The ſeparation of the ſilver out of the Regulus, made from the ſilver ore by means of lead, is to be performed in this manner: put two coppels of the ſame bigneſs, perfectly dry, and capable of containing at leaſt one third more than the Regulus, under a muffle in an aſſay furnace; make a ſtrong fire, and let them be red-hot for a quarter of an hour; then free the Regulus from its ſcoriæ, by ſtriking it gently with a hammer, and put it carefully into one of the hot coppels, and into the other put, at the ſame time, the ſame quantity of granulated lead alone, as was uſed in making the Regulus. When the Regulus boils and ſmoaks, diminiſh the fire a little, and let the coppels be kept moderately, but not violently redhot. When it has ſtood ſo long, that the ſkin of the litharge, continually produced from the lead, and covering the ſurface of the Regulus, diſappears, and the coppel ſhews the ſcoriæ only of the lead with the pure ſilver, either in fuſion, or hard and bright in the middle, let the coppel continue only a minute or two longer on the fire; then take it out with a pair of tongues, take away the metal in grains, and if any ſcoriæ, or fragment of the coppele adhere to it, wrap it together in a paper, and ſqueeſe it between the cheeks of a vice, or a pair of tongs, to break off that brittle matter without hurting the Regulus. If this Regulus be pure ſilver, it will now be very white; but, if it contain any gold, it will ſhew it by its yellowneſs.

To determine exactly how much ſilver the quantity of ore contained, weigh it nicely in a fine balance, and take out the ſmall reguline lumps from the other coppel, and, weighing that, deduct its weight from that of the other, becauſe ſo much ſilver that owes to the lead uſed in making it, and the remainder is the proportion of ſilver contained in the ore. *Cramer's Art of Aſſaying.*

Martial Regulus of antimony, is a mixture of little bits of iron, as the nails of horſe's ſhoes, melted with the Regulus.

In this operation the iron diſſolving and abſorbing the ſulphurous parts of the antimony, more ſtrongly than the fluxes in the former caſe, and turning it into a crocus; the antimony is hereby brought to a greater degree of purity, and rendered more efficacious than in the common Regulus.

The Regulus is ſometimes farther purified by repeated fuſions and detonations, with the addition of freſh antimony, and more nitre, alternately: in which caſe it becomes Regulus antimonii ſtellatus, or ſtarry Regulus of antimony.

Regulus *criſtatus*, the creſted or golden crown wren, the name of a very beautiful little bird, the ſmalleſt of the European birds. Its whole weight is not more than a drachm, and the crown of its head is adorned with a very beautiful ſaffron-coloured, or orange red ſpot, which is called its creſt, and by ſome its crown; and from this golden crown the bird has obtained the name of the Regulus, tyrannus, baſileus, and other appellations of royalty.

RE'LICS, *reliquiæ*, in the Romiſh church, certain remains of the bodies or cloaths of ſome ſaint or martyr, devoutly preſerved in honour to his memory, carried at proceſſions, kiſſed, revered, &c.

The abuſes in point of Relics are moſt flagrant: F. Mabillon, a Benedictin, complains of the great number of ſuſpected Relics expoſed on altars: he owns that, were there to be a ſtrict inquiſition into the Relics, vaſt numbers of ſpurious ones would be found offered every-where to the piety and devotion of the faithful; and adds, that bones are frequently conſecrated, ſo far from belonging to ſaints, that in all probability they do not belong to Chriſtians.

The catacombs are an inexhauſtible fund of Relics; yet it is ſtill diſputed who were the perſons interred therein.

In the eleventh century, a method was introduced of trying ſuppoſed Relics by fire.—Thoſe which did not conſume in the fire were reputed genuine; the reſt not.

It is an ancient cuſtom, which ſtill obtains, to preſerve the Relics in the altars whereon maſs is celebrated.—To this purpoſe, a ſquare hole is made in the middle of the altar, big enough to receive the hand; and herein is the Relic depoſited, wrapped in red ſilk, and incloſed in a leaden box.

The Romaniſts alledge a good deal of antiquity in behalf of their Relics.—The Manichees, it ſeems, out of hatred to the fleſh, which they held an evil principle, are recorded as refuſing to honour the Relics of ſaints; which is eſteemed a kind of proof that the catholics did it in the firſt ages.

Indeed folly and ſuperſtition got into religion but too early.—Even the touching of linen cloaths on Relics, from an opinion of ſome extraordinary virtue derived therefrom, appears to be as antient as the firſt ages; there being a hole made in the coffins of the forty martyrs at Conſtantinople, expreſly for this purpoſe.

RELI'GION (*Dict.*)— The following short account of all the Religions professed by the several nations, &c. of the known world, will, we presume, be acceptable to the reader.

1. Religions of Europe.

Sweden. The Swedes are Protestants, of the sect of the Lutherans. The gospel was first planted in this country, A. D. 829.

Denmark. The Danes are likewise Lutherans, having embraced the reformation much about the same time with their neighbours the Swedes.

Norway. The religion of this country is the same with that of Denmark, excepting that, in the northermost parts of the kingdom, the knowledge of Christianity is so greatly decayed, that the inhabitants, especially the Laplanders, differ but little from mere heathens.

Russia or Muscovy. The Russians are Christians, according to the doctrines and discipline of the Greek church; which they pretend to observe in the greatest purity; but, in truth, they have added thereto a great many superstitious practices and ridiculous ceremonies. They pay divine worship to the Virgin Mary, and the saints, and adore crucifixes. Christianity was first planted in this country, about the end of the Xth century, by the preaching of some Greeks, sent thither by the patriarch of Constantinople.

France. The only established religion in this country is that of the Romish church. But, though the French receive all the decisions of the council of Trent, in matters of faith; yet, in points of discipline and church-government, they claim certain privileges, called the rights of the Gallican church; which they never suffer to be infringed by any authority of the see of Rome.

Germany. The laws of the empire give free toleration to the exercise of three religions; namely, the Lutheran, Calvinist, and Popish.

Hungary. The prevailing religion of this country is that of the Romish church, especially since it is become subject to the emperor: however, the doctrines of Luther and Calvin are zealously maintained by multitudes of people.

Holland. No country in Europe can boast of more religions than Holland; where an universal toleration is granted to all sects and parties; and this for the sake of commerce. That publicly professed, and generally received, is the reformed Religion, according to the doctrines of Calvin.

Flanders. This country, being partly subject to the empire, and partly to France, possesses the Romish Religion, and that in its grossest errors.

Poland. The Polanders are, for the most part, Roman Catholics. Notwithstanding which, a general toleration is here granted to all Religions; insomuch that this country swarms with Greeks, Armenians, Lutherans, Socinians, Calvinists, Jews, Quakers, &c. The Lutherans are mostly found in Prussia. Christianity was established in various parts of Poland, at several times, and by several persons; being settled in Poland, properly so called, in 963; in Livonia, an. 1200; and in Lithuania, not till the year 1386.

Spain. The Spaniards are the closest adherents to the church of Rome, in her grossest errors and corruptions; and none are suffered to reside in this kingdom, who profess any other belief. For this reason the king of Spain is stiled the Catholic king. Christianity was first planted in Spain, according to an old Spanish tradition, by the apostle St. James, within four years after the death of Christ.

Portugal. The Portuguese are of the same Religion with their neighbours, the Spaniards; with this difference, that they tolerate Jews, and allow several foreigners, particularly the English factory at Lisbon, the public exercise of their Religion. This country received the gospel much about the same time.

Italy. The Italians, in general, are zealous professors of the Romish Religion: indeed, Italy is the very center of popery. The Christian faith was first preached in this country by St. Peter, who, it is said, went thither about the beginning of the reign of the emperor Claudius. The best summary of the Romish faith is the creed of Pope Pius IV.

Greece. The established Religion of this country, which is in subjection to the Turk, is Mohammedism; but the Christians, who are every-where tolerated in the Turkish dominions, are far more numerous in Greece, than the Mohammedans. The Religion of the Greek Christians is a schism or separation from the church of Rome, and consists, principally, in denying the procession of the Holy Ghost, purgatory, extreme unction, and confirmation; in administring the sacraments in both kinds, and to children of seven years of age; and in rejecting the use of images. Their clergy, as well as laity, are exceedingly illiterate and ignorant. Christianity was first preached in this country by St. Paul, the apostle of the Gentiles.

Little Tartary. The Crim-Tartars are, for the most part, zealous Mohammedans, excepting some few, who continue still Pagans.

The Danubian Provinces. The inhabitants of these different provinces are very different in point of Religion, but reducible to three classes, viz. Jews, Christians, and Mohammedans.

Scotland. The Religion of this northern part of Great-Britain is Presbyterianism.

England. The church of England pretends to profess the reformed Religion, in its choicest purity. In reforming their Religion, the English were not so hurried by popular fury and faction, as other nations were; but proceeded in a more prudent, regular, and Christian method, resolving to separate no farther from the church of Rome, than she had departed from the truth. So that the reformed church of England is the true mean between superstition and fanaticism. Her doctrine is entirely built upon the apostles and prophets: her government is truly apostolical: her liturgy an extract of the best primitive forms; and her ceremonies few, and such as tend only to decency and true devotion. All other sects and parties, except the Romish, are here allowed the free exercise of their Religion.

Ireland. The inhabitants of this island are partly Papists, and partly Protestants. The most civilised parts of the kingdom profess the reformed Religion, according to the platform of the church of England. But the far greater part of the native Irish still adhere to the Romish Religion.

2. Religions of Asia and Africa.

Tartary. The inhabitants of this vast country are partly Pagans, partly Mohammedans, and partly Christians. The Christian faith, it is thought, was planted in this country by the apostles, St. Philip and St. Andrew.

China. The prevailing Religion in China is gross idolatry; and, in some parts, the doctrines of Mohammed are professed.

Mogul's empire. The inhabitants of this country are mostly Pagans; and, next to Paganism, the Religion of Mohammed prevails.

The Peninsula of India, within the Ganges. The inhabitants of this tract of land are generally Mohammedans.

The Peninsula of India, beyond the Ganges. The inhabitants of this Peninsula are generally gross Idolaters.

Persia. The Persians are strict Mohammedans, but of the sect of Ali. Christianity was first planted in this kingdom by St. Thomas.

Natolia, or Asia Minor. The established Religion of this country is Mohammedism; but persons of all professions are tolerated here, and in other parts of the Turkish dominions.

Arabia. The Religion of Mohammed is professed in this country, where it took its first rise; that impostor being born in Arabia.

Syria. The inhabitants of this part of Asiatic Turkey are chiefly Mohammedans, with a mixture of Jews and Christians, particularly Greeks, Armenians, and Marionites. Christianity was planted here in the apostolic age.

Palestine. The inhabitants of this country are a mixture of Mohammedans, Jews, and Christians, who follow their respective Religions. Christianity was preached in this country by Christ himself, and his apostles.

The Euphratian provinces. The prevailing Religion in many parts of this country is that of the Armenians. Christianity was planted here by St. Bartholomew the apostle.

Egypt, Barbary, Bildulgerid, Zaarah, or the Desart; the Land of the Negroes: all Mohammedans or Pagans.

Guinea. Paganism is the Religion of this country, the profession whereof is attended with many ridiculous superstitions. In some places, on the Gold coast, the diabolical custom of human sacrifices is still in use.

Nubia. This spacious country was once Christian, having received the gospel in the earliest ages: but, for want of pastors, the inhabitants fell off from Christianity, and became either strict Mohammedans or gross Idolaters.

Ethiopia superior, or Abyssinia. This spacious empire contains a great mixture of people, as Pagans, Jews, and Mohammedans, of various nations; but the main body of the natives is Christian.

Ethiopia inferior. The numerous inhabitants of these countries are gross Idolaters.

From the foregoing view of the various Religions of the different countries of the world, it appears, that the Christian Religion, undoubtedly the true Religion, is of a very small extent, if compared with those many and vast countries, overspread with Idolatry or Mohammedism. This great and sad truth may be farther evinced by the following calculation, ingeniously made by some, who, dividing the inhabited world into thirty parts, find, that nineteen of them are possessed by gross Idolaters; six by Jews and Mohammedans; two by Christians of the Greek church; and three by those of the church of Rome and Protestant communion. If this calculation be true, Christianity, taken in its largest latitude, bears no greater proportion to the other false Religions, than that of five to twenty-five.

REMO'RA, *the sucking fish*, in natural history, a small oblong fish, whose body is of a cylindric figure, and tapers off to a thinness at the tail. Its mouth is triangular, and the upper part is shorter than its under. Its head is flat, and marked with streaks, so as to look like the palates of some fishes: these run transversely, and are carried on to the back, making a striated substance of two fingers breadth, by which it fastens itself to any other substance, as the body of a larger fish, the hulk of a ship, or the like. The eyes are small and yellow, with a black pupil. It has no teeth, but in their places a multitude of small prominences. It has two fins under the gills, and two more lower on the body. Besides these, it has two longitudinal fins, one on the back, the other on the belly, running the length of the body to the tail. The whole fish

fish is of a greyish colour, and it is caught in the East and West-Indies, and in many other seas.

RE'NTAL, a roll wherein the rents of a manor are written and set down, and by which the lord's bailiff collects the same: it distinguishes the lands and tenements, and the names of the tenants, the several rents arising, and from what time, usually a year. *Comp. Court-Keep.* 475.

RE'NTERING *, or FINE-DRAWING, in the manufactories, the sewing of two pieces of cloth, edge to edge, without doubling them; so as that the seam scarce appears at all: hence also called fine-drawing.

* The word is formed from the French, *rentraire*, which signifies the same thing; and which Menage after Salmasius derives from the Latin *retrahere* of *re*, in, and *trahere*, by reason the seam is drawn out of sight and covered.

Serges, &c. are to be sewed; cloths fine-drawn.—The author of one of the Lett. Edif. & Cur. speaking of the great dexterity of the fine-drawers in the East-Indies, assures us, that if you tear a piece of fine muslin, and give it one of them to mend, it shall be impossible for you to discover the place where it is rejoined, even though you had made a mark to know it by.

The dexterity of our own fine-drawers, though inferior to that above-mentioned, is nevertheless such, as puts them in a condition to defraud the king, by sewing a head or slip of English cloth on a piece of Dutch, Spanish, or other foreign cloth; or a slip of foreign cloth on a piece of English, so as to pass the whole as of a piece; and by that means avoid the duties, penalties, &c.—The trick was discovered in France, by M. Savary, author of the *Diction. de Commerce.*

To renter in tapistry, is to work new warp into a piece of tapistry damaged, eaten by the rats, &c. and on this warp to restore the ancient pattern or design.—The warp is to be of woollen, not linen.—Among the titles of the French tapistry-makers, is included that of Renterers.

Fine-drawing is particularly used for a rent, or hole, happening in the dressing or preparing of a piece of cloth, artfully sewed up or mended with silk.

All fine-drawings are reputed defects or blemishes, and ought to be allowed for in the price of the piece.—Hence, M. Savary establishes is as a rule, which is certainly founded on natural equity, that every manufacturer mark the fine-drawings of his cloths with a piece of packthread tied to the list, to direct the draper to the spot: and that the draper apprize the taylor or other person, to whom he sells it, of the same; that he may not come to damage in the cutting; there being instances of drapers condemned to take back their cloth, when cut to pieces, for omitting to mention the fine-drawings, and other flaws.

On this occasion M. Savary extols the procedure of an English merchant, who sending a piece of cloth damaged in one spot to his correspondent at Paris, put a piece of gold in the damaged place, to make up the damage.—But as this example is perhaps the only one of its kind, that author recommends it to the merchant or draper to unfold all the pieces entirely, as they come to him; to discover the fine-drawings and other flaws, in order to make the clothier accountable for them.

RE-ORDINA'TION, the conferring orders a second time. Re-ordination is practised in England when dissenting ministers conform to the church, the bishops contending that they alone have right to confer holy orders, and that every priest or minister who does not receive their hands, has no lawful, regular vocation. This proves a great obstacle to the re-union of those ministers to the church of England, many of whom are otherwise disposed to conform; inasmuch as Re-ordination implies their former vocation to be null; that they had administred the sacraments without any right thereto; and that all their ministerial acts were invalid.

REPE'LLENT *fluid*, a name given by Dr. Knight to a fluid which he supposes disseminated through the universe.

After proving that all the primary corpuscles of bodies are compounded of attracting and repelling matter, and that the smallest corpuscles in nature are such as mutually repel each other, the Dr. adds, 'A sufficient number of such Repellent corpuscles, collected together, will compose a fluid in all respects resembling pure elementary air, at least as far as we are able to judge from the known properties of that element. The common air, indeed, of our atmosphere is a fluid far less simple and homogene than what is here supposed: it is rather a chaos of all the substances in nature, and is on that account capable of producing a great variety of phænomena, that can in no wise be ascribed to so simple a cause. If therefore we would make a just comparison between the common air and our repellent corpuscles, we must suppose them also mixed with the same variety of other substances. Our Repellent fluid will be compressible and perfectly elastic, the distance of its particles will render it extremely rare and pellucid, and their distance and smallness together will make it exceed all other fluids in levity. If the air is really more elastic at different heights of the atmosphere, we need only conceive its particles of different sizes to account for it. The smallest, and consequently the lightest, will have most elasticity. Those, by the laws of hydrostatics, will rise highest, and vice versâ, the grossest and least elastic will occupy the lowest part of the atmosphere. *Knight's Attempt to demonstrate that all the Phænomena in Nature may be explained by two simple and active Principles, Attraction and Repulsion.*

REPETE'ND, in arithmetic, is used for that part of an intermediate decimal fraction, which is continually repeated ad infinitum.

Thus, in the intermediate decimal fraction, 317.45 316 316 316 316, &c. the figures 316 are called the Repetend. *Cunn. Treat. of Fractions.*

These Repetends often arise in the reduction of vulgar fractions to decimals; thus $\frac{1}{3} = 0.3333$, &c. $\frac{1}{7} = 0.142857$ 142857, &c. $\frac{1}{11} = 0.090909$, &c.

Single Repetend, is that where one figure only is repeated, as in 0.333, &c.

Compound Repetend, is that where two or more figures are repeated, as in 0. 09 09, &c. or in 0. 142857, 142857, &c.

Decimals with Repetends may always be reduced to vulgar fractions. For either the Repetend begins with the decimal or not:

If the Repetend begins with the first place of decimals, make it the numerator of a vulgar fraction, and make the denominator consist of as many nines as the Repetend has figures, then will this vulgar fraction be equal to the decimal.

Thus, if the Repetend be single, as in 0. 3333, the vulgar fraction equal to it will be $= \frac{3}{9} = \frac{1}{3}$. So, if the Repetend be compound, as in 0. 09, 09, &c. the equivalent vulgar fraction will be $\frac{09}{99} = \frac{9}{99} = \frac{1}{11}$.

And in like manner 0. 142857, 142857, &c. $= \frac{142857}{999999} = \frac{1}{7}$.

The reason is obvious from this consideration, that the decimal 0. 333, &c. is $= \frac{3}{10} + \frac{3}{100} + \frac{3}{1000}$, &c. the sum of which, by the rule mentioned under FRACTION in the Dictionary, will be equal to $\frac{3}{10}$ divided by $1 - \frac{1}{10} = \frac{3}{9} = \frac{1}{3}$, and so of the rest.

If the Repetend does not begin with the first place of decimals, but some place farther on towards the right as in the decimal 0. 83333, &c. where the Repetend does not begin till the second place of decimals, observe, that 0. 8333 +, &c. $= \frac{8}{10} + \frac{1}{10} \times \frac{3}{10} + \frac{3}{10^2} +$, &c. But $\frac{3}{10} + \frac{3}{10^2} +$, &c. $= \frac{3}{9} = \frac{1}{3}$, as before; therefore the proposed decimal is $= \frac{8}{10} + \frac{1}{10} \times \frac{1}{3} = \frac{8}{10} + \frac{1}{30} = \frac{250}{300} = \frac{25}{30} = \frac{5}{6}$.

Thus, also, if the decimal 0. 2, 27, 27, &c. were proposed, we shall find it $= \frac{2}{10} + \frac{1}{10} \times \frac{27}{100} + \frac{27}{100^2} +$, &c. And, $\frac{27}{100} + \frac{27}{100^2} +$, &c. being $= \frac{27}{99} = \frac{3}{11}$, the decimal will be $= \frac{2}{10} + \frac{1}{10} \times \frac{3}{11} = \frac{2}{10} + \frac{3}{110} = \frac{5}{22}$. The reason of which is obvious from what has been said. It may perhaps be worth while to observe, that, if the numerator of a vulgar fraction be unity, and the denominator any prime number, except 2 and 5, the decimal equal to the proposed fraction will always be a Repetend, beginning at the first place of decimals; and this Repetend must necessarily be a submultiple, or an aliquot part of a number expressed by as many nines as the Repetend has figures; that is, if the Repetend have six figures, it will be a submultiple of 999999; if four figures, it will be a submultiple of 9999, &c. From whence it follows, that, if any prime number be called p, the series 9999, &c. produced as far as is necessary, will always be divisible by p, and the quotient will be the Repetend of the decimal fraction $= \frac{1}{p}$.

REPRESE'NTATIVE *power*, in metaphysics, a term introduced by Leibnitz, to signify that power of the human soul, by which it represents to itself the universe, according to the situation of the body in the universe. See the article IDEA, in the Dictionary.

Wolfius calls this power vis representativa, to denote its being an active power, or rather a force actually exerting itself. For he expressly says, quod vis consistat in continuo agendi conatu. And he thinks, that, from this principle of a vis representativa, every phænomenon of the human mind may be accounted for. See his *Psycholog. Ration. Art.* 529.

But it may be presumed, that many will find this principle too obscure to be admitted.

When it is said, that our ideas are Representative of things without us, or of the universe; it may be asked in what sense this is to be understood? Do they represent it 1°. as a picture does its original? or 2°. as an effect of a cause? or 3°. as a sign represents the thing signified? The first opinion is exploded in part by Locke and the Cartesians, and totally by Dr. Berkeley, late bishop of Cloyne. The second is admitted by Hobbes, but denied by Leibnitz himself, and the idealists. The third should seem to be the opinion of Leibnitz, but he is not sufficiently explicit.

Dr. Berkeley admits ideas to be signs; but according to him they are arbitrary signs, depending on the immediate will of the Deity: hence the visual language; and ideas only signify or suggest each other, and spirits; but not bodies, the existence of which is totally unknown.

REPRODU'CTION (*Dict.*)—It is very well known, that trees and plants are to be raised from slips and cuttings, and some late observations have shewn, that there are some animals which have the same property.

The Polype was the first instance we had of this; but we had scarce time to wonder at the discovery Mr. Trembley had

made,

made, when Mr. Bonett discovered the same property in a species of water-worm.

Amongst the plants that may be raised from cuttings, there are some which seem to possess this quality in so eminent a degree, that the smallest portion of them will become a complete tree again.

It deserves enquiry, whether or not the great author of nature, when he ordained that certain insects, as these polypes and worms, should resemble those plants in that particular, allowed them this power of being reproduced in the same degree; or, which is the same thing, whether this Reproduction will or will not take place in whatever part the worm is cut: in order to try this Mr. Bonett entered on a course of many experiments on the water-worms which have this property. These are, at their common growth, from two to three inches long, and of a brownish colour, with a cast of reddish. From one of these worms he cut off the head and tail, taking from each extremity only a small piece of the twelfth of an inch in length, but neither of these pieces were able to reproduce what was wanting. They both perished in about twenty-four hours; the tail first, and afterwards the head. As to the body of the worm from which these pieces were separated, it lived as well as before, and seemed indeed to suffer nothing by the loss, the head-part being immediately used as if the head was thereon, boring the creature's way into the mud. There are, besides this, two other points in which the Reproduction will not take place; the one of these is about the fifth or sixth rim from the head, and the other the same distance from the tail; in all probability the condition of the great artery in these parts is the cause of this.

What is said of the want of the reproductive power of these parts, relates only to the head and tail ends; for as to the body, it feels very little inconvenience from the loss of what is taken off, and very speedily reproduces those parts. Where then does the principle of life reside in such worms, which, after having their heads cut off, will have, not only the same motions, but even the inclinations, that they had before; and yet this difficulty is very small, compared to several others, which at the same time offer themselves to our reason? Is this wonderful Reproduction of parts only a natural consequence of the laws of motion, are there lodged in the body of the creature a chain of minute buds or shoots, a sort of little embryos already formed and placed in such parts where the Reproductions are to begin? Are these worms only mere machines, or are they, like more perfect animals, a sort of compound, the springs of whose motions are actuated or regulated by a sort of soul? And, if they have themselves such a principle, how is it that this principle is multiplied and is found in every separate piece? Is it to be granted, that there are in these worms not a single soul (if it is to be so called) in each, but that each contains as many souls as there are pieces capable of reproducing perfect animals? Are we to believe with Malpighi, that these sorts of worms are all heart and brain from one end to the other? This may be, but yet, if we knew that it was so, we should know, in reality, but very little the more for knowing it; and it seems after all, that, in cases of this kind, we are only to admire the works of the great Creator, and sit down in silence.

The nice sense of feeling in spiders has been much talked of by naturalists; but it appears, that these worms have yet somewhat more surprising in them in regard to this particular. If a piece of stick, or any other substance, be brought near them, they do not stay for its touching them, but begin to leap and frisk about, as soon as it comes towards them. There want however some farther experiments to ascertain whether this be really owing to feeling or to sight; for, though we can discover no distinct organs of sight in these creatures, yet they seem affected by the light of the sun or a candle, and always frisk about it in the same manner, at the approach of either; nay, even the moon-light has some effect upon them.

A twig of willow, poplar, or many other trees, being planted in the earth, takes root, and becomes a tree, every piece of which will in the same manner produce other trees. The case is the same with these worms; they are cut to pieces, and their several pieces become perfect animals; and each of these may be again cut into a number of pieces, each of which will in the same manner produce an animal. It had been supposed by some, that these worms were oviparous; but Mr. Bonett, on cutting one of them to pieces, having observed a slender substance resembling a small filament to move at the end of one of the pieces, separated it, and, on examining it with glasses, found it to be a perfect worm of the same form with its parent, which lived and grew larger in a vessel of water into which he put it. These small worms are easily divided, and very readily complete themselves again, a day usually serving for the production of a head to the part that wants one, and in general, the smaller and the slenderer the worms are, the sooner they complete themselves after this operation. When the bodies of the large worms are examined by the microscope, it is very easy to see the appearance of the young worms alive and moving about within them; but it requires great precision and exactness to be certain of this; since the ramifications of the great artery have very much the appearance of young worms, and they are kept in a sort of continual motion by the systoles and diastoles of the several portions of the artery which serve as so many hearts. It is very certain, that what we force in regard to these animals by our operations, is done also naturally every day, in the brooks and ditches where they live. A curious observer will find in these places many of them without heads or tails, and some without either; as also other fragments of various kinds, all which are then in the act of completing themselves; but whether accidents have reduced them to this state, or they thus purposely throw off parts of their own body for the Reproduction of more animals, is not easy to determine. They are plainly liable to many accidents, by which they lose the several parts of their body, and must perish very early, if they had not a power of reproducing what was lost; they are often broken into two pieces, by the resistance of some hard piece of mud, which they enter; and they are subject to a disease, a kind of grangrene rotting off the several parts of their bodies, and must inevitably perish by it, had they not this surprising property.

This worm was a second instance, after the polype, of the surprising power in an animal of recovering its most essential parts, when lost; but nature does not seem to have limited her beneficence in this respect to these two creatures; Mr. Bonett tried the same experiments on another species of water-worms differing from the former in being much thicker: This worm, when divided in the summer season, very often shews the same property; for, if it be cut into three or four pieces, the pieces will lie like dead for a long time, but afterwards, will move about again, and will be found in this state of rest to have recovered a head, or a tail, or both. After recovering their parts, they move very little, and, according to this gentleman's experiments, seldom live more than a month. It should seem that the more difficult success of this last kind of worm, after cutting, and the long time it takes to recover the lost parts, if it do recover them at all, is owing to its thickness; since we always find, in that species of worms which succeeds best of all, that those which are thinnest always recover their parts much sooner than the others.

The water insects, also, are not the only creatures which have this power of recovering their lost parts. The earth affords us some already to grow in this manner from their cuttings, and these not less deserving our admiration than those of the water; the common earth-worms are of this kind. Some of these worms have been divided into two, others into three or four pieces, and some of these pieces, after having passed two or three months without any appearance of life or motion, have then begun to reproduce a head, or a tail, or both. The Reproduction of the anus, after such a state of rest, is no long work; a few days does it, but it is otherwise with the head, that does not seem to perform its functions in the divided pieces, till about seven months after the separation. It is to be observed that, in all these operations, both on earth and water-worms, the hinder part suffers greatly more than the fore-part in the cutting, for it always twists itself about a long time, as, if actuated by strong convulsions; whereas the head usually crawls away without the appearance of any great uneasiness.

REPU'LSION (*Dict.*) — The learned Dr. Knight observes that we have sufficient evidence of the existence of Repulsion from facts and experience. 'For, says he, all bodies are electrical, or capable of being made so: and electrical bodies both attract and repel. Secondly, both attraction and Repulsion are very conspicuous in all magnetical bodies. Thirdly, Sir Isaac has shewn from experiment, that the surfaces of two convex glasses repel each other. Fourthly, the same great philosopher has explained the elasticity of the air by supposing its particles mutually to repel. Fifthly, the particles of light are, in part at least, repelled from the surface of all bodies. Lastly, it seems highly probable that the particles of light mutually repel each other. The air is always rarified by heat; and that in a greater proportion, as the heat is more intense. What then must that rarefaction be in the focus of Villette's speculum? Perhaps a more perfect vacuum would not be produced by the best air-pumps. But suppose half the air still remaining, its expansive force will be equal to a column of mercury of fifteen inches in height; whose basis will be equal to an imaginary surface surrounding the whole focal space. But the atmosphere will press with a force equal to a column of the same base, and thirty inches in height. What is it that supports this extraordinary weight? A Cartesian will tell us perhaps, that there is no vacuum at all: but that the air is drove out of its place by the subtile matter; which being moved with great rapidity by the matter of the first element, i. e. light, and whirled round in a vortex, by its centrifugal force is determined every way to fly off, and so counter-acts the pressure of the air. But how can light, which moves, in this case, all of it in one direction, communicate a motion to the subtile matter so, that it shall act in all directions? Another difficulty arises from a defect in the momentum of light: which being supposed the primum mobile, ought to act with a force equal to several pounds of mercury. Now as all these difficulties vanish, if we only admit a Repulsion betwixt the particles of light themselves, and betwixt them and air, we can have no reason to doubt of the fact, especially since it is plain, from the arguments above, that there is such a cause as Repulfion in nature. 'For no caufe ought to be admitted, but what is really found in nature, and no more than are neceffary towards explaining the feveral phænomena'.

RESPIRATION (*Dict.*)—The alternate motion of the thorax and lungs in Refpiration is evident, but it is not eafy to determine the mechanifm by which thefe motions are performed. Dr. Martin thinks this has not been accounted for in a fatisfactory manner, either by Swammerdam, Borelli, Baglivi, Pitcairn, or Boerhaave, and has given us an effay on this fubject in the *Medic. Eff. Edinb.* Vol. I. *Art.* 12.

Dr. Hoadley endeavours to prove, that the external intercoftal mufcles ferve for infpiration, while the internal intercoftals are their antagonifts, depreffing their ribs in expiration. He thinks it proved by Dr. Hale's experiments, that there is air in the cavity of the thorax, between the lungs and the pleura, and endeavours to take off the force of Dr. Houfton's afferting that he faw the lungs and pleura contiguous. He grants, however, that fometimes there may be little or no air. He accounts for Refpiration much in the fame way with thofe who affume the contiguity of the lungs and pleura. He joins with thofe who think the impetus, which the internal furface of the lungs fuftains in common Refpiration, to be very little. The ufes of Refpiration are, to difcharge, from the venal blood and chyle, fuch parts as are unfit to render them arterial blood, and to admit air into the blood. From this doctrine he accounts for the phænomena of the difeafes of the lungs. He fubjoins the picture and defcription of an ingenious inftrument for illuftrating the manner in which Refpiration is performed.

Organs of RESPIRATION, *in fly-worms*. — Thefe afford us not only great matter of admiration in their general ftructure, but, by their almoft endlefs variety in the different fpecies of thefe creatures, give ample room for the forming claffes and genera from them.

The firft clafs of thefe creatures is of thofe with variable heads, whofe organs of Refpiration are principally behind, the large fenfible ftigmata, or breathing-holes, being placed there; and which have no fcaly legs, nor any regularly formed membranaceous ones; and which have, under their belly, certain flefhy protuberances, each feeming a portion of a ring, which is inflated at certain times.

Thefe are the characters common to a vaft clafs of thefe creatures, which are transformed into two-winged flies; but feem never to be the marks of thofe which are produced from the eggs of the four-winged clafs. *Reaumur's Hift. Infect.*

RESISTENCE (*Dict.*)— Refiftence of a globe, perfectly hard and in a medium, whofe particles are fo too; is to the force wherewith the whole motion may either be deftroyed or generated which it has at the time, when it has defcribed four thirds of its diameter, as the denfity of the medium to the denfity of the globe.— Hence alfo, infers Sir Ifaac Newton that the Refiftence of a globe is, cæteris paribus, in a duplicate ratio of its velocity. Or its Refiftence is cæteris paribus, in a duplicate ratio of its diameter. Or, cæteris paribus, as the denfity of the medium. Laftly, that the actual Refiftence of a globe is in a ratio compounded of the duplicate ratio of the velocity, and of the duplicate ratio of the diameter, and of the ratio of the denfity of the medium.

In thefe articles, the medium is fuppofed to be difcontinuous, as air probably is; if the medium be continuous, as water, mercury, &c. where the globe does not ftrike immediately on all the particles of the fluid generating the Refiftence, but only on thofe next it, and thofe again on others, &c. the Refiftence will be lefs by half. And a globe in fuch a medium undergoes a Refiftence which is to the force wherewith the whole motion it has, after defcribing eight thirds of its diameter, might be generated or taken away, as the denfity of the medium to the denfity of the globe.

RESISTENCE *of a cylinder* moving in the direction of its axis, is not altered by any augmentation or diminution of its length, and therefore is the fame with that of a circle of the fame diameter moving with the fame velocity in a right line perpendicular to its plane.

The Refiftence of a cylinder moving in an infinite unelaftic fluid, arifing from the magnitude of a tranfverfe fection, is to the force wherewith its whole motion, while it defcribes four times its length, may be taken away or generated, as the denfity of the medium to that of the cylinder, very nearly.

Hence, the Refiftences of cylinders moving length-wife, in infinitely continued mediums, are in a ratio compounded of the duplicate ratio of their diameters, the duplicate ratio of their velocities, and the ratio of the denfity of the mediums.

The Refiftence of a globe in an infinite unelaftic medium is to the force whereby its whole motion, while it defcribes eight thirds of its diameter, might be either generated or taken away, as the denfity of the fluids to the denfity of the globe, quam proximè.

Mr. James Bernoulli demonftrates the following theorems.

RESISTENCE *of a triangle*.— If an ifofceles triangle be moved in a fluid according to the direction of a line perpendicular to its bafe; firft, with the vertex foremoft, and then with its bafe; the Refiftence will be as the legs, and as the fquare of the bafe, and as the fum of the legs.

The RESISTENCE *of a fquare* moved according to the direction of its fide, and of its diagonal, is as the diagonal to the fide.

The RESISTENCE *of a circular fegment*, lefs than a femicircle carried in a direction perpendicular to its bafis, when it goes with the bafe foremoft, and when with its vertex foremoft (the fame direction and celerity continuing;) is as the fquare of the diameter, to the fame, lefs one third of the fquare of the bafe of the fegment. — Hence, the Refiftences of a femicircle, when its bafe and when its vertex go foremoft, are to one another in a fefquialterate ratio.

RESISTENCE *of a parabola*.—A parabola moving in the direction of its axis, firft with its bafis, and then its vertex foremoft, has its Refiftences as the tangent to an arch of a circle, whofe diameter is equal to the parameter, and the tangent equal to half the bafis of the parabola.

The Refiftence, if the vertex go foremoft, may be thus computed:—Say as the fum (or difference) of the tranfverfe axis, and latus rectum, is to the tranfverfe axis; fo is the fquare of the latus rectum to the fquare of the diameter of a certain circle, in which circle apply a tangent equal to half the bafis of the hyperbola or ellipfis. — Then fay again, as the fum (or difference) of the axis and parameter, is to the parameter; fo is the aforefaid tangent to another right line. And farther, as the fum (or difference) of the axis and parameter is to the axis; fo is the circular arch, correfponding to the aforefaid tangent, to another arch. This done, the Refiftences will be as the tangent to the fum (or difference) of the right line thus found, and the arch laft mentioned.

In the general, the Refiftences of any figure whatever, going now with its bafe foremoft, and then with its vertex, are as the figures of the bafe to the fum of all the cubes of the element of the bafe, divided by the fquares of the element of the curve line.

All which rules may be of ufe in the conftruction of fhips, and in perfecting the art of navigation univerfally: as alfo for determining the figures of the balls of pendulums for clocks, &c.

REST (*Dict.*)—Reft is either abfolute or relative as place is.

Some define Reft, the ftate of a thing without motion; and hence, again, Reft becomes either abfolute or relative, as motion is.

Sir Ifaac Newton defines true or abfolute Reft to be the continuance of a body in the fame part of abfolute and immoveable fpace: and relative Reft to be the continuance of a body in the fame part of relative fpace.

Thus, in a fhip under fail, relative Reft is the continuance of a body in the fame region of the fhip, or the fame part of its cavity.— True or abfolute Reft is its continuance in the fame part of univerfal fpace, wherein the fhip with its cavity and contents are all contained.

Hence, if the earth be really and abfolutely at Reft, the body, relatively at Reft in the fhip, will really and abfolutely move; and that with the velocity wherewith the veffel moves. — But, if the earth do likewife move, there will then arife a real and abfolute motion of the body at Reft, partly from the real motion of the earth in abfolute fpace, and partly from the relative motion of the fhip on the fea.—Laftly, if the body be likewife relatively moved in the fhip, its real motion will arife partly from the real motion of the earth in immoveable fpace, and partly from the relative motion of the fhip on the fea, and o the body in the fhip.

Thus, if that part of the earth where the fhip is, move eaftward with a velocity of 10010 parts; and the veffel be carried by the winds weftward ten parts; and at the fame time a feaman aboard walk with a velocity of one part: the feaman will be moved really and abfolutely in immoveable fpace eaftwards with 10001 parts of velocity; and relatively on the earth, with nine parts of velocity weftwards.

It is an axiom in philofophy, that matter is indifferent as to Reft, or motion.—Hence, Sir Ifaac Newton lays it down as a law of nature, that every body perfeveres in its ftate either of Reft, or uniform motion, except fo far as it is difturbed by external caufes.

The Cartefians will have firmnefs, hardnefs, or folidity of bodies to confift in this, that their parts are at Reft, with regard to each other: and this Reft they eftablifh as the great nexus, or principle of cohefion, whereby the parts are connected together.

Fluidity, they add, confifts in a perpetual motion of the parts, &c.—But the Newtonian philofophy furnifhes us with much better folutions.

REST *in mufic* (*Dict.*)—Refts are fometimes ufed in melody, that is, in mufic of a fingle part, to exprefs fome fimple paffion, or even for variety fake; but more frequently in harmony, or compofitions of feveral parts, for the fake of the pleafure of hearing one part move on while another refts; and this interchangeably.

Refts are either for a whole bar, or more than a bar, or but for a part of a bar. When the Reft is for a part, it is expreffed by certain figns correfponding to the quantity of certain notes of time; as minim, crotchet, &c. and is accordingly called minim Reft, crotchet Reft, &c.

The characters or figures, whereof, fee under CHARACTERS of mufic in the Dictionary; where the notes and correfponding Refts are found together.

When any one of thofe characters occurs either on a line or fpace, ſpace, that part is always ſilent for the time of a minim, or crotchet, &c. — Sometimes a Reſt is for a crotchet and quaver together; or for other quantities of time, for which there is no particular note: in which caſe the ſigns of ſilence are not many Reſts, but ſuch ſilence is expreſſed by placing together as if multiplied, as many as make up the deſigned Reſt. When the Reſt is for a whole bar, the ſemibreve Reſt is always uſed. —If the Reſt be for two meaſures, it is marked by a line drawn a-croſs a whole ſpace.—For three meaſures it is drawn a-croſs a ſpace and a half; and for four meaſures a-croſs two ſpaces. But, to prevent ambiguity, the number of bars is uſually writ over the ſign.

Some of the more ancient writers in muſic make theſe Reſts of different value in different ſpecies of time.— For inſtance, the character of a minim Reſt, in common time, ſay they, expreſſes the Reſt of three crotchets in triple time; in that of the triples $\frac{6}{4}$, $\frac{6}{8}$, $\frac{12}{4}$, $\frac{12}{8}$, it always marks an half meaſure, how different ſoever theſe may be among themſelves.

They add that the Reſt of a crotchet in common time is a Reſt of three quavers in the triple $\frac{6}{8}$; and that the quaver Reſt of common time is equal to three ſemi-quavers in the triple $\frac{6}{16}$. But this variety in the uſe of the ſame character is now laid aſide.

RETI'CULA, Reticule, in aſtronomy, a contrivance for the exact meaſuring the quantity of eclipſes, introduced about fifty years ago by the royal academy of Paris.

The Reticule is a little frame, conſiſting of thirteen fine ſilken threads, equidiſtant from each other, and parallel; placed in the focus of object-glaſſes of teleſcopes; that is, in the place where the image of the luminary is painted, in its full extent. —Of conſequence, therefore, the diameter of the ſun or moon is hereby ſeen divided into twelve equal parts or digits; ſo that, to find the quantity of the eclipſe, there is nothing to do but to number the luminous and the dark parts.

As a ſquare Reticule is only proper for the diameter, not for the circumference of the luminary; it is ſometimes made circular, by drawing ſix concentric equi-diſtant circles, which repreſents the phaſes of the eclipſe perfectly.

But it is evident that the Reticule, whether ſquare or circular, ought to be perfectly equal to the diameter or circumference of the ſtar, ſuch as it appears in the focus of the glaſs; otherwiſe the diviſion cannot be juſt.

Now this is no eaſy matter to effect, by reaſon the apparent diameters of the ſun and moon differ in each eclipſe; nay that of the moon differs from itſelf in the progreſs of the ſame eclipſe.

Another imperfection in the Reticule is, that its bigneſs is determined by that of the image in the focus, and of conſequence will only fit one certain magnitude.

But M. de la Hire has found a remedy for all theſe inconveniences, and contrived that the ſame Reticule ſhall ſerve for all teleſcopes, and all altitudes of the luminary in the ſame eclipſe. —The principle whereon his invention ſtands, is, that two object-glaſſes applied againſt each other, having a common focus, and there forming an image of a certain magnitude; this image will increaſe in proportion as the diſtance between the two glaſſes is increaſed, as far as a certain limit.

If then a Reticule be taken of ſuch a magnitude as juſt to comprehend the greateſt diameter the ſun or moon can ever have in the common focus of two object-glaſſes applied to each other; there needs nothing but to remove them from each other, as the ſtar comes to have a leſs diameter, to have the image ſtill exactly comprehended in the ſame Reticule.

Another improvement is, that whereas the ſilken threads are ſubject to ſwerve from the paralleliſm, &c. by the different temperature of the air; a Reticule may be made of a thin looking-glaſs, by drawing lines or circles thereon, with the fine point of a diamond; which ſhall be ſafe from any alteration of the air.

RE'TINA (*Dict.*)—The Retina is liable to two ſorts of diſeaſes; the firſt is a ſeparation of ſome parts of this membrane from the choroides. At the place where this ſeparation is made, there follows an elevation or fold, which ſtops the light, and hinders its paſſage to that part of the choroides which is covered by this fold; this occaſions a ſort of a ſhade, which the patients ſee in the air. The ſecond diſeaſe of the Retina is an atrophy or waſting of that membrane.

The cauſe of the firſt diſeaſe may, with a great ſhew of reaſon, be thus accounted for, that the blood-veſſels of the Retina become varicous; for it is eaſily conceived that the dilatation of theſe veſſels may ſeparate the Retina from the choroides, in that part which anſwers the dilated veſſels. I have always obſerved this diſeaſe to proceed from a cold in the head, after ſome violent exerciſe, or whatever elſe may have put the blood into a violent motion. Hence, I infer, that the external cold, by obſtructing the pores of the ſkin, has ſtopped the perſpiration of ſome part of the humours rarefied in the blood-veſſels, on the ſurface of the Retina; which, from the fineneſs of its texture, is damaged by this infraction, after the above-mentioned manner. I call this diſeaſe a ſeparation of the Retina from the choroides. As this membrane fills a conſiderable ſpace in the eye, this ſeparation is often made in ſeveral places; ſo that the ſigns of this diſeaſe anſwer to the number of the parts ſeparated.

