pulling by the following obſervations. When your hemp-ſeed is become large and well coloured, and the pods, or places where the ſeed is lodged, begin to open, ſo as through the ſmall clefts you may perceive the ſeed, you muſt forthwith pull it without loſs of time; for a ſmall delay may be fatal to the whole crop, both of ſeed and hemp. In the pulling it, you muſt obſerve the cautions given; that is, put the coarſeſt, in the middle, and the fineſt ſorts all by themſelves; and you muſt be careful, as you pull your female hemp, not to ſhed the ſeed; but, when your hemp is dry, you ought to have a wooden ſtool, with a ſheet under it, and beat the ſeed into the ſheet, breaking your hemp as little as may be. The female hemp cannot well be watered the ſame year it is pulled; ſo you have nothing to do with it that year, but to fit it for the barn, the ſame way as you was directed to do with the male hemp. When the ſeaſon offers for watering and graſſing, you muſt purſue exactly the rules given in reference to the male hemp.

9. When your hemp is fit for breaking, you muſt make uſe of breaks, which are common in this kingdom. If the weather be fair, you ought to expoſe it to the ſun and air to dry it, that it may break more kindly; but, if it be moiſt and damp, you muſt then dig a pit or hole in the ground about four or five feet deep, at each corner whereof you muſt fix a wooden fork, which fork muſt be three or four feet high from the ground: on theſe forks place ſticks whereon to ſpread your hemp; ſpread it very thin; kindle a gentle fire in the pit of hemp-ſtraw, and therewith dry your hemp: it will dry in a very little time. Take great care not to over dry it, and, above all, not to ſcorch it. When it is dry enough, break it with your breaks, and afterwards rub and ſcutch it.

10. After you have cleared your ſeed from your hemp, you muſt be very careful, while the ſeed is new, to prevent its heating, by frequent turning. Keep it in a place that is dry, but not cloſe; for the air will help to preſerve it. When you have ſcutched your hemp, and wrought it clean from the ſtraw and roots, tie it up ſeverally, according as the kinds and ſorts of hemp are, and put it into a place moderately dry, (for the place where you keep hemp ought to be neither too dry nor too damp;) there keep it until you have occaſion to uſe it. The longer you keep your hemp in this manner, the better will it work, and the goods which it produces will prove the better.

11. The heckling of hemp is of courſe the next thing to be treated of. This is to be more or leſs done according to the uſe to which you deſign to apply it: as, for inſtance, if you deſign your hemp for groſs or coarſe yarn, you need not heckle it in that caſe, but with a large-toothed heckle. If you deſign it for finer uſes, you muſt begin with your coarſe heckle, and heckle it again in the ſecond heckle. If you would have your hemp brought to be yet finer, you muſt heckle it a third time, and in a finer heckle. You muſt always work hemp gradually, and not heckle it at firſt with your finer or fineſt heckle: for, if you do, you muſt expect more tow than hemp fit for uſe and ſervice. When you have a mind to have it extraordinary fine, you muſt not in the leaſt heckle it, but you muſt work it entirely by the help of a bruſh for that purpoſe, made of hogs briſtles, and ſtiffened artificially with glew. This bruſhing does not ſo wear and tear it as the heckles do, but by eaſy degrees ſeparates the threads and fibres thereof. Any body that has a mind to make trial of theſe bruſhes, may be furniſhed with them at Edinburgh for a trifle. A bruſh will laſt many years, if well and carefully uſed. Hemp requires heckles with longer and larger teeth than flax does. If you deſign your hemp for ſail-cloth, two hecklings will ſuffice; and thoſe hecklings are to be in the firſt and ſecond large heckles. But, if you deſign it for cordage, one heckling may be ſufficient, and you may have a heckle with wider and ſtronger teeth for that purpoſe than is uſual. You may mix tow together with your hemp in the making of your cordage; but it were better for the goods and for the buyer to have them made of hemp only; and the tow may be uſed for many profitable purpoſes by itſelf. At all times when you are to heckle or bruſh hemp or flax, you muſt begin with the ends which grew next the ground, becauſe they are ſtrongeſt; and, when they once divide, the other end is more eaſily wrought.

Of ſoftening HEMP *and flax*.—After beating and firſt heckling of the hemp, take a large pewter ſtoup, or white-iron flagon; fill it full of made-up heads of hemp cloſe packed, and put it in a pot of boiling water; the mouth of the ſtoup or flagon is to be ſtopped cloſe with a cloth, ſo as no water get into it. Let it boil full two hours, and it will make the hemp ſoft to heckle, and ſpin as fine as any lint. The cloth of hemp laſts longer than any cloth whatſoever; and the hards of it, when thus prepared, will make good and ſtrong ſhirting and ſheeting, or napry, for country-people.

The ſame method will ſoften flax, and make the fibres of it ſeparate the better after heckling.

CA'NNEL *Coal*, a black bituminous foſſil, frequent in Staffordſhire and Lancaſhire, of a fine hard texture, ſo as to receive a poliſh, and become of ſervice for divers works inſtead of ivory, but chiefly uſed for fuel, as affording a brighter and purer flame than the common ſea-coal. See COAL.

CA'NON, in eccleſiaſtical affairs, a perſon who poſſeſſes a revenue allotted for the performance of divine ſervice, in a cathedral or collegiate church.

Canons are of no great antiquity: Paſquier obſerves, that the name Canon was not known before Charlemaign: at leaſt, the firſt we hear of, are in Gregory de Tours, who mentions a college of Canons, inſtituted by Baldwin XVI, archbiſhop of that city, in the time of Clotharius I.

Originally Canons were only prieſts, or inferior eccleſiaſtics, who lived in community; reſiding by the cathedral church, to aſſiſt the biſhop; depending entirely on his will, ſupported by the revenues of the biſhopric; and living in the ſame houſe, as his domeſtics, or counſellors, &c. They even inherited his moveables, till the year 816, when this was prohibited by the council of Aix la Chapelle. By degrees, theſe communities of prieſts, ſhaking off their dependance, formed ſeparate bodies, whereof the biſhops, however, were ſtill heads. In the tenth century, there were communities or congregations of the ſame kind, eſtabliſhed even in cities where there were no biſhops: theſe were called collegiates, in regard they uſed the terms congregation and college indifferently: the name chapter, now given to theſe bodies, being much more modern. Under the ſecond race of the French kings, the canonical, or collegiate life, had ſpread itſelf all over the country; and each cathedral had its chapter, diſtinct from the reſt of the clergy. But they were not yet deſtined to a life ſo eaſy as now-a-days.

They had the name canon, from the Greek κανων, which ſignifies three different things, a rule, a penſion or fixed revenue to live on, and a catalogue or matricula. Hence, ſome ſay, they were called Canons, by reaſon of the penſion or prebend; (whence they are ſometimes alſo denominated ſportulantes fratres:) others hold, they were called Canons, becauſe obliged to live according to the canonical rules and inſtitutions, which were given them; and others, as M. de Marca, becauſe their names were inſerted in the matricula, or catalogue of the cathedral.

In time, the Canons freed themſelves from their rules, the obſervance relaxed, and, at length, they ceaſed to live in community, yet ſtill formed bodies; pretending to other functions beſides the celebration of the common office in the church, yet aſſuming the rights of the reſt of the clergy; making themſelves a neceſſary council of the biſhop; taking upon them the adminiſtration of a ſee during a vacancy, and the election of a biſhop to ſupply it. There are ſeven more chapters exempt from the juriſdiction of the biſhop, and owning no head but their dean. After the example of cathedral chapters, collegiate ones alſo continued to form bodies, after they had abandoned living in community.

CANON *of ſcripture*, a catalogue or liſt of the inſpired writings; or ſuch books of the bible as are called canonical, becauſe they are in the number of thoſe books which are looked upon as ſacred, in oppoſition to theſe, which either are not acknowledged as divine books, or are rejected as heretical and ſpurious, and are called Apocryphal.

The Canon of ſcripture may be conſidered either as Jewiſh or Chriſtian, with reſpect to the ſacred writings, acknowledged as ſuch by the Jews, and thoſe admitted by the Chriſtians.

The firſt Canon, or catalogue of the ſacred books, was made by the Jews, but who was the author of it, is not ſo certain. The firſt books of Moſes were, queſtionleſs, collected into one body, within a ſhort time after his death; ſince Deuteronomy, which is an abridgment of the other four, was laid in the tabernacle near the ark, according to the command he gave to the Levites. So that the firſt Canon of the ſacred writings conſiſted only of the five books of Moſes. There were no more added to them, till the diviſion of the ten tribes; ſince the Samaritans acknowledged none elſe. However, ſince Moſes, there were ſeveral prophets and other writers, divinely inſpired, who compoſed either the hiſtory of their times, or prophetical books, and divine writings, or pſalms to the praiſe of God; but it cannot be diſcovered, that, any time before the captivity, they were collected into one body, and comprized under one and the ſame Canon. It is evident, that, in our Saviour's time, the Canon of the holy ſcripture was already drawn up, ſince he cites the law of Moſes, the prophets, and the pſalms, which are the three ſorts of books of which that Canon is compoſed, and which he often ſtyles the ſcripture, or the holy ſcripture.

It is generally received that Ezra was the principal author of this Canon, though Nehemiah had ſome ſhare in it; and that he re-eſtabliſhed, corrected, and ordered the ſacred books to be written in new characters.

The Jewiſh Canon is generally called the Canon of Ezra; but it is certain, that all the books were not received into the Canon of the ſcriptures in his time; for Malachi, it is ſuppoſed, lived after him; and, in Nehemiah, mention is made of Jaddua the high-prieſt, and of Darius Codomanus, a king of Perſia, who lived at leaſt a hundred years after his time. Dr. Prideaux, with great appearance of reaſon, ſays, it is moſt probable, that the two books of Chronicles, Ezra, Nehemiah, and Eſther, as well as Malachi, were afterwards added in the time of Simeon the Juſt; and that it was not till then, that the Jewiſh Canon of the holy ſcripture was fully compleated. And, indeed, theſe laſt books ſeem very much to want the accuracy and ſkill of Ezra, in their publication; for they fall ſhort of the exactneſs found in the other parts of the Hebrew ſcriptures.

There are ſome authors who pretend, that the Jews have made one or more Canons; and that they have added to the former the books of Tobit, Judith, Eccleſiaſticus, Wiſdom, and the Maccabees: But it is moſt evidently true, that the Jews had no other Canon but that of Ezra, nor confeſſed any other books for ſacred, but thoſe it contains. The two aſſemblies of the ſynagogue, which, as it is pretended, were held for that purpoſe, are mere chimeras; nor have any antient writers ſaid any thing of them.

As for the Chriſtian church, there is no doubt but it acknowledged thoſe books to be canonical, which were cited, as of divine authority, by Chriſt and his Apoſtles; the ancient catalogues of the canonical books of the Old Teſtament, which are to be met with in Chriſtian writers, are conformable to the Canon of the Jews, and contain no other books; the Chriſtian Church, for several of the first ages, receiving the inspired writings no further than the Jewish Canon. The first, and most ancient catalogue of this kind, is that of Melito, bishop of Sardis, who flourished in the reign of Marcus Antoninus. It agrees with the Jewish Canon, excepting his omission of Esther, and that he makes Ruth and Judges two books. Origen has given us a list of the sacred books, in which he takes in Esther, and joins Ruth with Judges. St. Gregory Nazianzen divides the books of scripture into *Historical*, *Poetical*, and *Prophetical*: he reckons twelve historical books, viz. the five books of Moses, with Joshua, Judges, Ruth, the two books of Kings, Chronicles, and Esdras. Five poetical books, Job, Daniel, and the three books of Solomon. Five prophetical books, viz. four great prophets, and twelve small ones. The council of Laodicea was the first synod in which the number of the canonical books was ascertained; this council assigns only twenty-two books to the Old Testament, including Esther, and joining Baruch and the Lamentations with Jeremiah. St. Epiphanius, reckons twenty-seven canonical books of the Old Testament, yet he admits no more than are in the catalogue of Origen, and observes that the Jews had reduced them to twenty-two. The third council of Carthage, in the year 397, admitted the books of Wisdom, Ecclesiasticus, Tobit, Judith, and the two books of Maccabees into the Canon. The Church of Rome has agreed herein with that of Africa; for Innocent I, in his letter to Exuperius, places the same books in the Canon of scripture, as Pope Gelasius, in the council held in the year 494; and the decree of Pope Eugenius, and the Canon of the council of Trent, agree with the Canon of the council of Carthage. That the council of Trent had no prior authority to proceed on, excepting some slender pretence from the council of Carthage above-mentioned, appears from the current testimony of the Latin Church.

As to the Canon of the New Testament, it is to be observed, that the four Evangelists, the acts of the Apostles, all the epistle of St. Paul (except that to the Hebrews) and the first epistles of St. Peter and St. John, have been received as canonical by the unanimous consent of all the churches in all times; the epistle of St. James, that of St. Jude, the first epistle of St. Peter, and the second and third epistles of St. John, were not received by all the churches from the beginning as canonical, but have since been acknowledged as genuine, and therefore admitted into the Canon.

We must observe, that the Canon of the New Testament was neither settled by any synod, or single authority: this collection was formed upon the unanimous consent of all the churches, who, by constant tradition, reaching to the Apostolical age, had received such a number of them as were written by inspired authors.

CANO'NICAL, in philosophical history, an appellation given by Epicurus to his doctrine of logic.

It was called Canonical, as consisting of a few canons, or rules for directing the understanding in the pursuit and knowledge of truth.

CANO'PUS, in astronomy, a bright star, of the first magnitude in the rudder of Argo, a constellation of the southern hemisphere.

CANO'W, a kind of boat in use among the Indians of America.

The word is also written Canoo, Canoe, and Cannow. It is borrowed from the Spanish canoa, which signifies the same, and that from the language of the Indians.

The common Canows, among the Indians, are those made of trees hollowed; being either greater or less, according to the size of the tree they are made of. They are rowed with paddles, and rarely carry sails; the loading is laid at the bottom: but, having no ballast, they are frequently turned upside down. They have no rudder, the want of which is supplied by the hind oars. The Negroes of Guinea use the same sort of Canows, though made in a different manner. They are long-shaped, having room only for one person in width, and seven or eight in length; they shew little wood above the water; those who row are extremely dextrous, not only in giving the strokes with cadence and uniformity, by which their Canows seem to fly along the surface of the water, but, also, in balancing the vessel with their bodies, and preventing their overturning, which otherwise, on account of their lightness, would continually happen.

Add that, when they are overturned, they have the address to turn them up again in the water itself, and mount them anew. They venture as far as four leagues to sea, but dare not to venture further.

They are usually sixteen feet long, and a foot or two wide, though there are some larger, as far as thirty-five feet long, five wide, and three high, used for the carriage of cattle, and expeditions in war. They are fitted with sails made of rushes.

CA'NTO, denotes a part or division of a poem, answering to what is otherwise called a book.

The word is Italian, where it properly signifies a song.

Tasso, Ariosto, and several other Italians, have divided their longer or heroic poems into Canto's. In imitation of them, Scarron has also divided his Gigantomachia, and Boileau his Lutrin, into chants, or songs. The like usage has been adopted by some English writers, as Butler, who divides his Hudibras, and Dr. Garth, his Dispensary, into Canto's.

CANTO, in the Italian music, signifies a song: hence, Canto simplice is where all the notes or figures are equal, called also Canto firmo: Canto figurato, that where the figures are unequal, and express different motions.

CANTO, signifies also the treble part of a song; hence Canto concertante, the treble of the little chorus, Canto ripieno, the treble of the grand chorus, or that which sings only now and then, in particular places.

CA'NTONING, in the military art, is a method of quartering troops in a town, where the garrison is so numerous, that several regiments must be quartered on the inhabitants for want of caserns or barracks to contain them.

In this case, they divide the town into as many parts as there are regiments to be so quartered, that the officers and soldiers of each may have a distinct part to themselves. This, in the military phrase, is called Cantoning of a town.

CA'NVAS, a very clear unbleached cloth of hemp or flax, wove very regularly in little squares. It is used for working tapestry with the needle, by passing the threads of gold, silver, silk, or wool, through the intervals or squares.

Most of the Canvas for tapestry, which is sold at Paris, is made in the neighbourhood of Monfort l'Amours, and particularly at a place called Mesnil.

There is coarse, middling, and fine Canvas: the finest are generally made of flax, and the others of hemp. All the pieces of Canvas are forty-five ells long, Paris measure. But their breadth is very unequal, some being a quarter of an ell wide, others a quarter and a half, half an ell, half an ell and $\frac{1}{16}$, half ell and $\frac{1}{2}$; $\frac{3}{4}$, $\frac{4}{5}$, and $\frac{5}{6}$ and an half of an ell, Paris measure. There are, however, some from thirty to forty-five ells long, by two ells wide: but the weavers make none of that sort, unless they are bespoke by the merchants.

Though tapestry seems no great object of trade, yet, besides what is used at Paris, and in the other great cities of France, they also export some into foreign countries, particularly into England, Poland, and some other places in the north of Europe.

CANVAS, is also a coarse cloth of hemp, unbleached, somewhat clear, which serves to cover women's stays, also to stiffen men's cloaths, and to make some other of their wearing apparel.

CANVAS, is also a very coarse cloth of hemp, unbleached, which serves to make towels. This sort of Canvas is made in Normandy, in the neighbourhood of Alencon; and in Perche, towards Mortagne. It is commonly sixty ells long, and $\frac{7}{12}$ of an ell broad, Paris measure.