Its ſigns are certain appearances in the air, more or leſs diſtant from the patient's eyes. They are a kind of ſhadows of different figures, modified according to the ſize and form of the parts of the Retina, which is ſeparated.

As to the prognoſtic, there is no danger of loſing the ſight in this diſeaſe; it is only troubleſome to the patient. As this diſeaſe begins with the ſame ſigns as a cataract, one diſorder may be taken for another; but to prevent the like miſtake, we ſhall propoſe the difference. In a cataract the ſight ſhortens and decays daily; whereas, in the preſent diſeaſe, the ſight continues the ſame both in quickneſs and extent.

Though remedies do not perfectly cure this diſeaſe, and that the perſons, once attacked with it, ſee ſome of theſe ſhades all their life, their number and compaſs in breadth may be ſtill leſſened. The following remedies are of ſervice; ſuch are broths made of crabs, repeated purges, eye-bright, tea drunk in the morning, powder of vipers, wood-lice, and eye-bright mixed together.

In an atrophy of the Retina, as the rays of light are not ſufficiently modified in that membrane, they make too vivid an impreſſion on the choroides, which is very detrimental to it. Hence, enſues a confuſed viſion; ſo that the patients, at the firſt look, can ſee very well; but, if they continue to read any time, or to look at any ſhining object, they feel a ſudden wearineſs in their head, and a dimneſs in their ſight, which obliges them to cloſe their eyes; then opening them a moment after they ſee, as at the firſt look, but for a ſhort time.

Embroiderers, ſtocking-weavers, and ſhoe-makers are ſubject to this diſeaſe; the firſt, becauſe the brightneſs of the gold, ſilver, and other colours damages the ſight by the lively impreſſion it makes on the eye; and the ſhoe-makers, in order to find the hole made by their awl to run the end through it, by this continual attention, fatigue and weaken their ſight ſo much that they are obliged to quit their trade. Theſe people can work but a few days in the week.

There are ſome people, though they do not work at theſe handicrafts, cannot, however, make uſe of their ſight a quarter of an hour, but their head is diſordered; of thoſe I chiefly treat.

No remedies cure this diſeaſe. Nothing avails but reſt and little exerciſe of the ſight. All thoſe perſons who are employed at fine or ſhining work, if they have a mind to continue, muſt make uſe of green ſpectacles.

RE'TORT, (*Dict.*)—The quantity of air riſing from ſome ſubſtances is apt to burſt glaſſes in diſtilling; Dr. Browne Langriſh has therefore given us a new contrivance of applying receivers to Retorts, by which ſuch accidents may be prevented.

To his firſt receiver he adapts a ſecond, inſerted into an opening at the top of the firſt, in order to give more room to the rarefied and new generated air. To an opening, at the bottom of each of theſe receivers, he fixes a bottle tied on cloſe by means of a bladder, ſo that they may be removed at any time, and another inſtantly placed in their room, by which means very little of the ſteam will eſcape. He alſo ties on a bladder to an opening, or upper neck of the ſecond recipient; and this bladder, being much thinner and weaker than any of the glaſſes, will always give way firſt, and prevent their burſting. And, even when there is the greateſt danger of this accident, the ſmalleſt pin-hole made through the top of the bladder, as ſoon as the fumes begin to riſe, will be ſufficient to let out the air as faſt as it is generated.

REY *graſs*, in huſbandry, a hardy ſort of graſs, much eſteemed among the farmers for that quality. It will grow on any land, and therefore produces crops where nothing elſe will. It thrives beſt of all on ſowre, clayey, and weeping grounds, and equally endures the ſevereſt droughts of ſummer, and froſts of winter, ſuffering no damage from either. It is the beſt of all winter foods for cattle, the ſhorter it is eaten the better, and it ſprings the earlieſt of any. There is no danger of over-ſtocking it, for, if it be left to grow too much, the ſtalk becomes hard and ſticky. It is beſt for horſes and for ſheep, and very much prevents the rotting of the latter. The beſt way of ſowing it is with clover. The common quantity of ſeed is two buſhels to an acre, but three buſhels is much better; though in ſome lands, where the clover is likely to ſucceed very well, they ſow eight pounds of clover ſeed and one buſhel of Rey ſeed to an acre, and this makes a crop that will laſt ſeven or eight years.

Some mow it as hay, and thraſh it for the ſeed, which, about London, ſells from half-a-crown a buſhel to three ſhillings. Four or five quarters of this ſeed will be ſometimes produced from an acre of the graſs. If at any time a field of this graſs is found to grow thin, it is only neceſſary to ſtrew on a buſhel of the ſeed, and roll it with a wooden roller, and the plants riſing from this addition will make the whole crop ſufficiently thick. Rey graſs has this great advantage, that it kills weeds without any other ſown plant; even thiſtles cannot grow among it. When the Rey graſs is cut for hay before perfectly ripe, the hay is the better; but the ſeed will not grow ſo well. When the ſeed is newly thraſhed, it muſt not be laid too thick, for it is very apt to heat and ferment, and the whole will be ſpoiled. *Mortimer's Huſbandry.*

RHE'UMATISM (*Dict.*)—The preceding cauſes of this diſorder

der are, a sanguineous habit, accompanied with an acrimony of the juices, a mature age, luxurious living, a sudden admission of the cold to the body, when over-heated; the influence of the weather in the autumn, an obstruction of perspiration, and a tough inflammatory state of the fluids, to be discovered by a pleuritic blood. It begins with a continual fever, and creates a violent dilacerating pain, which is greatly increased upon the smallest motion, is long fixed in one place, seizes the joints of any of the limbs, and is particularly incident to the knees, the loins, and the coxendix. It also sometimes affects the brain, lungs, and viscera, is accompanied with a tumor and redness of the part, and comes and goes periodically.

If it remains for a considerable time, and is increased, it often, after the most violent pains, deprives the limb of motion, and produces an anchylosis, which will hardly yield to any medicine.

The immediate cause of a Rheumatism seems to be so mild an inflammation, as not to degenerate into a suppuration in the lymphatic arteries of the membranes, contiguous to the ligaments of the joints. It is cured by venesection; repeated antiphlogistic purgatives, every evening after which a proper narcotic is to be exhibited; by mild tepid baths, and antiphlogistic fomentations applied to the parts affected; by drastic vesicatories and cauteries; by highly diluting and emollient medicines; by attenuating food; by rest, and the warmth of the bed; and towards the end of the cure by frictions with warm dry cloths, together with the use of antiscorbutic medicines.

A lumbago or Rheumatism seizing the loins, and sciatic pains, are cured in the same manner, though with somewhat greater difficulty.

Hence appear the reasons why this disorder is so frequent, and its appearances so various; why it is highly dangerous, when it seizes the brain or lungs; why in these parts it is not discovered without the greatest difficulty; and why the use of hot substances, or the too speedy exhibition of narcotics, must be dangerous in it. *Boerhaave's Aphor.*

This disease happens at any time, but especially in autumn, and principally affects such as are in the vigour of life. It is generally occasioned by exposing the body to the cold air, immediately after having heated it by violent exercise, or some other way. It begins with a chilness and shivering, which are soon succeeded by heat, restlessness, thirst, and the other concomitants of a fever. In a day or two, and sometimes sooner, there arises an acute pain in some one or other of the limbs, especially in the wrists, shoulders, and knees, which, shifting between whiles, affects these parts alternately, leaving a redness and swelling in the part last affected. In the beginning of the illness the fever, and the above-mentioned symptoms, sometimes come together; but the fever goes off gradually, whilst the pain continues, and sometimes increases, occasioned by the derivation of the febrile matter to the limbs; which the frequent return of the fever, from the repulsion of the morbific matter by external remedies, sufficiently shews.

This disease, when unattended with a fever, is frequently taken for the gout, though it differs essentially therefrom, as will easily appear to those who are thoroughly acquainted with both diseases; and hence it is, perhaps, that physical authors have not mentioned it; unless we should esteem it a new disease. But, however this be, it is at present very frequent, and though, when the fever is gone off, it seldom proves fatal, yet the violence of the pain, and its long continuance, render it no contemptible disease. For, in case of wrong management, it frequently remains not only several months, but some years, and even during life; though in this case it is not equally painful, but has its periodical returns, like the gout; and the pain may possibly go off spontaneously, after it has been of very long standing. But, in the mean time, the patient is deprived of the motion of his limbs during life, the joints of his fingers being contracted inwards, with stony concretions as in the gout, which rather appear in the internal parts of the fingers than the external, while the appetite may be very good, and the general health not amiss.

There is another species of this disease, though it is not generally esteemed of this kind, which may properly be called a rheumatic lumbago. It is a violent fixed pain in the loins, reaching sometimes to the os sacrum, and resembling a nephritic paroxysm; only the patient does not vomit. For, besides the intolerable pain near the kidneys, the whole conduit of the ureters, even to the bladder, is sometimes affected with the same, though in a less degree. I have been formerly led into an error hereby, as imagining it to arise from some gravel lodged in these parts; whereas, in reality, it proceeds from the peccant and inflamed matter of the Rheumatism, which affects only those parts, leaving the rest of the body free. Unless this acute pain be removed in the same manner as the former species, it continues as long, and proves equally violent; so that the patient cannot lie in bed, but is forced either to leave it, or sit upright therein, and be perpetually moving his body backwards and forwards.

Since both the kinds of this disease seem to arise from inflammation, as appears from their concomitants just mentioned, and especially by the colour of the blood taken away, which exactly resembles that of persons in a pleurisy, which is universally allowed to be an inflammatory disease; so I judge that the cure ought to be attempted only by bleeding, the heat of the blood being in the mean time abated by cooling and incrassating medicines, along with a proper regimen.

Accordingly, as soon as I am called, I direct ten ounces of blood to be immediately taken away from the arm or the side affected, and prescribe a cooling and incrassating julap, nearly after the following manner:

Take of the distilled waters of lettice, purslain, and water lily, each four ounces; syrup of lemons, an ounce and half; syrup of violets, an ounce; mix them together for a julap, of which let the patient drink at pleasure; or of the following emulsion:

Take seven blanched sweet almonds; of the seeds of melons and pompions, each half an ounce; the seeds of white poppies, two drachms: beat them together in a marble mortar, then pour on, by degrees, a pint and half of barley-water; mix them well, and, when strained, add two drachms of rose-water, and half an ounce of white sugar.

To ease the pain, I order a cataplasm, prepared of the crumbs of white-bread and milk impregnated with saffron; or a cabbage-leaf to be applied to the part affected, and frequently renewed. With respect to diet, I enjoin a total abstinence from flesh, and even the thinnest flesh-broths, substituting in their place barley-broth, water-gruel, panada, and the like. I allow only small-beer for drink, or, which is more proper, a ptisan prepared of pearl-barley, liquorice, sorrel-roots, and the like, boiled in a sufficient quantity of water. I, also, advise the patient to sit up some hours every day, because the heat which proceeds from always lying in bed, promotes and augments the disease.

The next day I repeat the bleeding in the same quantity; and in a day or two after, as the strength will permit, I bleed again; then interposing three or four days, as the strength, age, constitution of the patient and other circumstances indicate, I bleed a fourth time, which is generally the last, unless too hot a regimen has preceded, or heating remedies have been exhibited without necessity. But the use of opiates requires more frequent bleeding; and therefore, though the pain be ever so violent, during the whole course of the disease, yet, when I intend to effect the cure solely by bleeding, I judge it highly necessary to refrain from opiates, because the disease is fixed thereby, and does not yield so readily to bleeding; so that, where such medicines are given too frequently, bleeding must in consequence be oftener repeated than is otherwise necessary. Besides, in the height of the disease they do not answer the expectations we have conceived of them.

While the abovementioned remedies and regimen are carefully continued, I inject clysters made of milk and sugar, between times, on the intermediate days of bleeding; earnestly recommending the exact observance of these directions, for at least eight days after the last bleeding; and then I prescribe a gentle purging potion to be taken in the morning, and in the evening a large dose of syrup of white poppies in cowslip-flower water; whereby a check is put to the tumultuary motion of the blood, which might otherwise endanger a relapse. This being done, I allow the patient to return by degrees to his customary way of living, with respect to diet, exercise, and air; but at the same time caution him to refrain, for a considerable time, from wine, and all spirituous liquors, salt or high-seasoned flesh, and in general from all food of difficult digestion.

After having repeated bleeding, as above specified, the pain is greatly abated, though it does not go quite off; but, as soon as the strength returns, which bleeding had greatly impaired, the symptoms will vanish, and the patient recover perfectly; especially upon the approach of the following season of the year, which will be more conducive to recruit the strength, than that wherein he was first attacked with the disease.

But though this, or a similar method, seasonably used in the beginning of the disease, generally proves successful; yet it frequently happens, when the cure is attempted by a contrary procedure, that the patient is severely afflicted, during life, with flying pains, which are sometimes violent, and at others more gentle; whereby the unskilful are easily deceived, and they are commonly reckoned symptoms of the scurvy.

But it is here to be observed, that, when the Rheumatism hath taken deep root by a continuance of some years, it is improper to repeat bleeding at such short intervals as in the beginning of the disease, and better to interpose some weeks between the operations. By these means the morbific matter will either be quite exhausted, or at least in so great a degree, that the remains of it may be carried off entirely, by an issue made in one of the legs, and exhibiting a proper quantity of some volatile spirit, every morning and evenings in canary.

But, though there is a remarkable difference between the true Rheumatism and the scurvy, it must nevertheless be owned, that there is another species of the Rheumatism, which is near a kin to the scurvy: for it resembles it in its capital symptoms, and requires nearly the same method of cure; and therefore I call it a scorbutic Rheumatism. The pain sometimes affects one, and sometimes another part; but it rarely occasions a

swelling,

ſwelling, as in the other ſpecies, neither is it attended with a fever. It is, alſo, a leſs fixed pain, and accompanied with irregular ſymptoms; ſometimes it affects one limb, and ſometimes another; ſometimes it only attacks the internal parts and cauſes ſickneſs, which goes off again upon the return of the pain in the external parts. In this manner the patient is alternately afflicted, and the diſeaſe proves of long duration, like thoſe diſtempers which are eſteemed moſt chronical. It principally attacks the female ſex, and men of weak conſtitutions; ſo that I ſhould have concluded it ought to be referred to the tribe of hyſteric diſorders, had not repeated experience taught me, that it would not yield at all to hyſteric remedies.

Such, likewiſe, as have gone through a long courſe of the Peruvian bark, are ſubject to this diſeaſe, which, by the way, is the only ill effect I have ever obſerved from the uſe of this medicine. But, however it be, this diſeaſe, whether it proceeds from this or any other cauſe, is eaſily conquered by the uſe of the following remedies, which I ſhould have concealed, had I not preferred the good of mankind to any private intereſt:

Take of the conſerve of garden ſcurvy-graſs, two ounces; conſerve of wood-ſorrel, an ounce; compound powder of arum, ſix drachms; ſyrup of oranges, enough to make the whole into an electuary; two drachms of which is to be taken three times a day, for a month, drinking after it three ounces of the following diſtilled water:

Take of garden ſcurvy-graſs, eight handfuls; of water-creſſes, brook-lime, ſage, and mint, each four handfuls; the peel of ſix oranges; nutmegs bruiſed, half an ounce; infuſe them in ſix quarts of mum, and draw off only three quarts for uſe, in a common ſtill.

RHINO'CEROS, in zoology, the name of a genus of quadrupeds; ſo called from an horn growing on their noſe.

Of this genus there are only two known ſpecies. 1. The Rhinoceros with only one horn on its noſe; and, 2. The Rhinoceros with two horns.

In the year 1739 we had a young Rhinoceros ſhewn in England, of which Dr. Parſons has given a very accurate account in the *Philoſophical Tranſactions*.

The creature fed on rice, ſugar, and hay; his keeper uſed to mix the rice and ſugar in the following manner: ſeven pounds of rice and three pounds of ſugar made the proviſion for one day; he eat this at three meals; and beſides this, he eat about a truſs of hay every week, and a large quantity of greens that were brought to him, at different times, and of which he ſeemed more fond than of dried food. He drank often, and always was obſerved to ſwallow a large quantity of water at a time.

He appeared very peaceable in his temper, and bore to be handled on any part of his body, with great patience, except when he was hungry; but he was then always outrageous, as alſo when he was ſtruck. His moſt violent paſſions, even on the laſt occaſion, were however always immediately appeaſed by giving him victuals.

Notwithſtanding the lumpiſh aſpect, and heavy make of this creature, he would jump about very nimbly in his fits of paſſion, and often leap to a great height; and one common mark of his fury was the ſtriking his head againſt the walls, or any thing elſe that was in the way, and this he would do with terrible violence. He was very apt to fall into theſe paſſions in a morning before his rice and ſugar were given him, and from the whole he appeared quite untractable, and ſeemed able, in his paſſions, to have run ſo faſt, as that a man on foot could not have eſcaped him.

This creature was two years old, and did not exceed a young heifer in height, but was remarkably broad and thick. His head was very large; and the hinder part of it, near the ears, remarkably elevated above the reſt of the face, which was flat and ſunk down, in a remarkable manner in the middle, riſing again towards the origin of the horn, but in a much ſmaller degree. The horn ſtands upon the noſe of the animal as upon a ſort of hill; and when the ſceleton of the head is ſeen, that part of the ſkull on which the horn is fixed, is found to riſe into a blunt cone, to anſwer to a cavity in the baſis of the horn, which is very hard and ſolid; in other reſpects having no manner of hollow or core, like thoſe of other quadrupeds. The horn in this young animal did not riſe above an inch high from its tough baſis, and was black and ſmooth at the top, but ragged downwards; and the determination of its growth is backwards, not ſtraight up; this is very evidently ſeen in the horns of old Rhinoceroſes, which are always curved in a conſiderable degree that way. If we conſider the proportion of this animal's ſize to the length of its horn, and thence carry the proportion to that between the large horns we ſee in the muſeums of the curious, we muſt ſuppoſe the animal of a very ſtupendous ſize, when at its full growth. *Phil. Tranſ.* N°. 470.

The ſides of the under jaw, in this creature, ſtand very wide aſunder, ſlanting outwards to the lower edge, and backwards to the neck; the edges turn outwards from this ſtructure of the bones, and the head neceſſarily looks very large. That part of the head which reaches from the fore-part of the horn to the upper lip may be called the noſe; this is very thick and bulky, and has a kind of circular ſweep down towards the noſtrils; on all this part there are a great number of rugæ or wrinkles.

The noſtrils are ſituated very low, in the ſame direction with the opening of the mouth, and not more than an inch from it; and when viewed in a fore-view, the whole noſe, from the top of the horn to the verge of the lower lip, is ſhaped like a bell. The under lip is like that of an ox, but the upper more like that of a horſe, and he uſes it as that creature does, to gather up hay from the rack, or graſs from the ground; but with this ſuperior advantage, that this creature has a power of extending this lip to ſix or ſeven inches in length from the noſe, and there drawing it to a point; with this lip, thus extended, the creature is able to graſp a ſtick, or any ſmall ſubſtance, and hold it extremely faſt; and this power of prolonging the lips ſerves, in many purpoſes, to the ſame end as the trunk of that other unweildy animal the elephant.

The tongue of the Rhinoceros is ſaid to be ſo rough as to be able to rub a man's fleſh off from the bones; but in this young ſubject it was ſo ſoft, that it reſembled that of a calf. It may poſſibly grow harder with age; but the ſtory of its effects ſeems of a piece with the many other falſe marvels reported of this animal. The eyes are dull and ſleepy, much like thoſe of a hog in ſhape; he ſeldom opens them entirely; and it is to be obſerved, that they are ſituated nearer the noſe than thoſe of any other known quadruped. The ears are broad and thin towards the top, much like thoſe of a hog; but they ariſe each from a narrow round baſe, with ſome wrinkles on it, which iſſues out of a ſinus as it were ſurrounded with a fleſhy fold. The neck is very ſhort, and has two folds or wrinkles, wholly ſurrounding it, only that the anterior one is broken underneath; and has a flap hanging from it ſo deep, that it would contain a man's hand; from the middle of the poſterior plica of the neck, there ariſes another, which paſſing backward, is loſt before it reaches the body. The ſhoulders are thick and heavy, and have each a fold paſſing downwards. The body is very large and thick, and ſtands out at the ſides like that of a cow with calf. The legs are very thick and ſtrong; they are round, and ſomewhat ſmaller downwards than in the upper part; and when the creature ſtands upright, they bend inwards at the knee, ſo that they are nothing like ſtraight. In ſome quadrupeds the fetlock bends to the weight of the animal, but in this creature there is no appearance of any ſuch bending, ſo that he ſeems to ſtand upon four ſtumps, eſpecially when viewed behind. He has three hoofs upon each foot forward, but the back part is a great maſs of fleſh, rough like the reſt of the ſkin; and the ſole of the foot is very plump and callous in the ſurface, but eaſily yielding to the preſſure from the ſoftneſs of the ſubjacent fleſh. Its ſhape is like that of a heart, with a blunt apex before, and a broad baſe behind. The tail is very ſmall in proportion to the ſize of the animal, not exceeding ſeventeen or eighteen inches in length, and but thin or ſlender; it is very rough, and has a kind of twiſt or ſtricture towards the extremities, ending in a flat maſs; this gave occaſion to ſome authors to compare the whole tail to a ſpatula; on the ſides of this flat part, there grew a few ſhort, but very thick and ſtrong black hairs, but theſe grow much longer in the more advanced ſtate of the creature; and are not round, like other hairs, but flat, like ſmall pieces of whalebone. The creature has no other hair about it, except a very ſmall quantity at the edge of the ears. See two views of this creature, *Plate* XL. *fig.* 5, 6.

The penis of the male Rhinoceros is of a very remarkable ſtructure, being incloſed in two caſes. The female differs in nothing from the male except in the pudenda which are ſhaped like thoſe of a cow.

The ſkin of the Rhinoceros is thick, and ſeems almoſt impenetrable; it feels like a piece of board of half an inch thick. It is covered in all parts, more or leſs, with a ſort of incruſtations reſembling ſcales. Theſe are ſmall on the neck, and largeſt of all in the ſhoulders and hips; between the folds of this thick ſkin, the cuticle, which is left bare, is ſoft, and eaſily penetrable. The ſcabby incruſtations of the ſkin have been called ſcales, by ſome writers; but this is a very wrong term, for they have nothing of the nature of ſcales, nor any thing of regularity in them.

The creature is of the retromingent, and therefore probably of the retrogenerative kind; the penis, when erect, is not more than nine, or at the utmoſt ten inches long, and is curved backwards at the end. This was the deſcription of the Rhinoceros ſhewn in England at this time, and of all the others that have been ſeen in this part of the world, as to the general characters; but though theſe creatures which we have ſeen, have but one horn, it is very certain that there is a ſpecies of Rhinoceros which has two. Martial has mentioned a Rhinoceros, as ſhewn in the amphitheatre at Rome, which had two horns; but his commentators, ſuppoſing the copies erroneous, have been at great pains to alter it, ſo as to make it expreſs what they had ſeen or heard of, that is, a Rhinoceros only with one horn; but it appears from almoſt indiſputable teſtimony, that there not only is in nature ſuch a Rhinoceros with two horns, but that ſuch were ſhewn in the public ſports at Rome, and therefore the text ſeems to have been very right, and the commentators in the wrong. The creatures we have ſeen

R I C

seen have indeed only had one horn; and the accounts of travellers, and the great number of horns preserved in the cabinets of the curious, which are all single, seem to prove this; but, though the Rhinoceroses of Asia are all one-horned, yet it is certain, that there is a kind found in Africa which has two horns, and it is known, that the Romans had beasts from this last part of the world as well as the other. Peter Kolbe, in his Voyage to the Cape of Good-Hope, describes Rhinoceroses which he saw, and which had a horn on the nose, and another close behind it. Sir Hans Sloane's museum affords two horns of a Rhinoceros, standing just as this author has described them, which are still fixed to the same integument; and we are convinced of the Romans being acquainted with this species, from a brass medal of Domitian, which has on it a Rhinoceros, with two horns on the nose placed in this manner.

Redi who has been very sagacious in discovering the falsity of many of the pretended medicines taken from animals, yet gives us, on the testimony of his own experience, an account of some very remarkable virtues in the parts of the Rhinoceros. The blood he assures us is excellent in cholics and dysenteries. The decoction of the skin, he assures us, is a grand stomachic antidote, and the horns are very valuable and alexipharmic.

RHINOCEROS *avis, the Rhinoceros bird*, a name given by authors to a species of Indian raven, called by others corvus Indicus cornutus. The beak of which is frequently brought over into Europe.

It is a very ugly bird, and of a very rank smell. It much exceeds the European raven in bigness, and its head and neck are very thick. Its eyes are very large, and its beak of a very remarkable figure; having a large and thick horn-like protuberance on its upper part. The whole beak is bent like a bow, not hooked at the end like the beaks of the hawk, &c. It is of a yellowish white below, and on the upper part towards the head is of a fine gay red, and the rest of a yellowish white: the upper chap is serrated. The horn grows out from the head with this, and runs along it, and bends up at its extremity; its upper and under parts are red, its middle yellow. The bird feeds on carrion, and the guts of the dead animals. *Aldrovand de Avibus.*

RICKETS, *rachitis (Dict.)*—This disorder is a kind of partial tabes, and consists in an unequal nutrition, by which some parts are deprived of their due nourishment, and waste away, whilst others, receiving more than enough, are preternaturally increased with an incurvation of the bones and spine of the back.

The Cure.

When viscid, tough, and pituitous humours, deposited on the spinal marrow, are the cause of the Rickets, the first intention of cure is to resolve the viscidity of the juices, remove obstructions, and by that means promote a free circulation of the humours through all the body. For this purpose, in order to remove the fountain of the disorder lodged in the primæ viæ, we are, above all things, to use gentle laxatives; not neglecting, if it is necessary, and the constitution of the child admits, the use of mild emetics, consisting of a few grains of the root of ipecacuanha, exhibited with sugar and cinnamon-water, prepared without wine, or reduced to the form of an electuary, with some proper syrup; for by these means the viscid sordes, collected in the stomach and intestines, are not only excellently eliminated, but, also, by the stimulus of such medicines, a due resolution of the humours, and an opening of the obstructed vessels, are successfully obtained: only such stimulating medicines are not to be exhibited to patients whose strength is exhausted, who labour under any disorder of the mesentery, or a violent obstruction of the viscera; since, in such cases, it is more expedient to exhibit medicines of the deobstruent kind.

To the medicines already recommended we may also, now and then, add those of a gently resolvent kind, as diaphoretics generally are; such as the tincture of tartar, the acrid tincture of antimony, and preparations of cinnabar; which, in the Rickets, are preferable to mercurials, and highly beneficial in eliminating the serous impurities, partly by perspiration, and partly by urine; especially if they are exhibited in such infusions as dilute and purify the blood.

But, in particular, for removing the obstruction of the spinal marrow, and restoring the influx of the nervous fluid into it, various authors recommend frictions of the spine of the back, arms, and legs, with warm linen cloths; as also fumigations of frankincense, amber, mastich, and olibanum. But I can, from experience, recommend, as the most effectual remedy, baths of sweet water, boiled with nervous herbs, such as marjoram, lavender, mother of thyme, rosemary, chamomile, and baum. In such baths, the patient is to be frequently immersed, and have the spine of the back and joints rubbed and anointed with the following nervous ointment.

Take of human fat, and expressed oil of nutmegs, each half an ounce; of Peruvian balsam one drachm, and of the oils of rue, lavender, and cloves, each thirty drops.

By these means I have often seen many patients afflicted with the Rickets, not only surprisingly relieved, but also totally recovered.

When the Rickets are of a long standing, the patient's head is preternaturally large, and its sutures gaping; the thorax at the sides is compressed to the sternum, which rises in a kind of sharp arch; the extremities of the ribs are full of knots; the abdomen protuberant, and the teeth carious and black; which symptoms gradually increasing, frequently through the whole of the patient's life, produce the like terrible disorders, especially a spina ventosa, and a caries of the bones.

During the whole course of the Rickets, a slow fever preys upon the body, till the patient dies; and then in the carcase all the fibres, membranes, vessels, and viscera, are found soft and flaccid, while the humours are colliquated and mucous.

Hence, the immediate cause of the Rickets is, a languid, mucous cold, and vapid cacochymy, perhaps complicated with a latent venereal taint, and accompanied with a lax and flaccid state of the solid parts.

The cure of the Rickets is most effectually produced by light, easily-digested, dry, lean aliments, seasoned with mild aromatics, and frequently exhibited, though in a small quantity; by drinking a small quantity of generous liquors, especially of ale, though not old, but long boiled and thick; by a dry and somewhat hot air; by wearing very dry and warm cloaths, especially such as are made of wool; by lying upon couches prepared of aromatic, corroborating, and drying herbs, laid upon boards, in the upper rooms of the house; by gestation, concussion, oscillation, riding in a chariot in rough roads; by much dry and warm friction, especially of the abdomen and spine, performed with cloths, impregnated with the smoke of aromatic substances; sometimes by the repeated application of cantharides, by gentle emetics, frequently though prudently repeated; by purgatives, and then by corroborating medicines, exhibited for some days successively; and, lastly, by the long continued use of corroborating, drying, antiscorbutic medicines, and such as rouse the spirits. Hence we understand the uses of immersion in cold water, for the cure of this disorder, which, however, is not to be put into practice, till the viscera of the abdomen are, in some measure, eased of the load of humours which oppress them. Hence, also, the proper use of liniments may be understood, which ought to be of the nervous kind, and applied to the abdomen, and spine of the back; but not to the prominent parts of the affected bones.

The best aliments for children labouring under the Rickets are:

1. Well fermented bread and biscuit, mixed with a small quantity of saffron, nutmeg, cardamoms, cinnamon, seeds of celeri, and other grateful and corroborating aromatics.
2. Lean pigeons, fowls, rabbits, mutton, kid, and veal, gently roasted, cut small, and mixed with biscuit, salt, and a little parsley, thyme, and nutmeg.
3. Millet and barley, boiled with water and raisins, and then seasoned with a little wine and mild aromatics.

The most proper drinks for persons labouring under the Rickets are, ripe, red, and astringent French wines, an ounce of which is to be exhibited three or four times a day.

Half an ounce of Hippocratic wine, exhibited at the same time. Brunswick mum, British ale, and that species of Dutch ale which is sold at twelve florins.

With these malt liquors, in the summer-time, may be mixed an equal quantity of medicated chalybeate water, but rather of the spaw-waters.

Take of the following recent leaves dried in a shade, viz. of the male fern, three pounds; of marjoram, baum, and mint, each two handfuls: and of the following recent flowers, also, dried in a shade, viz. of melilot, sweet trefoil, elder, and roses, each two ounces. Reduce to a fine powder. Mix with double the quantity of barley-chaff, and put all into bags for couches, on which the patients are to lie; these are to be carefully preserved from moisture, and frequently dried.

Take of benzoin, mastich, olibanum, amber, and frankincense, each one ounce; reduce to a powder; of which throw a little upon live coals, and the steam arising from it is to be received in cloths, for rubbing the parts.

Take of the roots of ipecacuanha, one scruple; of white French wine, one ounce; and of sugar, two drachms; infuse for a whole night; and when depurated, exhibit in the morning. Let this be repeated every fourth day, for five times.

Take of the best rhubarb, half an ounce; of citrine myrobalans, without the kernels, three drachms; and of the troches of agaric, two scruples. Infuse in four points of cold strong beer, for twenty-four hours; and let the patient use this for common drink for a month: but, if it should prove too purgative, it may be diluted with an equal, or if necessary, a greater quantity of other ale.

The corroborative, drying, exciting, and antiscorbutic herbs, proper for curing the Rickets, are, agrimony, betony, the bark of caper roots, spleen-wort, succory, dorder, finicle, endive, male-fern, liver-wort, hart's tongue, baum, myrobalans, osmund royal, polypody of the oak, the leaves and acorns of the oak, rhubarb, the leaves and root of the bramble, white maiden-hair, scabious, the bark, flowers and leaves of the tamarisk, trichomanes, and male speedwell.

Of these medicated ales, wines and infusions may be prepared and exhibited with great success; as also conserves, and other things of a like nature, thus:

Take of agrimony, spleen-wort, fern-root, hart's tongue, the root of polypody, and white maiden hair, each two ounces. Having cut these small, mix them, and put them in a linen cloth, infuse them in twelve pints of cold ale, to be used for common drink.

Or, take of the leaves and flowers of betony, three ounces; of the bark of the roots of capers, tamarisks, and wild bramble, and of trichomanes, each two ounces; and of filings of steel, half an ounce. Infuse in eight pints of cold white wine, of which one ounce is to be exhibited thrice a day.

Take of Boyle's ens veneris, two grains; which are to be exhibited every evening in Canary wine, for three weeks.

Take of the filings of steel, one ounce; of the strongest distilled vinegar, ten ounces; and of sugar, three ounces. Boil all together gently, for twenty-six hours, in a tall phial; and let the liquor, when filtrated, be kept in a close vessel. Six drops of it are to be exhibited every morning and evening, in a little Spanish wine. *Boerhaav. Aph. & Mat. Med.*

RI'DGES.—The method of plowing land up into Ridges is a particular sort of tillage. The chief use of it consists in the alteration it makes in the degrees of heat and moisture; these being two of the grand requisites of vegetation, and very different degrees of them being requisite to the different sorts of plants. Those plants commonly sown in our fields require a moderate degree of both, not being able to live upon the sides of perpendicular walls in hot countries, nor under the water in cold ones, neither are they amphibious; but they must have a surface of earth, not covered, nor much soaked with water, which deprives them of a proper degree of heat, and causes them to languish. In this case they look weak, and their leaves yellowish. They cease growing, and, in fine, die in a very weak and bad state. The only way to cure the land of giving this disease to plants, is to lay it up in Ridges, that the water may fall off, and run into the furrows below, from whence it may be conveyed by drains and ditches into some river, or otherways carried wholly off from the land.

The more any soil is filled with water, the less heat it will have. The two sorts of land most liable to be overglutted with water are hills, the upper stratum of mould in which lies on clay; and, generally, all deep and strong lands. Hills are made wet and spewy by the wet that falls in rains, dews, and mists; and this wet, not being able to sink through the clay, in these soils, runs down between it and the mould; but extending itself through the mould all the way, and making it continually washy. The plowing this sort of land in Ridges, made from the higher to the lower part of the field, is of no benefit; for the water will press from below upwards in these Ridges, being forced by the addition of fresh supplies above.

There are two methods of draining a hill ground like this. The one is to dig several deep trenches cross-wise, or horizontally on the sides of the hill: let these be nearly filled up with stones, and the surface covered in the common method: the wet will be received into these in all parts, and discharged at the ends; and the plough will go over the stones, without striking through the depth of earth that covers them. Thus, the land will be dried for a time; but, as these channels fill up with earth, between the stones, they become of no use, and the expence of making new ones is very great.

The other way is to plow the land in Ridges almost horizontally, and then the furrows between them are so many drains, carrying off the water at their lower ends; if the plough is made to strike a few inches deep into the clay, and the ends of the furrows are no higher than the other parts: every furrow will be a drain to every Ridge, and the land of the Ridges will be kept dry. If there were no other manner of plowing the Ridges on the sides of hills, than there is in the plain lands, this method of having open furrows or drains on declivities would be impracticable; because the plough could not turn up the furrows against the hill and against the Ridge also, from the lower side of it. But the easy remedy against this inconvenience is to plow such Ridges in pairs, without throwing any earth into the trenches; and then the Ridges will be plain at top, and the rain-water will run speedily downwards to the next trench, and thence to the head land, and so out of the field. These trenches will be made, as well as kept always open, by plowing in pairs; and this is abundantly more easy than the way of plowing Ridges singly.

Every time of plowing the Ridges must be changed as to the pairs; so that the furrow, which had two Ridges, or lands, turned towards it one time, must have two turned from it the next time; and this method keeps the surfaces of all the Ridges or lands pretty nearly even. This, however, cannot be done on a hill, whose declivity is so great, that the plough is not able to turn a furrow against it; but, in this case, perhaps, it may be sufficient to plow the Ridges obliquely enough for the furrows to be turned both ways.

This plowing in an horizontal manner, on hills, is the best of all others; but our farmers are not to be easily brought into it, though they see thin lands of this kind ruined for want of it; their reasons for not doing it, are, that it would prevent the supposed benefit of cross-plowing; and that they lose more ground by having more furrows between the Ridges, than when they lay their lands flat, where the lands are made much larger than the round Ridges can conveniently be. But these are in reality very erroneous, as well as mischievous opinions; for more mischief than good is done by cross-plowing in general; and, instead of any real loss of land by Ridges, the true state of the case is, that much ground is gained by it; that is, the surface of the earth is increased in quantity; for if a flat piece be plowed into Ridges, and if in earth sixteen feet breadth, there be an empty furrow of two feet; and, yet, by the height and roundness of the Ridges, they have eighteen feet of surface, capable of producing corn equally with eighteen feet, while the piece was flat; there is, then, instead of any loss, one-eighth part of profitable ground, gained by altering the piece from a level into a Ridge.

RI'DING *cast*, in husbandry, a term used by the farmers for a particular method of sowing their grounds, by making two casts upon a ground at the same time. This is not much used, but it is a quicker way than the double cast, which is the method now most used. *Plot's Oxfordshire.*

RIDING *clerk*, one of the six clerks in Chancery, who, in his turn, for one year, keeps the comptrolment books of all grants that pass the great seal. *Blount.*

RING, in angling, an instrument intended to free the hook, when accidentally entangled among weeds. It is a circular piece of lead, of about six inches round, and is fastened to a long packthread, when it is to be used. It is slipped over the end of the angling-rod, and let down into the water where the line conducts it to the hook; the rod and line have then no farther business, but the hook is endeavoured to be disengaged by the pulling this Ring backwards and forwards by the string which is fastened to it; the hook is generally freed from the weed by this means; but if not, and nothing but the breaking the tackle will do, the breach is made in this manner near the hook; whereas, if done without this Ring, it might have happened in some other part of the line, or the rod itself might have been destroyed by it.

RINGS *of flies*, in natural history, the several rounds, or circular portions, of which the bodies of these and other insects are composed.

RING *dove*, in zoology, the name of a bird of the pigeon kind, called by Aldrovand, and other authors, the palumbus torquatus, and, by the Greeks, phassa. Its beak is yellow, its feet naked and red, its legs feathered almost down to the feet. The upper part of its neck has a very regular and beautiful white circle, from which the bird has its name; and its whole neck, above and below this, is beautifully variegated with changes of colours, according as it is opposed to the light. Its head and back are of a dusky blue-grey, and its throat and breast of a grey mixed with purple, its belly of a plain grey. The colours are all deeper and more lively in the male than female. It seldom flies single, but in large flocks, and builds on trees; its food is ivy-berries, and other vegetable matter. *Ray's Ornithology.*

RING *head*, an engine used in stretching of cloth.

RING *tail*, in zoology, the English name for the female of the subbuteo; the male and female, in this species, differing so much in colour, as to be called by two names; the male being called the hen harrier.

RIPIE'NO, in the Italian music, is used in pieces of music in parts, to distinguish those that play to fill up, from those that play throughout the piece. There are, says Mr. Brossard, two kinds of the Ripieno: one plays the part of the little chorus exactly, and does not, therefore, increase the harmony or number of parts. What is to be played by all the musicians is marked with the words tutti or omnes. This sort of Ripieno is found in almost all compositions. The other sort is much better, a different part being played, whereby the number of parts is increased, and the harmony made fuller. Thus in pieces where in strictness two trebles, and bass, and thorough bass are sufficient, because these parts are disposed in such a manner, as that their harmony is complete, when played all together; yet, in order to render the piece more perfect, and to give it more grandeur, a counter tenor, tenor, and often two violins are added, whose parts are entirely different from the other; and the harmony then has seven parts instead of three, and is consequently more complete and full. The parts thus added are properly called Ripieni. *Brossard.*

RI'PPERS, in the wire-works, are the people who attend in the mills, take the prepared small rods of iron, and work at the barrels where they are drawn into wire. *Ray's English Words.*

RI'SING-*timbers*, in a ship, are the hooks placed on her keel; and are so called, because, as they rise in proportion, so her rake and her run rise on her flat floor by degrees.

RI'VER (*Dict.*)—Some Rivers, at certain seasons of the year, swell, so as to overflow their banks, and drown the neighbouring lands.—Of these the most eminent is the Nile, which rises so as to cover all Egypt, except the hills. The inundation begins about the 17th day of June, and increases for the space of forty days, and decreases for as many: during which period the cities of Egypt, which are all built on hills, appear as so many islands.

To these inundations Egypt owes all its fertility; the heavens there affording no rain, or at least none in any respect considerable.—Hence, as the inundation is great or small, Egypt for that year is fruitful or barren.

The

The ancient Greeks, &c. were miſtaken as to the cauſe of this inundation; no body in thoſe days having travelled up to the ſource of the River: but the modern Engliſh and Portugueſe traders into Congo, Angola, Monomotapa, &c. have let us into the ſecret.— From them we learn that the ſpring or ſource of the Nile is in a large lake called Zaire, round which are a great number of huge mountains, called the mountains of the moon. Now, as theſe lie in the ſouthern hemiſphere, their winter will be at the time of our ſummer: but by reaſon of their nearneſs to the equator, being only 10° diſtant from it, they never feel any notable cold: hence it is, that, inſtead of ſnow in the winter, they have rain every day, at leaſt two hours before, and two after noon. In effect, the tops of theſe mountains are always covered with clouds, and the rains almoſt continual. Hence torrents are conſtantly guſhing down from the mountains; all ending in the lake of Zaire: whence they flow into the channel of the Nile, and other Rivers ariſing from the ſame lake, as the Cuamar, the Zaire, &c. Hence the inundation of the Nile.

The other Rivers, which have any notable ſtated inundations, are, the Niger, or Gambia, which overflows at the ſame time with the Nile. Leo Africanus ſays, it begins on the 15th day of June, increaſes for 40 days, and decreaſes as long.—The Zaire, a River of Congo, proceeding from the ſame lake with the Nile, and therefore affected in the ſame manner: the Rio de la Plata in Braſil, which Maffeus obſerves, overflows at the ſame time with the Nile: the Ganges: the Indus; both which laſt overflow in June, July, and Auguſt; at which times the natives ſave great quantities of the water in ponds, to ſerve them the reſt of the year: ſeveral Rivers flowing out of the lake Chiama, into the bay of Bengal, which overflow in September, October, and November. Theſe all bring a very great fertility with them to the ground; the River Macoa in Camboia: the River Parana or Paranaguaſa, which ſome will have to be the ſame with the ſilver River: ſeveral Rivers in Coromandelia, a part of India, which overflow in the rainy months from the great quantity of water iſſuing from the mountain Gatis: the Euphrates, which overflows Meſopotamia certain days in the year. Laſtly, the River Sus in Numidia.

The Rivers moſt celebrated for their length, breadth, ſwiftneſs of current, &c. are — The Nile, which runs almoſt in a ſtraight courſe 2520 geographical miles. The Niger, which runs 2400 miles. The Ganges, 1200 miles. The Ob, 1600 miles. The Jeniſcea in Aſia about the ſame length with the Ob. The River Orellana in America, 60 miles broad at its mouth, and 5000 miles long. The Rio de la Plata, 80 miles broad at the mouth. The Omarannan, another River of Braſil: and the great River of St. Laurence near 2500 miles long.

RIVER *horſe*, in zoology. See HIPPOPOTAMUS.

RIVOLGIME'NTO, in the Italian muſic, is the placing a treble or upper part in the place of the baſs or any low part, or vice verſa. This often happens in double counterpoint, where the treble ſerves for the baſs, or the baſs for the treble; and that in ſuch a manner, that the harmony, though different, remains as correct after this change, as it was in the natural order of the parts.

ROACH, in ichthyology, the Engliſh name of a fiſh, called by the generality of authors the rutilus and rubiculus, by ſome the rubellio. It is a ſpecies of the cyprinus, according to the new ſyſtem of Artedi.

ROA'STING, in metallurgy, is the ſeparation of volatile bodies from thoſe which are more fixed by the combined action of air and fire; and is generally the firſt proceſs in the ſeparation of metals from their ores: it differs from ſublimation only in this, that in this operation the volatile parts are diſſipated, when reſolved into vapours; whereas in that they are preſerved.

ROB (*Dict.*)— It is poſſible, that great improvements might be made, by introducing the uſe of this form among the malt-diſtillers. The great inconveniences attending that, are, that, the malt being of a large bulk, in proportion to its ſaccharine part, and requiring a large proportion of water to extract that ſaccharine part, many large veſſels, ſuch as maſh tubs, coolers, fermenting backs, &c. are neceſſary; and the neceſſary labour on the ſubject is increaſed, and the commodity rendered dearer. The remedy of this ſhould ſeem the introducing a new art ſubſervient to that of the malt-diſtiller, and confining itſelf to the boiling down of malt wort to a Rob, ſo as to ſupply the malt-diſtiller with his ſubject, in the ſame manner as the fine diſtillers are ſupplied with treacle from the ſugar-bakers. By this means the buſineſs of the malt-diſtiller would be reduced to a great degree of ſimplicity, and the ſpirit produced would be alſo much finer than that at preſent; becauſe the ſubject would come tolerably refined to his hands, and purged of his groſs, mealy, and huſky matter, which yields a diſagreeable oil in diſtillation, and is alſo apt to burn the ſtill, and ſpoil the ſpirit. It is poſſible that a ſpirit, purer and finer than that from treacle, might be procured from malt prudently managed.

ROCKS.—Theſe are generally ſuppoſed great enemies to vegetation, and the people of Scotland have been deterred from cultivating many of their beſt lands, from an obſervation that they had a rocky bottom. This is however but a vulgar error among them, for Rocks of a proper kind, and properly diſpoſed, as very many of theirs are, fertiliſe and are beneficial to the land, not hurtful.

In many parts of England we ſee gardens the moſt beautiful that can be imagined, both in regard to flowers and excellent plants, on a ſoil where the bottom is a hard Rock, and the earthy covering not more than a foot, or thereabout, in depth. In ſome of theſe, all the diſadvantages the Scotch complain of, take place, and yet the gardens are fruitful, many of them having lofty hills on the ſouth ſide, the declivity due north, and the Rock perfectly bare next the walls on the north ſide.

The north ſides of theſe hills in this very aſpect, only with the Rock covered with two or three feet of earth, make very good hop gardens, producing a vaſt quantity of a very valuable commodity at a ſmall expence; and it is remarkable, that thoſe gardens which ſtand in this expoſure, inſtead of being ſubject to particular evils, often eſcape thoſe blaſts and other miſchiefs which affect the plantations of the ſame kind on the ſouth ſide of the hills. It might be a very valuable article of trade, if the bleak hills of Scotland, or thoſe of ſome of our northern plantations in America, could be made thus fruitful in ſo uſeful a commodity, and there ſeems only the want of a proper trial.

Another extremely valuable plant that might be raiſed on thoſe barren rocky places, as they are generally ſuppoſed to be, is flax, in places where the deſcent is too ſteep for plowing in the common way. It has been proved that a hand plough with a ſtem of aſh of about ſeven feet long, and a plate on each ſide near the end to turn the turf, a coulter to be let out ſhorter or longer to four or five inches deep, to cut the earth up as deep as it lies upon the Rock, and an iron wheel, may be managed with eaſe and conveniency by two people, and will prepare ground for producing large crops of the fineſt flax. The beſt ſort of flax ſeed of Flanders, ſown on this ſort of ground, ſucceeds ſo well, that, if brought into general uſe, it might give the only advantage that is at preſent wanting to the Scotch Holland manufactory, and make it excel that of all the world beſides. The northern American colonies might alſo furniſh us with the ſame ſort of flax raiſed at a ſmaller expence than almoſt any other vegetable commodity, and coming to a ſure market and at a very conſiderable price.

Agriculture in Scotland is too much neglected, to the great impoveriſhing of the country, and the diſtreſs of a numerous poor, for whom it would find conſtant employment. It is not yet known whether many of the moſt valuable plants for medicinal and mechanic uſes will not proſper as well there, as where there are immenſe ſums made by the raiſing them; and the owners of lands would do well in this ſcheme to try the effect of liquorice, madder, woad, and the like plants on their grounds. Wherever the ground is deep enough, it is pretty certain that madder and liquorice would flouriſh, and the laſt of theſe needs ſo little culture, that, if once planted, it may almoſt be left to itſelf. The rocky bottoms of lands, not too bleak, may alſo ſucceed very well with ſaffron, which is one of the moſt profitable plants that can be cultivated. *Philoſ. Tranſact.* N°. 109.

ROCK-*cryſtal* (*Dict.*)— This kind of cryſtal is the moſt common of all others, and is what the generality of authors deſcribe under the name of cryſtal of the ſhops, being that kept for medicinal purpoſes.

The cleareſt, pureſt, and moſt tranſparent that can be had, ought to be choſen; and, to prove its genuineneſs, it may be tried with aqua-fortis, true cryſtal making no effervеſcence with that menſtruum. *Hill's Hiſt. Mat. Med.*

ROLL, in the manufactories, ſomething wound and folded up in a cylindrical form.

Few ſtuffs are made up in Rolls, except ſattins, gawſes, and crapes, which are apt to break, and take plaits not eaſy to be got out, if folded otherwiſe.—Ribbonds, however, and laces, galloons, and paduas of all kinds, are thus rolled.

To Roll hot.—By an arret of council in 1698, fullers, ſhearmen, &c. in Poictou, are prohibited to Roll any ſtuff hot, either by having fire over or under it, or by heating the rollers, or otherwiſe, on forfeiture of 100 livres for the firſt offence, or of being degraded from the privileges of maſterſhip in caſe of a relapſe.

The ancients made all their books up in form of Rolls, or little columns; and, in Cicero's time, the libraries conſiſted wholly of ſuch Rolls.— The dearneſs of parchment, and the cheapneſs of papyrus, whereof the Rolls were made, was the reaſon that ſcarce any but paper Rolls were uſed.

Voſſius ſays, they paſted ſeveral ſheets end to end, when filled on one ſide, and rolled them up together; beginning with the laſt, which they called umbilicus, and to which they faſtened an ivory or boxen ſtick, to ſuſtain the Roll.— To the other extremity they paſted a piece of parchment, to cover and preſerve it.

Theſe Rolls were placed in the libraries, perpendicularly to the horizon.— The Jews ſtill preſerve the ancient uſage of Rolls for the law, and the other books they read in their ſynagogues.

ROLL *of tobacco*, is tobacco in the leaf, twiſted on the mill, and wound, twiſt over twiſt, about a ſtick or roller.

The generality of tobacco in America is there ſold in Rolls, of of various weights: and it is not till after its arrival in England, Spain, France, and Holland, that it is cut.—Roll tobacco is what is chiefly used both for chewing and rasping.

ROLLER, in zoology, the common name of a bird of the mag-pye kind, called garrulus Argentoratensis by authors, and suspected to be the same with the bird described by Gesner under the name of the blue crow, cornix cærulea, and by Aldrovand under the name of pica marina. Its beak is black and long, somewhat crooked at the end, otherwise like that of the common mag-pye; its eyes are of a greyish hazel colour, and near them are two tubercles bare of feathers. Its rump and part of its wing feathers are of a fine blue, like the ultramarine colours used in painting; the middle of its back is of a reddish brown, and the head is of a bluish green, and its breast and belly are of a whitish blue or dove colour. It is brought to market in Italy, and some other places. *Ray's Ornithology*.

ROLLER, in gunnery, a round piece of wood of about nine inches diameter, and four feet long, which serves in moving mortars from one place to another when near. This is done by raising the fore-part of the bed so high that a Roller may be laid under it; then pushing the bed forwards, and laying another in its way, and another before that, and so on, the mortar is easily moved.

ROMAIN, in husbandry, the name of a plant cultivated in the fields in many parts of the world, particularly in France, and called by our farmers French vetches, or French tares; it is an annual plant but a very quick grower, and is extremely good food for cattle, particularly for horses: they let these creatures feed on it all the forepart of the summer, and then cut it for hay in August or September. Its short continuance in the ground makes it less valuable than saintfoin and clover, but it has this advantage over them, that it will grow on poor ground.

ROMPION.—This kind of bell flower was formerly much esteemed in England for the sweet taste of the roots, and universally cultivated in kitchen gardens; but we at present disregard it, though the French continue to be very fond of it. The seeds are to be sown in a bed of light dry earth in March, and in May the young plants will be of a size to remove, or they may be left when found, only houghing them up to four inches distance; being kept clean from weeds for the remaining part of the summer, they will be fit for eating in the succeeding winter.

ROOK, in zoology, a well known bird of the crow kind.

Rooks are very destructive of corn, especially of wheat; they search out the lands when it is sown, and watching them more carefully than the owners, they perceive when the seed first begins to shoot up its little blade; this is the time of their feeding on it, and they will not be at the pains of searching for it at random in the sown land; for that is more trouble than so small a grain will requite them for; but, as soon as the blades appear, they are directed without loss of time or pains by them to the places where the grains lie, and in three or four days time they will root up such vast quantities of them that a good crop is often thus destroyed in embryo. After a few days the wheat continuing to grow, its blades appear green above ground, and then the time of danger from these birds is over; for then the seeds are so far robbed of their mealy matter that they are of no value to that bird, and it will no longer give itself the trouble to destroy them.

Wheat that is sown so early as to shoot up its green blades before the harvest is all carried in, is in no danger from these birds, because, while it is in a state worth their searching for, the scattered corn in the harvest fields is easier come at, and they feed wholly on this, neglecting the sown grain; but as this cannot always be done, the farmers, to drive away these ravenous and mischievous birds, dig holes in the ground, and stick up the feathers of Rooks in them, and hang up dead Rooks on sticks in several parts of the fields; but all this is of very little use, for the living Rooks will tear up the ground about the feathers, and under the dead ones, to steal the seeds. A much better way than either is to tear several Rooks to pieces, and scatter the pieces over the fields; but this lasts but a little while, for the kites and other birds of prey soon carry off the pieces, and feed upon them. A gun is a good remedy, while the person who has it is present; but as soon as he is gone, they will return with redoubled vigour to the field, and tear up every thing before them.

The best remedy the farmer has is to watch well the time of the corn's being in the condition in which they feed upon it, and, as this lasts only a few days, he should have a boy in constant pay to watch the field from day-break till the dusk of the evening. Every time they settle upon the ground or fly over it, the boy is to halloo and throw up a dead Rook into the air; this will always make them rise, and by degrees they will be so tired of this constant disturbance, that they will seek out other places of preying, and will leave the ground even before the time of the corn's being unfit for them. The reason of their rising at the tossing up of their dead fellow-creature is, that they are a bird extremely apprehensive of danger, and they are always alarmed when one of their comerades rises. They take this for the rising of an out-bird, and all fly off at the signal. *Tull's Horsehoeing Husbandry*.

ROPE, an assemblage of several twists or strings of hemp, twisted together by means of a wheel: of various uses, as in binding, staying, drawing, suspending, &c.

When the Rope is made very thick, it is called a cable, and, when very small, a cord.

The greatest consumption of Ropes is in navigation, for the tackling of ships; where, though Ropes include the whole cordage:

Yet there are several Ropes particularly so denominated: as, the entering Rope, hung at the ladder to help people up.—The top Rope.—A bolt Rope, wherein the sail is sowed.—Buoy Rope, to which the buoy of the anchor hangs.—Guest Rope, to tow the long-boat.—The keel Rope.—The bucket Rope.—Rudder Rope, to save the rudder, if it should chance to be beat off.—Preventer Rope, to save the yard in case any part of tyes should be broke.—Breast Rope, to lash the pannels to the masts.—Guy Rope, to keep the foremast forwards, directly over the hatch-way.—Boat Rope, by which the boat hangs, or is fastened a-stern of the ship.—And port Ropes.

ROPE-MAKER.—This trade is of great account in England, we being noted for making the best cordage for shipping in the world.

The work taken throughout is laborious, as well as dirty; but then it is good pay, a good hand being able to get 4 or 5 shillings a day, especially in war-time.

To a master, who has 2000 l. in cash to turn about, and less will not make any great way, it is very profitable; for most of them get to be rich in a few years, some of whom have had 5000 l, nay, 10,000 l. in trade.

They will take with an apprentice 5 or 10 l, and sometimes they take them without money. They are at work very early in the morning, but then they leave off soon in the evening, nay, commonly in the afternoon.

ROPE-MAKING, the art of making all kinds of Ropes and cordage, for the use of shipping, &c.

Every Rope is composed of a certain number of threads, called by the workmen yarns; these are spun in the following manner:

The workman takes a quantity of coarse hemp, properly prepared, and fastens one part of it to a small iron hook called a jack, several of which are placed in a semicircular board, having small shivers on their axes, by which means they are turned round very swiftly, by the help of a line going round the circumference of a large wheel. When he has fastened the end of his thread to the jack, he walks backwards, spinning it with his thumbs and fore-fingers. When he is come to the end of the spinning yard, another person unties it from the jack, and fastens it to a reel, about which it is wound.

But, in order to give a better idea of the manner of spinning these yarns or threads, we have given a perspective view (*Plate* XXXIX. *fig.* 4.) of a covered spinning yard; but it was thought proper to shorten it, because, if the whole length of the yard had been exhibited, in a view of this bigness, the objects would have been rendered too minute, and the operations very confused.

A, B, are two great wheels with the jacks inserted in semicircular pieces over them, and two men in their proper attitudes turning the wheels. Near the wheel B, a spinner is mounted on a kind of step ladder, in the form of an inclined plane, in order to reach the crooks of the jacks, to one of which he fastens the hemp, in order to spin his thread. The wheel A, being lower, has no step ladder. At this wheel a man is untying the end of a thread belonging to a spinner, who, being arrived at H, the end of the yard, is telling the other that his thread is finished. When the thread is loosed from the jack, it is spliced to the end of another thread spun by the workman C, who is represented holding the end of his own thread in his hand, and moving towards A as fast as his thread is wound up on the reel D. It must be observed that all threads are overtwisted when first taken from the jack; the workman therefore as the thread runs through his hand, lets it untwist a little; and, in order that the thread may be wound tight round the reel, the thread passes through a pulley as at *a*, fixed to the floor of the spinning yard; and is also turned two or three times round a piece of spun-yarn, kept down by a large stone, represented at *b*. The Reel D is turned by a man, and the thread laid regularly on it by a boy, who holds, with a piece of list, the thread, in one hand, guiding it in close spirals round the reel; and, that they may lie smooth upon it, he is continually striking on them with a flat piece of wood. At E, the other extremity of the spinning yard, is represented another reel to receive the threads spun at the wheel B. Near the middle of the yard, at F, is represented a workman spinning a thread from a quantity of hemp fixed on a distaff; and another spinning from hemp wrapped round his waist; also a groupe of children picking up the flakes of hemp fallen on the floor. The utensil G, is called a stake head, and that at I, a rail and hooks; their uses are to support the threads.

The Rope-yarns or threads being thus spun, the next operation is to form them into strands, called skaining, which is done thus: they fix as many reels covered with yarn, either in a perpendicular or horizontal position, as they intend threads in each strand.

 Then

Then taking the end of a thread from each reel, they put them through an iron ring, and draw them out to the intended length of the Rope, faſtening the ſtrands, at one end of the Rope walk, each to a different hook placed in the croſs-piece of the fixed poſt; and at the other end of the walk, they are all faſtened to one hook in a machine called a cart, or ſledge. This account will be much eaſier apprehended from the perſpective view of it on *Plate* XXXV. *fig.* 13, where the reels placed in a horizontal poſition are repreſented at B, B, and in a perpendicular one at C, C. The threads deſigned to compoſe each ſtrand being put through the rings *a*, *a*, the workmen draw them out in the manner repreſented in the figure. Near one end of the yard is placed the fixed poſt D E, ſupported with ſpruts, that it may be able to reſiſt the power applied to it in twiſting the ſtrands, &c. The croſs-piece has ſeveral holes bored, through which the hooks are put, in order to twiſt the ſtrands. N, is the machine called a ſledge, laſhed faſt to the pile *b*, and loaded with ſtones *c*. The cart, as well as the fixed poſt, is ſupported by ſpruts, and its croſs-piece in the ſame manner bored with holes, in order to receive hooks for twiſting the ſtrands; ſo that it is the ſame, but placed on a ſledge, and therefore at liberty to approach the fixed poſt D E. F, repreſents one of the hooks which is paſſed through the holes of the fixed poſt and ſledge to which the ſtrands are faſtened, and by which they are twiſted.

The ſtrands being formed and faſtened to the hooks, as before mentioned, they are twiſted, and the Rope finiſhed in the manner repreſented *Plate* XXXIX. *fig.* 3. The men at K are twiſting the ſtrands of the Rope, and thoſe at P are twiſting them together, or what the workmen call laying the Rope. Each ſtrand at the fixed poſt is faſtened to a ſeparate hook, but at the cart they are all faſtened to one. In order to lay the ſtrands evenly over each other, and prevent their being more twiſted in one part than another, a piece of wood or metal, in the form of the fruſtum of a cone, having grooves at equal diſtances on its ſurface, is put between the ſtrands, and either held by a man, or faſtened to a cart, according as the Rope is large or ſmall. This inſtrument is called by workmen a top, and is repreſented at T, faſtened to the cart S, by lines round a pin going through it; one end of which is ſeen at R. A larger figure of it is delineated on a drawing (*fig.* 2.) ſuppoſed to be faſtened to the wall of the yard; R, R, are the two ends of the pin going through it; in this figure the manner of the ſtrands in the grooves on its ſuperficies is plainly expreſſed: and alſo a ſmall Rope which is faſtened to the pin and turned ſeveral times round the Rope, in order to give it a proper reſiſtance to the ſtrands, which would otherwiſe twiſt together in a very confuſed and irregular manner: and it muſt be obſerved the more the top reſiſts the ſtrands, the cloſer they will be laid together, and the harder the Rope will be twiſted; and, on the contrary, the leſs reſiſtance the ſtrands meet with from the top, the Rope will be twiſted the ſlacker. A larger figure of the ſingle hook by which the Rope is laid is alſo repreſented in the drawing againſt the wall; where G is the handle by which it is turned; the Rope is faſtened to it in the manner repreſented at M, and the ſpace H I, between the the button L and the crank H, is the part which moves in the hole of the croſs-piece of the cart. The button L, when the hook is in the hole of the cart, is placed againſt the crank H, in order to hinder that part of it from touching the croſs-piece.

Another operation, often performed in making Ropes, is worming them, that is, laying a ſmall line between the ſtrands of the Rope, by which means its circumference is rendered more even, and the Rope itſelf becomes nearly a cylinder. This operation they perform in the following manner: when they are laying the Rope, a perſon takes the end of the line appointed for this purpoſe, and, having put it through the eye of a tool called a wooller, faſtens it to the end of the Rope, and having turned the other four or five times round the Rope, holds the wooller very tight, directing the line between the ſtrands, as it is twiſting up by the men on the cart. If the Rope be large, two men are neceſſary for this operation, who perform the ſame by means of a double wooller. The man at Y, *Plate* XXXIX. *fig.* 3, is worming the Rope, or laying the line between the ſtrands; and the two men at Z are performing the ſame operation by means of a double wooller. And on the drawing, ſuppoſed to be hung up againſt the ſide of the Rope-walk, a ſingle wooller is repreſented at X, and a double one at *a*.

Thus have we deſcribed the whole operation of making a Rope which conſiſts of three ſtrands; but, as ſome are compoſed of four, five, and ſix ſtrands, a few obſervations will be neceſſary with regard to thoſe. The operation is indeed the ſame, except that there muſt be as many hooks at the fixed poſt as there are ſtrands, and the top, inſtead of having three grooves on its ſuperficies, muſt have as many as there are ſtrands; and alſo an hole bored in its axis, in order to receive the heart, or number of Rope-yarns twiſted together, in order to fill up the ſpace which would otherwiſe remain empty in the axis of all Ropes conſiſting of above three ſtrands. This ſpace, if not filled up, renders theſe Ropes not only very difficult to be laid, but alſo weaker. And the reaſon is eaſily conceived; for, as there is a vacancy, or empty ſpace, in the axis of the Rope, the ſtrands have nothing to ſupport them; and cannot, therefore, take any uniform arrangement round this empty axis, but by the means of a lateral preſſure againſt one another: now, the better to preſerve the regularity of this arrangement, there muſt be a perfect equilibrium between the ſtrands, which muſt be of an equal bigneſs and poſition, and equally twiſted; without which, there will infallibly be ſome ſtrand nearer to the axis of the Rope than the others; and ſometimes, eſpecially in the Ropes of five or ſix ſtrands, one of them will lodge at the center of the Rope, and the others conſequently roll themſelves on it; in which caſe this ſtrand would do nothing but wreath and twiſt itſelf about, whilſt the others would wrap round it in ſpiral directions.

A Rope of this kind of five or ſix ſtrands would be very bad; for, when it came to be uſed, the ſtrand of the axis muſt carry all the ſtreſs, which would break it; and then the Rope, being now compoſed but of the four or five remaining ſtrands, would loſe the fifth or ſixth of its ſtrength; beſides, the remaining ſtrands would be ill-diſpoſed towards one another, and moſt commonly unfit to unite in ſtrength together.

To avoid theſe accidents, the moſt part of the Rope-makers fill up the ſpace remaining between the ſtrands with a number of Rope-yarns, on which the ſtrands are coiled; theſe cords are called the heart of the Rope. *Plate* XXXIX, *fig.* 1, repreſents the whole operation of laying a Rope of four ſtrands; in which we may obſerve, 1. Two workmen turning the winch of the ſledge. 2. The maſter Rope-maker, who examines if the ſtrands are well laid near the top. 3. A lad who holds the heart which goes through the axis of the top, and fills the ſpace, which would otherwiſe be empty between the four ſtrands. 4. Four Rope-makers, who, together, turn the winches of the fixed poſt. 5. The cart which carries the block is to be drawn along as a ſledge, having no wheels to it, as that before deſcribed: we find both theſe ſorts of carts in the Rope-yards; but, in making uſe of the ſledge-cart, it is neceſſary that the floor be very even.

As to the ſtrength of Ropes or cordage, M. Reaumur takes occaſion, in the Memoirs of the Royal Academy, to conſider the queſtion, whether a Rope of ſeveral twiſts or ſtrands interwoven, for inſtance, ten, have more ſtrength to ſuſtain a weight, than the ten twiſts would have ſeparately, placed parallel over one another: or, which is the ſame thing, whether if each twiſt be capable of ſuſtaining the weight of a pound, the whole cord be able to ſuſtain more than ten?

There indeed appears no great difficulty in the queſtion; the evidence ſeems ſtrong on the ſide of the affirmative: for, 1. By virtue of the twiſting, the diameter of the Rope is made larger than are thoſe of the ten twiſts together; but it is apparently by its thickneſs that a Rope ſuſtains a weight, or reſiſts a fracture.

2. Twiſted ſtrands have not at all, as when parallel, a vertical direction with regard to the weight; ſeveral of them, and even the greateſt part, have oblique directions, and of conſequence do not bear all the ſhare of the burthen they would otherwiſe bear. In effect, they are inclined planes that are only preſſed with a part of the load.

Hence it would follow, that the ſurplus of the ſtrength of the twiſts might be employed in raiſing a larger weight.

On the other hand it is true, that in twiſting the ſtrands ſome are ſtretched, and others left more looſe, and the new tenſion, given the former, ſerves to weaken them, and has of itſelf the effect of a weight: thus they become leſs able to ſuſtain one ſo large. Thoſe more lax, on the contrary, wave in ſome meaſure the action of the weight, for the action is diſtributed equally on the ten ſuppoſedly equal twiſts; and, if ſome, by reaſon of their particular diſpoſition, receive leſs than their quota, the weight will act more forcibly on the reſt, and will break them firſt, as being more tenſe; after which it will eaſily diſpatch the reſt, as not being in ſufficient number to oppoſe it.

This is the ſum of what can be urged for and againſt the twiſting; to decide between them M. Reaumur had recourſe to experiment. The reſult was, that, contrary to expectation, he ſtill found the twiſting diminiſhed the ſtrength of the Rope; whence it is eaſily inferred, that it diminiſhes it the more, as the Rope is the thicker; for, inaſmuch as the twiſting diminiſhes, the more twiſting, the more diminution.

The reſiſtance or friction of Ropes is very conſiderable, and by all means to be conſidered in calculating the power of machines. M. Amontons obſerves, in the Memoirs of the Royal Academy, that a Rope is ſo much the more difficult to bend; 1. As it is ſtiffer and more ſtretched by the weight it draws. 2. As it is thicker; and 3, as it is to be more bent; i. e. as it is to be coiled, for inſtance, into a ſmaller ring.

The ſame author has thought of ways to prove in what proportion theſe different reſiſtances increaſe; that, ariſing from the ſtiffneſs or rigidity occaſioned by the weight which draws the Rope, increaſes in proportion to the weight; and that ariſing from its thickneſs in proportion to the diameter. Laſtly, that ariſing from the ſmallneſs of the gyres, or pullies about which it is to be wound, is indeed greater for ſmaller circumferences than large ones, but does not increaſe ſo much as in the proportion of thoſe circumferences.

On this footing the loſs a machine ſuſtains, by the cordage being eſtimated in pounds, becomes, as it were, a new weight, to be added to that which the machine is to raiſe. This augmentation of weight will render the cords ſtill more ſtiff, which exceſs is to be computed as before.

Thus we ſhall have ſeveral ſums ſtill decreaſing, which are to be added together, and it will be ſurpriſing to ſee what a ſum they will amount to.

Where Ropes are uſed in a machine, all the reſiſtance reſulting from their ſtiffneſs is to be put together, and all that occaſioned by the friction, which will make ſo conſiderable an augmentation to the difficulty of the motion, that a power, which to raiſe a weight of 3000 pounds, by means of a fixed and a moveable pulley, needed only 1500 pounds; muſt, according to M. Amontons, have 3942 pounds, on account of the frictions, and the reſiſtance of the cordage.

ROSA'CEOUS *Flower*, *roſaceus flos*, in botany, a term uſed to expreſs ſuch flowers as are compoſed of ſeveral petals or leaves, diſpoſed in a ſort of circular form, like thoſe of the roſe; ſuch are the flowers of the piony, crowfoot, cinquefoil, &c. In this ſort of flowers the diſpoſition only of the leaves is regarded, their number being of no conſequence. It is very ſeldom that the number is two or four, except in the circæa and onagra. The moſt frequent number of leaves in theſe flowers is five, as ſuch as have four differ from the cruciform flowers, not only in their diſpoſition, but in this, that the number is in the ſame ſpecies indeterminately four, five, or ſix, as is the caſe in the clematitis, the capers, and the ſpecies of rue, whereas in the cruciform ones it is ever conſtant. See *plate* XL. *fig*. 3.

ROSA'RIA, among the Romans, a kind of perfumes, ſo called, either from their being chiefly made of roſes, or becauſe they had a moſt exquiſite odour.

RO'SARY, is a word frequently met with in the ancient hiſtories of Ireland, and uſed to expreſs a peculiar ſort of baſe money coined abroad, in the form of the penny, current in that kingdom; but of ſo much baſer an alloy, that it was not worth quite half the real value of a penny. This and many other ſuch coins were decried, and it was made death to import any of them by Edward the Firſt, in 1300.

ROSE *Fly*, in natural hiſtory, the name given by authors to a peculiar ſpecies of fly found very frequently on Roſe buſhes, and produced out of a baſtard caterpillar, which feeds on the leaves of that tree.

The male of this fly has a long body, the female a ſhort and thick one; ſhe depoſits her eggs in ſmall holes, which ſhe makes in the bark of the young branches, and, for this purpoſe, is furniſhed with a very remarkable inſtrument placed at the hinder part of the body, which is a kind of ſaw. This is a four-winged fly, and is ſo common on Roſe buſhes, that it is ſcarce poſſible to miſs it in any of the ſummer months; and the parts of the branches where it has depoſited its eggs, are ſo vitiated by it, that they alſo are eaſily known. They are uſually ſwelled to a greater bigneſs, than either the part above or below them, and are uſually ſomewhat bent; they are often black on the underſide, and among this blackneſs the holes made for the eggs, and often the eggs in them, may be ſeen. The head and breaſt of this fly are black. Its wings alſo are edged with black, its body is yellow, and its legs yellow, with a few black ſpots.

If theſe flies be obſerved in a ſummer morning, as they are crawling upon the branches of the Roſe-tree, they will ſoon be found at work for the depoſiting of their eggs. Theſe creatures give us a very good opportunity of obſerving the manner in which they perform this, as they are of a very ſluggiſh diſpoſition, and will ſtand ſtill even to be taken between the fingers; ſo that, when one of them is in a proper ſituation, it may be examined, by bringing the eye near it, and by uſing the common magnifying glaſſes, without quitting its place or its work; and, if there be leaves of the tree, or ſmall branches of it in the way, they may be removed without diſturbing the creature. *Reaumur's Hiſt. Inſ.*

ROSE *Galls*, in natural hiſtory, a name given by authors to certain unnatural productions of the roſa ſylveſtris, or dog Roſe, occaſioned by the bites of inſects: there are two kinds of theſe, the one very common, the other more rare.

The ſcarcer kind is uſually found on the young ſhoots, and on the heps or fruit, and is of a woody ſubſtance; the other is hairy and ſpungy, and is found on the old branches. The woody kind uſually appears in the months of June and July, and is always found in cluſters. Theſe are compoſed often, of twelve or more galls of different ſizes and figures, ſome round, others oblong, ſome of the ſize of an olive, and others not larger than a pea. They are of the common ſubſtance of the white wood or blea of trees, and, when ſituated on the fruit, they prevent its ripening and make a very ſingular figure. They are of a reddiſh colour, and are uſually ſmooth and gloſſy, but ſometimes they are beſet with ſhort and fine prickles.

Eſſence of ROSES. There is ſcarce a more valuable perfume in the world than the eſſence of damaſk Roſes, and ſcarce any thing is obtained from its ſubject with more difficulty and in leſs quantity. All eſſences or eſſential oils are, while in the plant, contained in certain veſicles, lodged in different parts, and of different ſtructure; theſe veſicles are in the Roſe particularly ſmall and tender, and are placed very ſuperficially; the conſequence of this is, that there is originally but a very little of this eſſence in the flower, and this is the very ſubject that will be diſſipated and loſt, when the flowers are gathered and thrown in a heap together, as they are ſucculent, and very quickly heat in lying together. To avoid all diſſipation and waſte of this choice eſſence, the Roſes ſhould be thrown into the ſtill as ſoon as gathered, and diſtilled with very little water, and that in a balneum mariæ; the fire is to be continued ſo long as the flowers float ſeparate about in the water; but as ſoon as ever they form themſelves into a cake, and ſtick to the bottom, the diſtillation ſhould be finiſhed, as they then yield no more eſſence. With all theſe precautions, however, it is with great difficulty we can procure any eſſence of Roſes; what we obtain by this diſtillation being chiefly a very odoriferous and fragrant water. In the warmer countries the ſame caution affords a larger quantity of oil, which may be ſeparated and preſerved under the name of the eſſence. In Italy, they make ſome quantity of it, but there it is very dear; a vaſt quantity of the flowers yielding only a very little eſſence, and that being thick and troubleſome in the procuring, as it everywhere ſticks to the veſſels.

It is to be obſerved, that the ſeaſon of the year, as to wet or dry, makes a very great difference in the eſſential oils of all plants; they are always much finer in dry and hot ſeaſons than in cold and moiſt: we find our Roſe-water in England much finer and more fragrant, though diſtilled in the ſame proportion, in hot and dry ſummers than in colder and rainy ones; and Mr. Geoffroy gives an account that he ſucceeded, one very hot and dry year, in the making the eſſence of Roſes in France, in the following manner:

As the Roſes were brought to him freſh gathered, he turned them immediately into the ſtill; and drawing over the water into a glaſs matraſs, when it had ſtood by ſome time, and was perfectly cold, he diſcovered ſome of the eſſence fixed to the ſides of the matraſs, and the ſurface of the water covered with a thin reticular pellicle. All the contents of the matraſs were put to filtre through a paper, ſupported by a fine linen cloth; and the filtrated water was added to new Roſes for many ſucceeding diſtillations, the produce of which was all filtred thro' the ſame paper. After a long courſe of diſtillations, with freſh flowers every time, but ſtill with the ſame veſſels and the ſame water, there was found in the paper of the philtre a quantity of the thick eſſence; this, being carefully waſhed out of the paper with a ſmall quantity of the moſt fragrant of the water, and afterwards ſeparated pure from its ſurface, was very white, and extremely fragrant, and as thick as fine butter. This is not the only eſſential oil which naturally concretes into this firm ſtate; oil of aniſeed, though fluid, when diſtilled, always concretes in the ſame manner on the firſt approach of cold; and another oil of this kind is that of the laurel, which is uſed in ſome places, though very improperly, to give the ſcent and taſte of bitter almonds, or apricot kernels, to foods of different kinds.

Monſieur Homberg has taught us how to gain a larger quantity of the eſſential oil of Roſes than is uſual in diſtillation, by the previous addition of mineral acids, as the ſpirit of ſalt, vitriol, &c. thereto, which increaſe the fermentation, and, joining with the oil, render it more liquid, and eaſier to be raiſed by heat. He adviſed a perfumer, who before ſcarce obtained an ounce of oil from an hundred weight of Roſes, to ſteep his flowers for fifteen days in water made ſharp with ſpirit of vitriol, by which means the perfumer, upon diſtillation, found his quantity of oil increaſed almoſt a third.

The perfumers keep the ſtructure of the veſſel they employ in this diſtillation a great ſecret. Mr. Homberg tells us, it is a large convenient ſtill, that opens in a tube at the top to receive the water which muſt often be poured upon the Roſes to bring over the oil with it; this it does but very ſlowly, and ſo requires that its quantity be large; the ſtill alſo opens below, that the flowers, when they will yield no more oil, may be eaſily taken out; but the principal contrivance is the figure of the veſſel which receives the oil; this is made like an ordinary matraſs, from the lower part of the belly whereof comes a tube, as from an old-faſhioned cruet, and, riſing to the bottom of the neck of the receiver, it bends outwards; ſo that, though the veſſel uſually contains but two or three French pints, it conveniently receives and lets paſs many hundred pints of the Roſe water, without any neceſſity of being changed; for a change would loſe the ſmall quantity of the oil obtained. The water diſtilled runs through a pipe into a ſecond receiver: the oil, being lighter than the water floats upon its ſurface, and adheres to the neck of the veſſels as high as the aperture of the little pipe, while the water runs from the bottom of the firſt receiver into the ſecond. See *Mem. de l'Acad. des Sciences*, 1700.

ROT, *in ſheep*.— This is the greateſt of all the inconveniencies that attend the keeping theſe uſeful animals.

It is a very hard thing to prevent the Rot, if the year prove very wet, eſpecially in May or June. Salt marſhes and lands, where broom grows, are the beſt places of preſervation for them. Sheep are ſometimes all cleared of the Rot, when not too far gone with it, only by removing them into broom fields. Scurvy-graſs, muſtard, and thyme are alſo good for the prevention of it.

Some propoſe the giving ſheep half a handful of bay ſalt every month

month or oftener; and there is great probability that this may be of service; but the rational way of attacking all disorders in cattle, is by considering what are the causes of them. It will appear upon enquiry, that wet seasons are the general occasions of the Rot in sheep, and therefore it would be adviseable for the owners, when such seasons come on, to remove the animals into the driest pastures they can, and then to feed them principally with dry sweet hay, oats, bran, and the like; this would prevent the occasion; and, if they were already a little infected, some salt, given with their dry food, would be a happy means of curing them. *Mortimer's Husbandry.*

ROTCHET, an English name for the fish called by authors cuculus, and more frequently by us the red gurnard. *Willughby's Hist. Pisc.*

ROTOLO, an Egyptian weight of twelve ounces, each ounce consisting of twelve drachms, and each drachm of sixteen carrats. *Pocock's Egypt.*

ROTULA, in natural history, the name of a genus of the echini marini, of the general class of the placentæ. The characters of the Rotula are, that they are flat shells in form of a cake, composed of various flat pieces, and formed into a round, something like that of a wheel; but wanting one or more parts of its outer ring, and radiated or dentated. Their mouth is situated in the middle of the base, and the aperture of the anus in the third region of the axis, and marked with a cinquefoil flower at the summit. The great and obvious character is, however, the dentaged edge.

ROUP, in poultry, is a filthy boil or swelling upon their rumps, known by the staring or turning back of the feathers.

The Roup, if not soon remedied, will corrupt the whole body; to prevent which, the feathers are to be pulled away, the swelling laid open, and the matter pressed out; after which, the part is to be washed with salt and water, or brine. *Rust. Dict. in voc.*

ROWEL (*Dict.*) — The Rowelling of horses is a method of cure frequently had recourse to in inward strains, especially about the shoulders or hips; as also for hard swellings not easy to be resolved.

The operation is thus.—A little slit being made through the skin, about a handful below the part aggrieved, big enough to put a swan's quill in; the skin is raised from the flesh, the end of the quill put in, and the skin blowed from the flesh upwards, and all over the shoulder. — Then the hole being stopped with the finger, the place blown is beaten with a hazel-stick, and the wind spread with the hand all over; then let go. This done, horse-hair, or red sarsenet, half the thickness of the little finger, is put in a Rowelling needle seven or eight inches long; the needle is put into the hole, and drawn through again six or seven inches higher; then the needle is drawn out, and the two ends of the Rowel tied together: anointing it every day, as well as before the putting it in, with sweet butter and hog's grease, and drawing it backwards and forwards in the skin, to make the putrid matter discharge itself more plentifully.

Others, disliking these Rowels, as making too great a sore and sear, use the French Rowel, which is a round piece of stiff leather, with a hole in the midst; laying it flat between the flesh and skin, the hole of the Rowel just against that in the skin; sewing it with a needle and thread drawn through the hole and the skin; cleaning it once in two or three days, and anointing it a-fresh.

RUBIGO, in husbandry, is the name by which the ancients expressed what we call the blight in corn, &c. they give it this name from the resemblance of the colour of the blighted stalks to rusty iron.

They generally thought that it came from heaven, being ignorant of its true cause, which is want of nourishment in the earth. Virgil gives this up as an incurable distemper, and, tells the farmer, that, if his corn is blighted, he must live upon acorns, not supposing that any remedy could be devised for such a distemper.

Palladius gives many receipts to cure the blight, and other distemperatures of corn that come from above, as they imagined at that time. The chief efficacy of these seems to consist in certain secret sympathies and antipathies to fright the clouds away with. The world will easily judge how likely such means as these were to have success.

The ancient farmers generally used prayers, supplications, and sacrifices to their gods on this occasion; and, if these did not succeed, they proceeded to blasphemy and threatenings, and brandished bloody axes against the sky, as a token to their gods to desist from plaguing them, or else to expect no quarter. They used to hang up in their fields and gardens, on these occasions, pieces of red cloth, and the feathers and heart of an owl, as a way to fright the clouds from coming over those places. These people in general, having no true knowledge of the theory of husbandry, had recourse to magic, and used what they thought spells and enchantments on all occasions. Cato, Varro, and even Columella, are full of these ridiculous devices. A better knowledge in the real nature of husbandry has taught us to understand this matter, in a very different manner, and to apply more efficacious remedies to it. *Tull's Horse-hoeing Husbandry.* See BLIGHT.

RUBRICA, in natural history, a red earth used for marking, and in painting. There are two kinds of it, a harder and a softer.

The first, or harder kind, is but little in use, except among the turners in wood, as it does not mark so easily, requiring to be first wetted, and then pressed hard upon the substance to be marked. This is dug in Lincolnshire, Hampshire, and Sussex, and is a hard and dry earth, of a somewhat pale red, like the common pale red bricks; and is of a very regular and close texture, and always composed of a number of thin laminæ, lying closely and evenly on one another. It is of a rough uneven surface, adheres firmly to the tongue, is not easily broken between the fingers, and stains the hands a little; it is of a very astringent taste, and melts pretty readily in the mouth. It is very readily diffusible in water, mouldering to powder, soon after being thrown into it, and makes no effervescence with acids.

The second, or softer kind, is very common, and put to a number of different uses. It makes simply a very good pale red for the painters, and is very serviceable to them in their mixed colours. It is in constant use in many parts of the kingdom for the marking of sheep; and, when washed and separated from its sandy particles, is, by some of our modern druggists, sold under the name of bole-armenic.

It is found in many parts of the world; the best in England is that from several parts of Derbyshire, from whence the colour-shops and druggists of London are supplied; many of the latter thinking this a shorter method than the common one of our bole-armenic makers, of preparing it from a mixture of tobacco pipe clay, and that sort of the red ochre called Spanish brown. See BOLE and BOLUS.

This soft, or common ruddle, is a loose ponderous earth, of a lax texture, and very friable: and of a pale, but tolerably bright red, of a somewhat smooth and glossy surface, soft to the touch, adhering firmly to the tongue, easily broken between the fingers, and staining the hands. It is of a rough austere taste, very readily breaks, and falls to powder in water, and makes no effervescence with aquafortis. *Hill's Hist. of Foss.*

Arsenical RUBY, *rubinus arsenicalis*, in chemistry, a name given to a sublimation of a mixture of arsenic and common sulphur. These two bodies mixed together in different proportions afford very different appearances. If arsenic, mixed with one tenth part of its weight of sulphur, be thrown into a crucible red-hot upon the fire, and covered immediately with a tile, and finally poured out after two minutes fusion, it becomes a solid brittle mass of a very pale yellow. If arsenic be melted, in the same manner, with a fifth part of sulphur, the mass, when cold, will be of a red colour; and finally, if arsenic and sulphur be melted or sublimed together, in equal quantities, the product is a beautiful red transparent mass, called rubinus arsenicalis.

Counterfeit RUBY. — The way to give the true fine red of the Ruby, with a fair transparence, to glasses, is as follows: calcine, in earthen vessels, gold dissolved in aqua regia till it become a red powder. The operation will require many days in a hot furnace; when the powder is of a proper colour, take it out; and, when it is to be used, melt the finest crystal-glass, and purify it by often casting it into water; finally add, by small quantities, enough of this red powder, to give it the true colour of a Ruby, with an elegant and perfect transparence. *Neri's Art of Glass.*

RUFFE, in zoology, the English name of the cernua or small gilded pearch, a fish common in our rivers, and much resembling the pearch in figure.

The Ruffe is called by the generality of authors cernua fluviatilis; and by some chærus acerina and aspredo. It is called by Johnson and Charleton also serollus.

Willughby, as well as these authors, has mentioned the serollus as another species of fish; but it is proved, by observation, that they are evidently the same species. Artedi makes this fish a pearch, or perca; and accurately distinguishes it from the other fish of that genus by the name of the pearch, with only one fin on the back, and with a cavernous head.

This fish may be preserved alive in glass jars with fresh water, and be made very tame. It must be fed, for it cannot subsist on the animalcula of river-water as small dace can.

RUFFE, is also the name of a particular species of pigeon called the jacobine, but is larger, and has a longer beak. The iris of the eye is sometimes red, sometimes pearl-coloured. The feathers of the hood and chain are much longer than the jacobine's, though they do not come down so low to the shoulders of the wings, nor are they so compact and close, but are apt to blow about with every little blast of wind, and fall more backward off the head, and lie in a rough confused manner.

It is a common thing to match the jacobine pigeon with this species, with intent to improve its chain by the length of the Ruffe's feathers; but the event is, that the pigeon is always worse instead of better, being longer-beaked, and looser in its head and chain, without any real advantage. *Moore's Columb.*

RUGGIOLA, a sort of Spanish slate, serving in many places in the room of tiles and bricks. It is a flaky stone, of the nature of some of our grey slates, and is cut out of a mountain near Cordova; a plate of this, being well heated on both sides, will retain its warmth for twenty-four hours.

The people of Cornwal, and some parts of Yorkshire, use a stone, ftone, which is of a talcky nature, to warm themfelves when in bed, applying it at the feet of the bed. This they call the warming ftone from its ufe, and it will retain a fenfible heat fix or eight hours, after once moderately warming. *Plot's Oxfordfhire.*

RUM.—Rum differs from what we fimply call fugar fpirit, in that it contains more of the natural flavour or effential oil of the fugar cane; a great deal of raw juice, and parts of the cane itfelf, being often fermented in the liquor or folution of which the Rum is prepared.

The unctuous or oily flavour of Rum is often fuppofed to proceed from the large quantity of fat ufed in boiling the fugar; which fat, indeed, if coarfe, will ufually give a ftinking flavour to the fpirit, in our diftillations of the fugar liquor or wafh, from our refining fugar-houfes; but this is nothing of kin to the flavour of the Rum, which is really the effect of the natural flavour of the cane. The method of making Rum is this:

When a fufficient ftock of the materials is got together, they add water to them, and ferment them in the common method, though the fermentation is always carried on very flowly at firft; becaufe, at the beginning of the feafon for making Rum in the ifland, they want yeaft, or fome other ferment to make it work; but by degrees, after this, they procure a fufficient quantity of the ferment which rifes up as a head to the liquor in the operation, and thus they are able afterwards to ferment and make their Rum with a great deal of expedition, and in large quantities.