CANVAS, or *Kanefas*. Thus the Dutch call a sort of very coarse cloth made of hemp, very strong and very close, which is made in Holland, and serves to make sails for shipping.

CANVAS, among painters, is the cloth on which painters usually draw their pictures; the Canvas, being smoothed over with a slick-stone, then sized, and afterwards whited over, makes what the painters call their primed cloth, on which they draw their first sketches with a coal or chalk, and afterwards finish with colours.

Canvas is also a name sometimes given to sail-cloth.

CAP *of a gun*, is a piece of lead which is put over the touch-hole of a gun, to keep the priming from being wasted or spilt.

CA'PER, *capparis* (*Dict.*)—At Toulon they cultivate these plants upon the walls, by sowing of their seeds in the holes of the stone-walls, about three or four feet from the ground; so that the roots of the plants penetrate into the joints of the walls, and from thence draw their nourishment. In England it is very difficult to preserve these plants, especially if they are planted in earth; for these plants thrive much better in rubbish: so that, when any person is desirous to cultivate them, they should be planted in pots filled with lime-rubbish and sand, and placed into a moderate hot-bed, to forward their making new roots; after which time they may be exposed in the open air in summer; but in winter they must be sheltered from severe frost, which will destroy them. The stumps of these plants are generally brought over in plenty from Italy every year, by the persons who bring over orange-trees and jasmines; so that they may be purchased from them at a moderate price, which is by far the easiest method of being furnished with these plants; for the seeds are not easily obtained from abroad, nor do they succeed very well with us: although these plants require shelter, when planted in pots, yet they will endure the severest cold of our winters, if growing in a wall. See *plate* IX. *fig.* 1, where *a*, *a*, are the flowers, *b*, the fruit, *c*, the fruit open, *d*, the seeds, *e*, the calix.

CAPH, a Jewish measure of capacity for things estimated by Kimchi at the thirtieth part of the log, by Arbuthnot at the sixteenth part of the hin, or the thirty-second of the seah, amounting to $\frac{5}{6}$ of an English pint. *Arbuthn. Tab. Anc. Coins*, &c.

CA'PITAL *of a lanthorn*, the covering which terminates the lanthorn of a dome, either in the figure of a bell, as that of the Sorbonne, or of a cupolo, or aspiral, as that of the church of Sapienza, at Rome.

CAPITAL *of a mill*, the covering thereof in the form of a cone, which turns vertically on the round tower, in order to expose the sails to the wind.

CAPITAL, amongst merchants, bankers, and traders, signifies the sum of money which individuals bring to make up the common stock of a partnership, when it is first formed. It is also said of the stock which a merchant at first puts into trade for his account. It signifies likewise the fund of a trading company, or corporation, in which sense the word stock is generally added to it. Thus we say, the Capital stock of the bank, &c. The word Capital is opposed to that of profit, or gain, though the profit often increases the Capital, and becomes itself part of the Capital, when joined with the former.

CAPITAL *Picture*, in painting, denotes one of the finest and most excellent pieces of any celebrated master.

F. Chamillard gives a list of the pieces of each famous painter, and the places where they are found. Such are the transfiguration of Raphael, in the church of St. Peter in Montorio, at Rome. The nativity of Coreggio, in the palace of the duke of Modena. The St. Peter martyr of Titian, at Venice, in the church of St. John. The paradise of Tintoret, in the hall of the great council in the same city. The judgment of Michael Angelo, in the pope's chapel in the Vatican. The St. Michael of Guido, in the Capuchin church at Rome. The St. Jerom dying, of Dominichini, in the church of St. Jerom de la Carita at Rome. The marriage of Cana, by Paolo Veronese, in the Louvre at Paris. Raphael painted a multitude of fine madona's, but the most capital, in the judgment of all the connoisseurs, is that in the palace of Chigi, representing the holy Virgin holding the child Jesus by the hand, and St. Joseph approaching to kiss him.

CA'PITIS *Nutus*, in anatomy, the name given by Fallopius to one of the muscles of the head, described by Albinus under the name of the rectus capitis internus major, and by Winslow and others under that of the rectus capitis anterior longus.

CA'PITO, in ichthyology; the chubb is called also by some authors the sephalus and squalus, and in some parts of England the chevin. It is a longer-bodied fish than the carp, and its head is black, large, and somewhat flat. Its back is of a dusky green, and its belly and sides are usually white and silvery, but in the larger and fatter fish they become yellow, and spotted with small black spots; its scales are very large, and its mouth small.

It has no teeth either in the jaws, palate, tongue, or throat; its tail is forked, and all its fins are of a bluish black colour. Its belly is somewhat prominent; it is a river fish, and loves the covert of old stumps of trees and hollow banks, and gives the angler much diversion; it will not live in ponds; it spawns in May, and is in best season in April, when full of spawn, but is never a very delicate fish. *Ray's Ichthyogr.*

CAPI'TULUM, in the ancient military art, was a transverse beam, wherein were holes through which passed the strings whereby the arms of huge engines, as balustæ, catapultæ, and and scorpion, were played or worked.

CA'POC, a sort of cotton so fine and so short, that it cannot be spun; it is as soft as silk: they use it in the East-Indies, and even in Europe, to make beds, mattresses, cushions, pillows, &c. which are very easy and convenient. It serves also to line the palanquins. The Capoc is taken out of a large cod or pod, which contains it with several small seeds, of the bigness of a pepper-corn. Though this pod be but two inches and a half in diameter, and four inches long, yet it yields a large handful and a half of Capoc. When used, care must be taken to leave no seeds among it; for the rats are so fond of them, that they would gnaw the coverings of the mattresses, or other furniture, to come at them, and so spoil them. The tree which bears this fruit, is really of the kind of cotton trees; it grows very tall, and the trunk of some is so thick, that a man cannot grasp it with both his arms; its branches spread very much, and divide and subdivide themselves into three, to the very top. The leaves are large, and placed seven or eight on a stalk, spreading like a fan. The flower consists of one leaf, divided into five lobes, as those of all the cotton kinds are. This tree grows every-where in the East-Indies. The Capoc is sent into Tartary, where there is some demand for it. There are several sorts of trees that produce Capoc; but that which has been described is the best. The Capoc is looked upon as a sort of wad; but the wad which comes from Egypt, is quite different from that of the East-Indies.

CA'PON, a castrated cock.—Capons, besides their use for the table, serve to lead chickens, ducklings, turkey-pouts, peahens, pheasants, or partridges, in lieu of their natural dams, over which they have several advantages, by the largeness of their body, which will brood, or cover, thirty or forty young.

CAPONIE'RE (*Dict.*)—*To construct a* CAPONIERE.

From the exterior flanking angle D (*plate* XIV. *fig.* 1.) draw a line Dp to the angle of the counterscarp p; on each side of Dp draw parallel lines, at the distances of 1$\frac{1}{4}$, 2$\frac{1}{2}$, and fifteen yards from Dp; these lines, being limited by the lines of defence and counterscarp, form the Caponiere.

This work, which can be used only in a dry ditch, serves, besides its defence of the foss, for a convenient passage between the town and its outworks; and, in this case, there is usually a circular excavation made in the angle of the counterscarp, out of which the troops may defile without being seen by the enemy.

CA'POT, at piquet, is when one of the gamesters wins all the cards, in which case he gains forty points.

CAPPA'DINE, a sort of silk flock, taken from the upper part of the silk-worm cod, after the true silk has been wound off. It is called also lassis and carbass, because slight stuffs under those names are made of it.

CAPRIFICA'TION *, a method of impregnating fig-trees, by means of certain insects.

* The word is formed from *caprificus*, the wild fig-tree, from whose fruits the insects are produced, which are the chief instruments of Caprification.

Caprification, or the manner of impregnating fig-trees, of which the ancients speak with so much wonder, is not imaginary, as many have supposed. M. Tournefort assures us, it is still practised every year in most of the Grecian islands, by means of a sort of gnats, or flies, peculiar to the country. The fig-trees there bear much fruit; but this fruit, in which part of the riches of the country consists, would be of no advantage, if it was not managed in the following manner:

There are two sorts of fig-trees cultivated in these islands; the first called ornus, from the Greek ἐρινεός, which is the wild fig-tree, or the caprificus of the Latins; the second is the domestic fig-tree. The former bears three kinds of fruits, none of them fit to eat, but absolutely necessary for ripening the domestic ones. These fruits of the wild fig-tree are called fornites, cratitires, and orni.

The fornites appear in August, and continue unripe till November. In these small worms are bred, from the puncture of certain gnats, observed only about the fig-trees. In October and November, the same gnats wound the second fruits of the same trees. These which are called cratitires only appear at the end of September, and the fornites fall gradually off, after their flies have quitted them. But the cratitires remain on the tree till May, and inclose the eggs left by the flies of the fornites. In May, the third kind of fruit begins to bud on the same trees which bore the other two; this is by far the largest fruit, and is called ornus. When it is arrived at a certain magnitude, and its buds begin to open, it is wounded in that part by such of the flies of the cratitires as can shift from one fruit to the other, to deposit their eggs.

It sometimes happens that the flies of the cratitires lie in some places, and do not come out, though the orni are fit for their reception. In this case, the cratitires must be fetched from elsewhere, and put on the extremities of those branches whose orni are in a good forwardness, in order that they may wound them. If that season be lost, the orni fall, and the insects of the cratitires fly away, finding no orni to prick. The peasants who apply themselves to the culture of fig-trees, are the only judges of the proper season in which this may be prevented; in order to which they carefully observe the bud of the fig; for this part not only shews the season of the fly's exit, but also that in which the fruit may be successively wounded. If the bud be too hard and close, the fly cannot deposit its egg, and the fig drops, when the same eye is too lax and open.

But this is not all: these three kinds of fruit abovementioned are not good to eat; they are only appointed by the author of nature to ripen the fruit of the domestic fig-tree. The method of managing them is thus: in June and July the peasants take the orni, when the flies are ready to come out, and hang them on the domestic fig-trees; several of these they string on a straw, and lay on the tree, more or less, in quantity, as they see occasion. If they miss this season, the orni drop off, and the fruit of the domestic fig-tree, not ripening, falls also in a little time. The country people know so well these precious moments, that every morning, making their review, they lay only the best conditioned orni on the fig-trees, otherwise, they would lose their harvest. 'Tis true, they have a sort of remedy for this, by strewing on the domestic fig-trees the flowers of a plant called a scolimbros, in the tops of which flowers are sometimes found flies fit to wound the figs; or possibly the flies of the orni feed on this plant. In fine, the peasants manage the orni so well, that their flies ripen the domestic figs in about forty days.

These figs are very good crude; to dry them, they are laid in the sun for some time, after which they give them a heating in the oven, to preserve them for the rest of the year. They are the chief food of the peasants of the Archipelago, whose ordinary fare is only barley bread and dry figs. Yet are these figs far from being so good as those of Provence, Italy, and Spain; the heat of the oven deprives them of their fine relish, but, on the other hand, it destroys the eggs of the flies of the orni, which would infallibly produce little worms, which would destroy the fruit. This, one may say, is taking a great deal of pains for fruit that is naught at last. M. Tournefort could not enough admire the patience of the Greeks, who spent above three months in carrying the flies from one fig-tree to another; but he soon understood the reason, for, asking them why they did not cultivate the French and Italian figs, he was answered, that the great quantity of fruit that their own trees yielded, made them preferable. In reality, one of these trees produces generally 224 pounds of figs, whereas the French trees yield not 25 pounds.

As to the manner wherein the puncture of the flies contributes to the maturation of the fruit, poffibly it may be by lacerating the veffels, and extravafating the nutritious juice, when they depofit their eggs; or, when, with the egg, they alfo convey fome liquor which gently ferments with the juice of the fig, and foftens its pulp. Even the Provence and Paris figs ripen much fooner by wounding their buds with a ftraw or feather dipped in oil olives; plums or pears alfo, wounded by infects, are found to ripen the fooneft, and in thefe the pulp about the wound is more exquifite than the reft. *Mem. Acad. Scienc. An.* 1705.

CA'PSTAN (*Dict.*)—The parts of a Capftan are, the foot, which is the loweft part; the fpindle, the fmalleft part; the whelps, a fort of brackets fet into the body of the Capftan clofe under the bars; the barrel, the main body of the whole; the holes for the bars to be put into; the bars, which are fmall pieces of timber by which the men heave; laftly, the pawl, which is a piece of iron bolted to one end of the beams of the deck, clofe to the body of the Capftan, but fo as that it have liberty to turn about every way; and againft it do the whelps of the Capftan bear, fo as that by it the Capftan may be ftopped from turning back.

CA'PSULE, among botanifts, a fpecies of pericarpium compofed of dry elaftic valves, which ufually burft open at the points: this kind of pericarpium fometimes contains only one cell or cavity, fometimes more; in the firft cafe, it is called unilocular; in the fecond, bilocular, trilocular, &c. according to the number of cells in it for the reception of feeds.

CAPUCHI'NE, the name of a particular fpecies of pigeon, in fhape and make much like the jacobine or jack, but fomething larger than that; its beak alfo is longer, and it has a tolerable hood of feathers on the back part of its head, but has no cravat or chain down to the fhoulders as that fpecies has. Its marks are the fame with the jacobine, and it feems to be no other than a baftard breed, between that and a common pigeon. *Moore's Columbarium.*

CARA'COLI, a kind of metal, of which the Caribbees, or natives of the leffer Antilles, make a fort of ornament, in the form of a crefcent, which they alfo call Caracoli. This metal comes from the main land, and the common opinion is, that it is a compound of filver, copper, and gold, fomething like the Corinthian brafs of old. Thefe metals are fo perfectly mixed and incorporated together, that the compound which refults from them, it is faid, has a colour that never alters, how long foever it remains in the fea, or under ground. It is fomething brittle, and they who work it are obliged to mix a large proportion of gold with it, to make the compound more tough and malleable under the hammer.

The Englifh and French filver-fmiths have made feveral experiments thereon, in order to imitate this metal; they who come neareft to it, put, to fix parts of filver, three of copper, and one of gold: the fkilful found this imitated mixture, tho' very fine, was yet much inferior to that among the favages.

Father Labat, from whofe relation this article is extracted, is of opinion that the Caracoli is a fimple metal, as produced from the mines, and afterwards refined. They make with it, in the American iflands, rings, buckles, heads for canes, and fuch other fmall works.

CA'RAITES (*Dict.*)—The Caraites are faid to glory in a defcent from Efdras, and to prove the fucceffion of their churches, by an exact catalogue of all thofe perfons who have either taught or contended againft Caraifm. There are fome who boaft of a ftill greater antiquity, pretending they are defcended from the ten tribes led into captivity by Salmanefer, but it is all fiction. There are many other accounts given of this fect, which have not probability enough to be mentioned. It would be a difficult tafk to fix the exact time when Caraifm began: Father Morin, Dr. Prideaux, and fome others, with great probability, trace the original of this fect to the eighth century. In fact, Caraifm took its rife from the publication of the Talmud; for we do not find, that the word Caraite was fo odious before that time, as it has been fince. On the contrary, by the term Caraite, was intended a perfon who had a confummate knowledge of the facred fcriptures. The compilation of the Talmud appearing in the beginning of the fixth century, thofe of the moft learning among the Jews were prefently difgufted at the ridiculous and incredible fables with which it was ftuffed. They referved their belief for the written word, and admitted the other, as a work of human compofition, proper to explain and interpret the fcriptures in fuch paffages where it fhould be found conducive to that purpofe. However, this did not immediately produce a fchifm among them: but, about the year 750, Anan, a Babylonifh Jew, of the race of David, and his fon Saul, declared openly for the written word of God alone, and difclaimed all traditions, except fuch as manifeftly agree with it, abfolutely denying them the fame authority with the written fcriptures. This declaration produced a fchifm: thofe who maintained the Talmud, being almoft all Rabbins, or difciples of Rabbins, were called Rabbinifts: the other, who admitted the fcripture only as their rule, and made ufe of it for the refutation of the traditions, were called Caraites, or fcripturifts, from the word cara, which in the Babylonifh language fignifies fcripture; as we ourfelves have feen fome proteftants who called themfelves evangelifts, becaufe they would receive no other authority than that of the Gofpel, and rejected all traditions whatfoever. The Rabbinifts then gave them the odious name of Samaritans and Sadducees; not becaufe they really were fo, but becaufe they agreed with thofe fectaries on the head of traditions: though, fince that time, there have been Jews who have imagined, that a Caraite was in reality a Samaritan and a Sadducee; and they have been the more confirmed in this error, for want of applying themfelves to hiftory and chronology.

The Caraites are efteemed to be men of the beft learning, and the ftricteft probity, of all the Jewifh nation: there are very few of them, if any at all, in thefe weftern parts; moft of them are to be found in Poland, Ruffia, and the eaftern countries, where they have their own fynagogues, and obferve fuch ceremonies and cuftoms as are peculiar to themfelves. Upon a computation made of their number, in the middle of the laft century, it appeared to be between four and five thoufand, which is but a fmall number in comparifon of the other Jews.

Our modern critics have been very grofly miftaken, with regard to the Caraites, by too boldly relying on the authority of the Jewifh writings; for the Rabbinifts who are their inveterate enemies, have charged them falfly in almoft every refpect. It were to be wifhed, that thofe who fend to the Eaft for books, would get fome of the Caraites books brought over, moft of which are very learned, and there are but very few of them in Europe. Selden feems to have read moft of them. There are fome in the library of Leyden, but thefe are not much valued.