When the wafh is fully fermented, or to a due degree of acidity, the diftillation is carried on in the common way, and the fpirit is made up proof: though fometimes it is reduced to a much greater ftrength, nearly approaching to that of alcohol or fpirit of wine, and it is then called double diftilled Rum. It might be eafy to rectify the fpirit, and bring it to much greater purity than we ufually find it to be; for it brings over in the diftillation a very large quantity of the oil; and this is often fo difagreeable, that the Rum muft be fuffered to lie by a long time to mellow before it can be ufed; whereas, if well rectified, it would grow mellow much fooner, and would have a much lefs potent flavour.

The beft ftate to keep Rum in, both for exportation, and other ufes, is doubtlefs that of alcohol, or rectified fpirit. In this manner it would be tranfported in one half the bulk it ufually is, and might be let down to the common proof ftrength with water, when neceffary; for the common ufe of making punch, it would likewife ferve much better in the ftate of alcohol; as the tafte would be cleaner, and the ftrength might always be regulated to a much greater exactnefs.

The only ufe to which it would not fo well ferve in this ftate, would be the common practice of adulteration among our diftillers; for, when they want to mix a large portion of cheaper fpirit with the Rum, their bufinefs is to have it of the proof ftrength, and as full of the flavouring oil as they can, that it may drown the flavour of the fpirits they mix with it, and extend its own. If the bufinefs of rectifying Rum was more nicely managed, it feems a very practicable fcheme to throw out fo much of the oil, as to have it in the fine light ftate of a clear fpirit, but lightly impregnated with it; in this cafe it would very nearly refemble arrac, as is proved by the mixing a very fmall quantity of it with a taftelefs fpirit, in which cafe the whole bears a very near refemblance to arrac in flavour.

Rum is ufually very much adulterated in England; fome are fo barefaced as to do it with malt fpirit; but, when it is done with molaffes fpirit, the tafte of both are fo nearly allied that it is not eafily difcovered. The beft method of judging of it is, by fetting fire to a little of it; and, when it has burnt away all the inflammable part, examining the phlegm both by the tafte and fmell. *Shaw's Effay on Diftillery.*

RUN *of a fhip*, fo much of her hull as is always under water; growing thinner and lanker by degrees, from the floor timber to the ftern-pofts.

This is alfo called the fhip's way afterward.

A fhip is faid to have a good Run, when it is long, and the water paffes cleverly to her rudder, her tuck not lying too low, which is of great importance to her failing—If the water do not come ftrongly to her rudder, by reafon of her being built too broad below, fhe cannot fteer well; and a fhip that cannot fteer well, cannot keep a good wind, nor will have any frefh way through the fea, but will ftill be falling to leeward.

RUNCA'TION, a term ufed in the antient hufbandry, to exprefs the clearing away the weeds from among the corn and other fown plants.

They ufed, when the corn or other plants were an inch or two high, to draw a fort of rake or harrow over the ground indifcriminately over the corn and weeds, and, when this was done, a perfon followed over all the field, and picked up all the weeds with the hand; the treading the young corn, however, by this perfon's feet, and the injury done to it by the rake, were fo great, that the crop always fuffered greatly by it; many of the Romans chofe to omit the ufe of the rake or harrow, as a thing that did as much injury to the corn as to the weeds, and contented themfelves with the fending a perfon to pick up the weeds without it.

This was a fort of firft hint to the horfe-hoeing hufbandry of the moderns, though fo injudicioufly managed, that it was of very little, if any, ufe in its infancy. But had thefe farmers been inftructed to fow their corn in rows, and then to ufe the rake or harrow as we do the hoe, only between thofe rows, they would then have had all the advantage of deftroying weeds by it, and of ftirring the earth, and no injury would be done to the crop. *Tull's Hufbandry.*

RU'NIC, in feveral parts of Sweden, ftones may be met with which were formerly fet up as obelifks in memory of the dead; and thefe monuments are marked with the antient northern letters, called runor, or the Runic characters. In fome places, the characters vary from the Runic, particularly in free ftones found in Helfingland, of which Mr. Celfius has given us a defcription, with an explanation.

From thefe Helfingland infcriptions an alphabet of fixteen letters may be derived, which is very fingular. In other alphabets different founds are generally denoted by different figures; but here the fame character, according to the diverfity of its place and altitude between two parallels, denotes different founds.

But thefe characters, however different they may appear at the firft fight from the Runic, may eafily be derived from them; or, vice verfa, the Runic may be derived from the Helfingic, if thefe be fuppofed the moft antient. The fubtraction of a perpendicular line in the firft cafe, or its addition in the latter, brings the two characters to a near refemblance.

The infcription, which Mr. Celfius confiders, was publifhed in Monf. de la Motraye's Travels, but erroneoufly.

RUNT, the name ufed with the diftinction of places for feveral fpecies of pigeons. Thefe are the Leghorn, the Spanifh, and the Friefland Runt, &c. The columba domeftica Pifarum, Hifpaniæ, et Frifiæ of Moore.

The Leghorn Runt is a ftately large pigeon, feven inches or better in the legs, clofe-feathered and faft-flefhed, extremely broad-breafted, and very fhort in the back. He carries his tail, when he walks, fomewhat turned up like a duck's; his neck is longer than any other pigeon's, and he carries it bending like a goofe or fwan. He is goofe-headed, and his eye lies hollow in his head, with a thin fkin round it, like that of the Dutch tumbler. His beak is very fhort for fo large a bird, and has a fmall wattle on it, and the upper chap falls a little over. It is a very valuable pigeon, but is tender, and requires care.

The Spanifh Runt is the longeft-bodied of all the pigeons; it is fhort-legged and loofe-feathered, and does not walk fo upright as the Leghorn Runt. Thefe are of a great variety of colours, but are apt to have accidents in fitting, from their fitting too heavy, and often breaking their eggs.

The Friefland Runt is a large pigeon, and has all its feathers reverted, or looking as if placed the wrong way.

The Roman Runt is a pigeon of the fame general make with the common kind, but fo large and heavy that it can hardly fly.

The Smyrna Runt is middle-fized, and is feather-footed, and and that to fuch a degree fometimes, as to look as if there were wings upon the foot; the feathers of thefe are fometimes four or five inches long, and often pull the eggs and young out of the nefts. The common Runt is the common blue pigeon kept for the table, and known to every body. *Moore's Columb.*

RUPELLE'NSIS *Sal*, in chemiftry, a name given to a peculiar kind of falt, invented by Mr. Seignette at Paris, and extolled as a very valuable medicine.

The preparation of it was kept a great fecret, till difcovered by fome members of the Paris Academy. It was found to be a fpecies of fal polychreftum, and was properly a foluble tartar compofed of cream of tartar and the fixed falt of common potafhes well defpumated. This falt is of a very fingular nature; for, though it be a true alcaline falt, it yet is capable of cryftallifation, and it does not eafily diffolve in the open air as other fixed falts do; but, on the contrary, it calcines therein like vitriol and the Glauber's falts. *Philof. Tranf.* N°. 436.

Another peculiar property of it is, that, if it be fatiated with vitriolic acids, and the liquor be evaporated, there is obtained a falt which has the figure of Glauber's falt, and all the properties requifite to make Mr. Seignette's falt. In order to which, take falt of kali or pot-afhes of Alicant well purified one pound; diffolve it in water, and add to it cream of tartar half a pound: this is about the quantity ufually neceffary; but the true proportion, in this cafe, can no more be determined than in the making the common foluble tartar, otherwife than by trial every time, either from the falt of kali's having retained more or lefs humidity, or from the tartar's having more or lefs foulnefs. Boil the whole together, in order to diffolve the tartar; and, if the quantity of tartar have been too great after the fermentation is over, filtre the liquor, and, as it cools, the fuperfluous tartar will fall to the bottom; after the feparation of the tartar, evaporate the lixivium over a gentle fire to a proper ftandard, and then fet it in a cool place, and there will fhoot fine cryftals. If the liquor be a little too far evaporated, there will be no cryftals formed, but the whole liquor will congeal into a hard fubftance tranfparent like ice; but, upon diffolving this in more water, it will fhoot as fair as it would have done if properly evaporated at firft.

The virtues of this falt confift in its being an excellent purge; its

its dose is from one to two ounces; and it is to be dissolved in a large quantity of water.

RUPERT'S *Drops*, a sort of glass drops with long and slender tails, which burst to pieces on the breaking off those tails in any parts, said to have been invented by prince Rupert, and therefore called after his name.

This surprising phænomenon is supposed to arise from hence; that while the glass is in fusion, or in a melted state, the particles of it are in a state of repulsion; but, being dropped into cold water, it so condenses the particles in the external parts of their superficies, that they are thereby reduced within the power of each other's attraction, and by that means they form a sort of hard case, which keeps confined the before-mentioned particles in their repulsive state; but, when this outer case is broke, by the breaking off the tail of the drop, the said confined particles have then liberty to exert their force, which they do by bursting the body of the drop, and reducing it to a very peculiar form of powder.

This theory seems to be corroborated by making the drops red-hot, and letting them cool again by gentle degrees in the open air, for then there is no such effect. Yet, it must be allowed, that there is another experiment which seems to impugn this hypothesis; and that is by grinding away any part of the drop upon a grindstone, when the remaining part continues entire; though there appears no reason why it should not break and burst into dust, if the internal parts be the cause of it; since by this means they must needs be set at liberty, in the most ample manner possible, unless it be that, in grinding, the vacuities between the internal particles are filled up with the matter worn off from the stone; and, by this means fixing the parts of the glass next the stone, they destroy their repulsive force; constituting as it were another sort of hard external case, which confines the internal particles no less than the other did.

The history of these drops is this: they were first brought into England by prince Rupert, out of Germany, and shewn to king Charles the Second, who communicated them to the Royal Society at Gresham College; and a committee, appointed on this occasion by the society, gave the following account of them: They must be made of green glass well refined, for, till the metal, as the glass-men call it, is perfectly refined, they never succeed if made of it; but always crack and break soon after they are dropped into the water. The best way of making them, is to take up some of the metal out of the pot upon the end of an iron rod, and immediately let it drop into cold water, and there lie till it is cold. If the metal be too hot when it is dropped into the water, the business does not succeed, but the drop frosts and cracks all over, and falls to pieces in the water, and every one that does not crack in the water, but lies in it whole till it is quite cool, is sure to be good: there is great nicety in the hitting a due degree of heat in the metal, and the workmen who best know their business cannot promise before-hand which shall succeed, but often two fail for one that hits right. Some of them frost over the surface without falling to pieces, and others break into pieces before the red-heat is quite over, and that with a small noise; others break soon after the red-heat is quite over, and that with a small noise; others break soon after the red-heat is over, and make a great noise, and some neither break nor crack till they seem to be quite cold; and others hold together while they are in the water, but fly to pieces with a smart noise when they are taken out of it; some do this on the instant, others an hour or two after, and others will keep several days, nay weeks, and at last fall to pieces without being touched. *Neri's Art of Glass, by Merrett.*

If one of them be taken out of the water while it is hot, the small part of the neck, and so much of the thread or string it hangs by, as has been in the water, will upon breaking fall into small parts, but not the body, though it have as large cavities in it, as those which burst in pieces.

If one of these drops be cooled in the open air hanging on a thread, or on the ground, it becomes like common glass in hardness, solidity, and all other its qualities, and has nothing of the nature of the drops cooled in water.

When a glass drop falls into the water, it makes a hissing noise, the body of it continues red a pretty while, and there proceed from it many eruptions like sparkles that crack, and make it leap up and move, and several bubbles arise from it till it cools; but, if the water be ten or twelve inches deep, these bubbles diminish so in the ascending, that they vanish before they attain the superficies of the water, where nothing is to be observed but a little thin steam.

The outside of the glass drop is close and smooth like other glass, but, within, it is full of spungy cavities and blebs. The figure is a sort of oval or pear-like shape, such as pearls are pointed in, the bottom of which is rounded, and the top terminates in a long neck which is usually variously bent and crooked. Almost all those that are made in water, have a little protuberance or knob, a little above the largest part of the body, and most commonly placed on the side towards which the neck ends, but sometimes it is upon that side that lies uppermost in the vessel where it is made.

If the water be hot into which the glass drop is thrown, it always cracks and breaks in the water, either before the red-heat is over, or very soon after. If dropped into oil, they do not miscarry so often as when dropped into water: they produce also a great number of large bubbles, and continue longer bubbling than when dropped into water: those made in oil have also fewer blebs, and smaller than those which are made in water; and frequently they are smooth all over, not having those knobs which the others have. Some part of the neck of these also, and part of the small thread that is quenched in it, breaks like common glass; but, if the neck be broken off near the body, and the body held all the while close in one's hand, it will crack and break all over; but even then it flies not into so small parts, nor with so smart a force and noise as those do which are made in water, and the pieces will hold together till they are parted, and there then appear long streaks or rays upon them, pointing towards the center of the body, and thwarting the little blebs in it.

If the drops are dropped into vinegar, they frost and crack, so that they are sure to fall to pieces before they are cold, and the noise of their falling in is more loud and hissing than in water, but the bubbles are not so remarkable.

In milk they make no noise nor any bubbles that can be perceived, and never miss to frost and crack all over, and fall to pieces before they are cold. In spirit of wine they bubble more than in any other of the liquors, and while they remain entire, they tumble to and fro, and are more agitated than in other liquors, and they never fail to crack and fall to pieces; and by that time five or six of them have been dropped into this spirit, it will be set on a flame, but it receives no particular taste from them.

In water wherein nitre or sal armoniac have been dissolved, they succeed no better than in vinegar. In oil of turpentine, they first broke as in the spirit of wine, and the second set it on fire, so that it could not be used again. In quicksilver, being forced to be sunk by a stick, it grew flat and rough on the upper side; but the experiment could not be perfected, because it could not be kept under till it cooled. In an experiment made in a cylindric glass like a beaker, filled with cold water, out of seven that were tried, one only succeeded, the rest all cracking and breaking to pieces; and it was observed, in this experiment, that at the first falling of the drop into the water, and, for some time after, while the red-heat lasted, red sparks were shot forth from the drops into the water; and that, at the instant of the eruption of those particles, and of the bubbles which manifestly break out of it into the water, it not only cracks, and that sometimes with a considerable noise, but the body moves and leaps about, and that as well in those which succeed as those that break in the water.

A blow with a small hammer, or other hard body, will not break one of these glass drops, if struck upon the body; but, if the tip only of the neck be broke off, it flies to small particles, which easily crumble into dust; and, if it be broken, when the particles have liberty to disperse themselves, they will fly every way in an orb, in the manner of a granado.

If they are ground down ever so low into the body with water and emery, they do not fly; but rubbed on a dry tile, they usually fly to pieces as soon as the bottom is a little flatted, though sometimes they bear rubbing away deeper; and some, when rubbed half down, have been laid by without bursting, and have flown to pieces a little while after without being touched.

If one of them be broken in the hand under water, it strikes it more smartly than if in the open air; and, if it be broken near the surface of the water, the particles it flies into do not disperse themselves into an orb, as in the air, but all fall regularly and evenly to the bottom; and they burst in the same manner in the exhausted receiver of the air pump as in open air. One of these drops being fastened into a cement, all but a part of the neck, and then the tip of it broken off, it made a pretty smart noise, but not so great as if broken in the hand; and though, on examining, it appeared to pieces within, and its colour turned greyish; yet, the outside remained smooth, tho' cracked, and being taken in pieces, the parts of it rose like those of the flaky bodies, talc, or the like; the flakes were many of them conical in shape, and were also so cracked, that they easily fell into dust.

Another drop fastened into a ball of cement of half an inch in thickness, upon the breaking off the tip of it, burst the ball in pieces like a granado. And, when attempted to be bored by a lapidary, as they bore pearls, they fly to pieces as soon as the tool enters them, in the same manner as they do when the tip is broken off.

These were the several experiments tried on them by the gentlemen of the Royal Society, and these all tend to prove the before-mentioned account of their bursting to be true; and, indeed, none more than the dry and wet grinding of them; the wet emery, in the latter case, making a coat in the place of that it wore away; and the dry powder of tile in the former scarce answering the same purpose, and at best but very imperfectly, and preserving the body together only for a small time.

RUSH, *juncus*, in botany, the name of a genus of plants, whose characters are:

The flower is of the rosaceous kind, consisting of several petals, disposed in a circular form. From the center of the flower arises a pistil, which finally becomes a trigonal fruit or capsule, which opens three ways, and usually contains a number of roundish seeds.

Petrified RUSHE. — What is usually called by this name is a kind

kind of fossil coral. But we have in England also another not uncommon substance, frequently called by the same name; this is an incrustation of sparry matter, in form of a stony crust on the outsides of real Rushes; though, in this case, it is no real petrifaction, but only a covering of this stone-like matter. Incrustations and petrifactions are usually confounded together, and the generality of people do not attend to the distinction, which is, that, in a real petrifaction, the stony matter penetrates the very substance of the body, as is the case in the petrified wood of Ireland and other places; whereas, in these incrustations, the substance itself remains unaltered within, and its outer part alone is covered with the stony substance: this is the case with what is called petrified moss at Scarborough and in other parts of England; and this is the case in regard to what we call sometimes petrified Rushes. These being water plants, and growing by the sides of springs, loaded with spar, often fall in, and become covered over with it. We have near Kettering, in Northamptonshire, a spring which does this very quickly: a gentleman who tried the experiment, but putting in some Rushes, at about thirty yards from the source, found them in one day covered with a thin skin of spar; but, after lying some months there, it formed itself into a crust of half an inch thick, round them; and was so hard that it would not break by being thrown violently on the ground; but all this while the Rushes were not petrified, but only incrusted. *Woodw. Cat. Foss.*

RUST *of corn*, in husbandry, the name given by our farmers to a disease in corn or other vegetables, in which their stalks and leaves seem burnt up, and appear of a sort of Rust colour.

Wheat is blighted at two seasons, first in the blossom, and then its generation is prevented, many of the husks being empty in the ear, and the rudiments of the grains not impregnated: secondly, wheat is blighted when the grains are brought to maturity; and in this case they become light, and are of little value for making of bread, having scarce any flower in them.

The first of these cannot happen in England from frosts, because our wheat is not in flower till the month of June; but it is long and continual rains that chill the blossoms, and in this manner prevent their fertility: this, however, does not often happen to us; these rains are not common at this season of the year; and, if they were, this country lying much of it open, the winds dislodge these drops of water from the ears, and prevent the mischief they would do there.

Lammas wheat does not retain these drops so long as the bearded or cone wheat; and, in consequence of this, in the terrible blight in England, in the year 1725, the bearded wheat received infinitely greater mischief than the Lammas wheat.

The second kind of blight from light ears, is, that which is more frequent, and more general with us; this brings the greatest scarcity of wheat, and the cause of this is plainly want of nourishment of the grain, by whatever means that want is occasioned. Several accidents kill the plants, or injure their health, and in that case the grains are not filled; lightning does great mischief to the farmer in this kind, as is plain by the several black spots and patches in fields of corn, in years when there has been more lightning than usual. This is a disaster that must be quietly suffered, since it can neither be prevented nor remedied; but the other causes of blights, which are most general, and do the most damage, may be prevented in some measure at least.

One great and common cause of the blight is the lodging or falling of corn; in this case the stalks are broken near the ear, and the vessels are hurt which should carry up the nourishment to the ear. In this case, there can just juices enough pass for the keeping the plant alive, and bringing it to its full height, but it is languid all the time, and the grains can never be filled with flour. The earlier in the season this lodging of the stalks happens, the thinner and poorer the ears will be: hence it happens, that when dung and tillage have brought a wheat land into so good a state, that in April and May it seems to promise the farmer five or six quarters of wheat, it shall all be destroyed by falling in June, and scarce yield him five bushels, and this is so thin and lank, that the expences of reaping and thrashing are more than its value. The wind is generally accused of the throwing down these stalks, but this does not seem to be truly the case; the wind may press upon the plants; but the cause of their giving way to it is a weakness in their stalks, and this seems either owing to the want of nourishment, or the want of air, or of the sun's rays, and perhaps the want of all three together. A rich acre will maintain a crop of five quarters standing, while a poor acre will not be able to support such a crop, as would have yielded only about three quarters, had it stood. This is a proof of want of due nourishment being one great cause of the falling. Air is necessary to the nourishment of all plants, wheat in particular requires a very free air. It succeeds best in open hilly places where the wind comes freely to it, and shakes off the drops of water from the leaves, as well as their own recrements; and it is plain, that a great quantity of the sun's rays is necessary to keep the wheat strong; because in the hotter countries it is not so subject to fall, as it is with us, and in other northern countries.

There is another cause of the blight, which is the wheat's coming too late into blossom. It should blossom in the beginning of June, because there is not otherwise time during the hot weather for it to pass through the different stages to the perfection of the grain.

The causes of the blight being thus known, the cure or prevention may be attempted by the farmer on much more rational grounds than it was among the antients. It is advantageous to hasten as much as possible the time of blossoming of the corn, and to protract as long as we can the ripening of the grain, that it may have sufficient time to fill and swell.

The earliest sown wheat is generally observed to escape the best, and this is owing to its coming soonest into blossom. The antients used to let their sheep feed upon the corn while young in the blade, by way of preventing it from lodging or falling afterwards: some of our own farmers use this method also; and it is true, that the corn is prevented from falling by this; but the remedy is as bad as the disease, for the stalks are not made very strong by this practice, but the ears lighter. They therefore do not weigh down and lodge the stalks indeed, but they are in some sort blighted by this means, and the disease is caused by the means used to prevent it. This feeding down the wheat with sheep retards the time of its blossoming, and the only advantage of early sowing is thus taken away by it: what grows after the eating of the sheep is a sort of latter crop, and is always weaker and later than the first. The longer the corn remains on the ground, the more nourishment it requires from it; and, in this unnatural remaining on the land, there is no proper supply provided.

The general remedy for all the cases of the blight is the modern method of horse-hoeing husbandry. In this the hoe stirs up the ground as often as the farmer pleases, and every such stirring gives new life and nourishment to the plant: this was a supply of food for the ear, may be given, whenever it is necessary, and the wide intervals left for the hoe in the drilling the wheat; for this sort of husbandry gives a free passage for the sun and air to all the plants.

The most general blight of all that happen in these cold countries is caused by insects, which some think are brought in the air by an east-wind, accompanied by moisture, a little before the grain is filling with that milky juice which hardens into flour. These insects deposit their eggs within the outer skin or rind of the stalks; and, when the young ones are hatched, they feed on the parenchyma, and eat off many of the vessels which should convey this juice; then the ear is deprived of it, and must in consequence be thin and poor, in proportion to the number of the vessels eaten, and as the insects happen to come earlier or later; for sometimes they come so late, that the grains are sufficiently filled with this milky juice before they have any power to hurt the vessels.

In this case, though the straw, when examined by the microscope, appears to have its vessels eaten and torn, and to be full of black specks, which are caused by the same insects, yet the grain is plump and full. This is one of the many cases in which the early sown wheat escapes the blight. It has been seen, that, of the crop of wheat in the same field, some of which has been sown earlier and some later, though there has been no difference in the whole, yet the early sown wheat has been full-eared, and the late sown has been light-eared; and both have had their stalks equally eaten and spotted by the insects.

A proof that these mischievous insects are brought by the east-wind, is, that the corn on the eastside of hedges is often found blighted, and destroyed by them, while that on the westside of the same hedge is unhurt. Some suppose they are bred in the earth, and crawl up the stalks, because some whole fields are subject to them, and others escape them wholly; but this is more probably owing to the difference of the situation of these fields, as they are more or less exposed to the east.

Some wheat is more liable to be hurt by this insect blight than another, and the best remedy in this evil is to plant fields, which are most exposed to these blights, with such wheat as is least subject to be injured by them. The white cone, or bearded white, which has its stalk or straw like a rush, not hollow, but full of pith, except near the lower part, where it is very thick and strong, is very proper on this occasion; it is probable that this plant has sap vessels, that lie deeper, and so are not to be destroyed like those of common wheat: the stalks of this are often found spotted with black, which shews that the insects have been there, and yet the ears are are found full, and the grains plump in them.

There is another kind of blight, called by the farmers moor loor; this is occasioned by the earth's falling away from the roots of the wheat, and is cured by throwing up small furrows against the rows in the drilling method. The horse-hoeing husbandry is best of all others calculated to prevent blights, and to cure them when they happen; but, as there are some years when all wheat is blighted, even at these times, the horse-hoeing husbandry has an advantage; for, when the stalks fall, they never lie absolutely on the ground in this case, but the air has room to play between them; but the common sown wheat has not this advantage. The ears in the blighted wheat of the drilled kind are not so light nor poor as in others,

thers, but make the farmer ſome amends in the corn, though greatly leſs than in the common produce. *Tull's Horſe-hoeing Huſbandry.*

Corn is always more ſubject to blights after a wet ſummer than at any other ſeaſon; the reaſon ſeems, that, the roots being continually drenched with water, the plant runs up to ſtalk, and has very little ear, and the corn is never large or full.

It is obſerved, that when the mildews riſe, or blights fall, they generally infeſt only one kind of grain, ſometimes wheat, ſometimes oats, and ſometimes barley only; and the ſame ſort of obſervation holds good in regard to fruit; ſometimes only apples are blighted, ſometimes only pears, ſometimes cherries, and ſo on. *Mortimer's Huſbandry.*

RYE, *ſecale*, in botany.—This ſort of grain ſucceeds very well on any ſort of dry land, even on the moſt barren gravel or ſand. The farmers ſow it about the beginning of September, after a ſummer's fallow, in the drieſt time they can. Two buſhels of ſeed is the quantity generally allowed to an acre of land; but if it be ground newly broken up, or if it be ſubject to worms, they then allow a peck more to the acre. A little ſprinkling of dung, or mud, upon Rye-land, will greatly advance the crop, though it is laid but half the thickneſs that it is for other corn; its produce is commonly about twenty buſhels upon an acre.

The farmer knows it is ripe when the ſtraw is yellow, the ear bends, and the grain feels hard. It is not apt to ſhed the ſeeds; and therefore, if there are many weeds among the crop, it may be left lying upon the ground, or gravel, as they call it, eight or nine days after it is cut, before it is bound up, if the weeds are not dry ſooner: for, otherwiſe, they will grow moiſt in the barn, and cauſe the whole to give, and not to thraſh well, and ſometimes they will make it muſty.

As it is a grain that will grow in the ear ſooner than any other if it be wet, care muſt be taken, if rain falls after it is cut, to turn it as it lies upon the ground every other day, and at the ſame time to keep the ears as far from the earth, and as much above the ſtubble, as may be; this will prevent the miſchief. If it be pretty clear of weeds, it may be houſed as ſoon as it is cut. If either this grain or wheat lodge upon the ground, it is beſt to cut them, even though they are not ripe; for the ſtalk being broken will yield no more nouriſhment to the ear.

There is another very eſſential uſe to the farmer made of Rye. April is the ſeaſon of the year when food is of all others the ſcarceſt for cattle, eſpecially for ſheep and lambs: on this occaſion ſome ſplit the ridges of the wheat ſtubble, and ſow them with Rye; they harrow this in, allowing about a buſhel to an acre; they feed the ſheep with this in April, and in May they plow it up for fallow. *Mortimer's Huſbandry.*

In many parts of France there have been certain years, in which this grain, from no apparent cauſe, has proved noxious, and ſometimes even poiſonous. Mr. Perrault, travelling through Sologne, was informed that the Rye of that province was ſometimes ſo corrupted, that thoſe who eat of the bread that had much of the corrupted grain in it, were ſeized with gangrenes in different parts of the body, which was not preceded by any fever, inflammation, or any conſiderable pain; and that the gangrened parts uſually fell off after a time of themſelves, without the aſſiſtance of chirurgical inſtruments.

The grains of Rye thus degenerated are black on the outſide, and tolerably white within; and, when they are dry, they are harder and cloſer than the natural good grain: they have no ill taſte, but ſometimes they have a viſcous metallic like honey hanging to one end of them. They grow longer than the other grains in the ſame ear, and are found, from one or two, to ſeven or eight in the ſame ear. Some have ſuppoſed that theſe were not the proper ſeeds of the plant, but ſome other extraneous bodies that got in among them; but it is evident, from a cloſe inſpection, that they are really the genuine ſeeds only altered by ſome accident; the coats, and the furrow, and even the germen for the young plant, being entirely the ſame as in the natural ſeeds.

The places where the Rye is found to degenerate in this manner, are all a dry and ſandy ſoil. In theſe places there is ſcarce any ſoil in which more or leſs of theſe large ſeeds are not found among the others, but, when there are but few of them, the ill effects are not perceived. The ſeaſon when the degeneracy is greateſt, and the effects the worſt of all, is, when there have been exceſſive rains in the ſpring, and there come on exceſſive heats in the ſucceeding ſummer.

The bread which is made of the Rye that holds ever ſo much of this bad corn, is not diſtinguiſhable from other Rye bread by the taſte, and ſeldom produces its ill effect, till ſome conſiderable time after it is taken. Beſides the gangrenes already mentioned, it not unfrequently brings on other bad conſequences, ſuch as drying up the milk of women who give ſuck, and occaſioning ſometimes malignant fevers, accompanied with drowſineſs, ravings, and other dangerous ſymptoms. The part uſually ſeized by the gangrene is the legs, and this often in a very frightful manner. The arms are the parts moſt ſubject next, but all the other parts of the body are ſubject to it.

The firſt ſymptom of this approaching gangrene is a ſtupefaction and deadneſs in the part; after this there comes on ſome pain, though not violent, and the ſkin becomes livid; ſometimes the ſkin ſhews no mark of it, but the pain and ſwelling increaſe; and it is neceſſary to make an inciſion into the fleſh to find the gangrened part. In the more deſperate caſes, the only remedy is the taking off the part; and, if this is neglected, the fleſh is all waſted, and the ſkin becomes black, and clings round the bones, and the grangrene appears again in the ſhoulders.

The poorer people are only ſubject to this diſeaſe; and, as they principally eat the Rye bread, and as thoſe years when there is moſt of this bad grain among the ears of Rye produce moſt of theſe diſorders, it has been judged certain that the Rye is the occaſion of it. It may deſerve enquiry, however, whether that grain may not be innocent of the miſchief, and its degeneracy and the diſtemperature attributed to it may not both be the effect of the ſame bad conſtitution of the air. If it proves, on enquiry, that only thoſe who eat of the Rye are ſubject to the diſeaſe, it will ſeem a proof of its really being owing to it; and in this caſe the miſchief may be prevented by the ſifting the grain before it is ground, the degenerated grains being ſo long that they will all remain in the ſieve that lets the other through. The experiment has been made on the ſpot, by giving the flower of the corrupted grains alone to animals; but it is ſaid, they have been killed by it. *Phil. Tranſ.* N°. 130.

S.

SABÆ'ANS *, Sabæi, the adherents to Sabaiſm; a ſect of idolaters much ancienter than Moſes and the Jewiſh law.

* The word is ſometimes alſo written Sabians, Sabaites, Zabæans, Zabians, Zabaites, Tſabæans, Tſabians, and Tſabaiſts.

The Sabæans were very numerous throughout the eaſt: in later times they have mixed ſomething of Chriſtianity with their ſuperſtition. They ſet a great value on the baptiſm of St. John; whence they have been alſo denominated Chriſtians of St. John.

Some, indeed, doubt whether the Sabæans be the ſame with the Chriſtians of St. John; but Father Angelo de St. Joſeph, a Carmelite miſſionary, and Maracci, in his notes on the Alcoran, aſſert it expreſly. Be this as it will, Mahomet, in his Alcoran, and the Arabian authors ſince him, make frequent mention of them. Beidavius, in his comment on the Alcoran, repreſents them as a kind of mean between the Chriſtians and the Maguſians, who are the followers of the Magi, among the Perſians: he adds, that they pretend to be of the religion of Noah.—Keſſæus notes, that they pretend to be in poſſeſſion of the books of Seth and Enoch, though they own none of the books of ſcripture.

Some charge them with worſhipping the ſtars; and others, the angels, or dæmons. Maimonides attributes both to them, as is obſerved under the article Sabaism.

Abu Joſeph Aſchæus and Keſſæus place the Sabæans about Charan, or Charres, and Ghezira in Meſopotamia; which opinion is confirmed by this, that their books are in the Chaldee tongue, though in a character very different from the Chaldee.

Hottinger ſets aſide the common derivation of Sabæan from צבא militia, hoſt; and will not have it the name of a ſect of religion, but of a people in Arabia Felix, the deſcendants of Saba, grandſon of Cham.—But the critics, to a man, conſpire againſt this opinion.

SA'BAISM, an ancient kind of idolatry; the firſt that ever entered into the world.

Sabaiſm conſiſted in the worſhip and adoration of the ſtars; or, as the ſcriptures call them, צבא שמים tſeba ſchamaim, ſeba ſchamaim, i. e. hoſt, or militia of heaven; whence ſome moderns formed the word Sabaiſm, to denote the worſhip of the heavenly bodies, and that of Sabæans for the worſhippers. See SABÆANS. But as the Hebrew word, whence theſe are formed, is wrote with a צ tzade, which ſome expreſs in the modern tongues by an s, ſome by a z, others by ts, and others by tz; hence ariſe a great many different manners of writing the word among different authors. Some, for inſtance, writing Sabæans, others Zabians, or Zabæans, or Zabæiſts, as Buxtorf; others Tſabians, others Tſabæans, &c.

Maimonides makes frequent mention of this idolatry in his More Nevochim: it was very general, he obſerves, in the time of Moſes. The retainers hereto taught, that God was the ſpirit of the ſphere, that is, the ſoul of the world. Abraham, he adds, was brought up in the doctrine of the Sabæans, who admitted no other gods but the ſtars, and who, in their books, many of which have been tranſlated into Arabic, maintain expreſly, that the fixed ſtars and planets are inferior gods, and the ſun and moon the ſuperior ones. Abraham at length, he tells us, oppoſing theſe errors, firſt aſſerted the exiſtence of a Creator diſtinct from the ſun. The king of the Cuthæans clapped him up in priſon; but, he ſtill perſiſting, that prince, from an apprehenſion of his diſturbing the ſtate by teaching a new religion, confiſcated his goods, and baniſhed him to the extremities of the eaſt.—This relation, he tells us, is found in a book intitled, הצבורה הנבטיה the religion of the Nabathæans.

He adds, that the Sabæans, to the adoration of the ſtars, joined a great reſpect for agriculture; ſet a high value on cattle and ſheep; and taught that it was unlawful to kill them. He even adds, that they worſhipped dæmons, under the form of goats, and eat the blood of animals, though they judged it unclean, merely becauſe they imagined it was the food of dæmons.

This is a ſummary of what that Rabbin gives us concerning Sabaiſm; from whence, it is eaſy judging of what ſome people tell us, that Sabaiſm is a mixture of Judaiſm, Chriſtianity, Mahometaniſm, and Paganiſm. The truth is, the worſhip of the ſtars was eſtabliſhed long before not only Chriſtianity, but even before the law of Moſes. Not but ſome of the later Sabæans have given into divers articles of almoſt all religions.

SA'BBATH (*Dict.*)—The Chriſtians alſo apply the word Sabbath, by extenſion, to the firſt day of the week, popularly called Sunday, or the Lord's-day; as inſtituted by the apoſtles to take place of the Jewiſh Sabbath, and by us obſerved in remembrance, not of the creation, but of the work of redemption's being compleated by our Saviour's reſurrection on that day.

Thoſe who diſpute the divine appointment of a Chriſtian Sabbath, yet allow the moral neceſſity thereof as a wiſe deſignation of time for the recruiting of our bodies, and, at the ſame time, keeping up a ſenſe of the great benefits we have received from God, and a ſpiritual temper of mind. By allowing ſix days to labour, the poor has time to earn his bread, and the man of buſineſs time to diſpatch his affairs. Had more time been allotted to labour and buſineſs, and none to reſt; our bodies would have been too much fatigued and waſted, and our minds too long engaged about worldly matters, ſo as to have forgotten divine things. Greedy people, without ſuch an injunction, would ſcarce have ſpared their own bodies, much leſs their ſervants, ſlaves, cattle, &c.—The creation, therefore, would have ſuffered, had it not been provided for by the inſtitution of a Sabbath.

SABI'NA, *ſavine*, in botany, a genus of plants, whoſe characters are:

The leaves reſemble thoſe of the cypreſs, but are more compact; the berries are verrucoſe; it has a very ſtrong and ſingular ſmell.

Savine is an ever-green ſhrubby tree, that ſeldom grows very tall, having the branches ſet cloſe together, cloathed with narrow, ſhort, ſomewhat prickly leaves, pretty much reſembling cypreſs, of a very ſtrong ſmell; among theſe, after the tree is old, and has ſtood long in a place, grow ſmall, moſſy, greeniſh flowers, which are ſucceeded by ſmall flattiſh berries, leſs than thoſe of juniper, of the ſame blackiſh blue colour. It is planted in gardens, where it ſeldom produces fruit, and has therefore generally been reputed barren.

Savine is hot and dry, opening and attenuating, and a powerful provoker of the catamenia, cauſing abortion, and expelling the birth. It is very good to deſtroy worms in children. Mr. Ray recommends the juice of it, mixed with milk, and ſweetened with ſugar, as an excellent medicine for that purpoſe; beaten into a cataplaſm, with hog's lard, it cures children's ſcabby heads.

Boerhaave, in his Chymiſtry, aſſerts, that a water, prepared from ſavine by repeated cohobations, is a moſt excellent ecbolic, emmenagogue, and promoter of the hæmorrhoids; that it is heating, and a moſt excellent medicine, if uſed diſcreetly. He farther informs us, that the chymical oil of ſavine is a moſt powerful promoter of the menſes, when their retention proceeds from a languor and debility only.

A cataplaſm, made of the ſeeds of ſavine, bruiſed with ſal-gem and oil, is ſaid to be good for an anchyloſis; and a cataplaſm of the ſame leaves, mixed with honey, is frequently applied to the umbilical region, in order to deſtroy worms in the belly.

Theſe plants may be propagated by laying down their young branches in the ſpring; which, if duly watered in dry weather, will take root in a year's time, and may then be tranſplanted out, either into a nurſery, or the places where they are to remain: they may alſo be propagated by cuttings, which ſhould be planted on a moiſt ſoil about the beginning of October; which, if duly watered in dry weather, will take root, and the autumn following may be removed, as was directed for the layers.

The time for tranſplanting theſe plants is the ſame with laurels, lauruſtinus, &c. obſerving to do it in moiſt weather, laying a little mulch upon the ſurface of the ground, about their roots, to prevent their drying: after they are rooted, they will require no farther care but to keep them clear from weeds, and to dig the ground about their roots every ſpring, which will greatly promote their growth.

SA'BLE, in zoology, the name of the animal whoſe fur is ſo much valued, and ſold under the ſame name. It is a creature

 of

of the weazel kind, and called by authors mustella zibellina. See the article Zibellina.

Sable *mouse*, in natural history, the name of an animal found in Lapland, and in other cold countries; many extraordinary things are related of the manner of living of these creatures.

They are of the bigness of a squirrel, and their skin is streaked with brown and black; there are also some spots besides the streaks; the black is a very fine deep colour, the brown is pale; they have two very sharp teeth above, and two below of the same kind; their feet are like a squirrel's, and they have no tail; they are usually very fat and fleshy, and are so quarrelsome and fierce an animal, that if a stick be held out to them they will bite at it, and will hold it so fast, that they may be tossed and swung about in the air by it without letting it go. In their march they usually keep a direct line from north-east to south-west, and always travel in thousands in the same troop. The whole number forms a square body, and they march only from the time of the twilight to the morning, lying still all the day.

They march in lines, which are some ells distant, but always exactly parallel to each other, so that the places they have gone over look like the furrows of a plowed field. If they meet with any thing in their way that might deter another animal, it never stops them; but, though it be fire, a deep well, a pond, a torrent, or a bog, they, without hesitation, venture through, and by that means many thousands of them are destroyed, and are found dead in the morning, in the waters, or otherwise.

If they be met swimming over lakes, and attacked by men in boats, with the oars, boat hooks, or other instruments; they neither retreat nor offer to run up the oars, but hold on their course; and if they be put out of it they presently return into it again. When they are met in the woods or fields, they set themselves upon their hinder feet, and make a sort of squeaking noise, somewhat like the barking of a dog; they will leap up at a man, and rise as high as his head, and in this manner they will defend their line a long time; but, if they find themselves overpowered, they will disperse and run into holes, or any other places of secrecy, making a noise, which sounds something like the word biob, biob.

They never come into a house, nor meddle with any thing that we eat; if they chance to come to a house in their way, there they stop till they die; but, if they come to a stack of hay or corn, they eat their way through.

When they march over a meadow, they do it great damage, by eating the roots of the grass; but, if they encamp there, they wholly destroy the produce; the land looks like a place where there had been a fire, and the whole surface looks as if strewed with ashes.

They are said to be very fruitful, bringing forth eight or nine at a time; but it is certain, at least, that they bring forth more than one, for, in their marches, it is not unusual to see a female with a young one in her mouth and another on her back. They seem no great delicacy to creatures of prey. If dogs or cats kill them they eat only the head, and when a bird of prey seizes them it only feeds on the entrails; it is said only on the heart: the poor Laplanders, however, in want of other food, eat the whole body, and say it is as well tasted as a squirrel. In the severity of winter these creatures lie under the snow, and have their breathing-holes as the hares, and other inhabitants of these places use to have. The Laplanders are always glad to see these creatures on their march, for it always foretels plenty of more valuable creatures among them: the same cold, that sends these out, sending also a number of fowls, squirrels, foxes, and other animals the same way. Wormius has written a complete treatise on this animal, calling it mus Norwegius; this is reprinted at large in his Museum. *Phil. Transf.* N°. 251.

SA'CCHARUM *saturni*, sugar of lead, in medicine, is recommended by some internally for dysenteries, and hæmorrhages of all kinds; but the generality of the world condemn it, as containing all the poisonous qualities of the metal it is made from in their highest degree.

Externally, it has been long famous for its virtues in the erysipelas, in inflammations of all kinds, and in embrocations. It is used also in small quantities in collyriums for the eyes; it deterges, dries, and cicatrises ulcers; and in gonorrhœas is mixed in injections with great success.

It is well known that this salt made with the common vegetable or mineral acid, when distilled, will not give back the acid again, but only yields a water without any sharp taste and an inflammable oil; but if it is made into the animal acid of pismires, whether procured by distilling those insects fresh, or by throwing large quantities of them into water till it is sufficiently impregnated, it will, on distillation, yield back the same proportion of acid of the same strength. *Philos. Transact.* N°. 68.

SA'CRIFICE (*Dict.*)— The manner of sacrificing among the ancient Hebrews, is amply described in the books of Moses. That in use among the Romans is as follows:—In the choice of the victim, care was taken it were without blemish or imperfection, its tail not too small at the end; the tongue not black, nor ears cleft; and the bulls such as had never been yoked. The victim being pitched upon, they gilt his forehead and horns, especially if a bull, heifer, or cow. The head they also adorned with a woollen infula, whence hung two rows of chaplets, with twisted ribbons; and on the middle of the body a kind of stole, pretty large, hung down on both sides: the lesser victims were only adorned with bundles of flowers and garlands, together with white tufts or garlands.

The victims, thus made ready, were brought before the altar; the lesser were not led in a string, but driven to the place: the greater were conducted in an halter; if they made any struggle, or refused to go, the resistance was taken for an ill augury, and the Sacrifice set aside.—The victim, thus brought before the altar, was examined very circumspectly, to see if there were no defect in it: then the priest, being clad in his sacerdotal habit, and accompanied with the sacrificers and other attendants, and being washed and purified according to the ceremonies prescribed, began the Sacrifice, with making a loud confession of his unworthiness, acknowledging himself guilty of divers sins; for which he begged pardon of the gods, hoping they would be pleased to grant his requests.—These confessions were like those of the Hebrews; with this difference, that the Pagans confessed the frailty of mankind, and owned their faults; the Jews confessed chiefly the greatness of God, accompanying it with hymns and musical instruments.

The confession over, the priest cried aloud, Hoc age, i. e. Compose yourselves, and mind your business; and presently an usher, holding a rod in his hand, called commentaculum, went through the temple, and made all those withdraw, who were not initiated in the mysteries of religion, or such as were excommunicated.

The custom of the Greeks, from whom the Romans borrowed theirs, was, that the priest, coming to the altar, should ask aloud, Τίς τῇδε? Who is here? The people answered, Πολλοὶ κ᾽ ἀγαθοί, many good persons: then the usher went through the temple, crying, Ἑκὰς, ἑκὰς, ἔστε βέβηλοι, that is, out with the wicked. The Romans commonly used the words, nocentes, profani, abscedite.— All those who were driven out of the temples among the Greeks, were comprehended under these general words βέβηλοι, ἀμύητοι, ἀκάθαρτοι. The profane being withdrawn, they cried, favete linguis, or animis, and pascite linguam, to require silence, and attention during the Sacrifice.

These ceremonies ended, the chief sacrificer being sat down, and the rest of them standing, the magistrates or persons, who offered Sacrifice, came before him, and presented him with the first-fruits and victim, and sometimes made a short discourse, by way of compliment; as we find Homer makes Ulysses do, when he presented the high-priest with Iphigenia to be sacrificed.— As any person came to present his offering, he washed his hands in a place appointed in the temple for that purpose.

Lastly, when the offering was made, the priest that officiated, perfumed the victim with incense, and sprinkled it with lustral water; and having washed his hands, and got up again to the altar, he prayed to the god to whom he presented the Sacrifice, with a loud voice, that he would accept of those offerings, and be pleased with the victim he sacrificed to him for the public good, and for such and such things in particular.— In the close of the offertory and prayer, made by the priest to the gods, he came down the steps of the altar, and, from the hand of one of his assistants, received the sacred paste, called mola salsa, made of barley or wheat flour, mixed with salt and water, which he threw upon the head of the victim, sprinkling a little wine upon it, which was called immolatio.— Servius says, the priest scattered little bits of this paste upon the head of the victim, the altar where the sacred fire burned, and the knives, by way of consecration. He then took wine in a vessel called simpulum, and having tasted it himself first, and made his assistants do the same, to shew that they partook of the Sacrifice, he poured it between the horns of the victim, pronouncing these words of the consecration, Mactus hoc vino inferis esto; Let this victim be improved and honoured by this wine. This done, he pulled off the hairs from between the horns, and threw them into the fire; and commanded the victimarius, who asked him, Agon', Shall I strike? to knock down the victim with a blow on the head with an hammer or ax; upon which, another assistant, named popa, presently thrust a knife into his throat; whilst a third received the blood, wherewith the priest sprinkled the altar.

When the victim was slain, they flead him, if it was not a burnt offering, for then they burned skin and all; took the flesh off the head, and adorned it with garlands and flowers, fastened it to the pillars of the temples, as well as the skins, as ensigns of religion; carrying them about in procession in public calamities.—Not but that the priests often wore the skins, and others went to sleep upon them in the temples of Æsculapius and Faunus, that they might receive favourable responses in their dreams, or be cured of their maladies. They then opened the victim's entrails, and after circumspectly viewing them, to draw presages therefrom, according to the art of the aruspices, they floured them with meal, and sprinkled them with wine, and made a present of them to the gods, reddebant exta diis, by throwing them into the fire in small bits, boiled or parboiled; and hence the entrails were called porricæ.

The entrails being burned, and the other ceremonies finished, they believed the gods to be satisfied; and that they could not fail to find their vows accomplished, which they expressed by the word litare, q. d. all is finished, and well done; whereas non litare, on the contrary, intimated there was something wanting to the perfection of the Sacrifice, and that the gods were not appeased.— The priest afterwards dismissed the people with these words, Ilicet.

Hence it may be observed, that the Sacrifices consisted of four principal parts; the first called libatio, or the pouring a little wine upon the victim; the second immolatio, when, after they had scattered the crumbs of salted paste thereon, they killed it; the third, redditio, when they offered the entrails to the gods; and the fourth, litatio, when the Sacrifice was perfected, and accomplished without any fault.

SA'CRILEGE (*Dict.*)— The ancient Christian church distinguished several sorts of Sacrilege, which were punished with different kinds of censures.

The first kind of Sacrilege was, the diverting things, appropriated to sacred uses, to other purposes. 'If any one, say the apostolical canons, either of the clergy or laity, take wax or oil out of the church, let him be cast out of the communion, and make restitution, with the addition of a fifth part'. The same censure is denounced against such as apply to their own use the sacred utensils of gold, silver, or linen. The fourth council of Carthage excommunicates those persons, as guilty of Sacrilege, who withhold from the church such donations as are left to it by the deceased. And whether a man retracted what he himself had given to the church, or detained what was given by others, or robbed her of what she was actually possessed of, it was all the same species of Sacrilege, and equally punished with excommunication.

Another crime, punished under the name of Sacrilege, was, robbing the graves, or defacing and spoiling the monuments of the dead. The imperial laws made this offence capital.

Another sort of men, who were accused and condemned as sacrilegious persons, were those, whom they commonly called traitors, because they delivered up their bibles, and the sacred utensils of the church, to the Pagans, in the time of the Dioclesian persecution. The first council of Arles makes it deposition for any clergyman to be guilty of this base piece of treachery.

A fourth species of Sacrilege was, the profaning the sacraments, the churches, altars, holy scriptures, &c. There are some instances of turning churches into stables. We may reckon also all sorts of idolatry and divination, magic, and the abuse of the scriptures for lots, charms, and amulets, among this species of Sacrilege.

Fifthly, the molesting or hindering a clergyman in the performance of his proper office, is, in the civil law, called Sacrilege; and, by a law of Honorius, all such criminals were to be notified by public officers to the governor of the province, who was to proceed against them, and punish them as capital offenders.

Lastly, the ancients reckoned it Sacrilege to deprive men of the use of the scriptures, or the sacraments, particularly of the cup in the Eucharist.

The Romish casuists acknowledge these several species of Sacrilege, excepting only the last, which, for a very obvious reason, they never mention. But they call many things Sacrilege, which the ancients reckoned no crimes at all; as the laying taxes or tribute upon ecclesiastics, by the civil power, without consent of the Pope; for which secular princes are excommunicated by the famous bull in Cœna Domini: as also the bringing ecclesiastical persons, for any crime, before the secular tribunals. Some other things, very laudable in themselves, they brand with the odious name of Sacrilege; as, the removing images out of places of divine worship.

SA'DDLE, in the manage, a kind of stuffed seat, laid on the back of a horse, for the convenience of the rider.

The origin of the Saddle is not well known: Gorop. Becanus attributes its invention to the Salii, a people among the ancient Franks; and hence, says he, came the Latin sella, a Saddle.

It is certain that the ancient Romans were unacquainted with the use either of Saddle or stirrups; whence Galen observes in several places, that the Roman cavalry, in his time, were subject to several diseases of the hips and legs, for want of having their feet sustained on horse-back. And, long before him, Hippocrates had noted, that the Scythians, who were much on horse-back, were troubled with defluxions in their legs, because of their hanging down.

The first time we hear of Saddles among the Romans, was anno 340; when Constantius, endeavouring to deprive his brother Constantine of the empire, made head against his army, and, entering the squadron where he himself was, threw him off his Saddle, as we are informed by the historian Zonaras.— Before, they made use of square pannels; such as we see in the statue of Antoninus in the capitol.

The use of Saddles was first established in England, by a law of Henry VII, whereby the nobility were obliged to ride on Saddles.— It is but very lately that the Irish have taken to it.

There are various kinds of Saddles; as the

Running SADDLE, a very small one, with round skirts.

Burford SADDLE, which has the seat and skirts plain.

Pad SADDLE, of which there are two kinds; the one made with burs before the seat, the other with bolsters under the thighs.

French pad SADDLE, the burs whereof come all round the seat.

Portmantua SADDLE, furnished with a cantle behind the seat, to keep a carriage off the rider's back.

War SADDLE, furnished with a cantle, and a bolster both behind and before.

SADDLE-GALLED, is when a horse's back is hurt, or fretted with the Saddle.

It is cured by bathing the part with urine, or warm wine: when the sore is large, they bathe it with aqua secunda, strewing over it the powder of old ropes of flax, and consuming the proud flesh with vitriol or colcothar.

SAGE *Apples*, a name given by naturalists to a sort of soft gall or protuberance, found frequently on the leaves and stalks of Sage in the eastern part of the world, and much resembling the soft gall of the oak leaf, called the oak apple.

These are both owing to the same cause, the puncture of an insect of the fly kind, which deposits its eggs in the wound; and the worms or maggots, hatched from those eggs, feed on the inside of the gall, and occasion a preternatural derivation of juices to the part, whence it swells and assumes this form. The leaves of many other plants are also liable to the same accident, particularly those of ground-ivy, on which there grows eatable galls of this kind. The Sage apples are so frequent in the east, that they are brought to market at Constantinople, and eaten as delicacies.

SA'GENE, a Russian measure equivalent to seven English feet. Five hundred Sagenes make a werst. *Phil. Transf.* N°. 445.

SAGITTA'RIA *alexipharmica, arrow-root, dart-wort.*— This plant has a root two or three inches in length, geniculated, of the thickness of a man's thumb, white, and of a conic figure, every interval or space between the joints being half an inch in length, and every joint sending forth several fibres two or three inches long, for attracting nourishment. From the root arise various leaves on pedicles three inches in length, and of a good breadth, embracing one another, or the outer ones wrapping themselves about the inner, and surrounded with a white ring at the place of apposition. The leaves are four inches long, and two inches broad, near the round base, where they are broadest, and are thin, fibrous, and grassy, and of a greenish-yellow colour. In other respects it is like the canna Indica.

Sir Hans Sloane observed this plant in the gardens of Jamaica and the Caribbee Islands. It was transplanted to Jamaica from the island of Dominica, and is highly valued, on account of its alexipharmic virtue, and its efficacy against wounds inflicted by poisoned darts and arrows; for which purpose it is frequently used by the Indians, who bruise the herb, and apply it to the injured place. *Raii Hist. Plant.*

SAIL, in navigation, an assemblage of several breadths of canvas, or strong hempen cloth, sewed together by the lists, and edged around with a cord; fastened to the yards and stays of a vessel, to make it drive before the wind, which bears thereupon.

There are two kinds of Sails; the one square, generally used in large ships or vessels.— This has various names, according to the various masts it is fastened to; as the main Sail, fore Sail, the mizzen Sail, the sprit Sail, &c.

The others are triangular, called smack Sails, and by some Latin Sails, because chiefly used in Italy, and in flat-bottomed vessels; though they are also used on the mizzen-masts and stays of other vessels.— They need but few ropes, and little wind; but are dangerous, and not to be used in foul weather.

There are ordinarily ten Sails in large vessels; which number is increased at bottom by the addition of bonnets, and at the sides by case Sails.

A vessel is said to set Sail, to go with full Sail, to make all her Sail, that is, to open all her Sails. To be under Sail, is to have set Sail, &c.

SAILS, also denote the vanes of windmills; or the arms or flights, whereby the wind has its effect on windmills.— These are either horizontal or perpendicular.

SA'ILING (*Dict.*)— Sailing, in a more confined sense, is the art of conducting a vessel from place to place, by the working or handling of her sails and rudder: though what is done, by means of this latter, is more properly called steering or guiding.

To bring Sailing to certain rules, M. Renau computes the force of the water, against the ship's rudder, stem, and side; and that of the wind against her sails.— In order to this, he 1. considers all fluid bodies, as the air, water, &c. as composed of little particles, which, when they act upon, or move against any surface, do all move parallel to one another, or strike against the surface after the same manner. 2. That the motion of any body, with regard to a surface on on which it is to ſtrike, muſt be either perpendicular, parallel, or oblique. In the firſt caſe, the body ſtrikes with all its force, which will be greater or leſs, according as the body moves ſwifter or ſlower. In the ſecond caſe, the line of motion *a b*, *Plate* XLI. *fig.* 1. will not affect the ſurface at all; becauſe it is no way oppoſed to it; nor can the moving body ſtrike upon it, or touch it. In the third, if the line of motion. A D, be oblique to the ſurface D C, ſo that the angle of incidence be A D C, then the motion of the body in the line A D may be reſolved into two directions, *viz.* into A E or B D, and A B. But the direction or line of motion A E, being parallel to the ſurface D C, cannot affect it at all; ſo that the whole motion of the body A, in that oblique manner of ſtriking on the ſurface, will be expounded by the perpendicular line A B. And if D A be made the radius of a circle, whoſe center is at D, B A will be the ſine of the angle of incidence, A D C.

Hence it is deduced, that the force of a particle of air or water, as A, ſtriking againſt the ſurface D C, which may repreſent either a ſail or the rudder of a ſhip, in the oblique direction A D, will be to the perpendicular force thereof, as B A is to D A: that is, as the ſine of the angle of incidence is to the radius.

And ſince what is thus true of one particle, ſingly conſidered, will be true of all the particles of any fluid body collectively; it will follow, that the force of the air or water, ſtriking perpendicularly upon a ſail or rudder, to the force of the ſame, in any oblique impingency, will be, as the ſquare of the radius to the ſquare of the ſine of the angle of incidence: and, conſequently, that all oblique forces of the wind againſt the ſails, or of the water againſt the rudder, will be to one another, as the ſquares of the ſines of the angles of incidence.

If the different degrees of velocities be conſidered, 'it will be found, that the forces will then be as the ſquares of the velocities of the moving air or water; that is, a wind that blows thrice as ſtrong, or moves thrice as ſwift as another, will have nine times the force upon the ſail.— And it being alſo indifferent, whether you conſider the motion of a ſolid in a fluid whoſe particles are at reſt; or of thoſe particles moving all parallel againſt a ſolid that is at reſt; the reciprocal impreſſions being always the ſame; if a ſolid be moved with different velocities in the ſame fluid matter, as ſuppoſe water, the different reſiſtances which it will receive from that water will be in the ſame proportion, as the ſquares of the velocities of that body.

Let H M, *fig.* 2, repreſent a ſhip, C D the poſition of the ſail, and A B the courſe of the wind blowing towards B. Draw B G perpendicularly to the ſail, and G K perpendicular to the line of the keel produced H M K. By what is ſaid above, the ſail C D will be driven by the wind A B, according to the direction of the line B G. So that, if ſhe could divide the water every way with the ſame facility, as ſhe doth with her head, the ſhip would go directly to the point G, along the line B G. And, if H K repreſent her direct courſe, ſhe would have got forwards the length B K, and ſideways ſhe would have gone the quantity G K. But, as her length is much greater than her breadth, ſo ſhe will divide the water, or make her way in it with more difficulty with her ſide, than with her head or ſtern; on which account, ſhe will not run ſideways ſo far as K G, but fall ſhort of it in proportion to the ſaid difficulty of dividing the water with her ſide, that is, if the reſiſtance ſhe finds in her paſſing through the water ſideways, be to that of paſſing lengthways, ſuppoſe, as ten to one, then will not the ſhip get ſideways above a tenth part of the line G K.

Wherefore, if K G be found to G L, in the ratio of the reſiſtance of the ſide to that of the head, and the line B L be drawn; the ſhip will go to the point L, along the line B L, in the ſame time as it would have gone to G, if it could have divided the water every way equally.— This part, K L, is called the drift, or lee-way of a ſhip, and the angle K B L is her degrees of lee-way; as the angle A B K expreſſes how near the wind ſhe lies.

After this, the author proceeds to demonſtrate, that the beſt poſition or ſituation of a ſhip, ſo as ſhe may make the leaſt lee-way, but go to wind-ward as much as poſſible, is this: that, let the ſail have what ſituation it will, the ſhip be always in a line biſſecting the complement of the wind's angle of incidence upon the ſail; that is, ſuppoſing the ſail in the poſition B C (*fig.* 3.) the wind blowing from A to B, and conſequently the angle of the wind's incidence on the ſail A B C, and its complement C B E; then muſt the ſhip be put into the poſition B K, or move in the line B K, biſſecting the angle C B E. He ſhews farther, that the angle which the ſail ought to make with the wind, i. e. the angle A B C, ought to be but twenty-four degrees; that being the moſt advantageous ſituation to go to wind-ward, the moſt that is poſſible. And, in order to bring this to bear in practice, he directs to put marks to the ſheets, braces, and bow-lines of the lower ſails, to know when they are in their beſt ſituation; and then, even in the night, when the marks of a brace or of a ſheet ſhall come to the cleat, one may be pretty well aſſured, that the ſail trims well.

To this might be added, many curious things from Borelli de Vi Percuſſionis, concerning the different direction given to a veſſel from the rudder, when ſailing with a wind, or floating without ſails in a current; in the former caſe, the head of the ſhip always coming to the rudder, and in the latter always flying off from it.

SAINTFOIN, *ſanum*, or *ſanctum fœnum*, the name given by the French, and continued by us to a ſpecies of plant, frequently uſed for the food of cattle, either freſh or dried; it is called holy-hay, or wholeſome hay, from its excellent nutritive quality. The ſtalks of the plant are commonly about two feet long, but they grow ſometimes to five or ſix feet, and it has tufts of red flowers of three, four, or five inches in length.

This plant will make a forty times greater increaſe in poor ground than the common turf; and this is owing to its having a long perpendicular root, of that kind, called tap roots, which ſinks to a great depth to attract its nouriſhment. The length of this root is ſcarce to be credited by any but thoſe who have ſeen it; it is frequently drawn out of the ground to the length of twelve or fourteen feet, but it is ſaid to be often thirty feet or more in length.

The farmers have a general opinion, that this plant never ſucceeds well in any land, where there is not an under ſtratum of ſtone, or chalk, or ſome other hard matter, to ſtop its running; but that otherwiſe it ſpends itſelf in root, and comes to nothing above-ground. This is an error too groſs to need much refutation. It is certain, that, the roots being to plants what the ſtomach and guts are to animals, the more and larger roots any plant has, the more nouriſhment it receives, and the better it thrives.

Saintfoin always ſucceeds where its roots run deep, and the beſt crops of all are produced upon lands where there is no hard under ſoil to obſtruct their paſſage. An under ſoil of clay may kill the plants, by retaining the water, and chilling and rotting their roots.

The long root of Saintfoin has, near the ſurface, many horizontal roots iſſuing from it, which extend themſelves every way; there are of the ſame kind all the way down, as the roots go, but they grow ſhorter and ſhorter all the way. Any dry land may be made to produce this valuable and uſeful plant, though it be ever ſo poor, but the richeſt and beſt land will produce the beſt crops of it. The beſt way of ſowing it is by drilling, but the earth muſt be very well prepared, and the ſeed well ordered, or elſe very little of it will grow. The heads of theſe ſeeds are ſo large, and their necks ſo weak, that, if they be much more than half an inch deep, they are not able to riſe through the incumbent mould; and, if they are not covered, they will be malted, as the farmers expreſs it; that is, it will ſend out its root while it lies above-ground, and be killed by the air; and whether the farmer plants bad ſeed that will not grow, or good ſeed that is buried or malted, the event will be the ſame. The ground will be underſtocked with plants. A buſhel of ſeed to an acre of land is full twenty ſeeds to each ſquare foot of land; but, as there is ſome difference in the largeneſs of the ſeeds, there is no abſolute certainty as to this calculation. The worſt ſeaſons for planting it are the beginning of winter, and the drought of ſummer; the beſt is the beginning of the ſpring; and it is always ſtrongeſt when planted alone, and is not ſown together with corn, as is the practice of ſome farmers. If barley, oats, or any other corn, ſown with the Saintfoin, happen to be lodged afterwards, it kills the young Saintfoin. If it be planted with any other corn, it is beſt done by drilling in the horſe-hoeing way; in this caſe it is not much liable to be killed by the lodging of the corn, as the drilled corn ſeldom falls at all, and, when it does, never falls ſo low as the ſown corn.

The quantity of ſeed to be drilled upon an acre of land will depend wholly upon the goodneſs of it; for there is ſome ſeed of which not one in ten will ſtrike, whereas in good ſeed not one in twenty will fail. The method of knowing the goodneſs, is, by ſowing a certain number of the ſeeds, and ſeeing how many plants are produced by them. The external ſigns of the ſeeds being good are, that the huſk is of a bright colour, and the kernel plump, of a light grey or blue colour, and ſometimes of a ſhining black. The ſeed may be good, though the huſk be black, as that is owing ſometimes to the letting it receive the wet in the field, not to its being half rotted in the heap.

If the kernel be cut a-croſs, and appear greeniſh and freſh, it is a certain ſign that it is good. If it be of a yellowiſh colour, and friable, and look thin and pitted, they are bad ſigns. The quantity of ſeeds allowed to the acre in the drill way is much leſs than that by ſowing, and is to be computed according to the number of plants that are to be allowed in that ſpace, allowing for the common caſualties. It is not neceſſary to be exact in this calculation, or to ſay whether two, three, or four hundred plants are to be allowed to a ſquare perch; neither is it poſſible to know beforehand the preciſe number of plants that may live out of thoſe that come up; for ſometimes the grub takes them when they have only the two firſt leaves, and the crop is greatly diminiſhed by this means. Four gallons of good ſeed to an acre of land will cover it with plants, when judiciouſly managed.

Single plants of Saintfoin make the greateſt crops; but the farmers, in general, plant them ſo cloſe, that they ſtarve one another. The ſingle plants always run the deepeſt, and thoſe which do ſo will always draw moſt nouriſhment. The plants which ſtand crowded ſtarve one another, and often die after a few years; but the ſingle ones grow to a vaſt bigneſs, and are every year better and better.

The beſt way to calculate how many plants are to be allowed to a perch, is to compute how much hay each ſingle large plant will produce; for, if kept ſingle, and well cultivated, they will all be large ones. Without culture, theſe plants never arrive at a fourth part of the ſize that they do with it. The hay of a large ſingle cultivated plant will weigh more than half a pound, and a hundred and twelve plants upon a ſquare perch, weighing but a quarter of a pound a piece, one with another, amount to two tons to an acre. If Saintfoin be planted on ſome ſorts of land early in the ſpring and hoed, it will ſometimes produce a crop the following ſummer; in a garden the ſeeds ſown in February will yield plants of two feet high that will flower in the month of June following; and, though March be froſty, the young plants ſeldom ſuffer by it. This ſhews, that this plant is naturally a quick grower; but the farmers uſually plant it on poor or cold land, and give it too little culture, which make it backward, and ſlow of growth with them. The poor land, uſually allotted to this plant, alſo makes it generally yield but one crop a year, but on a rich land it will yield two very good crops annually, with a moderate ſhare of culture and management.

The farmer who expects to make a profit of this plant muſt not expect a good crop the firſt year. Nothing is ſo injurious to Saintfoin as its ſtanding too thick; if it be ſown ſo thick as to cover the ground the firſt ſummer, the plants will ſtarve one another for ever after; but, if the owner will be content to place them ſo thinly as to have but a ſmall crop the firſt year, they will increaſe prodigiouſly, and every ſucceeding crop will be better and better. When Saintfoin is well hoed, it will grow as much in a fortnight as it would otherwiſe do in ſix weeks; and this quick growing is of advantage to it every way, not only making the plants large, but of better nouriſhment to the cattle, whether they are eaten green or made into hay.

The proper diſtance to drill this plant for the horſe-hoeing huſbandry is at double rows with eight inch partitions between them, and thirty inch intervals between every two and two. Theſe intervals need only be hoed alternately, leaving every other interval for making the hay on. This method of hoeing is of vaſt advantage, and poor land by means of it will always produce two crops a year. The land is always to be perfectly cleared of graſs before the ſowing the Saintfoin, and the lumps of earth carefully broken. But no harrowing is to be allowed after it is drilled, for that would bury it; and it is not proper to roll it at all, unleſs for the ſake of barley, when they are ſown together; and when that is done, it ſhould be with a light roller and in dry weather. This ſhould be done lengthwiſe of the rows, and as ſoon as it is drilled; if it be not done at this time, it is beſt to ſtay three weeks before it is done, that the necks of the young Saintfoin may not be broken. No cattle are to be ſuffered to come in the firſt winter upon the Saintfoin, after the corn is out, among which it was ſown. Their feet would injure it by treading the ground hard, as much as their mouths by cropping it, and it would never come to good. Sheep ſhould not be ſuffered to come at it, even the following ſummer and winter. One acre of drilled Saintfoin, conſidering the difference of the quantity and goodneſs of the crop, is worth two acres of ſown Saintfoin on the ſame land, though the expence of drilling be twenty times leſs than that of ſowing. The firſt winter is the time to lay on manure after the corn is reaped off. Pot-aſhes, or the like, are very proper, and a ſmall quantity of them will do, as there are at this time no other plants to partake of the benefit, but the young crop has it all; and the young plants, being thus made ſtrong at firſt, will continue ſo, and be long the better for it.

It is obſerved, however, that in the drilling and horſe-hoeing way there is no neceſſity for any manure at all. Some farmers ſow eight or ten buſhels of the ſeed of Saintfoin to an acre along with their corn, with intent that it ſhould kill all the other weeds; but the conſequence is, that the plants ſtand cloſe, and ſtarve one another, and are no bigger than where the plant grows wild on the hills in Calabria, where it is ſo ſmall and ſeemingly deſpicable a plant, that it ſeems a wonder that any body ſhould be tempted to think of cultivating it: yet, when rightly managed, it ſeems capable of being as uſeful a plant as any in the world. Where theſe plants ſtand ſo thick, they draw out all the nouriſhment from the ground, in a few firſt years, and ſo die, though manured ever ſo carefully. Six or ſeven years ſeems their greateſt duration; whereas, when the ſeed is drilled in, and the plants are horſe-hoed, they will be as ſtrong and vigorous as ever, at thirty years ſtanding.

Some people who have turned their thoughts to huſbandry, have been of opinion, that the cytiſus would ſucceed better with us than the Saintfoin; it is probable enough that it would grow well; but the labour of ſheering it would, with us, where the pay of ſervants is ſo dear, run away with the greateſt part of the profits of the crop.

Lucerne is another thing which many have thought of introducing among us in the place of Saintfoin, but it requires ſo much care to ſuit it with a proper ſoil, that, whatever are the profits of it, it never can be ſo general as Saintfoin. *Tull's Horſe-hoeing Huſbandry.*

Saintfoin ſucceeds beſt alſo in high grounds, which is a great advantage in the article of making it into hay, as it has greatly more advantage of the ſun, and leſs to fear of miſchief from wet than graſs which grows in low grounds. On the high grounds the wind will dry more in an hour than it will in meadows that lie low in a whole day; and often the crops of Saintfoin make a very good hay in the ſame ſeaſons in which all the graſs hay is utterly ſpoiled. The ſun on the high grounds has alſo a more benign influence, and ſends off the dew there two hours earlier in the morning, and holds it up as much longer in the evening; by theſe advantages, the Saintfoin has more time to dry, and is made with half the expence of common hay.

All kinds of hay differ greatly in their goodneſs, according to the manner in which they are made; but the hay of Saintfoin differs more than all.

There are properly four kinds of the Saintfoin hay, differing according to the times of cutting them. Theſe are, firſt, the virgin hay; ſecondly, the bloſſomed hay; thirdly, the full grown hay; and fourthly, the thraſhed hay. The firſt of theſe, or virgin hay of Saintfoin, is the beſt of all, and excepting lucerne, has not its equal in the world. The Saintfoin for this hay muſt be cut before it begins to bloſſom; for when it ſtands till full blown, the moſt volatile ſpirituous and nutritive parts of its juices are ſpent on the generation; and this being done at once, the ſap is greatly depauperated, and the plant can never afterwards recover the ſtrength, vigour, and nutritive qualities it had at that time. The exact time of cutting this is, when a few of the bloſſoms, which are forwarder than the reſt, are beginning to look red. Saintfoin, cut in this ſtate, even though the weather prove bad, may be made up in ſmall ricks, and a chaff baſket drawn in the middle of each; this eaſy care will prevent it from firing; and, though the colour be a little altered, it will be as good and nouriſhing, as if made at the moſt favourable ſeaſon. Working ſtone-horſes have been kept for the whole winter on this hay alone without corn, and they are ſo fond of it, that they will refuſe beans and oats mixed with chaff in the common way for it.

Sheep will alſo be fatted in pens in winter with only this hay and water, better than with peaſe, oats, and the like; and, if the hay be weighed to them, and the whole expence and profit computed, the clear profit will be found to amount to four pounds a ton. Theſe creatures make no waſte in this way of feeding, but eat up every morſel of the ſtalks, though ever ſo thick, for they are always brittle, and are as well taſted as the reſt.

The bloſſom hay is very beautiful to the eye, and of a very ſweet ſmell; but it does not fatten the ſheep as the virgin hay does, nor can working horſes be kept fat upon this without an admixture of ſome corn.

The land ought to be well tilled for the virgin hay; for, if it ſtands on a poor land, without much culture, it will not be above four or five inches long before it flowers, and will therefore yield but a poor quantity, and will ſpring up again, but very ſlowly, for another crop; but, when on good land and well tilled, it will yield at this time two or three tons to an acre, and will ſpring up immediately very ſtrong for a ſecond crop.

This virgin hay is ſeldom ſold, it being worth a much greater price than the common, and is uſually kept by the farmer for his own uſe.

SAINTS, Sancti, in the Romiſh church, holy perſons deceaſed, and, ſince their deceaſe, canoniſed by the pope, after ſeveral informations and ceremonies.

One of the points wherein the Roman Catholics and Proteſtants differ, is, that the former addreſs, invoke, ſupplicate Saints, &c. to intercede for them; whereas the latter hold it ſufficient to propoſe their good examples for our imitation.

The number of Saints, allowed as ſuch, in the Romiſh church, is prodigious: Father Papebroche reckons ſeventeen or eighteen hundred to have died on the firſt of June, only. Indeed, the crowd of Saints wherewith their martyrologies are ſtocked, is ſcandalous, even to the more ſober of their own communion. Father Mabillon, in an expreſs diſſertation on the Worſhip of unknown Saints, obſerves, that honours are given to Saints, who, perhaps, were not Chriſtians; and whoſe names were never known. Hence, being under a neceſſity of giving them names, they are therefore called baptiſed Saints. He adds, that they every day beſeech Saints to intercede for them with God, when it is much doubted, whether they themſelves be in heaven.

Father Papebroche and his aſſociates have been a long time employed in writing the lives and acts of the Saints: they range them each on the day of the year wherein they died: for the firſt ſix months they have publiſhed twenty-four volumes in folio; and ſince Papebroche's death, in 1714, his ſucceſſors have publiſhed two more.

SAL *Aquarum*, in natural hiſtory, a name given by many of the ancient writers to the nitre of the ancients or natrum.

They

They had this salt principally from Egypt, and called it, in their works, the produce of the evaporated waters of the Nile; for this reason Hippocrates sometimes calls it Sal Ægypti, and sometimes Sal in aquis crescens, a salt growing in the waters.

SAL *circulatum*, in chemistry, a term used by Paracelsus for a preparation of sea-salt, of which he distinguishes two kinds, under the name of circulatum minus and circulatum majus. These seem to have a great affinity with the famous alkahest or universal solvent, so much talked of in the works of this author, and his successor Van Helmont.

The circulatum minus was a liquor procured by a tedious process from sea-salt; this salt, he says, is that body in which nature has placed the greatest perfection; and from this he, by incredible industry, procured a liquor which he calls a perpetual oil, and to which he also gives the name of the ens primum of salts. He calls it the highest and most successful of all salts, and declares that all poisons are subdued by it; and that being brought to the utmost degree of purity and subtility, it pervades all bodies, and readily dissolves them, itself remaining unaltered in the action. These are all properties expresly attributed by Helmont to the famous alcahest.

The circulatum majus, however, we are told, by the same author, was much more powerful and much more difficult to be obtained. This he calls the matter of mercurial salt, and the living fire. He acknowledges that the highest fire and celestial fire lie hid in common mercury, and says the quintessence of mercury is celestial fire: by this and a great many other enigmatic expressions in this writer, there is room to believe, that the alcahest, described by Helmont, is a preparation of mercury and sea-salts. *Boerh. Chem.*

SAL *diureticus*, a form of medicine of the nature of the terra foliata tartari, introduced into practice by the late College Dispensatory. The method of preparing it is this: take of any alcaline fixed salt a pound, boil it in four or five pints of distilled vinegar in a gentle heat. When the fermentation is over, pour on more distilled vinegar; and, when the fermentation arising from this addition is over, pour on still more, and proceed thus till the moisture being nearly all evaporated, fresh vinegar being added will excite no more fermentation: this generally happens when about ten quarts have been used; then evaporate to a dryness; the salt will be impure, and must be melted, for a small time, with a gentle heat, afterwards dissolved in the water, and filtred; if the melting has been rightly performed, the strained liquor will be pellucid as water; then evaporate this in a gentle heat to a dryness, and you will have a very white salt, soluble either in water or spirit of wine. *Pemberton's London Disp.*

SAL *marinum regeneratum*, in chemistry, the name given to a sea-salt, produced by adding an alcali to its acid spirit of salt drawn by distillation. The process is thus: dilute four ounces of oil of tartar, with three times its weight of fair water; put this mixture into a tall glass body, and heat it, and drop into it any of the kinds of spirit of sea-salt, whether Glauber's, or that prepared with bole; shake the vessel now and then, and continue to drop in the acid till the alcaline liquor is sated, and there rises no more effervescence; filtre the liquor, and evaporate to a pellicle, and set it by to crystallise, and there will be procured crystals of perfect sea-salt, in all things agreeing with common salt. *Boerh. Chem.*

SAL *martis*, salt of iron.—A chemical preparation which is made as follows: mix together a quart of water and eight ounces of oil of vitriol; pour the oil of vitriol in by a little at a time; and, having put this mixture into a glass vessel, add to it filings of iron, four ounces. When the ebullition is over, evaporate the liquor to a pellicle, and set it to shoot; there will be found a green vitriol or salt in fair crystals, which dry for use.

This salt is one of the most powerful preparations of iron; it opens obstructions of all kinds, and strengthens the viscera; it is an excellent medicine in cachexies, obstructions of the spleen and liver, and in suppression of the menses; it is also found good against worms.

The best manner of giving it is in solution, half an ounce in a quart of water, four ounces of which is a dose; and, if drank in the manner of the natural chalybeate waters, it will be found to excel most of them in its good effects.

SAL *mirabile*, Glauber's salt. See *Glauber's* SALT.

SA'LEP, in the materia medica, the root of a species of orchis. Salep should be chosen clean, firm, and hard; it is very little liable either to decay, or sophistication.

The people of the East are extremely fond of Salep; they look upon it as one of the greatest restoratives and provocatives to venery in the whole vegetable world.

That Salep is the root of an orchis, no way differing from our common orchis's in virtue, but owing its appearance to the manner of preparing it, and, consequently, that Salep may be prepared from the roots of orchis of our own growth, Mr. Geoffroy has proved in the following manner: He considered, that the method of curing one root in the eastern parts of the world was probably the same with that used in all; and observing that Kæmpfer had described the manner in which the Chinese prepare their ginseng to make it pellucid, which was by first steeping, or macerating it in water, and afterwards carefully drying it; he determined to attempt the curing the roots of the common orchis, in a method not unlike that used to the ginseng, in order to make Salep of it. The Salep, which we receive from Turkey, is a root of a white or reddish colour, according to its different age; and, as we receive it, is always transparent. As to our own orchis, if we attempt to dry the roots in the common way, they never will appear at all like the Salep, but will become shrivelled up and brown, and will always retain, or be ready to imbibe, from a humid air, a great quantity of moisture. To prepare these, in imitation of the Salep, Mr. Geoffroy chose the largest, plumpest, and fairest roots he could find; these he nicely skinned, taking off the whole outer rind; then throwing them into cold water, he suffered them to macerate there some time; after this he lightly boiled them; and after this taking them out of the water, and draining them, he had them strung upon threads, to be dried in a warm and dry air. When the roots were thoroughly dried, they were very transparent, and resembled pieces of gum tragacanth, and continued dry and hard. The roots thus prepared may be kept ever so long in a dry place, and will never attract humidity, or become mouldy and rotten; as they will always do in wet weather, if dried in the common way with their skins on.

The orchis roots thus prepared may be reduced to powder: this powder will dissolve away in boiling water, and a scruple of it will make a bason full of jelly, in the manner of the Turkish Salep. This jelly is an admirable medicine in all the cases, in which Salep is prescribed, and may be rendered agreeable by the addition of wine, sugar, spice, &c. and the powder may be given with great success in asses milk, for diseases of the breast.

If the water, in which the roots have been boiled, be evaporated over a gentle fire in an earthen vessel, there will remain an extract of a viscous texture, and a very agreeable smell, resembling that of a meadow of flowers when the wind blows over it. *Mem. de l'Acad. Scienc. Par.* 1740.

SALICA'RIA, *spiked willow-herb*, in botany, a genus of plants, whose characters are:

The calyx is tubulous, striated, and multifid; the flowers are rosaceous, hexapetalous, and grow out of the upper incisures on the inside of the tubulated calyx, almost in a series of whorls, and are furnished with a multitude of stamina, sometimes no fewer than eighteen. The ovary, which is adorned with a long tube, that has an apex shaped like a bason, when ripe, becomes an ovated, bicapsular shell involved in the calyx, and full of small seeds.

It grows in marshy places, and by the banks of rivers, and flowers in July. The herb, which is used in medicine, is an ophthalmic. The distilled water is a present remedy for wounds, punctures, and sugillations of the eyes, as well as dimness of sight and all other infirmities incident to those parts. It is a specific in inflammations. *Raii Hist.*

The decoction of the herb is an excellent remedy for the epidemic diarrhœa of Ireland. *Threl. Synop. Hib.*

SALICO'RNIA, *jointed glasswort*, or *saltwort*, in botany, a genus of plants whose characters are:

It hath an apetalous flower, wanting the empalement; for the stamina (or cives) and the embryoes grow on the extreme part of the leaves: these embryoes afterwards become pods or bladders, which for the most part contain one seed.

These plants grow on the sea-coast in many parts of Europe, and upon the shores in several places in England, which are washed every tide with the salt-water; but rarely planted in gardens, because it is very difficult to make them grow in any other situation, than in salt-marshes, and on the shores, where the salt-water frequently flows. Of these plants there seem to be two or three varieties, which appear remarkably different; but are not supposed to be distinct species.

The inhabitants near the sea-coast, where these plants grow, cut them up towards the latter end of summer, when they are fully grown; and, after having dried them in the sun, they burn them for their ashes, which are used in making of glass and soap. These herbs are by the country people called kelp, and are promiscuously gathered for use.

From the ashes of these plants is extracted the salt called sal kali or alcali, which is much used by the chemists.

The manner of gathering and burning of these herbs is already mentioned under the article of KALI in the Dictionary; so I shall not repeat it in this place.

In some parts of England these herbs are gathered and picked for samphire, though it is very different from either of these.

SA'LII (*Dict.*)—There were two companies or colleges of Salii: the ancient established by Numa, called Palatini; the latter by Tullus Hostilius, called Collini and Agonales. Though Servius tells us, there were two kinds instituted by Numa, the Collini and Quirinales; and two others by Tullus, the Pavorii and Palorii.

In singing, they used a peculiar ancient song, called Saliare carmen; and, after the ceremony, were entertained with a feast: whence Saliares epulæ, and Saliares dapes, passed into a proverb for good eating.

Their chief, called præsul, and magister Saliorum, was one of their number: it was he led the band, and begun the dance; the rest imitating all his steps and motions.—The whole company was called collegium Saliorum.

Sext. Pompeius makes mention of Salian maids, virgines Saliares, hired for the purpose, and joined with the Salii, wearing a kind of military garb, called paludamentum, with high round bonnets

bonnets like the Salii, and, like them, performing facrifices with the pontifices in the palaces of kings.

M. Patin takes it, there is a figure of one of the Salii on a medal of the Saquinian family; who, befides the buckler in one hand, holds the caduceus in the other. — But his look appears too grave and fedate, and, befides the buckler he holds, does not feem to be an ancyle, as being quite round and not indented any where. And again, why fhould a prieft of Mars, the god of war, be reprefented with a caduceus, the emblem of peace? It is probable, therefore, this is no figure of any Salius, as Patin imagines.

SALINE *Principle*, a term ufed by the chemical writers, to exprefs a conftituent part of feveral mixed bodies, on which their exiftence in that form depends; and which, though always exiftent in them, and always feparable by art, is yet not perceivable in many of them in the complex. See PRINCIPLE.

SALINE *Earths*. The chemifts under this, as a general head, reckon all thofe Saline and earthy fubftances, which are calcined or burnt in the fire; as all the kinds of lime, pot-afhes, foot, and the like; thefe being fo many mixtures of falt and earth; and all falts appearing to them, indeed, on a rigorous examination, to be only earths of different natures, which, when reduced to a certain degree of fubtility or finenefs of parts, fo as permanently to diffolve in water, are then emphatically denominated falts. *Shaw's Lectures.*

SALIVATION (*Dict.*) — There are many ways of raifing a Salivation, and all by mercurial preparations. The preparations which I have ufed myfelf, fays Turner, as the fafeft and moft commodious, are calomel and mercurius dulcis fix times fublimed, given inwardly, in the milder pox; or the fame being fafter radicated, and got into the bones, the crude mercury externally, in the way of unction.

The mercurius vitæ, arcanum corallinum with the red, yellow, and green precipitates (however in ufe with fome) I think too churlifh, and fcarce fafe for tender conftitutions; nor indeed can I fee any reafon for their ufe, whilft we have better and lefs hazardous medicines to fupply their room.

In falivating by the internal method, to an adult perfon, of a tolerably good habit, as to his ftrength, and who has not been much ufed to the medicine, I generally give fifteen grains of calomel with a little conferve of rofes in the morning, and the like dofe in as much of diafcordium without honey, at night, which I prefer to the larger given once, or, as cuftomarily, twice a day; becaufe it is now lefs liable to run fuddenly thro' them, or too haftily fublime, and endanger them that way, by the inflammation. Befides, in this gradual way of proceeding, it comes on more certainly, eafily, and alfo more fecurely to the patient; the effect of each dofe affording opportunity of forefeeing readily, what more be requifite, and when you muft intermit, if not entirely forbear its farther exhibition.

I know a phyfical writer hath lately acquainted us, that we are each time to double the dofe of calomel; as for the firft, fifteen grains, for the fecond half a drachm, for the third a drachm, and fo till the fpitting comes on; but I would advife, that no perfon take this author for his guide in this affair, left inadvertently he deftroy his patient, together with his own reputation.

After three, four, or five days of this management, we ufually obferve the fauces to inflame, the infide of the cheeks to become tumid, or high and thick, being ready to fall in betwixt the teeth, upon fhutting of the mouth; the tongue looks white and foul, the gums alfo ftand out, the breath ftinks (which is a favourable omen of its coming on) and in general, the whole infide of the mouth appears fhining, feems as it were parboiled, lying in furrows, as it appears, after ftrong fpirits have been retained in the mouth. They now begin to refufe their nourifhment, while the tongue, gums, and cheeks are fwelled, and fo fore that they cannot chew, efpecially folid food, but muft be now content with liquids and the fofter aliments. Befides, they are often fick at the ftomach, and frequently puke, or bulk up a thin phlegm, another promifing forerunner of a good Salivation, when the pukes are moderate and eafy, and come by intervals. But, if attended with cardialgia, or violent pains and torture at the ftomach, perpetual and inceffant reachings, fainting and cold fweats, nothing is more dangerous.

The infide of the mouth beginning to appear thus whealed, you may expect foon after to find it ulcerated, efpecially about the falival glands; and then it may be proper to defift for a day or two, if not give over, that you may the better obferve the increafe of the ulcers, what floughs are likely to be raifed, and of what depth and dimenfion they are like to prove; from which a near conjecture may be made of the duration as well as quantity of the fpitting, now begun; the confiftence of the effluent lymph being at the fame time confidered.

When the Salivation is thus raifed, the patient ought to be encouraged to proceed chearfully; and to be fometimes refrefhed with a little mulled wine, of what fort he likes beft; but red is preferable, if there be any tendency to a diarrhœa, adding a third, and fometimes one half of water. Let his diet be a fmall chicken broth, water-gruel, and panada; his drink a fmall fack-whey, or poffet-drink, with a draught of good fmall-beer and a toaft between whiles: but, in gripes or a loofenefs, the white drink, prepared of calcined hartfhorn or rice-water; alfo the decoction of the fhavings of hartfhorn and ivory, boiled with a cruft of bread, and fweetened to the patient's tafte, are to take place of the reft.

Thus having given him fome few days refpite, if after the coming on of the ptialifm, you find him hearty, and his chops but moderately fwelled on the outfide, and not very fore within, the ulcers not increafing, and few and no floughs appearing, the flux alfo inconfiderable in quantity, you may now again give him a fcruple of calomel in diafcordium, as he goes to reft, repeating the fame for two or three days following, as you find occafion.