The author of the Caraite commentary, called Aaron, about the thirteenth age, whofe manufcripts are kept in the library of the fathers of the oratory at Paris, is very juft in his account of the Caraites; he approves their books, which are in the Jewifh canon, and reckons their number as the other Jews do; and, what is ftill more remarkable, acknowledges them as they are pointed at prefent; for they have no other tranfcript than that of the Mafora; and, whenever they read in a different manner, it is as critics only.

CARBE'NSIS *Aqua*, in the materia medica, the name of a mineral water of Germany, of which Hoffman, from Petzlerus, has given the following account: all about the place of its origin, and along the canals through which it paffes, it depofits an earthy and ferrugineous matter, which concretes into a ftony hardnefs. When any alcaline liquor, whether fixed or volatile, is added to thefe waters, they become turbid, and precipitate a whitifh earthy matter to the bottom of the veffel; after the evaporation of the water they leave a fal enixum and an alcaline earth; two quarts of them yield two fcruples, and ten grains of the earth, and twelve grains of the falt. If it be kept for any time in a glafs, or earthen veffel, it depofits a fediment of yellow, ochreous, earthy matter, and when immediately taken from the fpring, it changes to a bluifh brown colour, on being mixed with galls. It contains a very large portion of a fubtile mineral fpirit; for, if a long-necked veffel be filled half full with it, and the orifice ftopped with the thumb, the whole, on a little fhaking, fends up a froth to the top; and when the thumb is taken off, the water fpirts out to feveral feet diftance. It makes an effervefcence, on mixing oil of vitriol with it, but this lafts but a very little time. From the whole it feems to contain a large quantity of calcareous earth, and fome fmall portion of ferrugineous matter; whence it purges both by ftool and urine, though moftly the latter way; the former operation which is pretty conftant, is owing to this alcaline earth meeting with an acid in the prima via, and being by it changed into a bitter purging falt, of the nature of Glauber's. *Hoffman.*

CA'RBUNCLE, *Dict.* — Our jewellers, among whom it is very rare, know the Carbuncle by no peculiar name, and not only now, but for many ages back, this has been the cafe; and, while the genuine Carbuncle was often feen, it was yet generally thought not to exift, and this merely from an error: its name importing a refemblance to a burning charcoal, the world, in general, grew into an opinion of its having the properties of a burning coal, one of which is the fhining in the dark; and fuppofing that property ftrongly commemorated in the name, and finding no gem which had it, they took it for granted that the Carbuncle no longer exifted; nay, the fertile imaginations of fome travellers have gone fo far as to affirm, that a gem, with this property, is yet to be feen in fome places, and given a thoufand abfurd relations about it.

To all this it is only to be anfwered, that the whole is an abfurd error; for that the ancients never attributed any fuch quality to their Carbuncle, but that the whole reafon of their giving the name anthrax to that gem was, that it was, of itfelf, of a very deep and ftrong red, but when held up againft the fun, or when fet upon a bright pale foil, it was exactly of that fort of red colour which is feen in burning charcoal.

Theophraftus, the greateft naturalift of antiquity, afferts this in plain words, and calls the gem that had this property anthrax. Others of the ancients have called it the Garamantine or Carthaginian Carbuncle; and it has been fuppofed, by the better writers among the moderns, to be the fame ftone with the true garnet: this, however, on comparing the ftones, appears

pears to be an egregious error, the difference in colour, and even in figure, between these two gems, being obvious and essential.

The Carbuncle is usually found pure and faultless, and is of the same degree of hardness with the saphire, being second only to the diamond. It is ever found naturally of an angular figure, smaller at the one end than at the other, and at the small end tapering to a pointed pyramid, composed of the same number of planes with the column, which are six, and those usually very unequal. It is found adhering by its base to a heavy and hard ferrugineous stone of the emery kind, and is always more finely coloured towards the point, than at the base of the column. Its usual size is near a quarter of an inch in length, and two thirds of that in diameter in the thickest part. Its colour is very beautiful, and a very deep red, resembling that of a mulberry when nearly ripe, and, where palest, going off into a fine scarlet, and into a purplish or violet tinge of the garnet; but, when held up against the sun, it loses its deep dye, and becomes exactly of the colour of the burning charcoal; so, that the propriety of the name, given it by the ancients, immediately strikes one, on making the trial. It bears the force of fire unaltered, not parting with its colour by it, as do most of the gems; nay, it even will not be at all affected by fire, nor become a whit the paler. This has been an experiment diligently tried by some of our jewellers, who, being disgusted by its too deep colour, have endeavoured the rendering it more vivid and striking to the eye, by divesting it of a part of it by this means, but always without success.

It is found only in the East-Indies, so far as is yet known, and that but very rarely.

The distinctions between the several red gems are very nice, and their names in some degree arbitrary. Many authors have confounded the Carbuncle with the ruby, and determined with Garcias, that every ruby that exceeds twenty-four caracts, in weight, was properly a Carbuncle. This gem, however, is by all trials proved to be evidently the Carbuncle of the ancients, and essentially different from the ruby in wanting the purplish tinge, into which the colour of that gem goes off, as is extremely evident in all the deep ones; this going off into a true scarlet, and for that reason giving the colour of a lighted charcoal in the sun, which neither the ruby, garnet, nor any other gem can do, which has the blue or purple cast. *Hill's Hist. of Foss.*

Artificial CARBUNCLE.— Take ten ounces of matter, prepared of natural crystal and saturnus glorificatus, and, having reduced them to an impalpable powder, add to it an ounce of gold calcined; mix the whole together, and put it into a good crucible, which must not be above half full; cover it and lute it well, let it dry; then put it into a glass-house-furnace for three days, bringing it by little and little nearer to the strongest fire.

After three days, take out the crucible, and put the matter into a marble mortar, which pound to an impalpable powder, to which add its weight of sal gemmæ, also in fine powder; which mix well together, and searce through a fine sieve, the better to incorporate.

Put this powder into a new crucible, which you must not fill above half-way; which cover, lute, and dry as before: then put it into a glass-house furnace, bringing it nearer to the fire by little and little, where let it stand ten hours.

After this, take your crucible out of the furnace, and put it into that where they set their glasses to anneal; let it stand for ten or twelve hours; then take it out, and, by breaking it, you will find the matter tinged of a Carbuncle colour, the most lively and resplendent that can be made by this art; whereof you may make what stones or works you please.

CARD, a sort of instrument or comb, composed of a great number of small pieces, or points of iron wire, a little incurvated like hooks towards the middle, and fastened very closely together by the feet, in rows. A piece of thick leather, which keeps them fast, is nailed by the edges on a flat piece of wood, which is an oblong square, about a foot long, and near half a foot broad, with a handle placed in the middle, on the edge of the longest side: there are always two Cards, between which are put the materials that are to be worked.

The Cards are of very great use in the manufacturies, where they serve to comb, disentangle, and range the wool and such other materials, in order to put them in a condition to be spun, by the manufacturers of cloths, stuffs, stockings, hair, &c. or, to be used unspun in several other works, in much the same manner as the wool and the hair, which the hatters employ in the manufacturing of hats.

CA'RDAMINE, *ladies smock*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of four leaves, and is of the cruciform kind; the pistil arises from the cup, and becomes finally a long pod, which is divided by an intermediate membrane into two cells, and contains usually roundish seeds. To these marks it is to be added, that the pods, when ripe, fly open with violence, and throw out the seeds to a considerable distance. The species of Cardamine, enumerated by M. Tournefort, are fourteen.

This plant is also known by the names of cuckow flower and meadow-cresses. It is a kind of nasturtium, and is pungent and discussive, but is not used either in composition, or common prescription.

CARDI'ACA, *motherwort*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, and is of the labiated kind; the upper lip which is imbricated, is considerably longer than the lower, which is divided into three segments; the pistil arises from the cup, and is fixed in the manner of a nail into the hinder part of the flower; this is surrounded by four embryo's, which afterwards, ripening into as many angular seeds, are contained in, and occupy the whole space of the cup, which before contained the flower.

The species of Cardiaca, enumerated by M. Tournefort, are three.

The Cardiaca is accounted attenuating, drying, detersive, and cordial. It promotes urine and the menses, is good in asthma's and palpitations, and is said to facilitate delivery. It may be taken either in powder, or in decoction.

CA'RDING, is the combing, disentangling, and preparing wool, with the instruments called cards described above, that it may be fit for making the several works it is designed for. They also card wad, cotton, flax, hair, and other materials proper for several sorts of manufactures.

Before the wool be carded, it must be greased with oil, of which one fourth part of the weight of the wool is required, for that which is designed for making the woof of stuffs, and the eighth part of that of the warp.

CARDI'OID, in geometry, is thus formed: let the diameter A B (*plate* XIV. *fig.* 2.) of the circle A M B A, revolve about the point A, and, on A B produced, let B *a*, M N, A D, M N, &c. be always equal to A B; then will the point *a* describe a curve, which, from its figure resembling a heart, is called Cardioid.

From the construction it appears, that $AN = BA + AM$, and that N A N is always double of the diameter A B, and is bisected by the circle in M.

This curve is algebraical; if $AB = a$, $aE = x$, $EN = y$, its equation will be,

$$y^4 - 6ay^3 + 12x^2y^2 - 6ax^2y + x^4 = 0 + 12a^2y^2 - 8a^3y + 3a^2x^2.$$

CA'RDUUS *Stellatus*. Star-thistle. — The root of the star thistle is single, about a finger thick, long, and running deep into the ground, of a whitish colour, having a pretty thick cortical part. The lower leaves grow flat on the ground, encompassing the root in a circle, much cut in, or jagged to, the middle rib. The stalk is divided into numerous branches, spreading about, and seldom arising above two feet high, with a few leaves here and there at the division of the stalks. The flowers grow thick upon the branches, consisting of reddish or purple fistular flowers, coming out of heads, which are composed of several scales, each ending in a long, straight, hard, and sharp thorn. The flowers pass away in down, containing white, flattish, oblong seed. The star-thistle grows near high-ways, and upon commons; and flowers in June.

The root is commended by some as a singular remedy against the stone, gravel, or cholic, by giving it either in decoction with wine or water, or in powder, with a convenient vehicle. *Miller's Bot. Off.*

Its leaves are very bitter, and give a faint tincture of red to the blue paper; the root gives it a deeper, and has the taste of an artichoke. The star-thistle contains a salt very like that which is natural in the earth; for its solution is very bitter, and loaded with sal ammoniac and nitre. It is likely, that the sal ammoniac predominates in this plant; for the nitre makes no impression upon the blue paper, whereas the sal ammoniac reddens it considerably: that, which is found in this plant, is joined with a considerable quantity of sulphur and earth; thus the star-thistle is febrifugous, vulnerary, and aperitive. For an intermitting fever they give to drink, at the beginning of the fit, four or six ounces of its juice. It removes the webs of the eyes, and cures wounds.

Camerarius affirms, that at Francfort they make use of the root of star-thistle, instead of that of eryngo: it is employed in aperitive ptisans and broths. One drachm of the seed of star-thistle, infused in a glass of white wine, takes away the viscid matter which obstructs the urinary passages. *Martyn's Tournefort.*

CA'RIA, in natural history, a name given by authors to a very mischievous species of ant, common in some parts of the East-Indies. This creature is larger than our ant, and is the common food of a great many other animals, as the squirrels, serpents, lizards, and a great many birds. In order to defend itself from so many enemies, it enters into large communities, which together erect great hills of earth, of five or six feet high. The fields in some places are full of these, and it is in vain to attempt beating them down, since they would be immediately made up again; the creature builds them with firm and tough clay, which it wets as it uses it; and the walls, or outer case, are built so thick and firm that scarce any rain can hurt them. The whole space within is full of different compartments, to every one of which there is a particular path-way; and these separate paths, joining as they come near one another, make at length one great and general road to the door, or gate of of the city. These animals are generally busied in their cells, and never go out, but at the necessary time to search for food; this excursion they always make regularly at one time of the day, and fall to work on the first corn, or other valuable plant, they find, which they gnaw off very quick, and carry into their habitation.

CARICATU'RA, in painting, an Italian word, principally applied to grotesque figures, which retain an extravagant and ugly, but real resemblance of the person they are designed to represent, and lash whomsoever the painter, carver, or graver, has a mind to satyrize, or divert himself with. Calot excelled in the Caricatura. But burlesque in painting, like burlesque in poetry, should be confined within due bounds.

CA'RIES (*Dict.*)—A Caries is properly a disorder in which the bone, from whatever cause, is deprived of its periosteum, and, having lost its natural heat and colour, becomes fatty, yellow, brown, and at length black; this is the first and lightest degree of the disorder, and is what, according to Celsus, the ancients called os vitiatum, and the nigrities ossium. But the greater degree of this disorder is where the bone is eroded and eaten, and becomes uneven by reason of the number of small holes, of which it is full, when it discharges a filthy sanies, whose acrimony softens, relaxes, and destroys the fleshy parts that grow round it. This is a true Caries or ulcer of the bone, and every bone of the body is subject to this disorder, and, though this ulcer may appear to be ever so safely or happily healed, yet, it too often happens, that, after the cicatrix is formed, and has been so for some time, a new abscess will be made, the whole disorder will return afresh, and the acrimonious and corrupted matter which continually spews out from the carious bone, being collected within, will produce many grievous symptoms, and destroy the neighbouring flesh again.

There have been many names, and many species reckoned of this disorder, and of others that are of kin to it; it is called a Caries, a spina ventosa, a spinæ ventositas, a gangrene, and cancer of the bone by Celsus, sometimes by the Greek term teredo, and sometimes pædarthrocaces. Some authors constitute as many species of this disorder, as there are here accounted names of it; but there is so small difference between these, that it will not warrant the making them so many species: they may very properly, however, be divided into two kinds, the one when the disorder begins in the internal part of the bone, the other when it begins on the outside, or from an external cause. This may be called a Caries, and that a spina ventosa, or, where it happens in children, according to Severinus, a pædarthrocaces.

There are two principal causes of a Caries of the bones; the one where the bone is deprived of its periosteum, by a wound, fracture, or other accident, and is corrupted, either by being exposed to the external air, or heated with greasy dressings; the other where the fluids are interrupted in their circulation by any external violence, or internal cause whatsoever, from whence an inflammation and suppuration succeed, and the bone and periosteum suffer, to such a degree, that, the vessels, which are sent to the part for its nourishment and support, being inflamed and corrupted, the bone is brought into consent, and quickly becomes carious: this disorder, if not quickly remedied, spreads and communicates itself to the neighbouring parts of the bone, and makes the same progress as ulcers do in the softer parts. There are, therefore, several degrees of the Caries of the bones; the first, is when the bone is laid bare, looks greasy, and turns yellowish: as soon as it becomes thoroughly yellow, brown, or black, the incipient Caries then degenerates into a worse state. The third degree is when the bone becomes uneven, rough, and rotten, and the greater erosion the bones have suffered, the more rough and uneven they will appear. When the cranium is perforated through both its tables, or the tibia or femur are eaten through to the marrow, this is a Caries of a very bad kind; but the worst of all Caries, and that in which the case may indeed be almost pronounced desperate, is that which falls upon the joints, or those parts of the bones which lie very deep, because in this case there is no access for the hands to clean the bone, and there is no remedy but the amputating the limb.

Many methods have been attempted for the cure of a Caries; the first and mildest is applied to the slightest degree of the disease, and is performed by the application of spirituous remedies, such as spirit of wine, Hungary-water; or by slight balsamics, such as the powder of birthwort, florentine, iris, myrrh, or aloes. Either of these powders is to be sprinkled on the part, after the sanies has been carefully wiped away with dry lint, and this continued till the cure is perfected. In a Caries that penetrates somewhat deeper, stronger remedies take place, such as powder of euphorbium, or its essence, made in well rectified spirit of wine; or oil of cloves, cinnamon, or guaiacum; either of these may be touched on with a pencil, or laid upon dry lint, and applied: some also use the corrosive medicines, the phagadenic water, and spirit of vitriol, or of sulphur; and, in the place of these, a solution of quicksilver in aqua-fortis may be used with great success. When, by these means, an exfoliation of the bone has been produced, the business is then to treat it with balsamics.

A second method of cure for a greater degree of Caries, is perforating the bone with the trepan, and dressing the part afterwards, either with balsamics or with dry lint. By these means the exfoliation of the bone is forwarded, and new-vessels push themselves through the foraminula, which, joining with the neighbouring flesh, make a new covering for the bone.

The third method of cure is performed by the raspatory, or chissel, taking off the corrupted or vitiated part of the bone, till all beneath appears white, or ruddy, and sound: and the fourth, which is the most ancient, and the most speedy, and certain method, is by the actual cautery, burning down the vitiated part of the bone. This method, however, is not necessary, except in great degrees of this disorder; and, in the performing it, great care must be taken not to injure the neighbouring soft parts. For this reason, an assistant should always draw back the lips of the wound both ways, while this is performed; and, if the opening be not wide enough, it should be opened and enlarged by sponge tents before, or widened by the knife, till the bone lies fair, and the part must be carefully wiped first with dry lint, from the sanies; and, if there be any fungous flesh, that must also first be removed. One application of the cautery, when the disorder is considerable, will seldom prove sufficient; it usually requires to be repeated several times, at proper intervals; and, if the Caries be of such extent that one cautery will not cover it all over, the first must be applied to the middle, and the succeeding towards its edges. This operation is not attended with any great pain, if care be taken not to injure any of the adjacent soft parts; for the bones are, in themselves, free from any sense of pain. Where the cranium is the seat of this disorder, the cautery is attended with great hazard, as it is also in a Caries of the ribs, or sternum, from the neighbourhood of parts of the utmost consequence to life. The carpus and tarsus also will very badly admit of cauterizing, because of the neighbourhood of the tendons and ligaments, which it is scarce possible to avoid injuring in the operation. After cauterizing the part, it is to be dressed with dry lint only, or, if the patient complain of great heat in the part, the lint may be dipped in spirit of wine before it is applied; afterwards balsamics are to be applied, till the part exfoliate, and then, if the cure be perfect, the vacuity will soon be filled with new found flesh. But, if the bone remains bare, or the flesh it is covered with, be soft and spongy, and does not adhere sufficiently to the subjacent bone, or where the bone remains discoloured, in either of these cases the cure will not stand, but the disorder will break out again, unless prevented. In these cases therefore, the work must be all done over again, the spungy flesh removed, and the actual cautery again applied, otherwise the cure can never stand. *Heister's Surgery.*

CARLI'NA, in botany, the name of a genus of plants, the characters of which are these: the flower is naturally of the radiated kind; its disk is made up of a number of flosculeS, affixed to the embryo seeds, but its outward edge or circle not of semiflosculeS, but merely of flat petals, affixed to no embryo's, but contained in the same general cup with the flosculeS, which is large and prickly. The embryo's finally ripen into seeds, winged with down, and divided from one another by imbricated leaves.

CARLI'NÆ RADIX, in the materia medica, the name of a root kept in the shops in some places, and distinguished into two kinds, the white and the black; the white is the root of the common carline thistle, which produces no stalk; the other of the Carlina caulescens, called the black chamelion thistle. The white carline root is of the thickness of one's thumb, and is often two feet long; it is brown on the outside, and white within, and should be chosen plump, firm, and well dried. It is accounted a very great medicine in pestilential diseases.

The black is a smaller and shorter root than the white, and is much less esteemed in medicine. The plant which produces the white grows very frequent with us on hilly places, and is a very singular plant, producing a number of fine long prickly and jagged leaves, and, in the center of them, a large purple flower, of the thistle kind, but growing close to the ground: the other is very frequent in France, but is not met with in England.

Carline is esteemed a very powerful sudorific and alexipharmic. Schroder tells us also, that it is good against worms, and in dropsies; and that it is a powerful emmenagogue and diuretic. *Pomet's Hist. of Drugs.*

CARMI'NE (*Dict.*)—To make Carmine take five drachms of cochineal, thirty-six grains of chouan, eighteen grains of the husk of the roucou, and the same quantity of roch alum; pulverize each of these ingredients apart in a clean mortar. Boil two pints and a half of clear river or rain water in a clean pot, and, while it boils, pour in the chouan, let it boil up three times, continually stirring the liquor with a wooden spatula; then pass it through a clean linen cloth, put the water so strained into a clean vessel, set it on the fire; as soon as it begins to boil, put in the cochineal, let that boil up three times; then add the roucou, and boil it up once; last of all, pour in the alum, and at the same time take the vessel off the fire. Immediately philtrate the liquid through a linen cloth, without squeezing, into a clean earthen or china dish; let this red liquor stand for seven or eight days, then pour off gently the clear which swims on the top, and let the bottom or fæces dry in the sun or a stove, and afterwards take it off with a brush or feather, and this Carmine will be of a fine powder and beautiful colour.

X x Observe

Obſerve Carmine is not to be made in cold weather, becauſe it does not precipitate readily but congeals and ſpoils.

The cochineal which remains in the linen cloath, after the liquor is ſtrained off, may be uſed over again; but the Carmine from this ſecond boiling will neither be ſo much in quantity, nor ſo good in quality, as the former.

Another method of making Carmine: take three pints of clean water, put them in a glazed earthen pan, ſet the pan before a coal fire, and add one grain of chouan; when the mixture boils, ſtrain it through a fine ſieve, then put this firſt water in the ſame pot over the fire again, and immediately add two drachms of meſtick or cochineal, and ſtir it once with your ſpatula. When the new mixture boils, add a grain of autour, and, directly after the autour, eight grains of cream of tartar finely pulverized, eight grains of white talc, and the ſame quantity of Roman alum powdered; let the whole boil two or three minutes, take it off the fire, let it cool without meddling with it, till it is lukewarm, and then the water will look redder than ſcarlet; paſs the liquor, when lukewarm, through a fine linen cloth into an earthen veſſel, leaving the groſs ſediment at the bottom of the pot to ſtrain off, and preſs into another veſſel, which will give you the common Carmine; let your veſſel ſtand three days, decant off the water, and the Carmine will remain at the bottom of the diſhes. Dry them in the ſhade, free from duſt, and you will procure about eighteen or nineteen grains of fine Carmine without reckoning the common.

Obſerve the talc muſt be cleanſed in the following manner to be uſed in this operation: take talc, calcine it in a good fire, then throw it into water, and knead it with your hands; when the water looks white, take it out with a cup and paſs it through a ſieve into a large veſſel, where let it ſtand two hours, in which time the talc will precipitate; then decant the water, dry the ſediment, and add eight grains thus prepared to make your Carmine.

Though the preceding methods may be good, we think the following which is that of Kunckel, deſerves the preference:

Take cochineal four ounces, alum well cleanſed one pound, and fine wool half a pound; pulverized tartar half a pound, wheaten bran eight large handfuls. Boil the bran in about twenty-four pints of water more or leſs at pleaſure; let this water ſtand for a night to ſettle that it may be very clear; and, to make it the clearer, filtrate it. Take a copper kettle of a ſufficient bigneſs to permit the wool to be at liberty; pour in equal quantities of bran water and common water in proportion to the quantity of wool you deſign to boil in it, put in your alum, tartar, and wool, then boil the whole for two hours, obſerving to ſtir the wool up and down, in order to cleanſe it thoroughly; after the wool has boiled its proper time, put it into a net, to let it drain; then take the other half of your bran water, to which add twenty-four pints of common water, and boil them well. In the heighth of the boiling put in your cochineal finely pulverized, mixed with two ounces of tartar; this mixture muſt be ſtirred inceſſantly to prevent it from burning. Put in the wool, boil it an hour and half, ſtirring as before directed; when it has taken the colour, put it again into a net to drain. It will now have a fine ſcarlet dye.

In order to extract the Carmine from the wool, take about thirty-two pints of clear water, in which diſſolve a ſufficient quantity of pot-aſh to make a ſtrong lye; cleanſe the lye by filtration, boil your wool in it till it has loſt all its colour, becomes white, and the lye has received all the tinge. Squeeſe your wool well, and paſs your lye through a filtrating bag. Then diſſolve two pounds of alum in water, pour this ſolution into the coloured lye, ſtirring the whole well; by this addition the dye will curdle and thicken; filtrate it again and it will come out quite clear; if it ſhould yet be tinged with the colour, it muſt be boiled over again, and a ſolution of alum added to it: at laſt it will curdle, and the colour or Carmine remain in the filtre. Care muſt be taken to pour freſh water on it frequently to take out the alum or any ſalts that may remain; then dry the colour and keep it for uſe, after having reduced it to an impalpable powder. If in the operation you find the water boil away too much, have boiling water at hand to add to it.

If you would make Carmine at leſs expence and trouble, you may omit tinging the wool, and make uſe of ſhreds of ſcarlet cloth, obſerving the proceſs as before directed. Kunckel aſſures us he has tried both methods, and always with ſucceſs.

Carmine is counterfeited by a preparation from Braſil or Fernambuca wood. They pound the wood in a mortar, and then infuſe it in white wine vinegar; then boil theſe ingredients together, and the froth affords a kind of Carmine, but vaſtly inferior to the beauty of that we have been ſpeaking of.

CARNA'TION, *caryophyllus*, in gardening, the name of a beautiful genus of flowers.

Theſe flowers, are propagated either from ſeeds (by which new flowers are obtained) or from layers for the increaſe of thoſe ſorts which are worthy maintaining; but I ſhall firſt lay down the method of propagating them from ſeeds, which is thus:

Having obtained ſome good ſeeds, either of your own ſaving, or from a friend that you can confide in; in the beginning of April, prepare ſome pots or boxes (according to the quantity of ſeed you have to ſow:) theſe ſhould be filled with freſh light earth mixed with rotten neats-dung, which ſhould be well incorporated together; then ſow your ſeeds thereon (but not too thick) covering it about a quarter of an inch, with the ſame light earth, placing the pots or caſes ſo as to receive the morning ſun only, till eleven of the clock; obſerving, alſo to refreſh the earth with water, as often as it may need it: in about a month's time your plants will come up, and, if kept clear from weeds, and duly watered, will be fit to tranſplant in the beginning of June, at which time you ſhould prepare ſome beds (of the ſame ſort of earth as was directed to ſow them in) in an open airy ſituation, in which you ſhould plant them at about three inches ſquare, obſerving to water and ſhade them as the ſeaſon may require, being careful alſo to keep them clear from weeds: in theſe beds they may remain until the beginning of Auguſt, by which time they will have grown ſo large as almoſt to meet each other; then prepare ſome more beds of the like good earth (in quantity proportionable to the flowers you have raiſed) in which you ſhould plant them at ſix inches diſtance each way, and not above four rows in each bed, for the more conveniently laying ſuch of them as may prove worthy preſerving; for in theſe beds they ſhould remain to flower.

The alleys between theſe beds ſhould be two feet wide, that you may paſs between the beds to weed and clean them. When your flowers begin to blow, you muſt look over them to ſee if any of them promiſe to make good flowers; which as ſoon as you diſcover, you ſhould lay down all the layers upon them: thoſe which are well marked, ſhould be reſerved to plant in borders, to furniſh you with ſeed; and thoſe which burſt their buds, and ſeem to have good properties, ſhould be planted in pots, to try what their flowers will be, when managed according to art: and it is not till the ſecond year that you can pronounce what the value of a flower will be, which is in proportion to the goodneſs of its properties.

Having made choice of ſuch of your flowers as promiſe well for the large ſort, theſe you ſhould mark ſeparately, for pots, and the round whole-blowing flowers, for borders; you ſhould pull up all ſingle flowers, or ſuch as are ill-coloured, and not worth preſerving, that your good flowers may have the more air and room to grow ſtrong: theſe having been laid, as ſoon as they have taken root (which will be ſome time in Auguſt) they ſhould be taken off, and planted out, thoſe that blow large in pots, and the other in borders, as hath been already directed.

The beſt ſeaſon for laying theſe flowers is in June, as ſoon as the ſhoots are ſtrong enough for that purpoſe, which is performed in the following manner: after having ſtripped off all the leaves from the lower part of the ſhoot intended to be laid, make choice of a ſtrong joint about the middle part of the ſhoot (not too near the heart of the ſhoot, nor in the hard part next the old plant;) then with your penknife make a ſlit in the middle of the ſhoot from the joint upwards half-way to the other joint, or more, according to their diſtance; then with your knife cut the tops of the leaves, and alſo cut off the ſwelling part of the joint where the ſlit is made, ſo that the part ſlit may be ſhaped like a tongue: and that outward ſkin being pared off, which, if left on, would prevent their puſhing out roots; and having looſened the earth round the plant, and, if need be, raiſed it with freſh mould, that it may be level with the ſhoot intended to be laid, leſt by forcing down the ſhoot you ſplit it off; then with your finger make an hollow place in the earth, juſt where the ſhoot is to come, and with your thumb and finger bend the ſhoot gently into the earth, obſerving to keep the top as upright as poſſible, that the ſlit may be open; and, being provided with forked ſticks for that purpoſe, thruſt it into the ground, ſo that the forked part may take hold of the layer, in order to keep it down in its proper place; then gently cover the ſhank of the layer with the ſame ſort of earth, giving it a gentle watering, to ſettle the earth about it, obſerving to repeat the ſame as often as it is neceſſary, in order to promote their rooting. In about five or ſix weeks after this, the layers will have taken root ſufficient to be tranſplanted; againſt which time you ſhould be provided with proper earth for them, which may be compoſed after the following manner:

Make choice of ſome good up-land paſture, or a common that is of an hazel earth, or light ſandy loam; dig from the ſurface of this your earth about eight inches deep, taking all the turf with it; let this be laid in an heap to rot and mellow, turning it once a month, that it may ſweeten; then mix about a third part of rotten neat's-dung, or, for want of that, ſome rotten dung from a cucumber or melon-bed; let this be well mixed together; and, if you can get it time enough before-hand, let them lie mixed ſix or eight months before it is uſed, turning it ſeveral times, the better to incorporate their parts.

In the middle of February, if the ſeaſon is good, you muſt tranſplant theſe layers into pots for their bloom (which ſhould be about ſeven or eight inches over at the top in the clear;) in the doing of which, obſerve to put ſome pot-ſherds or oyſter-ſhells over the holes in the bottoms of the pots to keep the earth from ſtopping them, which would detain the water in pots to the great prejudice of the flowers: then fill theſe pots

about

about half-way with the same good compost as was before directed, and shake the plant out of the small pots with all the earth about the roots; then, with your hands, take off some of the earth round the outside of the ball, and from the surface, placing one good plant exactly in the middle of each pot, so that it may stand well as to the height, i. e. not so low as to bury the leaves of the plant with earth; nor so high, that the shank may be above the rim of the pot; then fill the pot up with the earth before-mentioned, closing it gently to the plant with your hands, giving it a little water, if the weather is dry, to settle the earth about it; then place these pots in a situation where they may be defended from the north wind; observing to give them gentle waterings, as the season may require.

In this place they may remain till the middle or latter end of April, when you should prepare a stage of boards to set the pots upon, which should be so ordered as to have little cisterns of water round each pot to prevent the insects from getting to your flowers in their bloom; which if they are suffered to do, will mar all your labour by destroying all your flowers in a short time.

About the middle of April, your layers will begin to shoot up for flower; you must therefore be provided with some square deal-sticks, about four feet and half long, which should be thicker towards the bottom, and planed off taper at the top: these sticks should be put carefully in the pots as near as possible to the plant without injuring it; then with a slender piece of bass-mat fasten the spindle to the stick to prevent its being broken: this you must often repeat as the spindle advances in height; and also observe to pull of all side-spindles as they are produced, and never let more than two spindles remain upon one root, nor above one, if you intend to blow exceeding large. Towards the beginning of June your flowers will have attained their greatest height, and their pods will begin to swell, and some of the earliest begin to open on the one side; you must therefore observe to let it open in two other places at equal angles: this must be done as soon as you perceive the pod break, otherwise your flower will run out on one side, and, be in a short time past recovering, so as to make a compleat flower; and, in a few days after the flowers begin to open, you must cover them with glasses which are made for that purpose.

During the flowering season, particular care should be taken not to let them suffer for want of water, which should by no means be raw spring-water; nor do I approve of compound waters, such as are enriched with various sorts of dung; but the best and most natural water is that of a fine soft river; next to that is pond-water or standing water; but, if you have no other but spring water, it should be exposed to the sun or air two days before it is used, otherwise it will give the flowers the canker and spoil them.

Thus having been full in the culture of this noble flower, I shall just mention that of the pink, which differs not in the least from that of the Carnation in its manner of propagating, but only requires much less care, and need not be potted, growing full as well in good borders, where they make as elegant a shew, during the season of flowering, as any plant whatever, and afford as agreeable a scent. *Mill. Gard. Dict.*

CARP, in ichthyology, a fish too well known to need description. The Carp is the most valuable of all kinds of fish for the stocking of ponds. It is very quick in its growth, and brings forth the spawn three times a year; so that the increase is very great: the female does not begin to breed till eight or nine years old, so that in breeding ponds a supply must be kept of Carp of that age. The best judges allow, that in stocking a breeding pond four males should be allowed to every twelve females. The usual growth of a Carp is two or three inches in length in a year, but, in ponds which receive the fattening of common sewers, they have been known to grow from five inches to eighteen in one year.

A feeding pond of one acre extent will very well feed two hundred Carp of three years old, three hundred of two years old, and four hundred of a year old. Carp delight greatly in ponds that have marley sides; they love also clay ponds well sheltered from the winds, and grown with weeds, and with long grass at the edges, which they feed on in the hot months. Carp and tench thrive very fast in ponds and rivers near the sea, where the water is a little brackish, but they are not so well tasted as those which live in clear water. No fish will thrive in a pond where there are many roach, except the pike which feeds on them. Grains, blood, chickens guts, and the like, may be at times thrown into ponds where there are Carp, to help to fatten the fish.

If the breeding and feeding this fish were a thing more understood than it is at present, the advantages might be very great, and fish-ponds become as valuable an article as gardens. The gentleman who has land in his own hands, may, besides furnishing his own table, and making presents to his friends, raise a great deal of money, and very considerably improve his land at the same time, so as to make it really yield more this way, than by any other employment whatever. Suppose the place a meadow of forty shillings an acre, four acres of this in a pond will return every year, very easily, a thousand fed carps from the least size that is eaten to fifteen inches long, besides pikes, pearch, tench, and other fry. Suppose the Carps are saleable at from sixpence to a shilling a piece, they will bring twenty-five pounds, which is six pounds five shillings an acre for the land made into the pond.

When a great deal of water is designed to be brought, they first spit off the ground on which the bank is to stand, and form the pan of the pond. The gentleman who keeps land in his own hand, and will do this, will find no expence in making his pond, if near his other land; for the earth that is dug out may be laid on the lands, and will save all the price of manure for a long time.

If the soil about the waters be moorish, the making a pond will keep up a supply of water that will make it always moist, and it will serve excellently for the planting of oziers, which will turn to a very considerable account. If cattle graze near the large ponds, they will serve them for watering-places, and they will delight to stand in them in hot weather, in which case their dung which falls in is a fine food for the fish, at the same time that it does great good also to the cattle.