When in this way he has taken about half an ounce of calomel (though there is feldom occafion to go fo high) with but little alteration as to the fwelling or forenefs of his mouth, and as little appearance of the ptialifm; his pulfe and other circumftances, with refpect to any ill fymptom attending, favouring the fame, he may may be vomited with eight, nine, or ten grains of the turpeth mineral by itfelf, only made into a bolus with conferve of rofes, or farther mixed up with half a fcruple, or fifteen grains of the calomel, encouraging the operation with fmall draughts of common poffet-drink between whiles, upon each motion to reach; but without loading his ftomach, as is cuftomary in other emetics, left, happening to run downwards, it invert the order or courfe of its intended operation. The fame vomit, if found requifite, may be repeated two or three days after, which at thefe times often anfwers our end, by raifing the humours towards the jaws, and forwarding the Salivation much more effectually, than more dofes of the calomel, fimply repeated, would have done; and if, after this, it fhould fo happen, as in fpite of all endeavours to the contrary, it fometimes will, whether from fome fingular idiofyncrafy, the tenacity of the lymph, or fome defect in the glandular fecretion, that the fpitting will not rife to any quantity, notwithftanding the tumefaction, inflammation, ftench, and putrefaction, and fometimes ulceration alfo in the patient's mouth, you muft forbear and purge it off. The relief of the patient muft now be attempted fome other way, as by giving calomel once or twice a week, and purging it off again next day, or two days after; and on the intervening days, direct fome other antivenereal fpecific, fuch as the alterative pill of gum guaiacum, diaphoretic antimony, and the æthiops mineral, with a good ftrong decoction of the woods, well chofen and energetic, fuiting alfo with the temperament of the patient; as, if cold and phlegmatic, the fcobs of guaiacum; if hot and dry, the farfaparilla and China roots; which, however flighted by fome as infignificant, yet obferved with a ftrict difcipline, as to the other non-naturals, have certainly very great advantages attending them, as well perfpiring the noxious particles, and drying up the fuperfluous ferum by the one, as contemperating the acrid and four juices by the other. By this method, duly profecuted, though it may be fomewhat longer, the purpofe may be at length effected, which by the former was not to be obtained. Some have remarked, that thofe perfons who are purged with great difficulty, are with great difficulty falivated; which may arife from the fame caufe, the toughnefs of the humours, and flower fecretion. Although, in the evacuation downwards, we often find thin, choleric, and dry bodies are more eafily moved by lenients, as common oil, manna, lenitive electuary, caffia, diaprunnum, even a bit of frefh butter, or fat broth, than by ftronger purgatives of fcammony, colocynth, and the like.

When the ptialifm proceeds fuccefsfully, it may be left to take its courfe, till it declines fpontaneoufly, which, in proportion to the ulcers or thicknefs of the floughs about the parts of the mouth, may happen at the expiration of one and twenty days, or fometimes a month from the time of its firft rifing, which is ufually long enough to fubdue this difeafe, after it is confirmed. I faid, from the time of its rifing, or fpitting perhaps a pint and a half a day, till it comes to three, four, or five pints, in twenty-four hours, and fo gradually goes off again; for often the firft four or five days, and fometimes a whole week is fpent in bringing it to the firft proportion.

Befides this way of Salivating by the calomel, in the more ftubborn and rebellious pox, attended not only with cruel nocturnal pains, gummata, tophs and nodes, but alfo rotten or foul bones; where the patient has been long ufed to the taking of calomel, or a like mercurial preparation internally, and has perhaps been often falivated by fuch preparations to no purpofe, it is better to attempt the cure by falivating with the unction, in which little regard is to be had as to the choice of the ointment with which the quickfilver is to be incorporated, fince the ftrefs is entirely laid on the quickfilver. In this method, as well as in the other by calomel, care muft be taken not to proceed too haftily.

If you have one ounce of the quickfilver to three ounces of axungia (which is the proportion I have ufually obferved) about an eighth part may be ufed night and morning; letting the patient rub it gently, with his own hands, into his limbs before the fire, beginning from his ancles up his fhins to his knees, all round his joints; and fo to his thighs, which are prefently after to be covered clofe up with his yarn ftockings and

and flannel drawers; then let him use the remainder of this eighth part about his elbows, and so to his shoulders, wiping his fingers and hands clean about the glands of his armpits, or those of his groin: his body being all the while defended from the cold air, by a screen or blanket hung behind him, and after wrapped up warm in his flannels, as he must also be in the other method of salivating; such I mean as a flannel shirt or shift, waistcoat and drawers, a cap and muffler pinning up thereto behind, and covering well his throat, chin, and cheeks before, to keep these parts from the cold air, which above all is highly necessary.

Some also anoint the trunk, especially the spine; but I always found the pores of the other parts sufficient to let the globules of the mercury into the blood; and it is not material by what particular pores it had first its admittance.

For those who are very weak, once a day may suffice; but the robust and strong may be anointed twice, or, which is as well, and will save trouble, divide the unction into four parts, and consume one part about him every night, after which let him enter into a warm bed, with flannel sheets or blankets, disposing him to a gentle breathing sweat, with a draught of warm posset-drink, mace-ale, or, if very feeble, a cup of his mulled wine; by which the pores being opened, the mercurial particles may have the freer entrance.

It is usual to increase the mercury and ointment to four times the quantity, which we have directed. Thus Harvey prescribes one pound of axungia to be mixed with three ounces, and sometimes six ounces of quicksilver, adding also a little white hellebore and crude antimony in fine powder, pretending thereby to forward the Salivation, and increase the force of medicine in mastering any malignity. Mr. Wiseman's composition was also six ounces of mercury to one pound of the other materials, of which he used one ounce, or two ounces at a time, once or twice a day, for four, six, or eight times, according to the patient's strength, and the ease or difficulty of raising the flux. Hildanus directs six ounces of mercury to twenty ounces of axungia, and the other ingredients. But I can see no reason for using so much axungia, provided a half, or a fourth part of it, be sufficient to convey the quicksilver into the blood; nor to what end any other ingredients should be added to the axungia, unless the turpentine, being, as I conceive, more like to hinder, especially the species or powders, by stopping up the pores, than to forward the operation. But, leaving every one to follow the proportion he likes best, in relation to my own, I must farther observe, that if after the third unction, supposing the whole divided into four parts, the patient begins to complain of his mouth, or that the inside thereof appears ulcerated, you must stay a day or two to see the effect of what is already done, before you proceed farther. The like must be observed when gripes, or bloody stools, approach. But if the spitting comes not on, and no supervenient symptom contra-indicates, you may expend the remaining fourth part in like manner; and perhaps, in some bodies, there may be occasion for a half, or full as much more. However, it will always be found safest to proceed leisurely, when you have gone thus far, and sometimes to wait a day, two or three, before you continue the unctions; since, although at first it may seem as if the medicine had taken no effect, you may soon after find it sufficient. For, though a day or two after the fourth unction, the flux may be longer than usual in coming forwards, and the excoriations about the chops or inside of the mouth appear inconsiderable, yet in a day or two more they may be seen to spread and increase to a copious spitting, beyond what was expected. But when after rubbing in an ounce, or an ounce and a half of the mercurial ointment, the Salivation appears not, it may also be necessary here to administer a dose or two of the turpeth mineral, at a day or two days distance; and, where there are gummata, tophs, and nodes, you are in the unction more especially to rub the ointment well into these parts, laying over them afterwards the emplastrum de ranis, with a double quantity of mercury. This will both help the resolution of them, and encourage or keep up the ptialism, which being arrived to the quantity of four, five, or six pints, in a day and night, is accounted a sufficient discharge. Yet this is no absolute rule to go by, or upon which we can safely pronounce the patient whole and sound, any more than the quantity of the medicine to be used can be limited to any one certain, or constant proportion. Since we have known some who have spit more, yet miss their cure; whilst others who have come very short of such a quantity, have notwithstanding obtained theirs. However, during the Salivation this way raised, upon its too sudden declension (though it commonly happens that, the sloughs being deeper, and their mouths sorer, they usually spit longer than by proceeding internally with the calomel) it is often expedient to give a scruple of the same, every day, or every other day, for two or three times, as there may be occasion; and, towards the conclusion, you are to purge your patient with two or three ounces of the common infusion of senna, and one ounce of the syrup of buckthorn, or, for those that are very weak, an infusion of sliced rhubarb, senna leaves and tamarinds, with salt of tartar, adding to the strained liquor one ounce of the best manna, or solutive syrup of roses, which may be repeated once or twice a week for two or three times; and, when he is a little easy, his chops growing pretty well, he may be permitted to eat a little meat, as the flesh of a chicken or rabbit, also veal or mutton, but well roasted, without sauce or gravy. About this time also, it is usual to sweat them, at least before they go abroad, in their bed, or stove, or under the cradle, with spirit of wine burning just by, to be continued as their strength will bear, for an hour or two, and to be repeated at two or three days distance, if there be occasion, observing that the most care be now taken, that your patient be not injured by the cold air, and that he gradually cool himself, by lessening or withdrawing the heat or bed cloths he lies under, lest, getting cold, he make some fresh complaint of pains, which though arising from this new occasion, he may impute to the old one; and think the worse of his cure for some time.

During his sweat, let him rub his body thoroughly with warm napkins, conveyed to him in the bed; and, when faint, let his spirits be kept up with three or four spoonfuls of some proper cordial julap, or a draught of his burnt wine.

In order to promote this diaphoresis, he may take a little Venice treacle, with a scruple of the cinnabar of antimony, or half a scruple of bezoar mineral, upon which let him drink a draught of his diet-drink, made as hot as he can bear it. This drink he ought to be strictly confined to, for three weeks or a month after he comes out of the Salivation, that having by this evacuation secured his body from any relics of the disease, or its remedy, the redundant serosity remaining after the colliquation may be dried up, before the blood is supplied with fresh nutritious juices. By the neglect of this circumstance, and by running over hastily to their wonted liberty and custom of living, they too suddenly fill their blood with a load of improper and unsuitable juice, at this time in a weak infirm state, and, despising their purging, sweating, or diet, as needless pieces of formality, or an useless penance, too often incur the misfortune of an unhappy relapse. *Turner*.

SA'LIX, the willow. See the article WILLOW.

SAL'MON, *salmo*, a well known fish. It is distinguished from other fish of the truttaceous kind by these characters: it is of an oblong body covered with very small scales, a small head, a sharp nose, and a forked tail. Its back is bluish; the rest of its body whitish, or reddish, and usually spotted. Its under jaw is bent upwards, and that sometimes so much as to make itself a sinus in the upper, by constant motion, and sometimes to perforate it.

The Salmon is first produced from its parent's spawn in fresh rivers, thence it goes into the sea to acquire its growth and feed, and, at the time of its full growth, and in the season for spawning, it removes into the fresh waters again.

The Salmon in the different stages of its life and growth has different names. The Latins called it, when young, salar, when of a middle growth sario or fario, and only when full grown salmo. In England the fishermen have names for it in every year of its growth. In the first it is called a smelt, in the second a sprod, in the third year a mort, in the fourth a fork-tail, and in the fifth a half fish; finally, in the sixth it is called a Salmon. This is the common agreement of our fishermen, though there are some who say the Salmon comes much sooner to its full growth. *Willughby's Hist. Pisc.*

The Salmon is bred in rivers, but goes every year from thence into the sea; and at a certain season of the year it always returns up into the fresh water again; and what is remarkable, is, that, so far as observation has been able to trace them at any time, the same shoals of Salmon always return into the same river out of which they swam, not into any other; so that the people who live on the Salmon fishery are not afraid for their rivers being cleared, by all the fish in them going down into the sea, for they know that they will all return up to them again at a proper time. When the Salmon has once entered a fresh river, he always swims up against the stream, and often will go an hundred leagues up a river in the large and long rivers; and the people at this vast distance from the mouth have the pleasure of taking a fish, that is properly in part of the sea kind. It is also remarkable, that the rivers which most abound with Salmon do not make the seas, about their mouths, any more abound with them than others, particularly the harbour of Brest affords no Salmon; though the river Chateaulin, which discharges itself into it, is the richest Salmon river in France.

Another singularity, in regard to the Salmon, is their swimming up the rivers together in such vast numbers. It is to be allowed, indeed, that herrings, mackarel, and many other fish, do in the same manner appear on the coasts at certain seasons in prodigious numbers; but the reasons for their coming together, in these quantities, are much more easily explained than that of the Salmon's doing so. The herrings, when they come in such prodigious shoals to the coasts of Normandy, have been found to be allured thither in these numbers by a prodigious quantity of a particular sort of sea worms which are their favourite food, and which are found to cover the whole surface of the sea at that time. Rondeletius has described these insects under the names of sea caterpillars; they always appear in the months of June, July, and August, which are the herring seasons at that part of the world; and probably the same cause will be found to bring them to other places, if sufficiently enquired into, as these and some other fish

fish come to certain places in shoals to get food. The Salmon do it, in order to propagate their species. The spawn of the Salmon is never deposited but in rivers, and, at the time that these fish are found up the rivers, it is only with this intent; the females go first, and the males follow as far as the others please to lead them, which is usually to some convenient place in shallow water, where the spawn, when deposited, is not buried under too great a quantity of water, but has the advantage of a continual warmth from the sun's heat.

Salmon do not equally frequent all rivers, though they may seem to us equally proper for their reception. There are two rivers which open themselves into the harbour of Brest, very near one another; the one of these is famous for the quantity of Salmon in it, and the great advantage of the fishery; the other never has any of these fish in it. It most probably is owing to their finding plenty of food, and proper places for the depositing their spawn in the one of these rivers, and not in the other, that makes this regular choice. *Des Landes, Trait. Phys.*

SALMON *trout*, the English name of the fish called trutta lacustris by Gesner and other authors. It is caught in lakes in mountainous countries, and grows to a very considerable size, sometimes to thirty, forty, or fifty pounds weight. It resembles the trout in figure, but its belly is very flat, and has, as it were, a long furrow or cavity running the length of the belly. Its back and head are of a very beautiful bluish green colour; and the whole fish, especially its back and the upper parts of its sides, are marked with numerous black spots. Its back fin is also spotted with black, and its scales are small and silver-coloured. *Gesner de Pisc.*

Bay SALT. — This Salt is of two kinds: the first drawn from sea water, as is practised in France, Spain, and Portugal, and many other hot countries; the other from the water of salt springs, or lakes, as in the Cape Verd islands, in the island of Tortuga, Turks island, and many other parts of America.

The first kind is, in time of peace, imported into Great Britain in very large quantities, and our colonies and fisheries in America commonly supply themselves with the latter.

Bay Salt is not extracted from Sea water in the colder parts of Europe, as on the coasts of Germany, Denmark, and Sweden, but in places situated in a more southern climate, as on the coasts of France, Spain, and Italy. Some marine bay Salt has also, of late years, been made in England at Limington, and in some other parts of Hampshire, and in the Isle of Wight: but in these places it is only made in drier summers, and then rather by accident than design, it being collected from ponds, which were originally made for heightening of sea-water, or reducing it into a strong brine by the heat of the sun, in order to lessen the expence of fuel, in boiling it into white Salts. *Brownrig of Salt.*

The ponds, in which this Salt is made, nearly resemble a rude kind of Salt marsh, described by Agricola, in which the sea-water is received into a pool, and thence by a trench is conveyed into several pits dug in the earth; and, when it has stood some time in these pits, it is suffered to run out into others, and so on, till the brine is strong enough to crystallise.

This is the case in our English Salt works; but the French marshes, in which a vast quantity of bay Salt is annually prepared, are made in a much more artful manner. A full account of which is given in the *Philosophical Transactions*, N°. 51. See SALT *marsh*.

The several kinds of bay Salt, made in the different parts of the world, are found to differ greatly from one another in several particulars; as first, in the size of the crystals, which is owing to the heat of the sun, and the time it lies in the pits. The French cream of Salt, and the blown Salt of the isle of May, are fine and small-grained. The Portugal Salt is larger grained than that of France; and that of Tortuga is larger than either. Secondly, in purity. As all bay Salt has some mud, slime, or the like, in the making, and some kinds are mixed with the bittern Salt, or what is called Epsom Salt; they are all more white while dry, and more pellucid when moist, and they differ in colour, according to the earth which makes the bottoms of the pits. Thus, some of the French bay Salt is grey, some reddish, and some white, according as a blue clay has lined the pits, or a red, or white one. Fourthly, some kinds of bay Salt are more apt to contract a moisture from the air than others: it is sometimes owing to the smallness of the grain, and sometimes to a mixture of a calcarious or alcaline Salt with it. And, fifthly, some kinds have an agreeable smell in large heaps; such are the Portugal and the Hampshire bay Salts; and this seems owing to the sea-water they were made from, having a bituminous matter in it. Sixthly, It differs greatly in taste, according to the various foreign mixtures it contains; and it will often alter in taste, and other qualities, by long keeping. Thus the Salt of Peccais is so bitter, when new made, as not to be eatable, but after keeping a while it becomes very pleasant. This is owing to its containing at first a large portion of the bittern Salt, or Epsom Salt, which liquifies in keeping, and, running off in form of a fluid, leaves the rest of a good taste. In general bay Salt is much fitter for use, after it has been kept some time in a dry place, than when it is first made.

From the accounts already given of the bay Salt of other countries, and the manner of preparing it, it seems evident, that our being obliged to purchase it of other nations is the effect of our want of application to the making it ourselves; since it is evident that it may be very well made, both in England, and in many of our American colonies.

In England, a very advantageous sort of works might be set on foot in the following manner: a number of Salt pits should be made in a row in the marsh, and their bottoms lined with plaister, or some strong cement that will not easily break up; and, by this caution, the Salt may be drawn white and pure like the Portugal kind, not grey like the French. Over each pit covers should be made of thin boards, or rather of canvas painted white, and stretched on frames of wood; and these should be fixed to strong posts, erected on the north side of the pits, and contrived to be easily drawn back to them, in the manner of draw-bridges. These covers, thus fixed, may be let down over the pits, in manner of a shed or pent-house, in rainy weather to keep the brine from being diluted with fresh water; and in dry weather they may be raised almost to a perpendicular, but inclining a little towards the south, so as to form a wall with a south aspect; and thus they would serve for a double use, being a covering to the pits in rainy weather, and reflectors of the sun's heat in fair. The reflexion of so large a body of the sun's rays, in the course of a bright day, would greatly promote the evaporation of the brine; and the hinges, on which the reflectors turn, being placed at ten inches from the ground, when the reflectors stand upright, there will be a space under them, through which the air will continually flow in a brisk current, and this will greatly promote the evaporation of the water.

The passages of communication between the pits must be narrow and winding, and must be wholly stopped up in wet weather, that no fresh water run into the brine. This channel should be covered also with boards, and at the entrance of the pits there must not be a pond, as is the custom in France, but only a narrow covered trench running parallel with the side of the pits which is opposite to the reflectors; and the pond, which forms the entrance of the pits in the French Salt marshes, must in these be detached from them, and, instead of it, there must be formed a fourth brine pond, communicating with the third by a long and narrow channel.

If these contrivances should be reduced to practice in England, the Salt will probably crystallise much faster there than in the French marshes, and the brine may be kept as deep, and even deeper than in the French pits; and a shower of rain will only retard the work for the small time in which it is falling; whereas, in the French works, it throws them back three or four days, as no Salt can be formed till all the water it brought be evaporated.

Four cisterns may be dug adjoining to the brine pits, to admit the brine in the Salt ponds, when the weather is very rainy; and as to the Salt water in the reservoir, if it should be found necessary to preserve it from rain in cisterns, when so much rain falls, as to make it fresher than sea-water, it may be let out and sea water admitted in its place. And in order to promote the evaporation, and to make the Salt water in the reservoir fitter to supply the first brine pond with brine of a due strength, it may be proper, by means of a small fire engine, continually to force up the Salt water in the reservoir, as often as occasion requires, and by means of a diverger, fitted to the engine, to make it descend again into the reservoir, like a shower of rain; by which means, the evaporation of the watery vapours will be greatly promoted, after much the same manner as is practised in several of the Salt works in Germany, where the brine is very weak. *Brownrig of Salt.*

Thus by augmenting the force of the sun's heat, and of the air, by promoting the evaporation of the watery vapours, and preventing the brine from being diluted with rain, it is very probable that, during the summer season, double the quantity of Salt might be prepared at an English work with these contrivances, than is now usually prepared at a French Salt marsh of equal magnitude.

Besides these methods of managing sea-water, it is certain that very large quantities of bay Salt might be prepared in England, with great ease, from the natural brine of Salt springs, and from the common fossil or rock Salt of Cheshire dissolved in weak brine, or in sea-water. Upon the whole, bay Salt might thus be made here at a moderate price, and in sufficient quantities to supply both the nation itself, and all our colonies.

Brine SALT, a name given to that sort of common Salt which is not made from sea-water, but from the water of Salt wells and springs. Great quantities of this Salt are made in most of the inland countries, as in Germany, Switzerland, Hungary, and in some parts of France and England.

The ancient methods of boiling of brine into Salt, in Cheshire and Worcestershire, are accurately described in the Transactions of the Royal Society; and the method, formerly used in Staffordshire, is delivered in Dr. Plot's History of that country; but the method, now generally used in England, is this:

The brine, being received from the well into a large cistern, is thence received, as occasion requires, into the Salt pan. These pans are of the same form with those used in the boiling of sea Salt, and usually hold about eight hundred gallons: in some places these are made of iron, and in others of lead.

 When

When the brine is put into the pan, a little blood is mixed with it, in order to clarify it, and leaden pans are placed at the corners, to receive the ſcratch, or calcarious earth, that ſeparates from it in the boiling. An ounce of blood is ſufficient for eight hundred gallons of brine. As ſoon as it is boiled, it is carefully ſkimmed, and afterwards it is ſuffered to boil very briſkly for ſome time, till the Salt is granulated; after this the ſcratch is ſeparated, and the fire ſlackened, till the whole Salt is formed.

When they have ſeparated the ſcratch, and the Salt is ready to cryſtallife, they put into the pan ſeveral ſorts of ſeaſonings, as they call them, ſuch as ale, butter, and the like, which they ſuppoſe correct the bad qualities of the brine, and make the Salt of a ſmaller grain. After this they boil it very gently, and when as much Salt is formed, as will fill two or three of their wicker baſkets, they rake it up to the ſides of the pan, and fill it into the baſkets, placing them over the leach trough, that the brine may drain into it from the ſalt. The Salt taken out they call a draught of Salt, and the operation a clearing of the pan. In this manner they draw the Salt, and clear the pan five or ſix times during each proceſs, leaving at laſt only a few quarts of brine at the bottom of the pan. The baſkets, into which they put the ſalt out of the pan, are called alſo barrows: they uſually contain about a buſhel of ſalt, and are of a conic figure, open at the baſe. The whole proceſs of working a pan of brine uſually laſts about twenty-four hours. After the Salt has drained an hour or two in the baſkets, it is removed into the hot-houſe over the furnace, where it remains four or five hours to be thoroughly dried, and is then taken out of the baſkets, and laid up for ſale. In all the Engliſh Salt works, the leach brine, which is what remains in the pan after the Salt is cryſtalliſed, and what drains from the Salt in the baſkets, is not thrown away, as it is in Germany, but is added to the pan next to be boiled. And, beſides the Salt made in this manner, they have, at moſt of the Engliſh Salt works, a different kind, which they call ſhivery Salt.

They have alſo another kind of Salt, made up in form of ſugar loaves in ſmall wicker baſkets, which is thence called loaf Salt, or baſket Salt. This is the whiteſt, drieſt, and fineſt-grained of any Salt, and is therefore greatly eſteemed at table. In preparing this Salt they uſe ſome reſin, and other additions, to break the grain, and render it very ſmall; others alſo, to this purpoſe, boil it the more briſkly and ſtir it briſkly all the while. But in Cheſhire, where the beſt baſket Salt is made, they uſe no particular proceſs about it, but only take the third draughts of every pan, which always are the pureſt Salt; and they do not ſuffer theſe to lie ſo long in the pan, as when they make Salt of a larger grain, but take it out before it can form large cryſtals: by this means they have it of a fine ſmall grain, and they then preſs it it hard down into the wicker baſkets, and, when dried in the ſtove, they let it remain in the baſkets for ſale. *Brownrig of Salt.*

Not long ſince Mr. Lowndes publiſhed a method of greatly improving the Engliſh brine Salt, ſo as to make it at leaſt equal to the French bay Salt.

The method is this: let a brine pan, containing about eight hundred gallons of liquor, be filled with brine to within an inch of the top; then make and light the fire, and, when the brine is juſt lukewarm, put in either an ounce of blood from the butchers, or the whites of two eggs. Let the pan boil with all poſſible violence, and, as the ſcum riſes, take it off. When the freſh or watery part is pretty well decreaſed, throw into the pan the third part of a pint of new ale, or the ſame quantity of the grounds of any malt liquor. When the brine begins to grain, add to it the quantity of a ſmall nut of freſh butter, and, when the liquor has ſtood half an hour longer, draw out the Salt. By this time the fire will be greatly abated, and ſo will the heat of the liquor; let no more fuel be thrown on the fire, but let the brine gently cool, till a perſon can juſt bear to put his hand into it; keep it in that degree of heat as nearly as poſſible, and when it has worked for ſome time, and is beginning to grain, throw in the quantity of a ſmall nutmeg of freſh butter, and about two minutes after that ſcatter throughout the pan, as equal as may be, an ounce and three quarters of common alum, pulveriſed very fine; then inſtantly, with the common iron ſcrape-pan, ſtir the brine very briſkly in every part of the pan for about a minute; then let the pan ſettle, and conſtantly feed the fire, ſo that the brine may never be quite ſcalding hot, yet always a great deal more than lukewarm; let the pan ſtand working thus for about three days and nights, and then draw it, or take out the Salt. The brine remaining will, by this time, be ſo cold, that it will not work at all, therefore freſh coals muſt be thrown upon the fire, and the brine muſt boil for about half an hour, but not near ſo violently as before the firſt drawing; then with the uſual inſtrument take out ſuch Salt as is beginning to fall, and put it apart; then let the pan ſettle and cool. When the brine becomes no hotter than one can juſt put one's hand into it, proceed as before, and let the quantity of alum not exceed an ounce and a quarter, and about eight and forty hours after draw the pan, and take out all the Salt. *Lowndes's Brine Salt improved.*

This is Mr. Lowndes's proceſs; only he afterwards directs cinders to be chiefly uſed in preparing the fires, the better to preſerve an equal heat; and by that means alſo he propoſes ſaving a conſiderable expence, aſſerting, that at preſent cinders are ſo little valued in Cheſhire, as to be thrown out into the highways. Mr. Lowndes adds, that, in a pan of ſize beforementioned, there may be prepared, at each proceſs, ſixteen hundred pounds weight of Salt from the beſt brine in Cheſhire, and one thouſand and ſixty-ſix pounds from the ordinary brine of that county. This, as the proceſs continues five days, is a little more than five buſhels and a half of Salt a day, from the beſt brine, and a little more than four buſhels a day from the ordinary kind.

Sea SALT (*Dict.*)—The moſt convenient works for the making this Salt are conſtructed in the following manner: the ſaltern is erected at ſome convenient place near the ſhore; it is a long and low building, conſiſting of two parts, one called the fore-houſe, and the other the pan-houſe or boiling-houſe. The fore-houſe ſerves to receive the fuel, and cover the workmen; and in the boiling-houſe are placed the furnace, and the pan in which the Salt is made. And in ſome places they have two pans, one at each end of the building, and the fuel and place for the workmen are the middle. The furnace opens into the fore-houſe by two mouths, and from theſe is carried up a wall to prevent the aſhes from flying to the Salt pans, and in this is a door of communication between the two houſes. The body of the furnace conſiſts of two chambers, divided from one another by a brick work called the mid feather, which from a broad baſe terminates in a high edge nigh the top of the furnace, and, by means of ſhort pillars of caſt iron fixed upon it, ſupports the Salt pan. The pans are oblong and ſhallow, the common meaſure being fifteen feet in length, twelve feet in breadth, and ſixteen inches in depth; they are commonly made of plates of iron joined together with nails, and the joints filled with a ſtrong cement; and the bottom of the pan is prevented from bending down, or changing its figure, by hooks faſtened to ſtrong iron bars which are placed acroſs it.

Between the ſides of the pan and the walls of the boiling-houſe there runs a walk five or ſix feet broad, where the workmen ſtand to draw out the Salt. The roofs are wood, and are faſtened with pegs of wood, nails mouldering away into ruſt in a few months.

Not far diſtant from the ſaltern on the ſea ſhore, between full ſea and low water mark, they make a little pond in the rocks, or with ſtones in the ſand; this they call a lump, and from this pond they lay a pipe; through which, when the ſea is in, the water runs into a well adjoining to the ſaltern, and by this well they pump it into troughs, by which it is conveyed into their ſhip or ciſtern, in which it is ſtored up till they have occaſion to uſe it.

The ciſtern is built cloſe to the ſaltern, and may be placed moſt conveniently between the boiling-houſes on the backſide of the fore-houſe. It is made either of wood, brick, or clay, and ſhould be covered with a ſhed, that the Salt-water in it may not be weakened by rains, and ſhould be placed ſo high that the water may conveniently run out of it into the pans. When the ſea-water has ſtood in the ciſtern till the mud and ſand are ſettled from it, it is drawn off into the Salt pan; and, at the four corners of the Salt pan, where it is ſupported by the brick work, and conſequently the flame does not touch its bottom, there are placed four ſmaller leaden pans and ſcratch pans, which, for a Salt pan of fifteen feet, are uſually about a foot and half long and a foot broad, and three inches deep. Theſe have a bow or circular handle of iron, by which they may be drawn out with a hook when the liquor in the pan is boiling.

The Salt pan being filled with ſea-water, a ſtrong fire of pit-coal is lighted in the furnace, and then, for a pan which contains about fourteen hundred gallons, the Salt-boiler takes the whites of three eggs, and incorporates them all with two or three gallons of ſea-water, which he pours into the Salt pan, while the water contained therein is only lukewarm, and mixes this with the reſt by ſtirring it about with a rake. In many places they uſe inſtead of eggs the blood of ſheep or oxen to clarify the ſea-water; and in Scotland they do not give themſelves the trouble of clarifying it at all. As the water heats, there ariſes a black frothy ſcum upon it, which is to be taken off with wooden ſkimmers. After this, the water appears perfectly clear, and, by boiling it briſkly about four hours, a pan loaded in the common way, that is about fifteen inches deep, will begin to form cryſtals upon its ſurface. The pan is then filled up a ſecond time with freſh ſea-water; and, about the time when it is half filled, the ſcratch pans are taken out and emptied of a white powder, ſeeming a kind of calcarious earth, which ſeparates itſelf from the ſea-water, during its boiling before the Salt begins to ſhoot. When theſe have been emptied, they are again put into their places, where they are afterwards filled again. This powder, being violently agitated by the boiling liquor, does not ſubſide till it comes to the corners of the pan where the motion of the maſs is ſmaller, and it there falls into theſe pans placed on purpoſe to receive it.

The ſecond filling of the pan is boiled down after clarifying in the ſame manner as the firſt, and ſo a third and a fourth; but in the evaporation of the fourth, when the cryſtals begin to form themſelves, they ſlacken the fire, and only keep the liquor ſimmering. In this heat they keep it all the while that the Salt is granulating, which is nine or ten hours. The granules or cryſtals all fall to the bottom of the pan; and when the water is almoſt all evaporated, and the Salt lies nearly dry at the bottom, they rake it all together into a long heap on one ſide of the pan, where it lies a while to drain from the brine, and then is put into barrows and carried to the ſtore-houſe, and delivered into the cuſtody of his majeſty's officers. In this manner the whole proceſs is uſually performed in twenty-four hours, the Salt being commonly drawn out every morning. This is the method in moſt of our Salt works, but in ſome they fill the pan ſeven times before they boil up the Salt, and ſo take it out but once in two days, or five times in a fortnight. In the common way of four boilings, a pan of the uſual ſize, containing one thouſand three-hundred gallons, they draw from fifteen to twenty buſhels of Salt every day, each buſhel weighing fifty-ſix pounds.

When the Salt is carried into the ſtore-houſe, it is put into drabs, which are partitions, like ſtalls for horſes, lined at three ſides, and the bottom with boards, and having a ſliding board on the foreſide to draw up on occaſion. The bottoms are made ſhelving, being higheſt at the back, and gradually inclining forwards; by this means the brine, remaining among the Salt, eaſily ſeparates and runs from it, and the Salt in three or four days becomes ſufficiently dry; in ſome places they uſe cribs and barrows, which are long and conic wicker baſkets for this purpoſe, and in ſome places wooden troughs with holes in the bottom. The ſaline liquor which remains after the making of Salt is what is called bittern.

The ſides of the pans in which the Salt is made, are ſoon cruſted over with the ſame ſort of matter formed into cakes or cruſts, that falls in powder into the ſcratch pans; this the workmen call ſtone ſcratch; they are obliged to cleanſe the pans of it once in a week or ten days, otherwiſe they will be burnt: in England they do this with iron picks, but at Hall in Saxony they have a much better method; for they then take out the pans, and, turning them bottom upwards, burn ſtraw under them, by which means the matter of the cruſt looſens itſelf, and after this it falls off on being ſtruck with a mallet or hammer. *Brownrig of Salt.*

In Lancaſhire, and ſome other parts of England, ſea Salt is made in this manner: they pare off, in dry weather, in ſummer, the ſurface of the flats, which are covered at full ſea, and bare when the tide is out. When they have procured heaps of this, they put it into troughs, and pour freſh water on it; this waſhes off the Salt that hung about the ſand, and is received ſo impregnated into veſſels ſet underneath the troughs. So long as this liquor is ſtrong enough to bear an egg, they put on more water; when an egg ſinks in it, they throw the ſand out of the troughs, and put in freſh from the heaps. The water thus impregnated with Salt they boil in leaden pans, and evaporate to a dryneſs, the Salt remaining behind. *Ray's Engliſh Word.*

Salt upon SALT, a name given to a kind of common Salt prepared by the Dutch, of great uſe in preſerving herrings and other fiſh, and to which they principally owe their advantages in their herring trade. The Dutch prepare two kinds of refined Salt, one of a ſmall grain, intended for the uſe of the table, and called butter Salt. They export large quantities of this to the countries upon the Rhine, and into other parts of Germany. The other kind is a very ſtrong and pure Salt, and is of the largeſt grain of any boiled Salt, now made: this laſt they call the St. Ubes or Liſbon Salt, from its reſemblance to the pure bay Salt made in thoſe places.

The Salt, which they refine, is altogether marine bay Salt, and they chiefly have it from France and Spain; but they find, by experience, that any one kind of bay Salt does not anſwer their purpoſes ſo well as two or more kinds; they therefore frequently mix three parts of Cadiz Salt with one part of that of Souſton, which is of great ſtrength, but very dirty, and of a green colour, and does not coſt above half the price of the Spaniſh Salt; for diſſolving the bay Salt, they uſe ſea-water, which they bring in lighters to Dort and Rotterdam from below the Brill or Helvoet; out of theſe lighters it is craned into cellars, and is thus impregnated with bay Salt to a certain degree of ſtrength, which they determine by hydrometers made for that purpoſe. After the heavy droſs of the Salt is ſubſided to the bottom of the cellar, the clear brine is pumped up into the Salt pan through a mat, which retains the light ſcum, ſtraws, or other impurities, which floated on the ſurface of it. Theſe Salt pans are of iron, of a round figure, and commonly forty feet in diameter, and eighteen inches deep. Theſe pans are placed over a hearth furnace, and the only fuel they uſe in the boiling the Salt is dry turf. The fire is kept up ſo high, that the liquor boils briſkly all the time, and, if any ſcum ariſes, they carefully take it off, but they uſe no clarifying mixtures. A little before the Salt begins to granulate, they add to the pan a lump of butter, of the bigneſs of a walnut, and half a pint of ſour whey, which has ſtood at leaſt half a year. When theſe things are perfectly mixed in by a good ſtirring, they ſhut the doors and windows of the houſe, that no air can blow in cold, and the houſe is kept thus hot all the time that the Salt is forming. This method is not new, or peculiar to the Dutch works, for Agricola deſcribes an apparatus of board, to keep the cold air out of the Salt pan all the time that the Salt is forming; and the Germans uſe it in many places at this time.

It is out of this ſame brine, and by the ſame proceſs, that they make the table Salt and the ſtrong Salt; only towards the end of the proceſs they make this difference, if the pan is to be wrought into table Salt, the brine is kept gently ſimmering during the whole operation, and all is finiſhed in twenty-four hours; but, if it be to be made into the ſtrong Salt, they ſlacken the fire to ſuch a degree, that the operation takes up three days. In both caſes they let the ſalt remain in the pan till the whole is finiſhed; they then rake it out with wooden rakes, and after it has drained a while in wooden drabs, it is fit for uſe. The mother brine, of which there always remains a large quantity in the pan after the ſtrong Salt is made, as alſo the drainings of the drabs where the Salt is put, is reſerved to be boiled up into table Salt; but the mother brine of the table Salt becomes more ſharp and bitter after every proceſs, and is finally thrown away. *Brownrig of Salt.*

Sedative SALT, a name given by the modern chemiſts to a Salt, of the virtues of which they boaſt much. Thoſe who firſt deſcribed it gave the proceſs for making it in a very enigmatical manner; and their ſucceſſors invented many different ways of preparing it. The truth is, that all mixtures of borax with the vitriolic acids furniſh us with a ſedative Salt, as do alſo the mixtures of borax with ſpirit of nitre or of ſea Salt.

Vitreous SALT, in chemiſtry, a term uſed by ſome modern chemiſts for a kind of Salt, which, till of late, has wanted a name, and which is found in and ſeparable from the fixed alcaline Salts of vegetables.

It is bitter, hard, fixed, and not alcaline, and of a cryſtalline or gloſſy appearance.

The method preſcribed by Boerhaave for the procuring it with moſt eaſe, is this: put ſix pounds of the beſt pot-aſhes into a clean glaſs, add thereto twenty pints of cold rain water, ſtir them together with a ſtick, and ſuffer the whole to reſt. When the aſhes are thoroughly diſſolved, gently decant the clear lixivium, and there will be found at the bottom, mixed with the fæces, a number of ſmall greyiſh granules, of a bitter taſte, and of an almoſt glaſſy brittleneſs and hardneſs; theſe are the Salt required, and contain no alcaline quality; but, to obtain it in greater purity, diſſolve ſix pounds of pot-aſhes in fourteen-times their weight of water; filtre the lixivium while hot, and make it perfectly clear; then put it into a glaſs veſſel ready heated, and moiſtened, and ſuffer it to ſtand; a duſky cruſt will ſoon begin to ſhoot to the bottom and ſides of the glaſs, and will gradually become thicker and thicker; at length when no more appears to ſhoot, pour off the liquor, and there will remain behind a Salt like the former, but purer, and in larger quantities: if the remaining lixivium be boiled a little, and ſet to cryſtalliſe again, it will afford a ſmall quantity more of this Salt; but after this it will yield no more; whence there ſeems to be only a certain and determinate quantity of this Salt contained in the alcali. If this Salt be put into a veſſel of rain water and ſhook about, it does not diſſolve, only the alcali waſhes off, and the Salt remains purer than before: after this, it is to be gently dried and kept. *Boerhaave, Chem.*

SALT *marſh, ſalina*, a place where Salt is made, of which there are many natural ones in the hotter countries, where the ſea, exhaling the water of Salt lakes, leaves the Salt dry and ready for uſe at the bottom, without any art or labour of man to make it: thus, in Muſcovy and ſome other places, there are whole fields of Salt.

The countries, however, where this is not naturally performed, may effect it by art, and make ſaline or Salt marſhes, where they may uſe the ſun's heat to great advantage. This is annually done to great advantage in France, and there is no reaſon why we may not do the ſame, either at home or in our American colonies, though it has not yet been attempted.

In order to make a ſaline or Salt marſh, a low plat of ground muſt be choſen, adjoining to the ſea, and diſtant from the mouths of large rivers, and this muſt be near ſome convenient harbour for veſſels. The ground muſt be free from freſh water ſprings, and out of the reach of land floods, and if poſſible ſhould have a clayey bottom; and finally, it muſt be well defended from the ſea, either by natural or artificial banks of earth of a proper ſtrength and thickneſs.

The ground thus choſen muſt be hollowed out to three ponds or receptacles. The firſt into which the ſea-water is uſually admitted may be called the reſervoir. The ſecond receptacle, which is to be divided into three diſtinct ponds, communicating with each other by narrow paſſages, and containing brine of different degrees of ſtrength, may be called the brine ponds; and the third receptacle is to be furniſhed with an entrance, between which and the brine ponds there is to run a long, narrow, and winding channel; the reſt of it is to be divided into ſmall and ſhallow pits, containing a very ſtrongly ſaturated brine, which in them is to be converted into Salt, and they may therefore very properly be called the Salt pits.

The firſt receptacle or reſervoir muſt have a communication with the ſea by a ditch, defended on each ſide by walls of brick or ſtone, and made of ſuch a depth, that by it all the water of the reſervoir and other parts of the Salt marſhes may be able to run out at low water, and by it, alſo, the ſea may be admitted into it at high tide. So that at neap tides the marſh may be filled with ſea-water to the depth of ten inches in the reservoir; and, consequently, at higher tides, to the depth of two feet, when there is occasion to overflow the marsh, as is always to be done in the winter season, when there is no Salt to be made; for, by this means, the wood work is kept from decay, and the clay bottom from injuries by frost. The ditch between the reservoir and the sea must have a flood-gate, by which the sea water may be admitted, retained or let out as occasion may require. *Brownrig of Salt. Phil. Trans.* N°. 51.

The several ponds or receptacles must not have all their bottoms upon the same level, but must be made of unequal depths, so that the first receptacle or reservoir may be eight inches and a half deeper than the Salt pits in the third receptacle. The three brine ponds also situated between the reservoir and the Salt pits must be of unequal depths. The next adjoining to the reservoir must be the deepest, and that which is nighest the Salt pits the shallowest, but all of them must be shallower than the reservoir; and the three receptacles being thus constructed, the water standing at the same height in them all, and forming with its surface one continued plain, will be ten inches deep in the reservoir, when only an inch and half in the Salt pits.

The length and breadth of the brine ponds and reservoirs are to be at discretion; but it is best to err in making them too large, and in general they ought to be so large as to furnish the Salt pits with a constant supply of brine, fully saturated with Salt; and, for this purpose, it is necessary to have them of different dimensions, in different countries, according to the degree of heat.

The bottoms of the reservoir and brine ponds are to be lined with any kind of lean and tough clay, or earth, that will hold water; and the French use a red, or blue clay, to be had in in the neighbouring grounds. With them, the blue always succeeds better than the red, which colours the Salt much more; but in order to have a perfectly pure Salt from this kind of manufacture, the bottom should be lined with some clean cement, which will hold water perfectly, and will not be easily broken up. Id. Ibid.

The salina or marsh being thus constructed, the saltmen, at the proper season of the year, open the flood-gate when the tide is out, and drain off all the stagnating water; when this is done, they repair the bottom of the marsh in several places, where it is found necessary, and cleanse the several receptacles from mud and dirt: after this they admit the sea-water, at the next high tide, till it floats the whole marsh, and stands at about ten inches high in the reservoir. In a day or two most of the water in the Salt pits is exhaled, and what remains is a very strong brine; they then let in more sea-water at the two or three following tides, and so take care to admit as much water fresh into the marsh as has been wasted in vapour by the heat, constantly raising it to the height of ten inches in the reservoir, and, consequently, to an inch and a half in the Salt pits; and when the weather is extremely hot, or there are sharp drying winds, they fill them something higher than this.

All the parts of the marsh are thus supplied with water out of the reservoir, but the sea-water which is let into the reservoir, is not confusedly let into the other water or brine of the ponds and Salt pits; for, as the several parts of the work communicate only by narrow channels, it is provided, that the Salt water flowing out of the reservoir never returns to it again, but gently flows along till it arrives at the second brine pond, and from that to the third, being forced forwards by the sea water received from time to time into the reservoir: during this slow course, the watery fluid always flies off in great quantity by exhalations, and the brine is continually preparing for crystallisation, as it flows along gently, growing all the way stronger and stronger, as it approaches the Salt pits; so that, when it at length enters these pits, it is fully saturated with Salt; and particular care is taken to guard the entrance of the Salt pits by a long and narrow channel, by which means the strong brine contained in these pits is prevented from returning back, and mixing with the weaker brine in the brine ponds; care is also taken, that the strong brine in the Salts pits is spread out very thin, and exposed to the sun and air with a large surface, by which means the water more quickly exhales from it, and the Salt is left concreted into crystals. These crystals, or Salt, the workmen in France draw out every day, and dispose them at length together in a pyramidal heap, which they cover over at the top with thatch or straw, and so preserve them from the injuries of weather. Thus at a small expence and trouble a Salt is prepared, which is found very fit for all domestic uses; and France is furnished with a very profitable article for exportation into other countries.

Glauber's purging SALT (*Dict.*)— Though this be a well known preparation, and the result of a mixture of a vitriolic acid with marine Salt, and the world has supposed it could be no other way found than by such an union made by art; yet Mr. Heliot has communicated to the academy of sciences at Paris, an account of its being found in vitriol alone, without the addition of any foreign matter.