The Carp is a very cunning and wary fish; it very often escapes the net, and, when angled for, requires great skill and patience in the sportsman to make any great work of it. The Carp always chuses the deepest parts of ponds and rivers, and in the last it is generally found in places where the stream is least perceptible. The Carp will never bite in cold weather, and in the hot months the angler can never be either too early in the morning, or too late in the evening, for the sport; when he has once taken the bait, there is no fear of getting away, for he is one of the leather-mouthed fishes.

The tackle for fishing for Carp must be very strong, and it will be proper to bait the place beforehand where he is to be fished for, with a coarse paste. The red worm is the best bait in March, the cade in June, and the grasshopper in July, August, and September.

Not only these baits, but a sweet paste may be used in angling for Carp, with great success. There are many kinds of these pastes made up by the anglers, but the general basis of them all is sugar or honey with flour: these sorts of pastes are not only proper to bait the hook with, but they may be thrown into the water some hours before to draw the fish together. It may be proper also to bring the Carp to the place intended for the angling for them, by throwing in cow dung and blood, or bran and blood mixed together, some chickens guts cut small, and small pellets of these sweet pastes: this will learn them to frequent the place, as a part best supplied with food, and the having fed with safety before will make them the less suspect the bait on the hook. A very much esteemed paste is made thus: take common wheat flour, and veal, or any other young meat, of each equal quantities; beat them together in a mortar, till the meat is thoroughly dissolved or broke to pieces; then add about half the quantity of honey; beat it well together again, and finally add more flour till the whole is of a proper consistence. This has the advantage of a paste, and an animal bait at once, and hangs well to the hook, so that it seldom misses success. *Mortim. Husbandry.*

CA'RPENTERS.—The antiquity, utility, extent, and nature of their business are so well known, there needs no description. A lad for this trade ought to be stout, ingenious, write a tolerable hand, understand arithmetic, geometry, and architecture, without which qualifications they are often a little better than labourers.

Their working hours are from six to six, and their wages commonly fifteen shillings a week, but some make more. With an apprentice they take from ten to twenty pounds.

To set up a sort of a jobbing-master does not require a great deal besides tools: but there are several degrees of them, up to what are termed master-builders, who had need to have a good deal of judgment and money too; and some of these are also surveyors and draughtsmen, whose chief business is to draw plans, survey and estimate other men's works.

They were incorporated into a company in the year 1344, in the reign of king Edward III, with a power to make by-laws; and confirmed by king Edward IV. in 1474; livery-fine ten pounds.

Their hall is overagainst London-wall, between great and little Moor-gates; and their court-day on the first Tuesday of the month.

They have a stand, in Cheapside, in which they sit to attend the lord-mayor, on the day of his installation.

Arms, argent, a chevron ingrailed between three pair of compasses (pointing towards the base, and a little extended) sable. Motto. Honour God.

CA'RPENTRY (*Dict.*)—Carpentry is the most antient of all kinds of architecture; its origin goes back as far as the beginning of the world. Men, at first, ignorant of what treasures the earth contained within her womb, and knowing nothing but her external productions, felled trees in the forests to build their first cottages; they afterwards erected nobler buildings of the same materials. Architecture stands indebted to Carpentry for one of the prettiest embellishments of its orders, if it be true that fluted columns are done in imitation of the contraction of the trunks of trees as they grow upward. This metropolis even to this day furnishes remains of the antient custom of building in wood, and shews our ancestors preferred it it even to ftone. One may add, in favour of this art, the almoft univerfal cuftom of building in wood throughout all the northern countries.

The application of Carpentry in the art of building is infinitely ufeful; the Carpenter frames houfes, builds ftair-cafes, lays floors; and the roofs of our public edifices and churches are generally framed in timber, as well as thofe of our private houfes: by the help of this art are alfo made a number of ufeful machines.

The principal objections to it arife from the danger of fire, to which accident it is very liable; wherefore particular care fhould be taken in all buildings to difpofe of the timber properly fo as to guard againft it. Carpentry is of late years brought to great perfection, efpecially fince builders and undertakers have joined the ftudy of fome parts of the mathematics to their experience and practice; it is to be wifhed this was become more univerfal, though there is yet a great defect in this art for want of better methods with regard to the difpofition of the timber; for, by the number of pieces employed, and their mifapplication of them, the ftrength of the timber is much leffened; fee the article TIMBER, under which are fome remarks extracted from M. de Buffon.

CARPI'NUS, *the hornbeam*, in botany, the name of a genus of trees, the characters of which are thefe: the flower is of the catkin kind, being compofed of a number of fmall leaves, affixed to an axis in a fquamofe manner, under each of which there ftand a great number of ftamina: thefe are the barren male flowers, the embryo fruits appearing in other parts of the tree, between the leaves of larger and more beautiful fpikes; which finally become a fruit of an umbilicated kind, compreffed and ftriated, and containing a roundifh nut or kernel pointed at one end.

CA'RRIAGE (*Dict.*)— *Private* CARRIAGES are thofe which private people keep at their own expence, for their own conveniency, and that of their families; as thefe have no relation to the fciences, it is needlefs to give an account of them in this work.

Public CARRIAGES are thofe which every one is free to make ufe of, on paying fo much a head for perfons, or fo much per pound weight, for goods, merchandizes, or other effects.

There are again two forts of thefe Carriages, fome of which no man can keep, or let out, at leaft in France, but by virtue of a privilege; fuch are the waggons, carts, covered waggons, and horfes belonging to, or under the direction of the poft-office; as alfo the ftage-coaches and boats which fet out on a fet day, for certain towns in the provinces, and likewife poft-chaifes, calafhes, litters, and horfes.

The other public Carriages are thofe which every one is at liberty to have, keep, and let out, after what manner, and to whom he pleafes; fuch as drays, cars without racks, the waggons and carts ufed by carriers, higglers, and others.

Water CARRIAGES are, in general, all thofe veffels which ferve to carry perfons or merchandize by fea, rivers, lakes, or canals, whether failed, rowed, or drawn by men or horfes; but the word Carriage is feldom ufed, when we fpeak of fhips, frigates, or other large veffels, which fail over the fea.

A defcription of the CARRIAGES made ufe of by Ralph Allen, Efq; to carry ftone from his quarries, fituated on the top of a hill, to the water-fide of the river Avon, near the city of Bath.

Thefe quarries are at the diftance of a mile and an half from the river, and about 500 feet above the level of its furface, which makes a flope fo fteep, that the fmall price the ftone is fold at, would hardly defray the charges of bringing it down without fome proper contrivance, fuch as the following, which is a great improvement on fome Carriages and waggon-ways made ufe of at the coal mines near Newcaftle.

Plate XI. *fig.* 2. reprefents this Carriage in perfpective, as feen from a diftance of 12 feet from the left of the fore wheels, the height of the eye being about 6 feet. The geometrical plan was laid down from a fcale of 20 to an inch; that is, every 20th of an inch anfwers to one inch in the machine.

Fig. 3. reprefents the elevation of one of the fides of this Carriage, when both the fore-wheel and hind-wheel of that fide are locked, from a fcale of 20 to an inch.

From the confideration of thefe two figures, it will appear, that this Carriage confifts of a ftrong floor of oaken planks, three and a half feet wide, and about thirteen feet long, ftrengthened above by feveral ribs to defend it from the ftones that lie upon it, and fixed upon four beams of the fame wood, about four inches fquare and fourteen feet long.

At fix inches from the ends are fixed the fore-fide and back-fide ftrongly faftened to the beams, and to the floor, by feveral fcrews and nuts. See *fig.* 2.

To thefe two ends, when occafion requires, may be faftened two fides made of planks thirteen feet long, which fit into the fide of the outward beams by means of hooks and rings, and are kept up by means of latches to be feen in *fig.* 2, 3. Thefe fides are alfo further ftrengthened by a chain going acrofs in the middle of the Carriage.

At right angles under thefe beams, at a proper diftance (fee *fig.* 3.) are faftened two ftrong timbers, by means of large fcrews and nuts.

In thefe timbers well ftrengthened and plated with iron, where the greateft ftrefs lies, are placed two femicylindrical pieces of brafs at each end, to ferve as a collar for the axle-trees of the wheels, which, being well greafed, turn with very little friction.

There is likewife under thefe four beams already mentioned another piece of timber of about fix inches by four well faftened to it, at right angles, and at fuch a diftance, as is feen in *fig.* 3.

This piece ferves as a fixed point to place a lever, which locks, or keeps from turning, the hind-wheel, by preffing upon it.

The axle-tree is about three inches diameter.

One of its ends is fquare, the other round, and on thefe two ends the wheels are placed in an alternate pofition; that is, the right-handed fore-wheel is on a fquare, and the left on a round part of the axle-tree, whilft the right-handed hind-wheel is on a round end, and the left on a fquare end of the axle-tree; thereby any one of the wheels may be locked feparately; for, when the wheel placed on the round end is locked, the other, together with the axel-tree, revolves within it; and, when the wheel which is faftened on the fquare is locked, the other revolves notwithftanding as ufual upon the axel-tree, which is then unmoveable.

Thefe wheels are made of caft iron about twenty inches diameter, and have a flanch fix inches broad next to the Carriage, which hinders them from running off from the oaken frame on which they move.

The manner of locking and unlocking of the wheels is as follows: when either of the hind-wheels is to be locked, a ftrong lever, which they call the jigg-pole, is placed on that end of the timber next to the wheel to be locked, and after it is paffed the iron loop, to fecure it the better, a chain coming from the roller, to be feen in *fig.* 3, is clapped over the extremity, and by means of a fhort iron bar, and the rochet and clink, feen in *fig.* 3, one of the drivers, or perfons that attend the Carriage, in a very little time ftops the wheel either partly or intirely. To unlock which, it is only lifting up the end of the clink or catch, made long on purpofe; for then, the lever preffing no longer, the chain is flackened, taken off, and the jigg-pole laid in the cart, till another occafion ferves. They have two jigg-poles, one for each hind-wheel.

The fore-wheels are locked, by means of a thick fquare iron bolt, feen in *fig.* 3, coming out in the direction of the axletree, between the fpokes, or radii, of the fore-wheels: thefe bolts are protruded forward to lock the wheels, and draw back to unlock them feparately. Towards the middle of the backfide are two iron rods turning feparately on the fquare of an axle. When either of thefe is brought by the hand from a vertical pofition, in which they are drawn to an horizontal one, the iron rod, of which it takes hold by its lower end, is pufhed forward four or five inches, and fhoots the fquare bolt between the fpokes, or radii.

When the wheel muft be unlocked, this bolt is drawn back into its former pofition, by bringing the iron rod into its former vertical fituation. As thefe Carriages are loaded with a confiderable (often with upwards of four tons) weight of ftone, when they come down the hill, all the contrivances explained above would be ufelefs, and that great weight fink the Carriage too deep into the ground, without pieces of oak laid all along the way which thefe Carriages then pafs over. Thefe are fufficiently feen in *fig.* 2.

Although thefe Carriages are very heavy, even when empty, yet by means of the frame on which they move, and the little friction the axel-trees feel revolving in the brafs collars, two horfes not only draw them up the hill very eafily when empty, but draw them along on the plain when loaded, at a very good rate. As foon as the Carriages come to the brow of the hill, the horfes are taken off, and one or more of the wheels locked by the driver, who ftands behind, to moderate the motion as he thinks proper.

When the Carriages are come to the water-fide, and have been unloaded, they change the horfes from end to end, fo that the part of the Carriage which went before defcending, becomes the hind-part in afcending the hill, which avoids the trouble of turning with thefe wheels.

Thefe Carriages are loaded at the quarries, and unloaded at the water-fide, by means of a very good and curioufly contrived crane, fully defcribed under the article CRANE.

Though the above defcription is very intelligible, yet, to make every thing ftill plainer, we fhall further explain thefe curious Carriages by the following references.

Plate XI. *fig.* 2. ABCDIIIIHFEG, the body and bottom of the Carriage, without the fides, which are put on upon occafion, in the place BDHF, and faftened by means of the hooks *g g g*, and the latches *e f*.

IIII, the crofs pieces on the bottom to ftrengthen it.

MN, ftrong pieces of timber under the bottom.

K, A crofs piece under the bottom, having an iron loop at the top, to receive the end of a lever, that preffes on the hind-wheel L 2, to ftop it from turning round when the motion is too rapid.

L, L 1, L 2, three of the four wheels, the fourth being out of fight in this pofition of the Carriage, whofe circumferences have

have a flanch on the inside, that the other part may bear on the timbers, or waggon-way.

H, an iron roller for the chain to wind on, to hold down the stopping lever, as it presses on the hind-wheel.

O, O 4, O 1, &c. the waggon-way, or parallel timbers, laid with a descent, for the Carriages to run down by their own weight.

Fig. 3. FHDB, the right side of one of the Carriages, fixed, by means of the hooks at *gggg*, and the latches *ef*, shewn in the fourth figure.

L, a fore-wheel, with a round hole in the nave, to receive a round end of the axis, that goes through the piece of timber P, from another part of which the bolt *p* is shot between the spokes, to stop the wheel from turning round, when the motion is to be retarded.

H *p*, an iron rod pushed forwards from behind, to bolt or lock the fore-wheel above-mentioned.

L 2, a hind-wheel fixed upon, and turning round with the axis coming through the piece of timber Q, the end of which axis is made square for that purpose.

RK, a lever, whose end goes through an iron eye on the timber K, having there its center of motion, with the compass-piece *qq*, to press on the upper part of the wheel L 2, to stop it, upon occasion, from turning with the axis.

H, a roller, on which is wound the chain HR, which pulls down the end of the lever at R, and keeps it in its place, to press hard upon the wheel at *qq*.

O 2, O 1, the waggon-way which supports the strong part of the circumference of the wheel, while the flanch, or larger circumference of each wheel, falls on the inside of the timber, that the Carriage may not jump, or run out of the way.

A new CARRIAGE *for removing large weights by a small force.*—The whole of this machine is shewn in *plate* XI. *fig.* 8. in so plain a manner, that a short description will be abundantly sufficient. X is the load; suppose a block of stone of an extraordinary weight laid on the Carriage Y, which is supported on the wheels V V, and the other part of the machine on the wheels W W; in order to draw this Carriage, a pile, as R, is drove into the ground, to which the machine is fastened by a rope, as shewn in the figure. Then a rope is passed through the pulley S, and one of its ends, as T, is fastened, by means of a hook, to an eye-bolt in the machine; and the other end goes round the cylinder H, which is the axle-tree of the indented wheel FG. AB is a double lever, or balance, whose center of motion is at C. At a proper distance on each side of the center of motion, is a crotchet, as DO, EP, which move freely round on the iron pins D, E. Now it is evident, that, when the end A, of the balance AB, is pulled down, the points B and E will ascend, and the crotchet EP will cause the wheel G to move round, and, consequently, the the cylinder H; by which means the Carriage Y must advance. The same will follow when the end B is pulled down; for the points A and D will by that means ascend, and the crotchet DO will cause the wheel G, with its axis H, to move round, and, consequently, the Carriage Y to advance. It must also be observed, that, when the point B descends, the point E will also descend, and, consequently, the crotchet EP will move farther towards G, and take hold of some other notch in the wheel: the same will follow with regard to the crotchet DO, when the point A descends. And, consequently, by two ends of the balance AB, rising and falling alternately, the Carriage Y will be continually advancing in proportion as the rope NS winds round the cylinder H. The motion, indeed, is but slow; but strength is gained in the same proportion as time is lost.

In constructing this machine, after determining the semi-diameter HG of the wheel, and the length of the crotchets from their centers of suspension, the iron pins D and E must be placed in such a manner, that the lines of direction GI, and FK, be tangents to the circumference of the wheel, at the points F and G, when the balance AB is in a horizontal situation.

Block-CARRIAGE, is a cart made on purpose for carrying of mortars, and their beds, from one place to another.

Truck-CARRIAGES, are two short planks of wood, supported on two axle-trees, having four trucks, or wheels, of solid wood, about a foot and a half, or two feet diameter, for carrying mortars or guns upon battery, when their own Carriages cannot go, and are drawn by men.

Letter or *bill of* CARRIAGE, is a writing given to a carrier, or to the master of a waggon, cart, or other Carriage, containing the number and quality of the pieces, chests, bales, &c. of merchandizes which he is intrusted with, that he may demand the payment of the Carriage from those to whom the merchandizes are directed, and that the person who receives them may see whether they be delivered to him in a good condition, in the same number as they were given to the carrier, or on the day set down in the bill of Carriage.

CA'RRIED *over*, with book-keepers, is the sum total of the several sums set down in one page, which sum, when the page is full, is wrote down at the bottom of it, with these words before it, Carried over; to signify, that that sum is Carried over to the next page, on the top of which it is set down, with these words before it, Brought over.

CA'RRIER, one who carries merchandizes, or other goods, from one place to another, in waggons, carts, or other wheel-carriages.

CARRIER *pigeon*, a sort of pigeon used, when properly trained up, to be sent with letters from one place to another.

It is larger in size than most of the other kinds. Its length from the tip of the back, to the end of the tail, being often fifteen inches; but its greatest weight not twenty ounces. Its flesh is firm, and its feathers close; it is long-necked, and of a better shape than most other pigeons. The upper chap of the bill is half covered from the head with a white or blackish tuberous, furfuraceous flesh, which projects or hangs over both its sides, on the upper part nearest the head, and ends in a point about the middle of the bill. This is called the wattle. The eyes are surrounded with the same sort of corrugated flesh, for the breadth of a shilling, and their iris is red. Their beak is long, strait, and thick; their wattle generally broad across the beak, short from the head towards the point, and tilting forward from the head; and the head narrow, long, and flat; the neck very long and thin, and the breast broad; the feather is chiefly black or dun, though there are blues, whites, and pieds.

It has its name from its remarkable sagacity in carrying a letter from one place to another. Though you carry them hood-winked, twenty, or thirty, nay, sixty, or an hundred miles, they will find their way, in a very short time, to the place where they were bred.

CART, a vehicle mounted on two wheels, drawn by one or more horses, used for the carriage of various sorts of heavy things.

The word seems to be derived from the French charrete, which signifies the same; or rather from the Latin carreta, a diminutive of carrus.

A Cart differs from a wain, in that the former is drawn by horses, and has two sides called trills; whereas a wain is drawn by oxen, and has a wain-cope.

The parts and apparatus belonging to a Cart, are, the trill-hooks and back-band, which hold the sides of the Cart up to the horses; the belly-band, passing from one side, under the horse's belly, to the other; the Cart-rails, being the two rails on the top of the Cart; Cart-staves, those that hold the Cart and the races together; Cart-body, all that part where the loading is laid for carriage, called, in Sussex, the buck, q. d. belly of the Cart; Cart-ladders, the crooked pieces set over the wheels, to keep hay and straw loaden off them; Cart-saddle, the leathern or wooden pannel, laid on the fillar-horse; the floats, the under-pieces which keep the bottom of the cart together; the trigen, a pole to stop the wheel of a Cart when it goes too fast down a steep place.

CACTOU'CHES, in heraldry, a name given to a sort of oval shields, much used by the popes, and secular princes in Italy, and others, both clergy and laity, for the painting and engraving their arms on. Many suppose this form derogatory to the honour of the person; but, though the square shield, with the rounded and pointed bottom, is more in use with us, as also with the French and Germans, yet this is supposed, more truly, the figure of the Roman shield, borne by the soldiery, and therefore more ancient and honourable than either that, or the indented shield of the Germans. *Nesbit's Heraldry, pag.* 12.

CA'RTWRIGHT, a person who builds carts, &c.

CARTWRIGHTS *timber*, is that which is used by the Cartwrights and coach-makers. This timber is of two sorts, particularly elm-timber, which is chiefly used in Cartwrights work, namely, the round timber, and the hewn timber.

The round timber is that which is still in logs, or blocks, that is to say, which has not yet been squared with the saw, and has the bark upon it still; but has, nevertheless, been cut to a certain length, proportionable to the works in which the Cartwrights would use it.

Hewn timber is that which has been squared with the saw, and reduced to a thickness and size proper for other works of the Cartwright.

With the round timber they make the naves, or stocks of the wheels, the coach-beams, the jaunts, &c. The hewn timber serves to make the coach-standards, poles, beams, &c.

Rules concerning round elm-timber used by CARTWRIGHTS.—The round timber for naves, or stocks of wheels, ought to be six feet and a half high, and ten inches diameter, at least, at the thinnest end; those pieces which are from twelve to sixteen inches diameter, are reckoned the best, because they may serve for the largest cart-wheels.

The round timber for axle-trees must be six feet long, and from seven to eight inches diameter.

The pieces designed for pole, ought to be of several sizes, according as they are intended for coaches, or for other carriages.

Those for coaches must measure from ten to twelve feet in length, and the others from twelve to fifteen, without any knots, and be well bent.

For the jaunts, the pieces must be two feet eight or ten inches long, or even three feet.

Rules for the hewn timber used by CARTWRIGHTS.—The pieces of timber for supporting the standard of a coach must be cut six feet and a half long, six or seven inches broad, and four or five thick.

The standards, of six feet seven or eight inches long, five or six inches broad, and three or four inches thick.

And the poles, nine feet long, three inches and a half square at the smallest end, and four inches at the thickest end.

It must be observed, that there are several other pieces of elm-timber used in the Cartwrights business, which they themselves cut, the timber-merchants leaving several pieces, in the form of round timber, of divers sizes and lengths, for which there are no settled rules, the workmen chusing them at the sales, or in the timber-yards, according as they find them proper for the several works wherein they would use them.

Other timber for CARTWRIGHTS.—The ash timber is commonly cut into standards and poles: some of it is also cleft in pieces of round timber, proper to make those sorts of carriages on which they carry wine in France. These pieces of round ash timber ought to be from ten to eighteen feet long, and eight or nine inches diameter.

The yoke elm-timber is commonly cut into axle-trees, and other pieces in which elm is used; but it is seldom employed but in those provinces where elm is scarce.

Of the branches of elm and yoke-elm, which are not large enough to be cleft in round timber, or cut for the several pieces of Cartwrights work mentioned above, they commonly make the spokes of wheels, though they make them also sometimes of other wood, and particularly of oak.

CA'RVING, the art of engraving or cutting figures in wood, &c.

To carve a figure or design in wood, it must first be drawn, or pasted on the wood; which done, the rest of the block, not covered by the lines of the design, are to be cut away with little narrow pointed knives. The wood, fittest for this use, is that which is hard, tough, and close, as beech, but especially box. To prepare it for drawing the design on, they wash it over with white lead, tempered in water, which better enables it either to bear ink, or the crayon, or even to take the impression by chalking. When the design is to be pasted on the wood, this whitening is omitted, and they content themselves to see the wood well planed. Then wiping over the printed side of the figure with gum tragacanth, dissolved in water, they clap it smooth on the wood, and let it dry; which done, they wet it slightly over, and fret off the surface of the paper gently, till all the strokes of the figure appear distinctly. This done, they fall to cutting, or carving, as above.

CARYOPHY'LLUS, *the clove* (*Dict.*)—The Dutch, who have ingrossed all the clove-trees, make immense advantage of the fruit, which are so much esteemed throughout Europe, and for which the Spaniards and Portuguese struggled so long, and to so little purpose. This valuable and noble spice grows only in the island of Amboyna, the Moluccas, which are five in number, and the islands of Meao, Cinomo, Cabel, and Marigoran.

The Indians call cloves callafar, and the inhabitants of the Moluccas call them chinke. The trees which bear cloves, are much like our laurel-trees, only the leaves of the cloves are a little narrower, and resemble the leaves of almond and willow-trees. The very wood and leaves taste as strong as the cloves themselves. These trees bear a great quantity of branches and flowers, and each flower brings forth a clove. The flowers are at first white, then green, at last they grow beautifully red, and pretty hard, and are properly the cloves. While they are green, they emit a most sweet and comfortable odour. When they are dry, they are of a red colour; but, when gathered, they assume a smoaky black. They do not gather them one by one, as they do other fruit; but they tie a rope to the bough, and so strip it off by force: that hurts the tree for the next year, but the year after it bears a great deal more. Others beat the trees with long poles, as we do walnut-trees, and the cloves fall down, and commonly the tree bears more fruit than leaves. They grow with little stalks, hanging on the tree like cherries: they sell them with these stalks, dirt, and dust together, to the Indians; but the cloves that are transported to Holland, are clean, and without stalks. If you leave them on the tree without gathering them, they grow thick, and are called the mother of cloves. The Javanese value these more than others; but the Dutch chuse rather to buy the least.

They never trouble themselves to plant clove-trees; for the cloves that fall on the ground produce enough of them, and the rain makes them grow so fast, that they bear fruit when they are eight years old, and continue bearing for above one hundred years. Some are of opinion, that clove-trees do not grow well on the sea-side, or when they are too far from the sea; but many seamen, who have been in the island, assure us, that they grow very well every-where, upon mountains, in the valleys, or near the sea-side. They ripen from the latter end of August to the beginning of January. Nothing groweth about them, for their heat draws in all the nourishment and moisture of the ground. See *plate* XIII. *fig.* 2. which represents a branch of the clove-tree; *d*, the common clove; *e*, its blossom; *f*, a ripe clove; *g*, fruit open; *h*, seed.

CARYOPHILLUS is also the name of a genus of plants, called in English Carnations. See CARNATION.

CA'SHOO, a medicinal and aromatic drug, which is reckoned among perfumes.

Cashoo is extracted from a tree which is called *catee*, in the country where it grows. That country is a province of Indostan, or the mogul's empire, which is called Behar; the capital of it is Patna. This province, which the famous river Ganges crosses, lies a hundred leagues above the kingdom of Bengal. Cashoo is properly nothing but an extract made by a decoction and maceration of the parts of that tree, and rendered solid by evaporation. There are two sorts of simple Cashoo, the rough, and the purified, or refined; the latter is a compound of purified Cashoo, mixed with aromatic drugs, and made into lozenges of several sizes, the biggest of which are as large as a half-crown piece. This Cashoo is made for the use of the Indians, who chew it, either alone, or mixed with pinang, or areca. Rough Cashoo is a commodity which is brought down the Ganges as far as Bengal, whence it is distributed, by means of trade, throughout all the Indies, where there is a great consumption of it; and to the Europeans, who send it into Europe, but mostly purified; for Cashoo is never used rough, neither in the Indies nor elsewhere.

They purify the Cashoo to different degrees, according to the use which the Indians would make of it. It appears, that the Cashoo which comes into Europe, is purified to the first degree only.

CASK, a wooden vessel, in which is put wine, or any other liquor; and also sometimes dry goods, as sugar, almonds, &c.

A Cask in staves, is that of which all the staves are ready prepared, and want only to be joined and hooped. They often put them thus on board the vessels designed for the American islands, because they take less room, and can be easily made up, either with the hoops, which are also often carried in bundles, or made in those places where wood proper for them is to be met with.

CASK-*gauging*, the method of finding the contents of all kinds of Casks.

Under the article GAUGING in the Dictionary, we have enumerated the general forms, or varieties of Casks, and, under the name of each solid, shewn the method of gauging it; to which we shall here add the two following, omitted in the Dictionary.

How to gauge a CASK *in the form of an hyperbolic spindle.* See *plate* XXXIII, *fig.* 17, in the Dictionary. The middle frustum of which GAHICF shall represent a Cask, whose diameter at the bung AC = 31 inches, and the diameter at the heads GF, HI, are each 24 inches, and the length KL = 32.5 inches; and to find the content of this frustum in ale and wine gallons.

A general Rule for gauging a Cask in the form of an hyperbolic spindle.

To twice the square of the bung diameter add the square of the head, and call this the first number. To the square of the length add the difference of the squares of the bung and head diameters; multiply this sum by fourteen times the square of the difference between the bung and head diameters, which product is a dividend: from thirty-five times the square of the length, take five times the square of the difference of the head and bung diameters, and the remainder is the divisor; the quotient of this division call the second number: then multiply the difference of the first and second numbers, by the length of the Cask, and that product divide by 1077.15 for ale, and by 882.354 for wine (which are no more than three times the divisor for circles) will give the content in gallons respectively; = 74.5 ale gallons, or 91.2 wine gallons.

But the content of the middle frustum of the hyperbolic spindle may be more expeditiously found, by finding a mean diameter thus:

The Rule.

To the head diameter add two thirds of the difference of the diameters, and to this add one twelfth of the quotient found by dividing the square of the difference of the diameters by the head added to twice the bung diameter, and this sum is the mean diameter sought.

How to gauge a CASK *in the form of a circular spindle.* See *plate* XXXIII, *fig.* 14, in the Dictionary.

Definition.

If the arch of the circle CAD be turned about upon its chord CD, it will describe a solid CFAH, DIBGC, called a circular spindle.

A general Rule for gauging a circular spindle.

First, to twice the square of the bung diameter add the square of the head diameter, and call that sum the first number. Secondly, to the square of the length add the square of the head diameter, and from that sum take the square of the bung diameter, and multiply the remainder by fourteen times the square of the difference of the head and bung diameters, and that product is a dividend; then multiply the square of the length by 35, added to five times the square of the difference of the diameters, and that shall be a divisor; the quotient of this division is the second number. Then multiply the difference of the first and second numbers by the length of

the

Printed for J. Hinton in Newgate Street.

the Cask, divide the product by 1077.15 for ale, and by 882.354 for wine, and this gives the content in ale and wine gallons respectively.

But the content of the circular spindle may be found more expeditiously, by finding a mean diameter thus:

The Rule.

To the head diameter add two thirds of the difference of the diameters, and to this $\frac{11}{100}$ of the square of the difference of the diameters divided by the head, and twice the bung diameter, and this sum is the mean diameter sought.

As it is requisite to find the length of a Cask before the contents of it can be calculated, several instruments have been invented, but the sliding callipers seem best adapted to this purpose; a view of which instrument, placed on a Cask, is given in *plate* XXXIII, *fig.* 11, in the Dictionary.

CASKETS, in the sea-language, are small ropes made of sinnet, and fastened to gromets, or little rings, upon the yards; their use is to make fast the sail to the yard, when it is to be furled.

Breast-CASKETS, are the longest and biggest of these, or those in the midst of the yard, betwixt the ties.

CAST, is particularly used to denote a figure, or small statue of bronze.

CAST, among wax-chandlers, denotes a ladle-ful of melted wax, poured on the wicks of candles, made by the ladle.

CAST, among founders, is applied to tubes of wax, fitted in divers parts of a mould of the same matter, by means of which, when the wax of the mould is removed, the melted metal is conveyed into all the parts which the wax before possessed.

CAST also denotes a cylindrical piece of brass, or copper, slit in two, lengthwise, used by the founders in sand, to form a canal, or conduit, in their moulds, whereby the metal may be conveyed to the different pieces intended to be Cast.

CAST, among plumbers, denotes a little brazen funnel, at one end of a mould, for casting pipes without soldering, by means of which, the melted metal is poured into the mould.

CAST of the country, with miners, the colour of the earth.

CAST, in falconry, denotes a set, or couple of hawks. *Dict. Rust.*

CASTA'NEA, *the chesnut-tree*, in botany, a genus of trees, whose characters are: the flower is of the amentaceous kind, being composed of a number of stamina, arising from a five-leaved cup, and fixed to a slender capillament, or axis. These are the male flowers, but the fruit grows on other parts of the tree: these are roundish, echinated, and open into four parts, and contain chesnuts with their kernels.

M. Tournefort has enumerated four, and Mr. Miller five species of Castanea.

These trees are propagated by planting them in February, in beds of fresh, undunged earth: the best nuts for sowing are such as are brought from Portugal and Spain, and are commonly sold in winter for eating, provided they are not kiln-dried, which is generally the case of those brought from abroad, which is done to prevent their sprouting, or rooting, in their passage; therefore, if they cannot be procured fresh from the tree, it will be much better to use those of the growth of England, which are full as good to sow, for timber, or beauty, as any of the foreign nuts, though their fruit are much smaller; these should be preserved, until the season for sowing, in sand, where mice, or other vermin, cannot come to them, otherwise they will soon destroy them. Before you set them, it will be proper to put them into water, to try their goodness, which is known by their ponderosity; those of them that swim upon the surface of the water, should be rejected, as good for nothing; but such as sink to the bottom, you may be sure, are good.

In setting these seeds, or nuts, the best way is, to make a rill with an hoe (as is commonly practised in setting kidney-beans) about four inches deep, in which you should place the nuts, at about four inches distance, with their eye uppermost; then draw the earth over them with a rake, and make a second rill at about a foot distance from the former, proceeding as before, allowing three or four rows in a bed, with an alley between, three feet broad, for a conveniency of cleaning the beds, &c. When you have finished your plantation, you must be careful, that it is not destroyed by mice, or other vermin, which is very often the case, if they are not prevented by traps, or other means.

In April these nuts will appear above ground; you must, therefore, observe to keep them clear from weeds, especially while young: in these beds they may remain for two years, when you should remove them into a nursery, at a wider distance. The best season for transplanting these trees is either in October, or the latter end of February; but October is the best season: the distance they should have in the nursery, is three feet, row from row, and one foot in the rows: you must be careful, in transplanting these trees, to take them up without injuring their roots, nor should they remain long out of the ground; but, if these trees have a downright tap-root, they must be cut off, especially if they are intended to be removed again: this will occasion their putting out lateral roots, and render them less subject to miscarry, when they are removed for good.

The time, generally allowed them in this nursery, is three or four years, according to their growth; but, the younger they are transplanted, the better they will succeed; during which, you should be careful to keep them from weeds, observing also to prune off the lateral branches, which would retard their upright growth; and, where you find any that are disposed to grow crooked, either by their upper bud being hurt, or from any other accident, you may, the year after planting, in March, cut them down to the lowermost eye next the surface of the ground, which will cause them to make one strong upright shoot, and may be afterwards strained into good straight trees; but this should not be practised, unless the plants have absolutely lost their leading shoots; for, although the stems of the trees should be very crooked, (as is generally the case with the trees when young) yet, when they are transplanted, and have room to grow, as they increase in bulk, they will grow more upright, and their stems will become straight, as I have frequently observed, where there have been great plantations. But, in doing of this, you must be careful not to disturb their roots, which, perhaps, might destroy them. These trees require no other manure than their own leaves, which should be suffered to rot upon the ground; and, in the spring of the year, the ground should have a slight digging, when these should be buried between their roots, but not too close to the trees, which might be injurious to their young fibres.

After having remained three or four years in the nursery, they will be fit for transplanting, either in rows, for avenues to a house, or in quarters, for wilderness plantations; but, if you intend them for timber, it is by much the better method to sow them in furrows (as is practised for oaks, &c.) and let them remain unremoved; for these trees are apt to have a downright tap-root, which, being hurt by transplanting, is often a check to their upright growth, and causes them to shoot out into lateral branches, as is the case with the oak, walnut, &c.

CA'STLE, *castellum*, in hydraulics, is used for a kind of pavilion, or water-house, in which are inclosed the cocks of several water-pipes, with a little bason, in order to make a distribution thereof.