The common green vitriol or copperas is well known to be made in England, by an union of the sulphureous acid of the common pyrites and iron. Old iron is thrown into large quantities of a solution of the pyrites, that it may be dissolved; and the union produces a concrete in the form of a regular salt. This Salt we well know contain a sulphureous matter; whether that be obtained from the pyrites, or from the iron that enters its composition; since, in the distillation of its oil, there ever escapes a very strong and penetrating scent of sulphur through the junctures of the vessels.

There are also some vitriols, particularly the common Swedish kind, which may very probably be aluminous; since the yellow shining gold-like marcasite from which it is made, yields in its native state true sulphur in distillation, and afterwards affords vitriol in the lixivium, after the remainder has been long exposed to the air; and, finally, it yields also alum, by the addition of urine and pot-ashes to what they call the mother water of vitriol.

Mr. Lemery has shewn, that after a moderate distillation of green vitriol, a salt of the nature of alum may be drawn by a lixivium from the colcothar; and, besides this, Mr. Heliot has found in that colcothar, a vitrifiable earth, and a genuine Glauber's Salt. Those who are at all acquainted with chemistry, know that Glauber's Salt is a concrete composed of the vitriolic acid and Sea salt, and it is generally received as a certainty that any other acid joined to sea Salt cannot afford this concrete; therefore, if Glauber's Salt is to be produced from sea Salt alone, and yet is proved to be found in pure vitriol; it must follow, that pure vitriol does contain sea Salt, or at least, that substance which is the basis of sea Salt: and this will prove a less singular observation, if it can be evinced, according to Becher, that all the known Salts owe their origin to marine Salt.

Mr. Lemery, in order to procure his aluminous salt from vitriol, does not push his distillation too far, that the acid may remain engaged and entangled in that earth, by the union with which it is to form this salt, which is afterwards to be separated by lixiviation; but Mr. Heliot pushes the distillation to the utmost degree with a violent fire of three or four days and nights, such as Kunckel prescribes, for the divesting vitriol of all its acid, that the remainder in the retort may contain little or no salt at all. He took eighteen pounds of English vitriol, which he calcined to a redness, and by that means reduced it to six pounds. This quantity, though put in a covered earthen vessel, acquired nine ounces in weight from the humidity of the air in two days; and in this state it was put into a German retort, and urged to that degree by the violence of fire, for so long a continuance, that the remaining black mass, though treated with all the care imaginable, and washed by repeated lixiviation, yielded only two ounces and a half of Salt, and that of a very earthy kind. About nine ounces of phlegm had been separated at the beginning of the distillation, but when the white vapours began to appear, the vessels were all closed, and so kept to the end of the operation; the produce of which was an icy oil of vitriol, which was found in a black crystalline form.

The success of the operation, as to the procuring this icy oil of vitriol, depends on the nice luting the junctures of the vessels, so as to prevent all communication with the external air; for otherwise the vapours attract a moisture from the air, which renders them fluid in the receiver.

The receiver must also be placed at a considerable distance from the retort, that it may be cool enough to condense the vapours, and large enough to prevent their exploding for want of room; for though the preceding calcination has carried off the more valuable parts, yet there remains matter enough for great explosion, and for the formation of a substance not less inflammable, than crude sulphur, were the acid in a less proportion.

The best method is to fit to the neck of the retort a receiver with two necks; the one of which receives that of the retort, and the other is received into a capacious single receiver, of the common kind.

The icy oil is not easily got out of the receiver, for it exhales so strong a sulphureous vapour, that if it be placed lower than the operator's head, it would suffocate him in a moment.

This icy oil is black, because it carries over with it a quantity of that oily matter, which no vitriol is ever entirely free from, and which is always found in the mother water, as it is called, of vitriol, after the repeated crystallisations of the salt from it; and it is well known, that any inflammable substance, in ever so small a quantity, will turn the purest oil of vitriol black; nor is this all, for the acid spirits also, when urged by a violent fire, carry over with them iron, or at least such particles as are capable of becoming iron. This is easily demonstrated in either the common or the blackest crystals of the icy oil of vitriol; for, if these be dissolved in a large quantity of pure distilled water, and allowed to stand seven or eight days, there always precipitates to the bottom of the vessel a sediment, which, after it has been calcined, has many particles which readily answer to the magnet. Besides this oily matter, and these particles of iron, the oil of vitriol carries with it also a white, heavy, and crystalline substance, of the nature of earth, which may be separated, by means of spirit of wine, from

from oil of vitriol, ever so well rectified. The same sort of earth is also found in the Salt, which is extracted from the caput mortuum, left after the distillation of the icy oil. The lixivium, made by this author from the remaining mass, left after the distillation of the icy oil of vitriol, was exposed to the air, in a glass cucurbit, for the space of six months; and the saline liquor, concentrated by evaporation in a sand-heat, became green, and would by no means crystallise. The first saline pellicles had a saline but earthy taste; these precipitated by degrees of themselves, and were finally succeeded by others, which tasted acid, but not greatly so. This liquor being evaporated to a dryness, an ounce of the remainder was put into a retort, and four ounces of oil of vitriol were put on it, with one ounce of water, to forward the dissolution; this was kept in digestion twenty days, at the end of which time the liquor acquired a green colour, which shewed that there were yet in the mass metallic parts for it to dissolve: this was finally distilled with a gentle heat to separate the phlegm, and afterwards the fire was increased to drive over the acid; the oil of vitriol came over as strong, as it was when put on, but much more sulphureous. The distilled oil, being returned upon the salt, with the fresh addition of a small quantity of water, became so hot, that the vessel could not be held in the hand; which had not been the case in the first mixture, at least not in any sensible degree. Several more cohobations made it yet more and more acid, and at length it became so caustic, as to leave an eschar on being just touched upon the tongue.

The green colour, which the acid first received, became at length changed into a blue one, which gave suspicion that there was copper, as well as iron, in the vitriol. This might appear strange, as it was English vitriol that was used; but Kunckel has proved by experiments, that there is some copper in all vitriol, even in the English; nay, he advances, that in the vitriol of iron, made with oil of vitriol, and filings of that metal, there may always be discovered some portion of copper; and, in fine, that there is no iron but contains some portion of copper, and no copper but contains some portion of iron.

After the sixth cohobation of this blue liquor, there remained a granulated and filamentous saline sediment, on the surface of which there was a small quantity of a yellow sublimation, resembling flower of sulphur; warm water, being poured upon this matter, became of a greenish colour; and this, being digested in a sand-heat, became afterwards reddish, and precipitated to the bottom a white and very heavy powder; which, on a series of examinations, proved to be of the nature of that opake white stone, usually found among the ores of metals, and called by the Germans quartz. The saline liquor, from which this was separated, became yet redder, by longer digestion, but, when cold, it turned to a fine green.

This liquor, being concentrated, by evaporation, to the quantity of two or three ounces, was put into a glass vessel, with its pellicle, which soon precipitated itself to the bottom, in form of a thin crust, covering the surface of the glass in the manner of a wet paper. In five or six weeks time, there became formed in this vessel, both at the bottom and sides, a number of large crystals, of a beautiful green colour, and, as the liquor dried away, these mouldered into a brownish red powder. In fine, there appeared, in the remainder of this liquor, another sort of crystals; these were white and transparent, and were formed in square columns, with their extremities cut in the manner of those the pyramids of the columns of Glauber's Salt; they had also a better taste, and left a remarkable sense of coldness on the tongue. These appeared indisputably, by these and all other trials, to be true Glauber's Salt. *Mem. de l'Acad. Scien. Par.* 1738.

It is to be observed, that, though Glauber made this Salt known about the middle of the preceding century, yet Kunckel in his Laborat. Chymic. assures us it was known in the electoral house of Saxony an hundred years before. However this be, we owe the knowledge of it to Glauber, who called it admirable; and it soon acquired, and has ever since maintained, the reputation of an excellent internal medicine in many cases.

Glauber's Salt may be obtained from borax, by mixing oil of vitriol with it. Mix four ounces of borax with one ounce and one drachm of oil of vitriol; upon sublimation, this gives the sal sedativum of Homberg, and the residuum, exposed to a strong fire, affords Glauber's Salt. This operation may be shortened very much, for, instead of sublimation, the salt may be obtained by crystallisation, in light foliated laminæ. This Salt, whether prepared by sublimation or by crystallisation, has the property of dissolving in spirit of wine; and, if this spirit of wine be set on fire, the flame is green. Spirit of wine has no effect on borax, and the oil of vitriol, digested with it, does not make its flame green. Therefore it is necessary, in order to give this greenness to the flame, that borax should be united to an acid. *Philos. Trans.* N°. 436.

SALT-*petre*. See NITRE, *Dict.* and *Sup.*

SAMARITANS (*Dict.*)—Salmanazar, king of Assyria, having conquered Samaria, led the whole people captive into the remotest parts of his empire; and filled their place with colonies of Babylonians, Cutheans, and other idolaters. These, finding themselves daily destroyed by wild beasts, desired an Israelitish priest to instruct them in the ancient laws and customs of the land they inhabited. This was granted them; and they thenceforth ceased to be incommoded with any beasts. — However, with the law of Moses, they still retained somewhat of their ancient idolatry. The Rabbins say, they adored the figure of a dove on mount Gerizim.

Be this as it will, it is certain, the modern Samaritans are far from idolatry: some of the most learned among the Jewish doctors own, that they observe the law of Moses more rigidly than the Jews themselves.—They have a Hebrew copy of the Pentateuch, differing in some respects from that of the Jews; and written in different characters, commonly called Samaritan characters; which Origen, Jerom, and other fathers and critics, ancient and modern, take to be the primitive character of the ancient Hebrews; though others maintain the contrary. The point of preference, as to purity, antiquity, &c. of the two Pentateuchs, is also disputed by the modern critics.

The Samaritans are now few in number; though it is not very long, since they pretended to have priests descended directly from Abraham. They were chiefly found at Gaza, Neapolis (the ancient Sichem) Damascus, Cairo, &c. They had a temple, or chapel, on mount Gerizim, where they performed their sacrifices.

Joseph Scaliger, being curious to know their usages, wrote to the Samaritans of Egypt, and to the high-priest of the whole sect, who resided at Neapolis. They returned two answers to Scaliger, dated in the year 998 of the Hegira of Mahomet. These answers never came to the hands of Scaliger. They are now in the French king's library, and have been translated into Latin by father Morin, priest of the oratory; and printed in the collection of letters of that father in England, 1682, under the title of Antiquitates Ecclesiæ Orientalis. M. Simon has inserted a French translation, in the first edition of Ceremonies & Coutumes des Juifs, by way of supplement to Leo de Modena.

In the first of these answers, wrote in the name of the assembly of Israel in Egypt, they declare, that they celebrate the passover every year, on the fourteenth day of the first month, on mount Gerizim; and that he who then did the office of high-priest, was called Eleazar, a descendant of Phineas, son of Aaron.—At present they have no high-priest. In the second answer, which is in the name of the high-priest Eleazar and the synagogue of Sichem, they declare, that they keep the sabbath in all the rigour wherewith it is enjoined in the book of Exodus; none among them stirring out of doors, but to the synagogue. They add, that on that night they do not lie with their wives; that they begin the feast of the passover with the sacrifice appointed for that purpose in Exodus; that they sacrifice no where else but on mount Gerizim; that they observe the feasts of harvest, the expiation, the tabernacles, &c. They add further, that they never defer circumcision beyond the eighth day; never marry their nieces, as the Jews do; have but one wife; and, in fine, do nothing but what is commanded in the law: whereas the Jews frequently abandon the law to follow the inventions of their rabbins.

At the time when they wrote to Scaliger, they reckoned one hundred and twenty-two high-priests; affirmed that the Jews had no high-priests of the race of Phineas; and that the Jews belied them, in calling them Cutheans, whereas they are descended from the tribe of Joseph, by Ephraim.

The truth is, the Jews impose abundance of things on the Samaritans: they frequently confound them with the Sadducees, as if they were infected with their errors.—Rabbi Benjamin, who lived in the XIIth century, confirms the best part of what we have said of the Samaritans: he observes, they had priests of the tribe of Aaron, and who never married with any but those of the same tribe: that they sacrificed on mount Gerizim, where they had an altar of stone raised by the Israelites after passing over Jordan. He adds, that they are of the tribe of Ephraim; that they change their habit to go to the synagogue, and wash before they put it on.

SAMARITAN *Medals*, (*Dict.*)—These medals have been infinitely canvassed by the critics, both Jewish and Christian; particularly rabbi Alascher, rabbi Bartenora, rabbi Azarias, rabbi Moses, father Kircher, Villalpandus Waserus, Conringius, Hottinger, father Morin, Walton, Hardouin, Spanheim, &c.

The learned jesuit Souciet, in an express dissertation on the Samaritan Medals, rejects all Hebrew medals, whose inscriptions are in Chaldee characters, as spurious; and allows of none to be genuine but the Samaritan.—Of these there are four kinds.

The first bear expressly the name of Simon, and the subject for which they were struck, viz. the deliverance of Jerusalem. The second kind have not the name Simon, but only the deliverance of Sion, or Jerusalem. The third kind have neither Simon, nor the deliverance of Sion, but only the epocha's, first year, second year, &c. The fourth class have neither any inscriptions, nor any thing whence one may judge of the time when they were struck.

The

The three first kinds were certainly struck after the return from the Babylonish captivity, and in the time of Simon Maccabeus, after Jerusalem had been freed from the yoke of the Greeks. But, though struck after the captivity, father Souciet observes, their character shews itself to be that of the ancient Hebrew, which was used before the captivity, and the use whereof was lost by the people, during their sojourn in Babylon and Chaldea; but restored, after their return, on the same footing as before. He adds, that the inscriptions are pure Hebrew, such as it was spoke before the captivity; that the character, therefore, is the true ancient Hebrew character: that it was customary to write each language in its proper character: that, if they had departed from this rule, they had doubtless used the new character they brought with them from Babylon: that there could be no other reason, but that of settling all things on the same foundation they were on before the destruction of Jerusalem, that could have induced them to use this character on their coins. And, lastly, that these medals were not struck by the Samaritans, but by the Jews, and in Jerusalem.

F. Souciet is very full on all these points, and, to the proofs drawn from medals, adds two others foreign thereto: the first drawn from the resemblance of the Greek letters, introduced by Cadmus the Phœnician, with this Hebrew character; which was the same with that of the Phœnicians, as the language of those people was the same with that of the Hebrews. —The second drawn from several various readings in the scriptures, which cannot be well accounted for otherwise, than by supposing, that the books wrote before the captivity were in the same character with these medals, and which shew, that it is the conformity which certain letters have in that character, that has deceived the copyists.

From the whole, he concludes, that this character of the medals is the true antient Hebrew character; and, that to judge of the various readings of the Hebrew text, and the differences of the ancient Greek and Latin translations, either from themselves, or from the Hebrew text, recourse must be had to this character.

SA'MLET, an English name for a fish of the truttaceous kind, caught in Herefordshire, and some other parts of England, and called, by Willughby, salmulus. *Willughby's Hist. Pisc.*

SAMP, in our American colonies, a name given to a sort of bread made of the maiz, or Indian corn.

They first water the corn for about half an hour, and then beat it in a mortar, or grind it in a hand mill; they then sift out the flour, and winnow the husks from it; they then mix this into a thin paste with water, and bake it in flat loaves, which they call Samp loaves, or Samp bread.

Besides this they have another dish prepared of this corn, which they esteem a great delicacy, and call by the name of Samp, without the addition of loaf or bread. To make this, they only bruise or grind the corn to the size of rice, and then, winnowing away the husks, they boil it gently till it is thoroughly tender, and then add to it milk and butter, and sugar: this is not only a very wholesome, but a very pleasant dish. It was the first diet of our planters when newly settled there, and is still in use, as an innocent food in sickness as well as health.

The Indians, who feed on this sort of food, are found never to be subject to the stone, and to escape several other painful diseases.

The English have found a way of making a very good sort of beer of the grain of this Indian corn: they do this either by using the bread made of it, or else by malting it as we do our own corn. When they make the beer of the maiz breed, they break or cut it into lumps as big as a man's fist; they mash these in the same manner that we do malt, and boil up the wort in the same manner, either with or without hops. *Phil. Transf.* N°. 142.

SA'NCTUARY, among the Jews, was the holiest and most retired part of the temple of Jerusalem; wherein was preserved the ark of the covenant, and into which nobody was allowed to enter but the high-priest, and that only once a year, to intercede for the people.

The Sanctuary, called also sanctum sanctorum, or holy of holies, is supposed to be a type or figure of heaven, and of Jesus Christ the true high-priest, who is ascended thither to make intercession for us.

Some will have it, that the whole temple was called the Sanctuary; and that the sanctum sanctorum, where the ark was kept, was only a little chapel or oratory therein.

To try or examine a thing by the weight of the Sanctuary, is to examine it by a just and equal scale; in regard, among the Jews, it was the custom for the priests to keep stone weights, to serve as standards for regulating all weights by; though these did not differ from the royal, or profane weights.

SANCTUARY, *or asylum*, also signified, a place of refuge or protection.

Some pretend, the first asylum in Greece was that established by order of the oracle of Jupiter Dodonæus, which commanded the Athenians to grant their lives to all those who fled for Refuge into the Areopagus, to the altars of the Goddesses. But others say, the first asylum was built at Athens, by the Heraclidæ, and was a refuge for those who fled from the oppression of their fathers. The asyla of altars and temples were very ancient in the time of Pausanias; who writes, that Neoptolemus, the son of Achilles, was slain near the altar of Apollo at Delphos, as a just punishment for his killing Priam, king of Troy, who had fled to the altar of Jupiter Herceus for refuge. The temple of Diana at Ephesus was the most famous asylum. The privileges of the asyla were inviolable; whence Tacitus complains, that the Grecian temples were filled with the worst of slaves, with insolvent debtors, and criminals, who fled from justice; and that no authority was sufficient to drive them from thence. Yet we meet with instances of obliging such persons to quit their Sanctuary, by starving them, or by setting fire to their place of refuge. All temples were not Sanctuaries, but such only as received that privilege from the manner of their consecration; and, of those which enjoyed this privilege, some were free for all men, others appropriated to certain persons or crimes. Nor was this honour paid to the Gods only, but also to the statues, or monuments, of princes, and other great persons.

When Romulus built Rome, he left a place, covered with wood, between the capitol and the Tarpeian rock, as an asylum to all persons, who should fly thither, whether freemen, or slaves. This asylum at Rome remained sacred, and was not violated, till the reign of Tiberius, who, seeing its abuses, abolished it. At last the asyla were so little regarded, that they served only as a protection for small offenders; for the magistrates made no scruple of forcing great criminals from the very altars.

The Jews had their asyla; among these, the most remarkable were the cities of refuge; in order to provide for the security of those who, by chance, and without any design, happened to kill a man. They were six in number, three on each side Jordan. They were commanded likewise, when they should enlarge their borders, to add three more: but, as this command was never fulfilled, the Rabbins say, the Messiah, when he comes, will accomplish it. Besides the cities of refuge, the temple, and especially the altar of burnt-offerings, enjoyed the privilege of an asylum.

This privilege began to be enjoyed by the Christians about the time of Constantine; but whether that prince made any laws concerning it, is doubted by learned men; for none appear that are older than the time of Theodosius. At first, only the altar, and inward fabric of the church, was a place of refuge; but afterwards any outer buildings, or precincts of the church, had the same privilege granted them; such as the houses or lodgings of the bishop, and clergy, gardens, baths, courts, and cloysters: and, in after-ages, this exemption was extended to the graves and sepulchres of the dead, to crosses, schools, monasteries, and hospitals. This privilege, originally, was not intended to patronise wickedness, or screen the guilty from justice; but as a refuge for the innocent, the injured, and the oppressed; or, in doubtful causes, to give men protection, till they might obtain an equitable and fair hearing: in all such cases, they were allowed thirty days protection. But, that no one might expect this indemnity, who had not a just and legal title to it, several crimes and cases were excepted by law, for which the church could grant no protection; as, first, protection was denied to public debtors, who had either embezzled, or kept back by fraud, the public revenues of the state; secondly, the Jews, who pretended to turn Christians, only to avoid paying their debts, or suffering legal punishment for their crimes; in other cases, they had the common benefit of the Sanctuary with other men: the third sort of persons, to whom this privilege was denied, were heretics and apostates; the fourth, slaves, who fled from their masters; and the fifth, robbers, murderers, conspirators, ravishers, adulterers, and other criminals of the like nature. This shews, that the original intention of Sanctuaries in the Christian church was only to protect the innocent and injured, and, in dubious cases, to grant the supposed offender a little respite. The conditions, upon which protection was granted, were, first, not to fly with arms to the church; secondly, to raise no clamour or tumult in flying thither; and, thirdly, not to eat, or lodge, in the church, but to be entertained in some outward building.

Paulinus, in the Life of St. Ambrose, relates a remarkable instance of the violating of the asyla.

Modern Sanctuaries are a great abuse of these ancient asyla of the Christian church, in giving protection to almost all sorts of criminals, and so enervating the force of the civil laws. The canon law of Gratian, and the decretals of the popes, grant protection to all criminals, except house-breakers, highway-men, and such as commit enormous crimes in the church itself, upon presumption of its protection. Polydore Virgil censures the English for granting protection to all sorts of criminals, not excepting traitors and rebels: but at present we have no such practice; no sanctuary in England, to screen offenders from justice.

SAND, *arena*, in natural history, a genus of fossils, the characters of which are: that it is found in minute concretions forming together a kind of powder, the genuine particulars of which

which are all of a tendency to one determinate ſhape, and appear regular, though more or leſs complete concretions; not to be diſſolved or diſunited, by water, or formed into a coherent maſs by means of it, but retaining their figure in it; tranſparent, vitrifiable by extreme heat, and not diſſoluble in, nor effervefcing with acids. *Hill's Hiſt. of. Foſſ.*

Theſe are ſubject to be variouſly blended and intermixed either with homogene, or heterogene particles, particularly with flakes of talc; and according to theſe, and their different colours, are to be ſubdivided into ſeveral kinds, as red, white, &c.

Dr. Liſter divides the Engliſh Sands into two claſſes; the firſt, ſharp or rag Sand, conſiſting of ſmall tranſparent pebbles, naturally found on the mountains, and not calcinable: theſe he farther divides into fine and coarſe, and ſubdivides each, according to the colours, into white, grey, reddiſh, brown, &c.

The ſecond, ſoft or ſmooth, which he ſubdivides into that with flat particles broken from lime-ſtones, that with ſilver-like particles, and that with gold-like particles.

As to Sand, its uſe is to make the clayey earth fertile, and fit to feed vegetables, &c. for earth alone, we find, is liable to coaleſce, and gather into an hard coherent maſs, as is apparent in clay: and earth thus embodied, and, as it were, glued together, is no-ways diſpoſed to nouriſh vegetables: but if with ſuch earth, Sand, &c. i. e. hard cryſtals, which are not diſſolvable in water, and ſtill retain their figure, be intermixed, they will keep the pores of the earth open, and the earth itſelf looſe and incompact, and by that means give room for the juices to aſcend, and for plants to be nouriſhed thereby,

Thus a vegetable, planted either in Sand alone, or in a fat glebe, or earth alone, receives no growth or increment at all, but is either ſtarved or ſuffocated; but mix the two, and the maſs becomes fertile. In effect, by means of Sand, the earth is rendered, in ſome manner, organical; pores and interſtices being hereby maintained, ſomething analogous to veſſels, by which the juices may be conveyed, prepared, digeſted, circulated, and at length excerned, and thrown off into the roots of plants.

Grounds that are ſandy and gravelly, eaſily admit both of heat and moiſture; but then they are liable to theſe inconveniencies, that they let them paſs too ſoon, and ſo contract no ligature, or elſe retain it too long, eſpecially where there is a clay bottom; and by that means it either parches or chills too much, and produces nothing but moſs, and cankerous infirmities; but if the ſand happens to have a ſurface of good mould, and a bottom of gravel, or looſe ſtone, though it do not hold the water, it may produce a forward ſweet graſs; and, though it may be ſubject to burn, yet it quickly recovers with the leaſt rain.

Sea Sand is accounted a very good compoſt for ſtiff ground; for it effects the two things following, viz. it makes way for the tree or ſeed to root in ſtiff ground, and makes a fume to feed it.

Sand indeed is apt to puſh the plants, that grow upon it, early in the ſpring, and make them germinate near a month ſooner than thoſe that grow upon clay, becauſe the ſalts in the Sand are at full liberty to be raiſed, and put into motion, upon the leaſt approach of the warmth of the ſun; but then, as they are haſty, they are ſoon exhaled and loſt.

It is remarkable that Sand, though it appear a very hard, denſe, and indiſſoluble body, yet is contained inviſibly in the brine, or ſalt water of our ſalt ſprings; and even on the ſhooting of the ſalt, after evaporation, there ſtill remain the particles of it in the clear pellucid Salt; and this, though wholly ſoluble in water, yet when a brine, made by ſuch a ſolution, is boiled, depoſits as much of the Sand as the common brine of the pits, or ſea water.

Dr. Plot, who was very curious to know the true hiſtory of this ſingular effect, procured experiments to be made in the following manner: eight folds of fine Holland, and as many of much finer cambric, were put together, and, a quantity of the brine of the Staffordſhire ſalt pits being ſtrained through this, there was nothing ſeparated from it but a ſmall quantity of black duſt, which ſeemed to have fallen in by accident, and which was not at all like Sand; yet, on evaporating this brine, it was found to contain no leſs than one fourth part as much Sand as ſalt; the quantity of brine, yielding a buſhel of ſalt, yielding alſo a peck of Sand.

Some have ſuppoſed from theſe, and the like obſervations, that the Sand was generated during the time of the boiling the liquor, but the more careful examiners think otherwiſe; it appearing to them, that the particles of this Sand may be ſeen in the brine, by the help of a microſcope, before the boiling, in form of rectangular oblong plates, ſome nearly ſquare; theſe were ſo ſmall, as readily to paſs the ſtrainer with the water; and appearing as numerous in it after, as before the ſtraining, ſhew that they are no more to be kept, by ſuch means, than the ſalt.

The pores of the fineſt ſtrainers, examined by the microſcope, appear twenty times bigger than theſe plates, or particles of the Sand, and therefore it is not to be wondered at, that they let them through. There requires, therefore, no more to the formation of the Sand, than the coaleſcing of ſeveral of theſe particles into one larger granule, and ſo on; and this is very likely to be done by means of the evaporation of a part of the fluid which kept them ſeparate, and of the motion given to them in boiling, which naturally and neceſſarily brought them into the ſpheres of their own mutual attractions, at a time when their attraction with the fluid they ſwam in, was alſo much diminiſhed with its quantity. This attraction ſeems even evidently to increaſe between the particles, as the water becomes evaporated, and, when finally the Salt is drawn from it, and it is examined, as it drops from the baſkets, in which the ſalt is put to drain, it is ſeen to contain more numerous particles of this ſandy matter than before; and theſe are found to coaleſce into yet larger concretions, by degrees, as the remainder of the fluid evaporates from them on the glaſs.

The particles of this ſtony matter, when once thus united, are no more to be ſeparated by water, nor is the matter any longer ſoluble in that fluid. The common ſpar found in form of ſtalactites and incruſtations on the roofs, walls, and floors of old caverns, ſhews that it was once diſſolved in water, and by that means brought to thoſe places, and made into thoſe forms; and it ſhould ſeem, that this Sand, as it is called, was only this ſort of ſpar, which is contained more or leſs in all water; and which, on the evaporating of that water and ſeparation of the ſalt, which might help in making the water a menſtruum proper for the retaining it, ſhoots out into its own natural concretions; for the figure of theſe thin plates is the true and natural thin parallellopiped or rhomboidal figure of the ſmaller concretions of that matter, and even of thoſe pieces into which it falls on breaking. *Phil. Tranſ.* N°. 145.

Sand ſeems to have been the firſt ſubſtance added to proper ſalts for the making of glaſs. Joſephus, Tacitus, Strabo, Pliny, Agricola, &c. all mention this, and tell us of the ſtores, from which the Sand for this uſe was brought, being inexhauſtible. Latter ages have found that ſtones which have cryſtal for their baſis make a finer glaſs than Sand; of this kind are flints, &c. but theſe are all ſo expenſive in their preparation, that Sand is ſtill uſed in much greater abundance than any other ingredient. All the preparation it requires, is, that it be well waſhed before it is uſed; which much of what is uſed is found ready to their hands, being brought from the ſhores and beds of rivers.

Our glaſs-houſes, in London, uſe for their white glaſs the common white Sand uſed in writing, and have it from Maidſtone in Kent in vaſt quantities. For their green glaſs they uſe a common coarſe and greeniſh looking Sand, of which there are vaſt ſtrata at Woolwich. *Merret's Notes on Neri.*

Common Sand is a very good addition by way of manure to all ſorts of clay lands; it warms them, and makes them more open and looſe. The beſt Sand for the farmers uſe is that which is waſhed by rains from roads, or hills, or that which is taken from the beds of rivers; the common Sand that is dug in pits never anſwers nearly ſo well. Sand mixed with dung is much better than laid on alone: and a very fine manure is made by covering the bottom of ſheep-folds with ſeveral loads of Sand every week, which are to be taken away, and laid on cold ſtiff lands, impregnated as they are with the dung and the urine of the ſheep.

Beſides clay land there is another ſort of ground very improveable by Sand; this is that ſort of black foggy land on which buſhes and ſedge grow naturally, and which they cut into turf, in ſome places. Six hundred load of Sand being laid upon an acre of this land, according to the Cheſhire meaſure, which is near double the ſtatute acre, meliorate it ſo much, that without plowing, it will yield good crops of oats or tares, though before it would have produced ſcarce any thing. If after this crop is taken off, the land be well dunged, and laid down for graſs, it will yield a large crop of ſweet hay.

Once ſanding this land will improve it for a vaſt number of years, and it will yield two crops of hay in the year, if there be weather to make it in. Some land in Cheſhire has been, by this means, rendered of twelve times its former value to the owner. The bogs of Ireland, when drained, have been rendered very fruitful land, by mixing Sand in this manner among the earth, of which they conſiſt. Add to this, that in all theſe boggy lands, the burning them, or firing their own turf upon them, is alſo a great advantage. The common peat, or turf aſhes, mixed with the Sand for theſe purpoſes, add greatly to its virtue.

Sea Sand, which is thrown up in creeks and other places, is by much the richeſt of all Sand for manuring the earth; partly its ſaltneſs, and partly the fat and unctuous filth that is mixed among it, give it this great virtue. In the weſtern parts of England, that lie upon the ſea coaſts, they make very great advantages of it. The fragments of ſea ſhells alſo, which are always in great abundance in this Sand, add to its virtues; and it is always the more eſteemed by the farmers, the more of theſe fragments there are among it.

The ſea Sand uſed as manure in different parts of the kingdom is of three kinds: that about Plymouth, and on other of the ſouthern coaſts, is of a blue grey colour like aſhes, which is probably owing to the ſhells of muſcles, and other fiſh of that or the like colour, being broken and mixed among it in great quantity.

quantity. Westward, near the land's end, the sea Sand is very white, and about the isles of Scilly it is very glistering, with small particles of talc; on the coasts of the north sea the Sand is yellowish, brown, or reddish, and contains so great a quantity of fragments of cockle shells, that it seems to be chiefly composed of them. That sea Sand is accounted best, which is of a reddish colour: the next in value to this is the bluish, and the white is the worst of all.

Sea Sand is best when taken up from under the water, or from Sand banks, which are covered by every tide.

The small-grained Sand is most sudden in its operation, and is therefore best for the tenant who is only to take three or four crops; but the coarse or large-grained Sand is much better for the landlord, as the good it does last many years.

Where the Sand is dredged out of the Sea, it is usually twice as dear as where it is taken from the Sand banks.

When the land has been well manured with the large Sand, they take four crops of corn from it, and then lay it down for pasture for six or seven years before they plow it again. The grass is so good, that they commonly mow it for hay the first year; it always abounds very much with the white-flowered clover. If the grass grows but short, it is the farmer's interest to feed his cattle upon it, and it will turn to as good account this way, being very sweet and rich, and making the cattle fat, and the cows yield a very large quantity of milk. *Mortimer's Husbandry.*

Indian SAND. The substance, commonly called Indian Sand, is famous for answering to the magnet. It is brought into several parts of Europe, and is said to be gathered on the sea shore in Persia. After it is gathered, it is boiled in water to wash away the sea Salt and other impurities it may contain. After this operation, it is dried and sent abroad in form of a black powder, consisting of grains of different sizes. Some of these grains are very rough in every part of their surface, and others have one side only rough, the others perfectly smooth and glossy. Their figure is very irregular, and resembles that of the grains of common Sand only; the grains of this Indian Sand are usually smaller than those of our common Sands.

These little lumps have neither taste nor smell, and are so friable, that they are easily reduced to an impalpable powder by rubbing. Some of the particles are strongly attracted by the loadstone, and others are so inactive as to be scarce at all affected by it. Those particles, which are of the deepest dusky black, are most of all affected by the loadstone; those which are not affected by it, seem rather of the colour of lead, of a bluish black and shining; these are in the greatest quantity, and the others are selected from among these by the loadstone. *Philos. Trans.* N°. 432.

SAND *flood.*— Violent winds break through the turf that covers these hills, and then the Sand, lying loose and naked, is soon carried down upon the plains, where it covers and buries the grass, and in a very little time eats through the light turf, and mixing itself with the Sand underneath, becomes one bed of this dry matter never to be covered with turf again. A large body of Sand being thus got together, nothing stops it progress; but it, at every storm, rolls over more and more ground, so that in a few years it extends itself a vast way, especially where the ground, over which it passes, is of the same sandy nature, and only covered with a thin turf.

In some parts of Suffolk the ground encourages this change so greatly, that a bed of Sand broke loose from a neighbouring hill, and covering only a few acres, perhaps eight or ten, will, before it has travelled four miles forward, which it does in a small course of years, deluge a thousand acres. It travels down hill faster than any way else, but will not be stopped by ascent, but will move up the steepest hill, only that it requires more time. The making of fences, in the common way, to keep it out, is vain. It runs through the hedges, and flies over the tops of the banks; and, when it reaches a village, in its course, will bury the cottages, unless preserved at more charge than they are worth. It will in a very little time beat up to the eves of a house, of the low kind, that are usually built in a country village, and has often weight enough to break down walls in its passage.

The best way of stopping its progress is by hedges of furze, planted one over another, as they become levelled; these, if well kept up, will, by degrees, stop or divert the progress; and some who have tried this, with resolution, after they have had the Sand raised twenty feet high, have found it stop its increase, and then, having manured this adventitious soil with dung, found it as good ground as that which made the surface before.

About Thetford, the villages were wholly destroyed by this about ninety years ago, and the branch of the river Ouse, called then Thetford river, so blocked up by it, that very small vessels only could go up it, where very large ones used before. The river has been of great service in stopping its progress into Norfolk, where otherwise its course would have carried it, and its vast spreading sideways, in proportion to its going forward, would have made it bury vast quantities of land in a few years.

The most probable conjecture, as to the cause of this strange sort of deluge in these parts of England, is, that this portion of the county of Suffolk lies east-north-east of a part of the great level of the fens, and is by this exposed to very impetuous winds, which acquire more than ordinary force, by their passing thro' so large a tract of country uninterrupted; the storms seem to be one great cause of the mischief, and the sandy nature of the soil the other. There are old stories, in the country, of suits at law commenced among the farmers, for grounds blown out of the owners possession; but the people who gain this sort of wandering land are the greatest sufferers. A little Sand sprinkled by the winds over a tract of land, where there is a bed of Sand under the turf, soon eats through that obstacle; and what was at first only a thin coat of Sand, becomes then a deep plain of it, capable of being blown away to the depth of eight, ten, twenty, or more feet, and is carried over every thing in its progress before the winds, when once taken up by them. *Philos. Trans.* N°. 37.

SAND-*lands*, a term used by our farmers to express such grounds as consist wholly of a pure sheer Sand.

This is of different colours, as white, blackish, reddish, or yellowish, and is very different in its nature, and in the size of its particles, some being harsher and some milder, and some very light, seeming only to be mere dust. The grey, black, and ash-coloured Sand-land are the worst of all, and generally are found on heaths and commons. Gravelly lands approach much to the nature of these, and those which consist of the largest stones, and are mixed with the harshest Sands, are of all the most barren.

The properest plants for arable land, of this kind, are white oats, rye, black wheat, and turneps. The natural produce, in weeds, is quick grass, sorrel, broom, furze, fern, and heath.

The best manure for them is either marl, or such clay as will break with the frosts. Cow dung is also a good manure for these lands, and many use with success chalk, mud, and the half rotten straw from dunghills.

When the farmer has a mind to raise corn on these lands, he must order them the same as they do the clays; but where they are over-run with broom, furzes, and such sort of weeds, marl is to be laid on in great quantities. This is the practice in Staffordshire, and by it they rid themselves of these troublesome weeds, and procure good crops of corn, though at some expence.

The first sowing of this land is with black wheat, and for this they make three fallowings in winter, and stir them in the May following; at this time they sow them, allowing one bushel of seed to an acre, which generally yields them sixty again. Then once plowing these lands, after this crop is off, they are fit to sow rye on.

In Oxfordshire, they seldom give these lands more than two fallowings for wheat, except they are very much over-run with weeds; and they esteem the white and Lammas wheat the most agreeable for this sort of land, and then after a fallow rathripe barley. They afterwards generally fallow them every other year, and reckon them unfit for beans and peas, though they sometimes sow them with winter vetches. If they sow peas on them, they esteem the rathripe kinds the best.

In Herefordshire, they are much subject to moss growing upon their sandy lands, and they make a great improvement by burning it on the ground, and mixing the ashes with lime, which they plow in.

They generally sow them with rye after this manure, and that yields a very great increase upon them, and brings on a very good kind of grass, if they are laid down after a crop or two. *Mortimer's Husbandry.*

SA'NDIVER (*Dict.*)—It is reported, by many authors of great credit, that this salt, in its genuine form, and no way differing from such as is separated from glass, is thrown out in great abundance in the eruptions of the burning mountains, and lies about in lumps of a spungy texture and great size, or in smaller solid ones among the sciarri and ashes thrown out at those times. The more firm and solid pieces are the most pure, and are generally of a fine white; the others not unfrequently are tinged bluish or yellow, and have sometimes some of the melted matter of the sciarri blended among the mass, and filling up some of the cavities. In the catalogue of the specimens of substances thrown out of Mount Ætna in one of its eruptions, and sent as a present to the Royal Society, we find mention of several pieces of Sandiver, but without any particular description. *Philos. Trans.* N°. 53.

SANGUINA'RIA, *puccoon*, in botany, the name of a genus of plants whose characters are:

The flower is inclosed in a sheath, composed of two oval concave leaves, which fall off: the flower hath eight oblong petals, which are alternately narrow: these spread open, and in the center is situated the pointal, attended by several short stamina: the pointal afterwards becomes an oblong swelling pod, opening both ways, and including many round-pointed seeds.

It is a native of most of the northern parts of America, where it grows plentifully in the woods; and in the spring, before the leaves of the tree come out, the surface of the ground in many places is covered with the flowers, which have some resemblance to our wood anemone; but they have short naked pedicles, each supporting one flower at the top: some of these flowers will have ten or twelve petals; so that they appear to have a double range of leaves, which has occasioned their being termed double flowers: but this is only accidental, the ſame roots, in different years, producing different flowers : the roots of this plant are tuberous, and the whole plant has a yellow juice, with which the Indians uſe to paint themſelves.

SANGUI'NEOUS *Fevers*, a term uſed by the medical writers to expreſs a kind of fever, in which there is always a plethora or fulneſs of blood, which nature is attempting to leſſen by means of this accelerated motion of it, either by forming ſome hæmorrhage, or by throwing a part of it off in form of ſweat. It is very obvious to reaſon, therefore, that bleeding is the firſt thing neceſſary in theſe fevers.

The continent fevers, ſuch as the ephemera and ſynocha, are of this kind. *Junker's Conſp. Med.*

SANHE'DRIM, or SANHEDRIN (*Dict.*)—Many of the learned agree, that the Sanhedrim was inſtituted by Moſes, Numbers ch. xi. and conſiſted at firſt of ſeventy perſons, all inſpired of the Holy Ghoſt, who judged finally of all cauſes and affairs; and that it ſubſiſted, without intermiſſion, from Moſes to Eſdras. — Others will have it, that the council of ſeventy elders, eſtabliſhed by Moſes, Numb. ch. xi, was temporary, and did not hold after his death; adding, that we find no ſign of any ſuch perpetual and infallible tribunal throughout the whole Old Teſtament.

The Jews, however, contend ſtrenuouſly for the antiquity of their great Sanhedri: M. Simon backs and defends their proofs, and M. le Clerc attacks them.— Be the origin and eſtabliſhment of the Sanhedrim how it will, it is certain it was ſubſiſting in the time of our Saviour; that it was held at Jeruſalem; and that the deciſion of all the moſt important affairs belonged to it.—The preſident of this aſſembly was called Naſi.

There were ſeveral inferior Sanhedrims in Paleſtine, all depending on the great Sanhedrim at Jeruſalem. The inferior Sanhedrim conſiſted each of twenty-three perſons; and there was one in each city and town. Some ſay, that, to have a right to hold a Sanhedrim, it was requiſite there were one hundred and twenty inhabitants in the place. Where the inhabitants came ſhort of the number of one hundred and twenty, they only eſtabliſhed three judges.

Into the great as well as the inferior Sanhedrim were admitted prieſts, levites, and laymen, of all the tribes, provided they were of noble extraction, rich, wiſe, without any blemiſh of body, and expert in magic; which laſt was eſteemed a neceſſary qualification, to enable them to obviate and deſtroy it: very old people and eunuchs were excluded.

In each Sanhedrim there were two ſcribes; the one to write down the ſuffrages of thoſe who were for condemnation; the other to take down the ſuffrages of thoſe who were for abſolution. Selden has a learned work on the ſubject of the Jewiſh Sanhedrim, de Synedriis, printed at London in 1635, in three volumes, quarto.

SANI'CULA, *ſanicle*, or *ſelf-heal*, in botany, the name of a genus of plants, whoſe characters are:

It is an umbelliferous plant, whoſe flower conſiſts of five leaves placed orbicularly, but are generally bent back to the center of the flower, reſting on the empalement, which becomes a fruit compoſed of two ſeeds, that are gibbous and prickly on one ſide, but plain on the other: ſome of the flowers are always barren.

This plant is found wild in woods and ſhady places, in moſt parts of England; but being a medicinal plant, may be propagated in gardens for uſe: it may be increaſed by parting of the roots, any time from September to March; but it is beſt to do it in autumn, that the plants may be well rooted before the dry weather in ſpring comes on: they ſhould have a moiſt ſoil and a ſhady ſituation, in which they will thrive exceedingly.

SANI'DIUM, in natural hiſtory, the name of a genus of foſſils, of the claſs of the ſelenitæ, but neither of the rhomboidal nor columnar kinds, nor any other way diſtinguiſhable by its external figure, being made up of ſeveral plain flat plates.

SANS *Pareille*, in conchyliology, the name of a peculiar ſpecies of buccinum, which has its mouth opening a contrary way to that of all other buccina. This is a ſingle ſpecies among the recent buccina, but we find more than one with this peculiarity among the foſſil ſhells, and that in great abundance in many places in England.

SANTOLI'NA, *lavender-cotton*, in botany, the name of a genus of plants, whoſe characters are:

It hath a globoſe floſculous flower; conſiſting of many florets, divided into ſeveral ſegments, ſitting on the embryo, contained in the intermediate little leaves, hollowed like a gutter, and a ſquamous hemiſpherical empalement: the embryo afterwards becomes a ſeed, not at all furniſhed with down: to theſe notes muſt be added larger flowers than thoſe of wormwood and ſouthernwood, alſo the whole face of the plant.

Theſe plants may be propagated by planting ſlips or cuttings of any of the kinds during the ſpring, which ſhould be put into a border of light freſh earth, and watered and ſhaded in hot dry weather, until they have taken root; after which they will require no farther care, but to keep them clear from weeds till autumn, when they ſhould be carefully taken up, and tranſplanted where they are deſigned to remain: but, if the ground is not ready by that time to receive them, it will be proper to let them remain in the border until ſpring; for, if they are tranſplanted late in the autumn, they are liable to be deſtroyed by a little cold in winter.

Theſe plants are very hardy, and, if planted in a lean, gravelly, or ſandy dry ſoil, will continue many years, and reſiſt the cold very well: but, if they are in a wet or rich ſoil, they are often deſtroyed in winter. *Miller's Gard. Dict.*

SA'NTSI, in botany, a name given by the Chineſe to a plant famous among them for its medicinal virtues.