CA'STOR, the name of a fixed star, of the second magnitude, in the head of the first of the Twins.

Its latitude northwards, for the year 1700, according to Hevelius, was 10°. 4′. 23″. and its longitude, of Cancer, 16°. 4′. 14″. It is also called Rasalgenze, Apollo, Aphellon, Avelar, and Arular. *Hevel. Fermam. Sobiesc.*

CAT-*gut*, a denomination given to small strings for fiddles, and other instruments, made of the intestines of sheep, or lambs, dried or twisted, either singly, or several together.

These are sometimes coloured red, sometimes blue, but are commonly left whitish, or brownish, the natural colour of the gut. They are used also by watch-makers, cutlers, turners, and other artificers. Great quantities are imported into England, and other northern countries, from Lyons and Italy. *Savar. Dict. Comm.*

CAT-*harpings*, are small ropes, running in little blocks, from one side of the shrouds to the other, near the deck: their use is to force the shrouds, and make them tight, for the more security and safety of the masts.

CAT, or CAT-*head*, in a ship, is a short piece of timber, lying aloft right over the hawser, having at one end two shivers, wherein is reeved a rope, with a great iron hook fastened to it, called cat-hook.

CAT'*s-head* is also a denomination given to a sort of waste stony lumps, not inflammable, found in coal-mines. In these there are frequently impressions of ferns. *Philos. Trans.* N°. 360.

CAT-*holes*, in a ship, are over the ports, as right with the capstan as they can be: their use is to heave the ship a-stern, upon occasion, by a cable, or hawser, called stern-fast.

CAT-*salt*, a name given by our salt-workers to a very beautiful granulated kind of common salt. It is formed out of the bittern or leach-brine, which runs from the salt when taken out of the pan. When they draw out the common salt from the boiling-pans, they put it into long wooden troughs, with holes bored at the bottom for the brine to drain out; under these troughs are placed vessels to receive this brine, and across them are placed certain small sticks, to which the Cat-salt affixes itself in very large and beautiful crystals. This salt contains some portion of the bitter purging salt, and is very sharp and pungent, and is white when powdered, though pellucid in the mass. It is used by some for the table, but the greatest part of what is made of it, is used by the makers of hard soap.

CAT-*silver*, a name given to certain fossil substances, usually called also glemmer, and in Latin micæ. They are various species of the biacteria, or foliaceous talcs, in small spangles.

CA'TACOMB, a vast assemblage of subterraneous sepulchres about Rome, in Italy, chiefly at about three miles from that city in the Via Appia; supposed to be the sepulchres of the martyrs; and which are visited accordingly, out of devotion; and reliques thence taken, and dispersed throughout the catholic countries, after having been first baptized by the pope, under the name of some saint.

These Catacombs are said by many to be caves, or cells, wherein the primitive Christians hid, and assembled themselves together; and where they interred such among them as were martyred. Each Catacomb is three feet broad, and eight or ten high; running in form of an alley, or gallery, and communicating with others: in many places they extend within a league of Rome. There is no masonry or vaulting therein,

therein, but each ſupports it ſelf: the two ſides which we may look on as the parietes, or walls, were the places where the dead were depoſited; which were laid lengthwiſe, three or four rows over one another, in the ſame Catacomb, parallel to the alley. They were commonly cloſed with large thick tiles, and ſometimes pieces of marble cemented in a manner inimitable by the moderns. Sometimes, though very rarely, the name of ſome of the deceaſed is found on the tile: frequently a palm is ſeen painted, or engraven, or the cypher X p, which is commonly read *pro Chriſto*.

The opinion held by many proteſtant authors is, that the Catacombs are heathen ſepulchres, and the ſame with the puticuli mentioned by Feſtus Pompeius; maintaining, that, whereas it was the practice of the ancient Romans to burn their dead, the cuſtom was, to avoid expence, to throw the bodies of their ſlaves to rot in holes of the ground: and that the Roman Chriſtians, obſerving, at length, the great veneration paid to relicks, reſolved to have a ſtock of their own: entering, therefore, the Catacombs, they added what cyphers and inſcriptions they pleaſed, and then ſhut them up again, to be opened on a favourable occaſion. Thoſe in the ſecret, add they, dying, or removing, the contrivance was forgot, till chance opened them at laſt. But this opinion has even leſs of probability than the former.

Mr. Monro, in the Philoſophical Tranſactions, takes a medium between the two extremes. He ſuppoſes the Catacombs to have been originally the common ſepulchres of the firſt Romans, and dug in conſequence of theſe two opinions, that ſhades hate the light, and they love to hover about the places where the bodies are laid.

Laying up the bodies in caves is certainly the original way of diſpoſing of the dead, and appears to have been propagated by the Phœnicians throughout the countries to which they ſent Colonies: the interring as we do now, in the open air, or in temples, was firſt introduced by the Chriſtians. When an ancient hero died, or was killed in a foreign expedition, as his body was liable to corruption, and for that reaſon unfit to be tranſported intire, they fell on the expedient of burning, in order to bring home the aſhes, to oblige the manes to follow, that ſo his country might not be deſtitute of the benefit of his tutelage. It was thus burning ſeems to have had its original; and by degrees it became common to all who could bear the expences of it, and took place of the ancient burying: thus Catacombs became diſuſed among the Romans, after they had borrowed the manner of burning from the Greeks; and now none but ſlaves were laid in the ground. Places, thus prepared, might afford convenient reſortments for the primitive Chriſtians, but could never be built by them. When the Empire became Chriſtian, they were again diſuſed; till the reading of I know not what author who mentions them, occaſioned them to be again looked into.—As to the famed cypher X p, it is obſerved to have been in uſe among the ancients, long before Chriſtianity aroſe. The abbot Bencini ſays, it was compoſed of the Greek letter X P, under which ſomething myſtical was comprehended; but no author gives any account what that myſtery was.

CATAPU'LTA (*Dict.*)—The Catapulta had a force, which it is not eaſy to comprehend, but which all good authors atteſt. Vegetius ſays, that the baliſta diſcharged darts with ſuch rapidity and violence, that nothing could reſiſt their force. Athenæus tells us, that Agiſtratus made one of little more than two feet in length, which ſhot darts almoſt five hundred paces. Theſe machines were not unlike our croſs-bows. There were others of much greater force, which threw ſtones of three-hundred weight, upwards of an hundred and twenty-five paces. We find ſurprizing effects of theſe machines in Joſephus: "The darts and force of the Catapulta deſtroyed abundance of people. The ſtones from the machines beat down the battlements, and broke the angles of the towers. There was no phalanx ſo deep but one of theſe ſtones would ſweep an whole file of it from one end to the other. Things paſſed this night that ſhewed the prodigious force of theſe machines. A man who ſtood by Joſephus, had his head taken off by a ſtone at an hundred and ſeventy-five paces diſtance."

Battering CATAPULTA.—*Plate* XIV. *fig.* 3, 4. repreſents the form and conſtruction of a Catapulta, that is ſuppoſed to carry an hundred weight, which may ſuffice as the doctrine of all the reſt to ſuch as carried twelve-hundred and upwards, it being eaſy to increaſe their powers.

The baſe is compoſed of two large beams 2, 3. The length of thoſe beams is fifteen diameters of the bore of the capitals, which meaſure will be explained when we deſcribe the capitals 9. At the two extremities of each beam, two double mortiſes are to be cut to receive the eight tenons of the two croſs beams 4, 5, each of them four of the diameters in length, without their tenon, obſerving to mark the center of them exactly by a line cut ſtrong in the wood 6. The croſs-beam 5 muſt be hollowed a little on the upper ſide, or made not ſo thick as that at the other end 4, to give the greater bent to the tree or arm 22, of which we ſhall ſoon ſpeak.

In the center of each of the beams of the baſe 2, 3, at the ſixth diameter of their length, a bore 8, perfectly round, ſhould be cut ſixteen inches in diameter: theſe bores muſt be exactly oppoſite to each other, and ſhould increaſe gradually to the inſide of the beams; ſo that each of them, being ſixteen inches on the outſide towards the capitals 9, ſhould be ſeventeen and an half at the opening on the inſide; the edges to be carefully rounded off. We come now to the deſcription of the capitals 9, which are in a manner the ſoul of the machine, and ſerve to twiſt and ſtrain the cordage, that are its principle, or power of motion.

The capitals 9 are either of caſt braſs, or iron, each conſiſting of a wheel with teeth, 10, of two inches and half thick. The hollow or bore of theſe wheels ſhould be eleven inches, and about a fourth in diameter, perfectly round, and with the edges ſmoothed down. The inward ledge muſt be four inches deep and one thick; but, as that thickneſs would make it larger by one inch than the outſide bore of the beams 2, 3, they muſt be cut to the depth of four inches ſo as to receive it exactly. As the friction would be too great, if the capitals rubbed againſt the beams by the extreme ſtraining of the cordage which draws them towards theſe beams, that inconvenience may be eaſily remedied by the means of eight little wheels 13 of an inch in diameter, and an inch and one ſixth in length, as in figure placed circularly, and turning upon axes as in *fig.* 4.

Theſe little wheels or cylinders of caſt braſs ſhould be round, and equal in their diameters, that the capitals may work equally on all ſides.

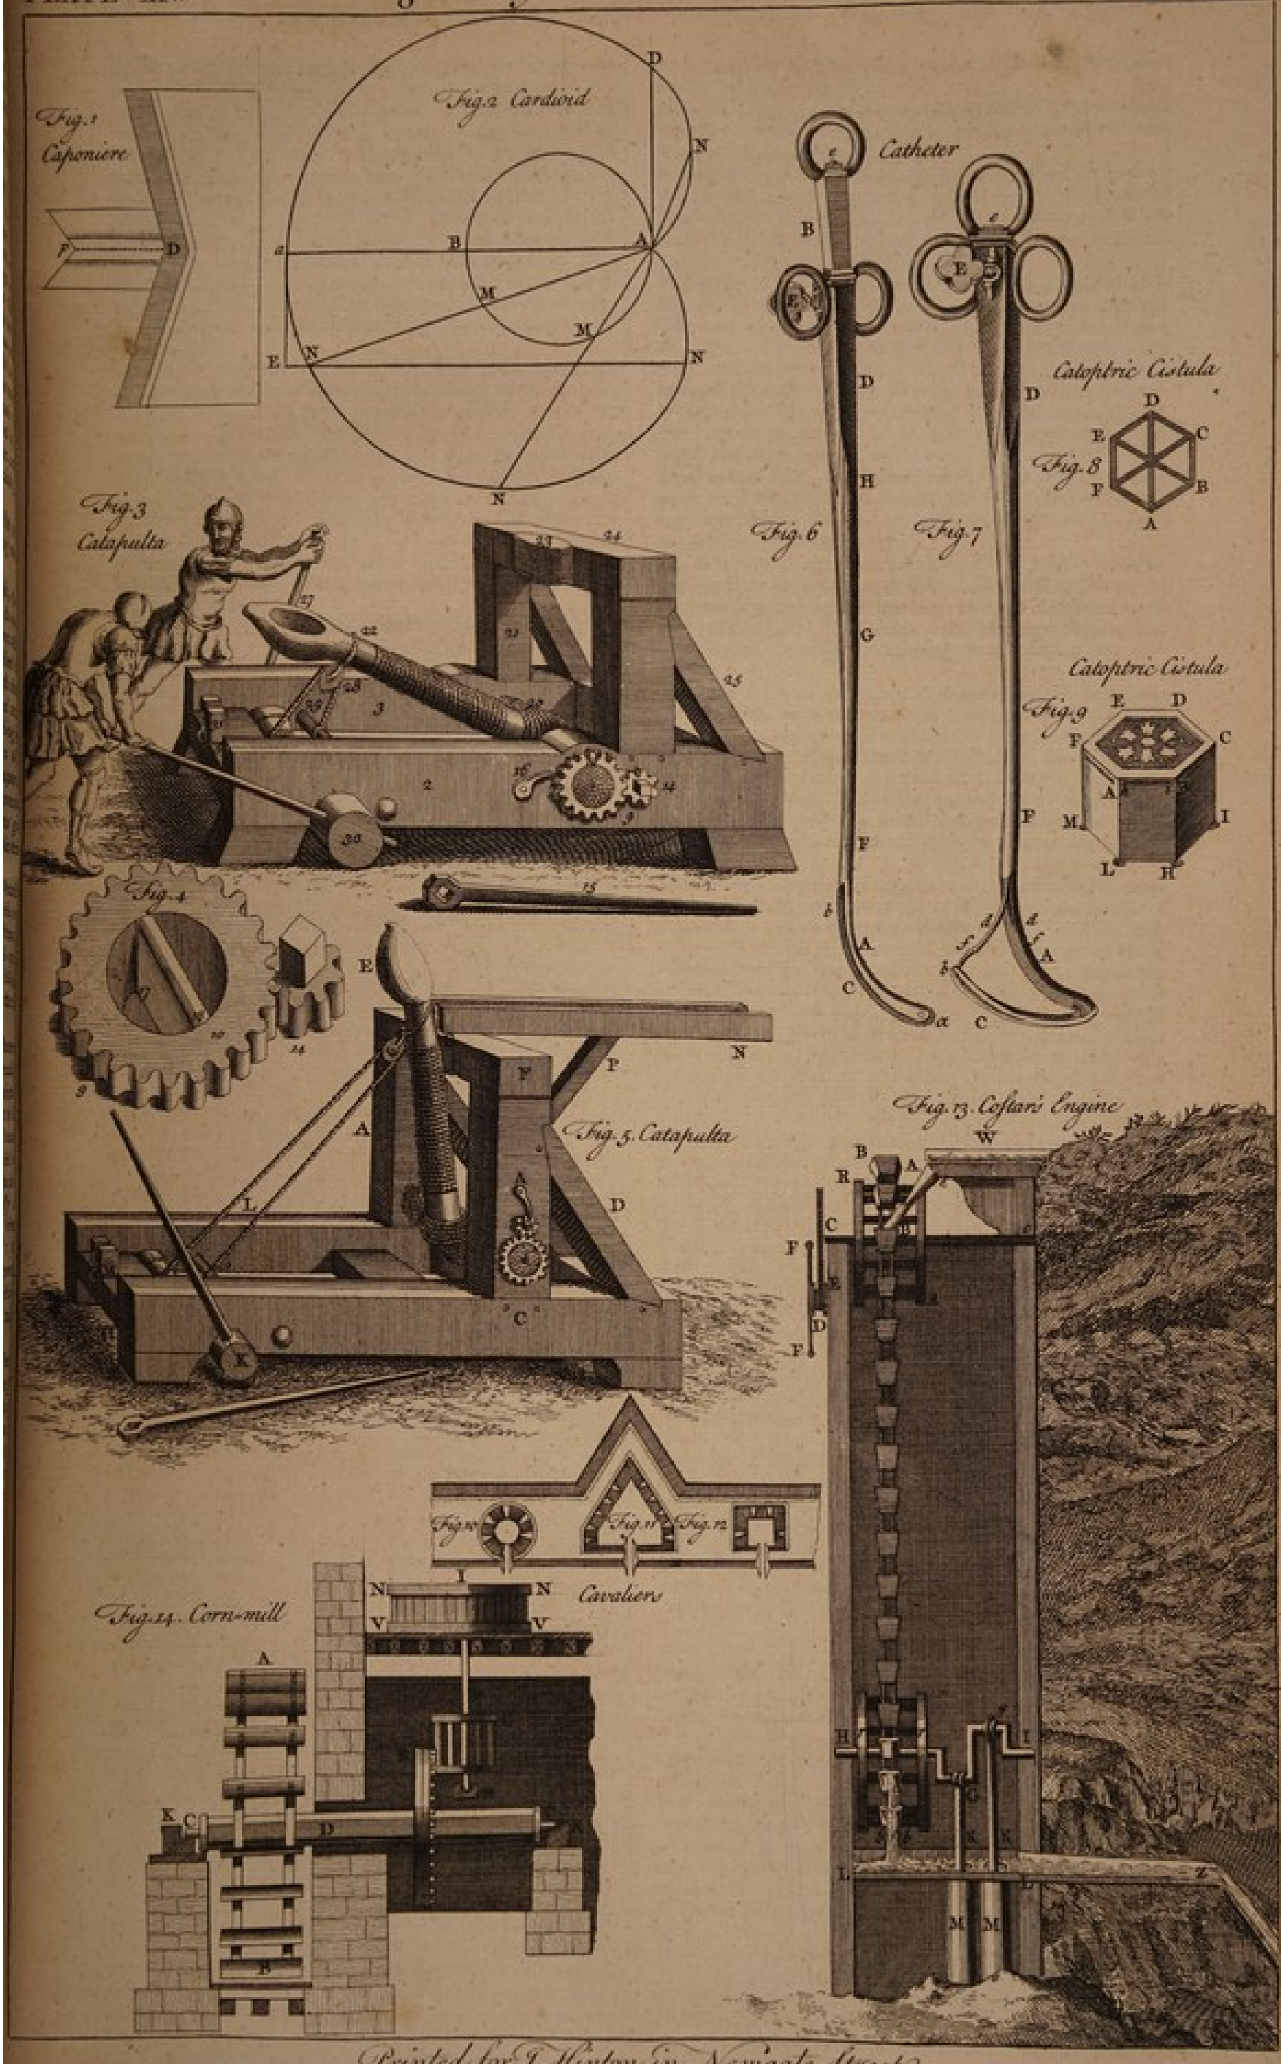
Upon this number of cylindrical wheels the capitals, 9, muſt be placed in the beams 2, 3, ſo that the cylinders do not extend to the teeth of the wheels, which muſt receive a ſtrong pinion 14. By the means of this pinion, the wheel of the capital is made to turn for ſtraining the cordage with the key 15. To the wheel a ſtrong ſtay 16 is annexed, and another of the ſame kind may be added, to prevent any thing from giving way through the extreme and violent force of the ſtrained cordage. Theſe precautions are neceſſary upon account of the cylindrical wheels, which, by entirely preventing the friction of the capitals, make them the more eaſy to give way through the extraordinary and almoſt inconceivable tenſion of the cordage.

This muſt be ſtill greater in a Catapulta carrying four-hundred weight or upwards. In ſuch large machines, the wheels ought to be multiplied, and, for the greater precaution, a ſtrong ſtay added to every wheel. We come now to the capital-piece, or piece within the capital, over which the cordage is folded, and which ſuſtains the whole force in ſtraining it to the proper height.

This capital-piece is a nut or croſs pin of iron, 17, hammered cold into form, that divides the bore of the capitals exactly in two equal parts at their diameters, into which it is inſerted at the depth of about an inch. This piece or nut ought to be about two inches and one third thick at the top 18, and rounded off and poliſhed as much as poſſible, that the cords folded over may not be hurt or cut by the roughneſs or edges of the iron. Its height ought to be eight inches, decreaſing gradually in thickneſs to the bottom, where it ought to be only one inch. It muſt be very exactly inſerted in the capitals: its depth of eight inches adds force to the engine, and prevents its giving way through the ſtraining of the cordage. Perhaps, its being caſt with the capital, and of the ſame metal, might have an equal, if not a better effect.

After applying the two capitals to the bores of the two beams in the baſe, in an exact line with each other, and fixing the two croſs diametrical nuts or pieces, over which the cordage is to fold, one end of the cord is put through the void ſpace of one of the capitals in the baſe, and made faſt to a nail withinſide of the beam. The other ſide of the cord is then carried through the bore in the oppoſite beam and capital, and ſo folded or wound over the croſs pieces of iron in the center of the two capitals till they are full, the cordage forming a large ſkain 20. When this is done, the laſt end of the cord is tied to the firſt which I have mentioned. The tenſion or ſtraining of the cordage ought to be exactly equal, that is to ſay, the ſeveral foldings of cord over the capital-pieces ſhould be equally ſtrained, and ſo near each other, as not to leave the leaſt ſpace between them. As ſoon as the firſt folding or bed of cord has filled up one whole ſpace or breadth of the capital-pieces, another muſt be carried over it; and ſo on, always equally ſtraining the cord till no more will paſs through the capitals, and the ſkain of cordage entirely fills them, obſerving to rub it from time to time with ſoap. The cord may alſo be carried through with both ends, taking it from the center.

At three or four inches behind the cordage, thus wound over the capital-pieces, two very ſtrong upright beams 21 are raiſed: theſe are poſts of oak fourteen inches thick, croſſed over at top by another of the ſame ſolidity. As this part of the machine is two or three inches behind the ſkain of cordage, it muſt have a ſmall obliquity towards the cordage, in ſuch a manner, that, the arm or tree 22 fixed at the bottom, exactly in the center of the cordage, half of which holds it on one ſide, and half on the other, it is neceſſary, I ſay, that the arm ſtrike with ſome obliquity againſt the cuſhion or ſtomacher 23, which muſt be placed exactly in the middle of the croſs beam 24. Without this obliquity the ſpring of the cordage would be



Printed for J. Hinton in Newgate Street.

be somewhat abated from relaxing before the tree reached the cross beam. The height of the upright beam 21 is seven diameters and an half, and three inches, each propped behind with very strong props, fixed at bottom in the extremities of the base 2, 3. The cross beam 24 must be propped in the same manner in the center. The upright and cross beams, props, &c. in this part of the machine, should be strengthened, especially in the joints, with double squares of iron of four inches broad, and a quarter of an inch thick, pinned with strong pins, keyed at the end of them to keep them firm. Care must be taken to place the cushion or stomacher in the center, as has been said. It should be covered with tanned ox-hide, and stuffed with hair, the arm striking against it with inconceivable force.

When the Catapulta is to batter with stones, the bottom of the arm must be placed exactly in the center of the skain or cordage. This is the more important, because, if it be not exactly in the middle, the tension will be unequal; and, whatever should be more on the one than the other side, will infallibly break in straining, which is worth nothing. To prevent mistakes in so important a circumstance, a piece of wood, of the same bigness with the end of the tree or arm, might be fixed in the skain of cordage when formed. The same piece of wood might serve to mark the center of the cords, in carrying them backwards or forwards through the spaces in the capitals.

The tree, arm, or stylus, as Ammianus Marcellinus calls it, should be of excellent ash, the soundest that can be got. Its length is from fifteen to sixteen diameters of the bore of the capitals. The end at bottom to be fixed in the middle of the skain is ten inches thick, by fourteen broad: that is to say, it should be narrower in the first than the second dimension, to make it the stronger, and prevent its bending: for, if the arm bends, it must have more breadth.

The bottom of the arm which the cords receive, must have these dimensions, its edges being smoothed off; for, without that precaution, they would fret or cut the cordage, which are of Cat-gut. The rest of the arm should be made in an elliptical form, not so thick by an inch as the end fixed in the cords, and of the same breadth, to the place where it strikes against the stomacher, which ought to be somewhat thicker, but flat, lest the violence of the stroke cut it in two: in the same place the arm should form a little curve.

To strengthen the arm or tree, of which the force of being discharged is every thing that can be conceived of most violent, it should be wrapped round with a cloth dipped in strong glue like the tree of a saddle, and bound very hard with waxed thread of the sixth of an inch in diameter from the large end at bottom, almost to the top, as in the plate.

The force of this arm is entirely surprizing, when the trigger is struck. The experiments Mr. Follard made of it in his Catapulta convinced him of this. Though his machine threw only a weight of half a pound, the working of the arm in great machines might be judged from it. The ancients who experienced the same every day, had no better expedient to prevent the arms of this kind of machine from breaking, than to make them of two pieces of wood of equal length. These they joined together with abundance of art and care, and strengthened with a strong binding of wax cord.—We shall now proceed to the manner of working the Catapulta.

At the top of the arm, just under the iron hand or receiver 27, a strong cord is made fast, with two loops to it twisted, the one within the other, for strength. Into these two loops the hook of the pulley 28 is put; this pulley should be of brass with double wheels. Upon occasion another may be hooked on at bottom, and to the center of the cock or trigger. The cord 29 is then put through the wheels of the two pullies, and fastened to the roll 30, round which, in turning, it divides itself. The roll ought to be placed in such a manner that the end of the arm at top, to which the pulley is hooked, may almost touch it when the hand or receiver is come to its proper place at bottom. The cock or trigger 31 which serves as a stay, is then brought to it, and made fast by its hook to the extremity of the hand, which is either in the form of a spoon, as in the plate, or of an iron hand, with three branches a little curving; in this the body to be discharged is put. If the machine is to throw flints, they are put into an osier basket, that exactly fits the hand or receiver: the pulley at the neck of the arm is then unhooked, and, when the trigger is to let it off, a stroke must be given upon it with an iron bar or crow of about an inch in diameter; the arm then goes off with a force little unequal to that of a modern mortar. It is to be observed, that the tree or arm describes an angle of ninety degrees, beginning at the cock, and ending at the stomacher or cushion; which we shall farther explain in describing another Catapulta for throwing large darts.

My little Catapulta, says Mr. Follard, is only ten inches long, by thirteen broad. It throws a ball of lead of a pound weight almost five-hundred yards. This kind of machines carry a greater or less distance, according to the points of elevation given them, and the different degrees of the cordage which we have carried to thirty-six. We believe, that a Catapulta, according to the proportions here laid down, must carry at least eight hundred yards. However, adds he, we do not pretend to advance this as a certainty, not having had opportunity to make the experiment.

Plate XIV. *fig.* 5. represents another battering Catapulta with its capitals affixed in its upright beams, and canal for throwing great darts, or many at a time.

A, Are the two double beams of the capitals fixed upright upon the base C, and supported by the props D, with tenons and mortises, which serve to strengthen them against the stroke of the arm E upon the cross-beam F, which should have its cushion or stomacher G.

When the arm E is to be brought down to the cross-beam H, it is done by the roller K, round which runs the cable L. The cock M is then brought to it, which ought to form a little curve. This Catapulta is scarce less simple than the former, and, according to Mr. Follard, might be of great use in besieged places, if planted at bottom and behind the walls.

It was particularly used for throwing darts of an extraordinary size, and sometimes several together; the other threw both stones and darts at once, and in very great numbers. The same author saith, that he doubted at first whether the Catapulta could do this or no, but was not long without discovering the mystery. As there is something curious in it, he gives the following explanation of it:

N, Is a canal of oak rounded withinside in form of a gutter. Its length is six diameters of the capitals, and its breadth in proportion to the size of the large dart, or bundle of darts to be discharged. These darts were larger and longer, and more or less in number, according to the size of the machine.

When arrows were to be shot in the manner of cartridges, the end of the canal or gutter was placed in a cut of the depth of two inches in the center of the cross-beam F, which is fitted exactly. It entered about two inches into the cushion or stomacher, supported by the prop P, to hinder it from bending or giving way. The upper part of the arm ought to be flat at the place where it strikes the great dart or cartridge, and covered with a plate of steel, a quarter of an inch thick.

To discharge a bundle of large darts, they undoubtedly made use of a deal box of a round form, into which the bundle of arrows were put, tied with a very small twine in the middle, to keep them in a right line and parallel with each other. This box was put into the canal or gutter, and projected six or seven inches beyond the cushion towards the arm. It must have been very slight, loosely put together, and of little or no weight, except at the end struck by the arm, which, it is supposed, might be an inch thick or upwards. Its length was according to that of the arrows, that is to say, it should be about half as long, their length being two diameters and an half of the bore of the capitals, as in the former Catapulta. The trigger was then struck, and the arm, coming flat against the box, drove it with the arrows to a very great distance. The wind took the pieces of the box, which soon separated, and the arrows, scattering and spreading in their flight, did terrible execution in the ranks of the enemy.

My little Catapulta, says Mr. Follard (from whose Polybius most of these extracts are made) discharged ten arrows in this manner, to the distance of almost an hundred paces, at eight degrees of elevation. The antients no doubt made use of the quadrant in planting their machines, as the moderns do for their mortars.

CATARACT *of water* (*Dict.*) — In most rivers the descent of the stream passes as it were by insensible degrees from their fountains to their mouths, where they empty themselves into the sea; but there are some whose fall in certain places is much more violent and rapid than the common current of the stream, and these are termed Cataracts. The Rhine, for example, forms two, one at Bilefeld and the other near Schaffouse. The Nile has several and two among them very remarkable, which fall down from a great height between two mountains. The river Vologda in Muscovy has two famous Cataracts near Ladoga. The river Zaira in Congo begins with a kind of Cataract which falls from the precipice of a mountain. But the most famous Cataract of all is that of the river Niagara in Canada; it falls like a prodigious torrent, one hundred and fifty-six feet perpendicular, and is near a mile broad; the mist or fog it makes by its descent may be seen at five leagues distance; it rises to the clouds, and forms a very fine rain-bow, when the sun shines. At the bottom of this Cataract the eddy of the water is so violent, and the whirlpools so terrible, that the river is not navigable for six miles below it. Father Charlevoix's description of it is very particular, and we apprehend may not be unacceptable to our readers. My first care, says he, was to visit the finest cascade that is perhaps in nature. I perceived, at first view, that baron de la Hontan was so much deceived, as to the height and figure of it, that one could scarce imagine he had ever seen it.

It is true, if you take the mensuration of its height from the three mountains, which you pass in your way to it, the fall is not much less than six hundred feet, as M. de l'Isle has laid it down in his chart, no doubt on the credit of La Honton and father Hennepin. But, after I arrived at the top of the third mountain, I observed that, the remainder of the

the way to this water-fall which is about three leagues, we went ſometimes up, ſometimes down hill, which certainly theſe travellers did not attend to. As this Cataract can only be approached on the ſide, and conſequently ſeen in profile, it is not eaſy to meaſure its height with inſtruments: we therefore attempted it with a rope fixed to a long pole, and, after repeated experiments, could find no greater depth than one hundred and fifty feet, ſometimes but one hundred and twenty; the pole might poſſibly meet with ſome rock that bulged out, but, from all the obſervations I could make, I apprehend it about one hundred and forty or one hundred and fifty feet.

As to its figure, it reſembles a horſe-ſhoe, and is about four hundred paces in circumference; exactly in the middle it is divided by a narrow iſland, one eighth of a league in length, at the lower extremity of which the waters unite again.

It may be obſerved as a truth in general, that, in whatever countries the number of inhabitants is not ſufficient to form political bodies of men, the earth is uncultivated, irregular, uneven, the beds of rivers are unequal, not level, and ſubject to Cataracts. The rendering the Rhone and Loire navigable has been the work of ages. It is by confining the waters within their banks, cleaning the bottoms of rivers, and directing their courſe, that they become uſeful and ſerviceable. In all countries where there are few inhabitants nature is imperfect, or at leaſt loſes much of her beauty.

CATA'RRHAL *Fever*, a ſecondary or ſymptomatic fever, by means whereof nature endeavours to correct the vitious quality of the lymph, and expel it the body.

CATCH-*word*, among printers, denotes the firſt word of a page, which is put alſo at the bottom of the preceding page, in order to ſhew how the leaves and ſheets follow each other, and facilitate the folding and binding.

CATE', or CATEA, in natural hiſtory, the name of the tree which produces the drug called caſhoo. It grows in the province of Behar, and in ſome other provinces of Indoſtan, or the Mogul's dominions. It was by a miſtake that Garcias, who was firſt phyſician to a viceroy of Goa, gave the name of that tree to the lozenges, or ſmall cakes of caſhoo, otherwiſe called catechoo, which miſtake Monſ. Lemery has followed. The ſame phyſician alſo miſtook the tree called Caté for a kind of lycion, or rather for that of the ancient Greeks and Romans; for that Indian tree does by no means anſwer the deſcription which Dioſcorides has given us of the lycion. It is preſumed that the Caté is rather a kind of acacia: the caſhoo is made of its bark. They trade in that commodity at Bengal, whither this drug is carried by the river Ganges.

CATERPI'LLAR, *eruca*, in natural hiſtory, an inſect too well known to need deſcription.

There are ſeveral kinds of this inſect, which are very pernicious to a garden; but there are two ſorts which are the moſt common, and deſtructive to young plants: one of them is that which the white butterfly breeds: it is of a yellowiſh colour, ſpotted with black; and commonly infeſts the tender leaves of cabbages, cauliflowers, and Indian creſs. Theſe eat off all the tender parts of the leaves, leaving only the fibres intire; ſo that very often we ſee, in autumn-ſeaſon, whole gardens of winter cabbages and ſavoys almoſts deſtroyed by them; eſpecially in thoſe which are crouded with trees, or are near great buildings. They always increaſe moſt in very dry ſeaſons, and, when the plants have been ſtinted by the drought, they are conſtantly attacked; whereas thoſe which are in vigour, ſeldom ſuffer much by thoſe inſects. Nor is there any other method found out to deſtroy them, that I know of, but to pick them off the plants before they are ſpread from their neſts; by which means, though perhaps many may be overlooked, yet their numbers will be greatly diminiſhed. But this work muſt be often repeated during the warm weather, when the butterflies are abroad, which are continually depoſiting their eggs, and in a few days time will be metamorphoſed to perfect Caterpillars. But as theſe, for the moſt part, feed upon the outer leaves of plants, ſo they are more eaſily taken than the other ſort, which is much larger: the ſkin is very tough, and of a dark colour; this is called, by the gardeners, a grub, and is exceeding hurtful. The eggs of this ſort of Caterpillar are, for the moſt part, depoſited in the very heart or center of the plant, (eſpecially in cabbages;) where, after it has obtained its form, it eats its way out through all the leaves thereof; and alſo the dung, being lodged between the incloſed leaves of the cabbages, gives them an ill ſcent.

This inſect alſo burrows juſt under the ſurface of the ground and makes great havock on young plants, by eating them through their tender ſhanks and drawing them into their holes. The miſchief is chiefly done in the night: whenever you obſerve this, you ſhould every morning look over your plat of plants; and, wherever you ſee any plants eaten off, ſtir the ground round about the place with your fingers an inch deep, and you will certainly find them out. This is the only method I know of deſtroying them. For the metamorphoſes of Caterpillars, ſee the article BUTTERFLY.

CATERPILLAR-*eaters*, a name given by ſome authors to a ſpecies of worms which are bred in the body of a Caterpillar, and eats its fleſh: theſe are owing to a certain kind of fly which lodges her eggs in this animal, and they, after their proper changes, become flies like their parents.

CATHE'TER (*Dict.*)—The learned Mr. Le Cat, in the Philoſophical Tranſact. Numb. 476, has publiſhed the following new Catheter.

The body G (*plate* XIV. *fig.* 6.) of the Catheter is almoſt intirely ſolid, leaving in its center but juſt room enough for the paſſage of the wire. Without this ſolidity, and this narrowneſs of the paſſage of the wire, the Catheter would not be firm; and the wire itſelf, liable to waver, would not run true, but would impart its weakneſs, or want of juſtneſs, to the moveable piece C, which is the guide of this operation.

This body, G, is ſoldered to the piece D at H, making it enter ſquare into the ſaid piece D, till it meet the ſlider B, which I ſuppoſe intirely within the piece D. The rings are very large and ſtrong for the conveniency of uſing it.