It is deſcribed by the writers, who have been on the ſpot, in ſo remarkable a manner, that it cannot eaſily be miſtaken, provided their deſcriptions are juſt. They tell us that it grows wild on the mountains in ſome of the provinces of China, and that each root of it uſually ſends up eight ſtalks, the middle one greatly higher than the reſt.

They have no branches, and have each only three leaves at the top, and the middle ſtalk bears cluſters of flowers. The root they ſay is four inches thick, and puſhes out ſeveral ſide branches, of the thickneſs of a finger. The bark of theſe roots is rough and brown, and their internal parts ſoft and yellow.

The ſmall roots only are uſed in medicine, the great ones being ſeldom found. The plant flowers in the month of July, and the ſpring ſeaſon is accounted the beſt for taking up the roots.

The way of multiplying the plant is to cut the great root into ſlices tranſverſly, and plant theſe an inch deep in a good ſoil; they will ſoon ſhoot up the natural number of branches, and in three years the plant will grow to its utmoſt perfection.

The great uſe of the plant is in hæmorrhages, in which caſe it is ſaid to be almoſt infallible. *Obſerv. ſur les Cout. de l'Aſie.*

SAP (*Dict.*)—The notion of the Sap's circulation was entertained by ſeveral authors much about the ſame time, without any communication from one another; particularly M. Major, a phyſician of Hamburgh, M. Perrault, Mariotte, and Malpighi. It has met, however with ſome conſiderable oppoſers, particularly the excellent M. Dodart, who could never be reconciled to it.

One of the great arguments for it is, that the ſame experiments of ligature and inciſion, which evince a circulation of the blood in animals, ſucceed in the like manner in plants, particularly in ſuch as abound with a milky Sap, as the great tithymale, milk-thiſtle, &c. if the ligature be faſtened tight round them, the part above is found to ſwell very conſiderably, and that below it, a little: whence it appears, that there is a juice aſcending from the branches; and that the latter is thicker than the former, which quadrates exactly with the common ſyſtem; the juice being ſuppoſed to ariſe in capillary veſſels, in form of a ſubtile vapour, which, condenſed in the extremes of the plant, by the neighbourhood of the cold air, turns back in form of a liquor, through the more patent pipes of the inner bark.

M. Dodart, inſtead of the ſame juices going and returning, contends for two ſeveral juices; the one imbibed from the ſoil digeſted in the root, and from thence tranſmitted to the extremes of the branches, for the nouriſhing of the plant; the other received from the moiſture of the air entering in at the extremities of the branches: ſo that the aſcending and deſcending juices are not the ſame.

One of his chief arguments is, that if two trees of the ſame kind be tranſplanted in one day, after firſt cutting off their roots and branches, and if, after they have taken root again, ſome of the new ſhoots put forth each year be cut off one of them, it will not thrive half ſo well, notwithſtanding its root and trunk being intire as the other.

This he conceives to be a proof of the plants deriving nouriſhment by the branches, and concludes it to be of an aerial nature, becauſe formed of the moiſture of the air, dew, &c. whereas that imbibed from ſoil is terreſtrial, &c. *Hiſt. de l'Acad. Roy. Ann.* 1709.

The humour or Sap of a plant, then, is a juice furniſhed by the earth, and changed into the plant, conſiſting of ſome foſſil parts, other parts derived from the air and rain, and others from putrified animals, plants, &c. Conſequently, in vegetables, are contained all kinds of ſalts, oil, water, earth, &c. and, probably, all kinds of metals too, inaſmuch as the aſhes of vegetables always yield ſomewhat which the loadſtone attracts.

This juice enters the plant in form of a fine and ſubtile water; which the nearer it is to the root, the more it retains of its proper nature; and, the farther from the root, the more action it has ſuſtained, and the nearer it approaches to the nature of the vegetable.

Conſequently, when the juice enters the root, the bark whereof is furniſhed with excretory veſſels, fitted to diſcharge the excrementatious part, it is earthy, watery, poor, acid, and ſcarce oleaginous at all.

In the trunk and branches it is further prepared, though it ſtill continues acid; as we ſee by tapping or perforating of a tree in the month of February, when it diſtils a watery juice apparently acid.

The juice being here carried to the germs or buds is more concocted; and here, having unfolded the leaves, theſe come to ſerve as lungs for the circulation and further preparation of the juice.

For

For these tender leaves, being exposed to the alternate action of heat and cold, moist nights, and hot scorching days, are alternately expanded and contracted, and the more on account of their reticular texture.

By such means is the juice still further altered and digested, as it is further in the petala or leaves of the flowers which transmit the juice, now brought to a further subtility, to the stamina: these communicate it to the farina or dust in the apices, which is, as it were, the male seed of the plant, where having undergone a further maturation, it is shed into the pistil, which performs the office of an uterus or womb; and thus, having acquired its last perfection, it gives rise to a new fruit or plant.

The root or part whereby vegetables are connected to their matrix, and by which they receive their nutritious juice, consists of an infinite number of vasa absorbentia, which, being dispersed through the interstices of the earth, attract or imbibe the juices of the same: consequently, every thing in the earth that is dissoluble in water, is liable to be imbibed; as air, salt, oil, fumes of minerals, metal, &c. and of these do plants really consist.

These juices are drawn from the earth very crude; but by the structure and fabric of the plant, and the various vessels they are strained through, become changed, further elaborated, secreted, and assimilated to the substance of the plant.

The motion of the nutritious juices of vegetables is produced, much like that of the blood in animals, by the action of the air; in effect, there is something equivalent to respiration throughout the whole plant.

The discovery of this is owing to the admirable Malpighi, who first observed, that vegetables consist of two series or orders of vessels.

First, such as receive and convey the alimental juices, answering to the lacteals, veins, &c. of animals.

Secondly, tracheæ or air vessels, which are long hollow pipes, wherein air is continually received and expelled, i. e. inspired and expired; within which tracheæ he shews all the former series of vessels are contained.

Hence, it follows, that the heat of a year, nay, of a day, of a single hour, or minute, must have an effect on the air included in these tracheæ, i. e. must rarefy it, and consequently dilate the tracheæ; whence arises a perpetual spring or source of action, to promote the circulation in plants.

For, by the expansion of the tracheæ, the vessels containing the juices are pressed, and by that means the juice contained is continually propelled, and so accelerated; by which propulsion, the juice is continually comminuted, and rendered more and more subtile, and so enabled to enter vessels still finer and finer, the thickest part of it being at the same time secreted, and deposited into the lateral cells or loculi of the bark, to defend the plant from cold, and other external injuries.

The juice having thus gone its stage, from the root to the remote branches, and even the flower; and having in every part of its progress deposited something both for aliment and defence; what is redundant passes out into the bark, the vessels whereof are inosculated with those wherein the Sap mounted; and through these it re-descends to the root, and thence to the earth again: and thus a circulation is effected.

Thus is every vegetable acted on by heat and cold, during the day-time especially, while the sun's force is considerable, the Sap-vessels squeezed and pressed, and the Sap protruded and raised, and at length evacuated, and the vessels exhausted; and, in the night again, the same tracheæ being contracted by the cold of the air, the other vessels are eased and relaxed, and so disposed to receive fresh food for the next day's digestion and excretion.

What course the juice takes, after it is imbibed by the roots, is not very clear; the vessels that take it up, to convey it to the plant, are too fine to be traced; and hence it has been controverted, whether it is by the bark, or the pith, or the woody part, that the plant is fed.

The more common opinion is for the bark: the juice, raised by the capillaries of the wood, is here supposed to descend by the larger fibres, placed in the inmost part thereof, immediately over the wood; in which descent, the Sap, now sufficiently prepared, adds a part of its substance to the contiguous wood, and thus increases by apposition: and hence it may be, that hollow, carious, or rotten trees, which have neither pitch nor wood except just enough to sustain the bark, do grow and bear.

Some contend for the wood, which they observe to consist of slender capillary tubes running parallel to each other from the root up to the trunk, being proper to receive in a fine vapour; in the ascent whereof the fibres become opened, and their substance increased: and thus the trunks of trees are said to increase in their circumference.

As for the pith; as the woody substance of the trunk becomes more woody, the pith is compressed and streightened to such a degree that in some trees it quite disappears: whence it seems, that its office in vegetation is not very important, since its use is not perpetual. By its spongious substance, it should seem fitted to receive any superfluous moisture transuding through the pores of the woody fibres: and, if by the excess of such moisture, or the like cause, it corrupt and rot, as it frequently happens in elms, the tree does not grow the worse for it; which is a convincing proof it is of no great use.

The learned Dr. Boerhaave distributes the juices of plants into six classes.

First, the first class comprehends the crude nutritious juice, or the juices of the root and stem of plants, which are little more than the mere matter of the element, as drawn by the root from the body it adheres to, whether it be earth, water, or the like.

This juice is found in every part of the plant, and therefore may be held an universal juice; yet he considers it as the juice of the root and stem, because it is chiefly found in them.

This he takes to be a subacid watery lymph, without any specific taste or smell, as not being yet arrived to the maturity of oiliness.

To this class belong those juices which distil in great abundance from wounds or incisions made in the woody parts of plants; such, for instance, is that tart liquor ousing from the root of the walnut-tree, when cut off in the month of May.

Such also is that limpid, subacid humour, flowing out very plentifully at an incision in the birch-tree in the month of March, to the quantity of several gallons in a few days.

Such also is the juice issuing out of the vine wounded in the spring-time, which always tastes tartish, and ferments like the grapes themselves.

This juice may be esteemed as yet fossil, being generated of and in the earth; for the juice of the earth, being received into the canals of this plant, retains its nature during two or three circulations; nor does immediately commence a vegetable juice.

This class of juices therefore he accounts as the chyle of the plant, being chiefly found in the first order of vessels, viz. in the roots and the body of the plant, which answers to the stomach and intestines of animals.

Secondly, the second class of the juices is that of the leaves, which are the real lungs of plants, and accordingly make a further change of the juice, which they receive from the roots and stem by force of the air. The juice of leaves is different therefore from the first juice, as being more sulphureous, and farther elaborated; not that it derives any sulphur from the sun, but that, its watery part exhaling, it becomes more oily, and less volatile.

The juice of leaves he distinguishes into three kinds:

The first is the nutritious juice of the leaves; which is that already described, only further elaborated in the minute vesiculæ of the leaves, and consequently less watery, and more oily and saccharine.

The second is wax, which, exuding out of the leaves, adheres to the surface, and is scraped off by bees with their rough thighs, to build their combs withal. This is chiefly afforded by lavender and rosemary: upon the latter of which, the wax may be plainly perceived sticking to the leaves of it.

The third is manna: not that with which the Israelites were fed in the desart, but a drug sold among us: it is an essential saccharine salt, exuding chiefly by night, and, in the summer-season, from the leaves of a sort of ash growing in Calabria and Sicily, and adhering thereto in the form of a crust, to be gathered the next morning before the sun is up.

The like substance is found to exude from the leaves of the linden-tree and poplar, in the heats of May and June; at which time they have an honey-taste, and are even seen with a fatty juice on them, which, at the approach of the cold evening, gathers into grains.

Thirdly, the third class of juices are those of flowers, or the genital parts of plants; in these are:

First, a pure, elaborated, volatile oil or spirit, wherein the particular smell of the plant or flower resides, and which, by reason of its extreme volatility, exhales spontaneously; insomuch that, if the flower be laid for some time in a warm place, the odorous juice or spirit will be all fled.

The second is the juice expressed from the flower, which in reality is the same with that of the root and leaves, only farther prepared; it is thicker than the former, and has scarce any smell at all: thus, if you bruise an hyacinth, or other fragrant flower, and express the juice, it will be found altogether inodorous.

The third is the sweet juice called honey, which exudes from all flowers; aloes, colocynthis, and other bitter flowers, not excepted.

In all male flowers, that have utricles at the bottom of the petala, which Dr. Linnæus stiles the nectarium, is found a viscid, ruddy, sweet juice in some plenty; and accordingly we see the children gather cowslips, fox-gloves, honeysuckles, &c. and suck the honey from them: the bees too visit these flowers, and, putting in their proboscides or trunks, suck out the honey, and load their stomachs therewith, to be afterwards discharged and laid up in their combs: so that honey is a vegetable juice.

Fourthly, the fourth class of juices are those of the fruit and seed; the preparative whereof is nature's final work: which performed, the plants seem to die for a time, as all animals are seen to languish after the emission of their semen.

The juice of the fruit is like that of the root, only farther elaborated.

The juice of the seed is an essential oil or balm, elaborated and exalted to its last perfection. This juice or oil is not found in the very point or embryo in the center of the placenta; all we meet with in that part, is a few fine watery particles secreted from

from the placenta: but it is in the placentula or cotyledons themselves, which consist of innumerable little folliculi or cells, wherein this only juice is contained, serving to defend the embryo, and preserve it from being corrupted by water, which, it is well known, will hardly pass through oil.

Thus, if you take, for instance, fennel-seed, cut it through the middle, and apply it to the microscope, you will easily perceive a clear shining oil in the cells of each lobe, investing the tender embryo. Without this oil, it were impossible a seed should live a month, and, much less, a year or two, intire and uncorrupted in the ground.

This oil is found in the seeds of all plants; in some, for instance, in almonds, cocoa-nuts, &c. in very great quantities; in others less, as pepper, arum, &c. where one would scarce imagine any oil at all: and these seeds lose their vegetative quality very soon.

Fifthly, the fifth class of juices are those of the bark; which is an artful congeries or bundle of perspirative ducts, and absorbent vessels.

Of these juices there are divers species; for the several humours raised and distributed through the leaves, flowers, and other parts of the plants, have all circulated through the bark, and accordingly are frequently found to distil from wounds made therein. In some cases, even the whole plant is no more than bark, the pulp having been eaten out; as in willows, poplars, &c. which will live a long time in that state.

The bark serves divers purposes; for it not only transmits the nutritious juices of the plants, but also contains divers fat oily humours, to defend the fleshy parts from the injuries of the weather.

Sixthly, as animals are furnished with a panniculus adiposus, usually replete with fat, which invests and covers all the fleshy parts, and screens them from external cold; so are plants incompassed with a bark replete with fat juices, by the means whereof the cold is kept out, and in winter-time the spiculæ of ice prevented from fixing and freezing the juices in their vessels; whence it is that some sorts of trees remain ever-green the year round, by reason their barks have more oil than can be spent and exhaled by the sun; and their leaves are covered with a thick oily film over their surface, which prevents their perspiring so much as other plants, and also defends them from the cold, &c.

All the juices of barks are reducible to eight, viz.

First, the crude, acid, watery juice, called the chyle of the plant.

Secondly, an oily juice, which, bursting the bark in the beginning of the summer, exudes out of several plants; as cypress, pine, fir, savin, juniper, and other ever-greens; and such alone: this oil dissolves by the smallest degree of warmth, and is easily inflamed, and is that which defends the plant; which is the reason why most of these plants will not thrive in very hot climates.

For balm, or fatty liquor, more glutinous than oil, is nothing but the last-mentioned oily juice, which was more fluid during the spring-time; but which, by the greater heat of the sun, has evaporated all its most subtile parts, and is converted into a denser liquor. Thus the finer part of oil of olives being exhaled by the summer's warmth, there remains a thick balsam behind: thus also oil of turpentine, having lost its more liquid parts by heat, becomes of the thick consistence of a balm.

Thirdly, a pitchy juice, which is the body of the oil itself, inspissates, and turns black, when put into a great warmth: this is the most observed in the pine and fir.

Fourthly, resin, which is an oil so far inspissated, as to become friable in the cold, and may be procured from any oil, by boiling it much and long. Thus, if turpentine be set over a gentle fire, it first dissolves, and becomes an oil, then a balsam, then pitch, and then a resin; in which state it is friable in the cold, fusible by fire, and withal inflammable and combustible; dissoluble in spirit of wine, but not in water, which makes the character of resin.

Hence the oil is most abundant in the barks in the winter-time, the balsams in summer, and the resin in autumn.

Fifthly, colophony, which is a Resin still farther exhausted of its volatile part, being pellucid, friable, and approaching to the nature of glass.

Sixthly, gum, which is an humour exuding out of the bark, and, by the warmth of the sun, concocted, inspissated, and rendered tenacious, but still dissoluble in water, and at the same time inflammable, and scarce capable of being pulverised. This oily mucilage serves as a pigment to cover over, and defend the buds of trees, from the injuries of wet and frost in winter; but will melt with a moist warmth, and easily run from them, when the gentle warmth of the spring approaches: nor is ever so far hardened into a crust, as to do any injury to the inclosed shoot. This oily substance always contains in it an acid spirit; which is a preservative against putrefaction.

Seventhly, a gummous resin; which is an humour secreted in the bark, and dried by the heat of the sun; and thus constituting a body that is partly gummous, and, as such, tenacious, and soluble in water; and partly resinous, and therefore friable, and soluble in oil, or spirit of wine, but not in water.

Botanists are now generally agreed, that all plants are furnished with organs and parts necessary both for chylification and sanguification; that they have veins, arteries, heart, lungs, adipose cellules, &c. If so, it is obvious, that there must be some difference between the juices, which have not undergone the action of those parts, and such as have already circulated a number of times.

The several juices, hitherto recounted, are the first or nutritious juice, called also the chyle of the plant, under such alterations, and new modifications, as it undergoes in being received, and kept some time, in parts of a peculiar structure; as leaves, flowers, seed, &c. This last juice, called the blood, is the same nutritious juice farther altered, by being divers times passed through each of those parts, and remixed, and at length converted into a new juice, with properties different from any of them all.

To prove the circulation of the Sap, instances are brought from experiments made by Mr. Fairchild; as, his budding or inoculating of a passion-tree, whose leaves are spotted with yellow, into one of that sort of passion-tree whose leaves are plain: for though, the buds did not take, yet, after it had been budded a fortnight, the yellow spots began to shew themselves about three feet above the inoculation; and, in a little time after that, the yellow spots appeared on a shoot, which came out of the ground from another part of the plant; which has been accounted a plain proof of the Sap's circulation.

Another instance is, a second experiment of the same person, who grafted the ever-green oak, or ilex, upon the common oak. The leaves of the common oak, which was the stock, decayed, and fell off, at the usual season of the year; but the ever-green oak, which was the cyon grafted upon it, held its leaves, and continued shooting in the winter. From whence it is concluded, that, when trees drop their leaves, the Sap keeps full in motion, and is not gone into the root, as some persons think.

There are also other experiments of the same person, which were shewn before the Royal Society; as the New-England cedar, or rather juniper, grafted on the Virginian: and what is taken to prove the circulation in it, is, the branch which was grafted was left several inches below the grafting; which continued growing as well as the upper-part above the grafting.

And also another, which is the viburnum, with the top planted in the ground, which was become roots; and the roots turned up, which were become branches: which plant was in as good a state of growing, as it was in its natural state.

A third experiment of his was on a pear-tree, which he inarched upon two pear-stocks, in March 1721-2, having the roots out of the ground; and was in a good flourishing state, with a branch in blossom, that receives no other nourishment but by the juices that return down the other two branches; which, though it had been done above two years, yet it continued shooting suckers out of the root; which is esteemed as a proof, that the branches are as useful to support the roots, as the roots the branches: and thence he infers, that it is not strange, that so many trees miscarry in planting, when there are no branches left to the head to maintain the circulation to the roots.

A fourth experiment he made on the cedar of Lebanon, grafted on the larix, which dropped its leaves in the winter, yet maintained the cedar in a flourishing condition, as if it had been on a tree which held its leaves all the winter; and the circulation of juices supported the graft below the grafting, and kept it in as good health as above the grafting.

In opposition to the notion of the circulation of the Sap in trees like to that in animal bodies, the rev. Dr. Hales, in his excellent treatise on Vegetable Statics, presents us with various experiments, and says:

When the Sap has first passed through that thick and fine strainer, the bark of the root, we then find it in greatest quantities in the most lax part, between the bark and wood, and that the same through the whole tree.

And if, early in the spring, the oak, and several other trees, were to be examined near the top and bottom, when the Sap first begins to move, so as to make the bark run, and easily peel off, he believes it would be found, that the low bark is first moistened; whereas the bark of the top branches ought first to be moistened, if the Sap descends by the bark. As to the vine, he says, he is pretty well assured, that the lower bark is first moistened.

He adds, that it is to be seen in many of the examples of the experiments he has given in that book, what quantities of moisture trees daily imbibe and perspire: now the celerity of the Sap must be very great, if that quantity of moisture must most of it ascend to the top of the tree, then descend, and ascend again, before it is carried off by perspiration.

The defect of a circulation in vegetables seems, in some measure, to be supplied by the much greater quantity of liquor, which the vegetable takes in, than the animal, whereby its motion is accelerated: for, by the first example he gives, we find the sunflower, bulk for bulk, imbibes and perspires seventeen times more fresh liquor than a man every twenty-four hours.

Besides, nature's great aim in vegetables being only, that the vegetable life be carried on and maintained, there was no occasion to give its Sap the rapid motion which was necessary for the blood of animals.

In animals, it is the heart which sets the blood in motion, and makes it continually circulate: but in vegetables we can discover

cover no other cause of the Sap's motion, but the strong attraction of the capillary Sap-vessels, assisted by the brisk undulation and vibration caused by the sun's warmth; whereby the Sap is carried up to the top of the tallest trees, and is there perspired off through the leaves: but, when the surface of the tree is greatly diminished by the loss of its leaves, then also the perspiration and motion of the Sap are proportionably diminished; as is plain from many of his experiments.

So that the ascending velocity of the Sap is principally accelerated by the plentiful perspiration of the leaves, thereby making room for the fine capillary vessels to exert their vastly attracting power; which perspiration is effected by the brisk rarefying vibrations of warmth; a power that does not seem to be any-ways well adapted to make the Sap descend from the tops of vegetables, by different vessels, to the root.

If the Sap circulated, it must needs have been seen descending from the upper part of large gashes, cut in branches set in water, and with columns of water pressing on their bottoms in long glass tubes, in his forty-third and forty-fourth experiments. In both which cases it is certain, that great quantities of water passed through the stem; so that it must needs have been seen descending, if the return of the Sap downwards were by trusion or pulsion, whereby the blood in animals is returned through the veins to the heart; and that pulsion, if there were any, must necessarily be exerted with prodigious force, to be able to drive the Sap through the finer capillaries.

So that, if there be a return of the Sap downwards, it must be by attraction, and that a very powerful one, as may be seen by many of these experiments, and particularly by experiment the eleventh. But it is hard to conceive what and where that power is, which can be equivalent to that provision nature has made for the ascent of the Sap, in consequence of the great perspiration of the leaves.

The instances of the jasmine-tree, and of the passion-tree, have been looked upon as proofs of the circulation of the Sap; because their branches which were far below the inoculated bud, were gilded. But we have many visible proofs in the vine, and other bleeding trees, of the Sap's receding back, and pushing forwards alternately, at different times of the day and night; and there is great reason to think, that the Sap of all other trees has such an alternate receding and progressive motion, occasioned by the alternacies of day and night, warm and cold, moist and dry.

For the Sap in all vegetables does probably recede, in some measure, from the tops of branches, as the sun leaves them; because, its rarefying power then ceasing, the greatly rarefied Sap and air mixed with it will condense, and take up less room than they did, and the dew and rain will then be strongly imbibed by the leaves, as is probable from experiment 42d, and several others; whereby the body and branches of the vegetable, which have been much exhausted by the great evaporation of the day, may, at night, imbibe Sap and dew from the leaves.

For, by several experiments in the first chapter of the book of Vegetable Statics, plants were found to increase considerably in weight in dewy and moist nights.

And by other experiments on the vine, in the third chapter, it was found, that the trunk and branches of vines were always in an imbibing state, caused by the great perspiration of the leaves, except in the bleeding season; but, when at night the perspiring power ceases, then the contrary imbibing power will prevail, and draw the Sap and dew from the leaves, as well as moisture from the roots.

And we have a further proof of this in experiment 12th, where, by fixing mercurial gauges to the stems of several trees which do not bleed, it is found that they are always in a strongly imbibing state, by drawing up the mercury several inches; whence it is easy to conceive, how some of the particles of the gilded bud in the inoculated jasmine may be absorbed by it, and thereby communicate their gilding miasma to the Sap of other branches; especially when, some months after the inoculation, the stock of the inoculated jasmine is cut off a little above the bud, whereby the stock, which was the counter-acting part to the stem, being taken away, the stem attracts more vigorously from the bud.

Another argument for the circulation of the Sap is, that some sorts of grafts will infect and canker the stocks they are grafted on; but by experiments twelfth and thirty-seventh, where mercurial gauges were fixed to fresh-cut stems of trees, it is evident, that those stems were in a strongly imbibing state; and, consequently, the cankered stock might very likely draw Sap from the graft, as well as the graft alternately from the stock; just in the same manner as leaves and branches do from each other in the vicissitudes of day and night.

And this imbibing power of the stock is so great, where only some of the branches of the stock will, by their strong attraction, starve those grafts; for which reason, it is usual to cut off the greatest part of the branches of the stock, leaving only a few small ones to draw up the Sap.

The instance of the ilex grafted upon the English oak seems to afford a very considerable argument against a circulation, for, if there were a free uniform circulation of the Sap through the oak and ilex, why should the leaves of the oak fall in winter, and not those of the ilex?

Another argument against an uniform circulation of the Sap in trees, as in animals, may be drawn from Dr. Hales's thirty-seventh experiment; viz. where it was found, by three mercurial gauges, fixed to the same vine, that, while some of its branches changed their state of protruding Sap into a state of imbibing, others continued protruding Sap, one nine, and the other thirteen days longer.

That the Sap does not descend between the bark and the wood, as the favourers of a circulation suppose, seems evident from hence, viz. that, if the bark be taken off for three or four inches breadth quite round, the bleeding of the tree above that bared place will much abate; which ought to have the contrary effect, by intercepting the course of the refluent Sap, if the Sap descended by the bark.

But the reason of the abatement of the bleeding, in this case, may be well accounted for, from the manifest proof we have in these experiments, that the Sap is strongly attracted upwards by the vigorous operation of the perspiring leaves and attracting capillaries; but, when the bark is cut off for some breadth below the bleeding place, then the Sap which is between the bark and the wood below that disbarked place is deprived of the strong attracting power of the leaves, &c. and consequently the bleeding wound cannot be supplied so fast with Sap, as it was before the bark was taken off.

But the most considerable objection against this progressive motion of the Sap, without a circulation, arises from hence, viz. that it is too precipitate a course for a due digestion of the Sap, in order to nutrition: whereas in animals nature has provided that many parts of the blood shall run a long course before they are either applied to nutrition, or discharged from the animal.

But when we consider that the great work of nutrition in vegetables, as well as animals (I mean after the nutriment is got into the veins and arteries of animals) is chiefly carried on in the fine capillary vessels, where nature selects and combines, as shall best suit her different purposes, the several mutually attracting nutritious particles, which were hitherto kept disjoined by the motion of their fluid vehicle; we shall find, that nature has made an abundant provision for this work in the structure of vegetables: all whose composition is made up of nothing else but innumerable fine capillary vessels, and glandulous portions or vesicles.

Upon the whole, he thinks we have, from these experiments and observations, sufficient ground to believe, that there is no circulation of the Sap in vegetables; notwithstanding many ingenious persons have been induced to think there was, from several curious observations and experiments, which evidently prove, that the Sap does, in some measure, recede from the top, towards the lower part of plants; whence they were, with good probability of reason, induced to think, that the Sap circulated.

SAPI'NDUS, *the soap-berry*, in botany, the name of a genus of trees, whose characters are:

It hath a flower, which, for the most part, is composed of four leaves, expanding in form of a rose: from whose four-leaved empalement arises the pointal, which afterwards becomes a spherical fruit, having a thick oily cover, inclosing a nut of the same form.

This tree is very common in Jamaica, Barbadoes, and most other places in the West-Indies, where it rises to the height of thirty-feet, or more; but in Europe it is preserved by those persons who are curious in cultivating exotic plants, for the singular structure of the leaves, which are very long and narrow, having borders on each side, which, at about every two inches, have pinnæ, or wings, opposite to each other, and terminated by an odd one. The flowers are produced at the ends of the branches, which are small and white, growing in clusters. These are succeeded by spherical brown berries, about the size of cherries, which have very little pulp; but a brown skin covering the nut, which is round, black, and hard. These nuts were formerly brought into England to make buttons; for which purpose they were very proper, because they never crack. The skin which surrounds the nut will lather like soap, and is used in America to wash linen, though many people say it will burn it, when it is often used. *Miller's Gard. Dict.*

SA'PPHIRE-*colour*.—To give this elegant and beautiful blue to glass, the workers in the glass-houses use the following method: take an hundred weight of rochetta frit, and add to it a pound of prepared zaffer, and to this one ounce of manganese; mix all well together, and put them into the furnace to melt and purify, and, when it is become perfectly pure and fine, work it into vessels, &c. This small quantity of manganese, with the zaffer, gives a most beautiful violet blue.

SAPPHIRE-*paste*. The method of making the counterfeit Sapphires in paste is this: take of crystal prepared two ounces, minium, or common red lead, six ounces, zaffer prepared five grains, manganese prepared seven grains; mix all the powders perfectly together, and put them into a crucible; cover it with a strong lute, and put the whole into a potter's kiln, to stand in the hottest place for twenty-four hours; it will be of a most beautiful deep Sapphire-colour. Blue pastes of two other degrees of blue are also made in the following manner: for a sky blue take crystal prepared two ounces, red lead six ounces, prepared zaffer twenty-one grains; mix all well together, and bake them as before. For a deep violet

let blue take cryſtal two ounces, and lead four ounces, and four grains of painters blue ſmalt; mix all, and bake together in the kiln. Theſe both make good blues, but much inferior to the firſt proceſs. *Neri's Art of Glaſs.*

SAPPHIRI'NA *Aqua*, or blue eye water, is thus made: pour a pint of ſtrong and freſh lime water into a copper veſſel; add to it a drachm of crude ſal armoniac, and throw in ſome filings, or ſmall pieces of copper; it ſoon acquires a beautiful blue colour, and is not only uſed as an eye water, but alſo to deterge old ulcers; and ſometimes is mixed with other things in injections for gonorrhœas.

SAPPHI'RO-RUBI'NUS, in natural hiſtory, a name given by ſome modern writers on gems to a ſtone, partly a ſapphire, and partly a ruby, or, more properly ſpeaking, a ſapphire tinged in ſome part with the ruby colour, while the reſt remains blue. The Indians call this nilacundi.

SARCI'TES, *the fleſh-ſtone*, a name given by ſome authors to the cornelian, from its being of the colour of fleſh, as it is very exactly in ſome pieces.

SARCITES, *or* SAURITES, is alſo a ſtone ſuppoſed to be found in the belly of a lizard; it ſeems to have been a ſpecies of pale cornelian. Pliny mentions it, but gives no deſcription of it.

SARCITES, *the fleſh-ſtone*, in natural hiſtory, is alſo a name given by ſome authors to a ſpecies of ſtone, whoſe fibres were ſuppoſed to repreſent thoſe of beef. It was of a black colour and firm texture.

SA'RCLING-*time*, is the time or ſeaſon when huſbandmen weed their corn.

SA'RCOMA *of the eyes*, a fleſhy excreſcence or tubercle formed on the inner ſurface of the eye-lids. Theſe tubercles, in their beginnings, are uſually ſmall; but they, by degrees, advance often to a very conſiderable bulk. Some of theſe are of ſmooth ſurfaces, others rough and unequal, like a raſberry, or mulberry.

They are always to be cured by extirpation, getting them out by a hook, a pair of pliers, or a needle and thread, and then cutting them out to the roots with ſciſſars; the wound ſhould be ſuffered to bleed a while, and afterwards waſhed with a collyrium made of aloes, tutty, and ſugar of lead mixed in roſe-water, till it is perfectly healed. Some uſe the cauſtic to theſe humours, but the ſciſſars are more ſafe and leſs painful. *Heiſter's Surgery.*

SA'RDA, *the cornelian*, in natural hiſtory, the name of a genus of the ſemi-pellucid gems: the characters of which are that they are ſemi-pellucid ſtones, compoſed of cryſtal with a ſmall admixture of earth, of a plain uniform ſtructure, not tubulated, nor cruſtated, and uſually of one ſimple colour. See CORNELIAN in the Dictionary.

SARDA'NUS, in zoology, the name of a fiſh of the harengiform kind, caught in the Mediterranean, and common in the markets of Rome and Venice. Its body is broader than that of the pilchard, and its back green, and the line which runs along the belly is much leſs rough than in that fiſh. It is indeed eaſy to be diſtinguiſhed from the pilchard, but not ſo eaſy to ſhew in what it differs from the common herring more than in ſize. It ſeems very probable, that it is no diſtinct ſpecies of fiſh; but that the herring, like the pilchard, is always ſmaller in the Mediterranean than in the ocean. *Willughby's Hiſt. Piſc.*

SAR'DAR, in the Turkiſh military orders, the title of an officer choſen from among the caias of the Janizaries on ſome particular occaſion, ſuch as to head a detachment ſent to war, or on any other occaſion. The word is of Perſian origin, and is derived from *ſar*, which in that language ſignifies a head or chief.

This officer is a colonel of a detached body; he is attended in his expedition by his deputy, and two ſecretaries, and his office expires at his return from the buſineſs he was diſpatched on. *Pocock's Ægypt.*

SARDO'NYX, in natural hiſtory, the name of a genus of the ſemi-pellucid gems, which are conſiderably tranſparent, of the true onyx ſtructure, either zoned or tabulated, and are compoſed of the true matter of the onyx, variegated with zones of that of the red or yellow cornelian.

Of this genus there are four known ſpecies: 1. The thin-zoned red Sardonyx, or whitiſh onyx, with thin, ſnow-white, and red zones; this is one of the moſt beautiful of the ſemi-pellucid gems: the ground of this is a cryſtalline matter, ſomewhat whitiſh, otherwiſe very little differing from pure cryſtal, either in colour or tranſparence; and the zones are always extremely fine and ſlender, and laid with a beautiful regularity over one another; they are of the true matter of the cornelian, and ſome are of the plain red cornelian, others of the white, and others often of a pale fleſh colour, made by an admixture of the two former. It is only found in the Eaſt-Indies, and is greatly valued among our lapidaries. *Hill's Hiſt of Foſſ.*

SARO'NIA, Σαρώνια, among the Greeks, a feſtival kept in honour of Diana, ſurnamed Saronia, from Saro, the third King of Trœzene, by whom a temple was erected, and this feſtival inſtituted to her. *Potter, Archæol. Græc.*

SA'ROS, σαρὸς, in chronology, a period of 223 lunar months. The etymology of the word is ſaid to be Chaldean, ſignifying reſtitution, or return of eclipſes; that is, conjunctions of the ſun and moon in nearly the ſame place of the ecliptic.

SA'ROSEL, in the glaſs trade, the name of the room into which the mouth of the leer opens, and in which the glaſs veſſels are placed, when taken out of the leer.

The men who attend to do this are called the ſaroſemen. *Neri's Art of Glaſs.*

SA'RPLAR *of wool*, a quantity of wool otherwiſe called a pocket, or half ſack; a ſack containing eighty tod, a tod two ſtone, and a ſtone 14 pounds. In Scotland it is termed ſarpliath, and contains eighty ſtone.

SARRACE'NA, *the ſide-ſaddle flower*, in botany, the name of a genus of plants, whoſe characters are:

It hath a flower conſiſting of ſeveral leaves which are placed circularly, and expand in form of a roſe, and reſting in a many-leaved empalement: from the middle ariſes the pointal, which is membranaceous, and ſhaped like an hood, and afterwards becomes a roundiſh fruit divided into five cells, which contain oblong ſeeds.

Theſe ſtrange plants are natives of New-England, Virginia, and ſeveral places in North-America, where they grow on bogs, and ſuch places where the waters uſually ſtand in winter.

The name was given to this plant by Dr. Tournefort, in honour of Dr. Sarrazin, a curious botaniſt, who ſent the plant from Canada to Dr. Tournefort at Paris.

As theſe plants grow on bogs, it is very difficult to cultivate them in England: for, although the winters are much more ſevere in the places of their natural growth than they generally are in England, yet, their ſummers being much warmer, they thrive much better, and produce their flowers and fruit annually, whereas it is with great difficulty they are kept alive for a year or two in England.

SARRI'TION, *ſarritio*, among Roman authors, the term uſed to expreſs what we call hoeing in huſbandry, or ſomething analogous to it, that is, a way of ſtirring up the earth about young plants, and deſtroying the weeds that would grow among them. When the plants had been ſome time come up, they ſtirred the land with wooden rakes or harrows, and then went over the fields, and pulled up the weeds by hand.

SA'SSAFRAS (*Dict.*)— The culture of this tree is a hard taſk, it being a very difficult tree to keep long alive, though it will do very well for ſome time. It will not live in green-houſes, and hard winters kill it in the open air.

The beſt way to manage it is to remove it in April into a warm and well defended place, where it will be ſafe from the cold winds, and from too much open ſun. It muſt not, however, be under the droppings of other trees. In winter ſome mulch muſt be laid on the ground round the ſtem, and in the ſummer ſeaſon all the weeds muſt be cleared away about it.

It is brought from Virginia and Carolina, in both which places it is common. Ximenes, an author of conſiderable credit in the world, has ventured to tell us, that the chips of the Saſſafras tree put into ſea-water will, in a few days, render it freſh and potable. He was probably impoſed on by ſome perſon, in whom he placed too much confidence in this article, for experiments ſhew it to be falſe; ever ſo large a quantity of this wood, kept for ever ſo long a time in ſea-water, having no ſuch effect. *Redi's Eſperienza.*

The oil of Saſſafras forms into cryſtals like the oil of thyme, obſerved by Mr. Neuman, and which he ſuppoſed like to camphor.

SASSARO'LLO, in zoology, the name of a peculiar ſpecies of pigeon, called by ſome columba rupicola, or the rock pigeon.

It is of the ſhape of a common pigeon, but ſmaller, and has red legs, and a grey variegated back. It ſeems the ſame with the livia of other authors. *Aldrovand de Avib.*

SA'TTIN *, or SATIN, a kind of ſilken ſtuff, very ſmooth and ſhining, the warp whereof is very fine, and ſtands out; the woof coarſer, and hid underneath: on which depends that gloſs, and beauty, which gives it its price.

* The word comes from the French *ſatin*, which Menage derives further from the Latin *ſeta*, a briſtle, or hair; others from the Hebrew *ſadin*; or from the old French *ſade* and *ſadinet*, handſome, genteel.

There are ſome Sattins quite plain, others wrought, ſome flowered with gold or ſilk, others ſtriped, &c.—All the varieties in the fabric of Sattins are made by uſing new warps, or woofs. The fineſt Sattins are thoſe of Florence and Genoa; yet, the French will not allow thoſe of Lyons any thing inferior thereto.— The Sattins of Bruges have their warp of ſilk, and their woof of thread.

India Sattins, or Sattins of China, are ſilken ſtuffs, much like thoſe manufactured in Europe.— Of theſe, ſome are plain, either white, or of other colours; others worked, either with gold, or ſilk, flowered, damaſked, ſtriped, &c. They are moſtly valued becauſe of their cleaning, and bleaching eaſily, without loſing any thing of their luſtre. In other reſpects they are inferior to thoſe of Europe.

F. le Comte obſerves, that the Chineſe prepare their Sattins in oil, to give them the greater luſtre; but this makes the duſt liable to hang to them.

SATTINET *, or SATTINADE, a very slight, thin sort of sattin, chiefly used by the ladies for summer night-gowns, &c. and ordinarily striped.

* The word is a diminutive of *sattin*.

SATURATION, in chemistry, is the impregnation of an acid with an alkali, or of an alkali with an acid, till either will receive no more, and the mixture becomes neutral.

SATUREIA, *savory*, in botany, the name of a genus of plants, whose characters are:

It is a plant of the verticillate kind, with a labiated flower, whose upper lip, or crest, is divided into two parts; but the lower lip, or beard, is divided into three parts, the middle part being crenated: these flowers are produced from the wings of the leaves, in a loose order, and not in whorles or spikes, as are most of this tribe of plants.

The winter savory is an abiding plant, and may be propagated by slips or cuttings, which, if planted in a bed of light fresh earth in the spring, and carefully watered, will take root in a short time, and may then be transplanted where they are to remain. There seem to be two species of this, differing in their manner of growth, and also in the size of their flowers.

This plant should have a dry soil, in which it will endure the cold very well, as may be seen by its growing in some places upon the tops of walls, where it defies the severest cold of our climate.

SATURN (*Dict.*)—The ring of Saturn sometimes disappears, concerning which, we have a paper in the *Philos. Transact.* N°. 471.

This Phænomenon is rare. It ought to happen every fifteen years; but from the situation of the earth, with respect to the sun and to Saturn, it happens not above once in 30 or 45 years.

SATURNALIA (*Dict.*)—The Saturnalia held three days; beginning on the 16th, others say, the 17th, and others the 18th day of December.

During the solemnity the slaves were reputed masters; they were allowed to say any thing; and, in fine, were served at table by the masters themselves.—Every thing run into debauchery and dissoluteness, and nothing was heard or seen in the city of Rome, but the din, riot, and disorder of a people wholly abandoned to joy and pleasure.

M. Dacier observes, that the Saturnalia were not only celebrated in honour of Saturn, but also to keep up the remembrance of the golden age, when all the world was on a level. It was a piece of religion not to begin any war, or execute any criminal, during this feast.

The Saturnalia were not only observed at Rome, but also in Greece; and were, in reality, much older than Rome itself.—Some ascribe their institution to the Pelasgi, who were cast upon the island of Delos; others to Hercules, and others to Janus.—Goropius Becanus makes Noah the author of them. Orig. lib. 4. That patriarch, he tells us, in the ark, instituted a feast to be held in the tenth month, in memory of this; that, in that month, the tops of the mountains began to appear above the water; and this he makes the origin of the Saturnalia: but it is very probable the year then begun in autumn, and, of consequence, December could not be the tenth month. Vossius goes still higher, and will have it, that the Saturn, in honour of whom this feast was instituted, was Adam.

SATURNUS *glorificatus*, the name of a composition used in making artificial gems.—The preparation is as follows:

Take of good litharge, or rather good ceruse, what quantity you please, grind it into a subtile powder, put it in a large glass cucurbit; pour on it good distilled vinegar, till it rise about three inches above the ceruse.

Then put this vessel on a soft ash fire, or sand heat, and, when the vinegar is well coloured and impregnated with the salt, decant it off into another vessel; continue to put new vinegar on your matter, which stir well with a stick, to facilitate the solution of the salt; and do it so often, till your vinegar shall have extracted all the tincture from the ceruse.

Then take all your coloured vinegar, rectify it four times on tartar calcined to whiteness, then filtre it carefully, and put it in a glass cucurbit on a sand heat or ash fire, where gently evaporate it till a pellicle appears on the surface. Then put the vessel into a cold place, having taken care to cover it, for fear of any foulness tumbling into it, and in a little time you will find pure crystals, which you must take out of your vessel; then put your vessel on the same fire to evaporate the remaining vinegar, till a pellicle appears; then set it in a cool place to crystallise as before.

When you have taken out all the crystals, dry them well, and reduce them to a subtile powder; and keep them in a vessel well stopped. Thus you have Saturnus glorificatus.

SAW (*Dict.*)—The Saw is one of the most useful machines, in the mechanic arts, ever invented: the fable, which is perhaps founded on some surer tradition, attributes the invention thereof to Icarus; who, vying with his father Dædalus, enriched the rising arts with several discoveries.—It is added, he took the first hint from the spine or backbone of a flat fish, such as the soal. The Saw is made of steel, with teeth, but those differently filed and turned, according to the use it is designed for.—There are also a kind of Saws without teeth, used in the sawing of marbles and other stones.

The best Saws are of tempered steel, ground bright and smooth; those of iron are only hammer-hardened: hence, the first, besides their being stiffer, are likewise found smoother than the last.—They are known to be well hammered by the stiff bending of the blade; and well or evenly ground, by bending equally into a bow.

The edge, wherein the teeth are, is always thicker than the back, in regard the back is to follow the edge.—The teeth are cut and sharpened by a triangular file; first fixing the blade of the Saw in a whetting-block.

When filed, the teeth are to be set, that is, to be turned askew, or out of the right line, to make the wider kerf or fissure, that the back may follow the better. This is done by putting an instrument, called a Saw-wrist, between every other two teeth, and giving it a little wrench, which turns one of the teeth a little towards you, and the other a little from you.—The teeth are always set ranker for coarse cheap stuff, than for hard and fine; in regard, the ranker the tooth is set, the more stuff is lost in the kerf; and, if the stuff be hard, the greater the labour of sawing it.

The workmen, who make the greatest use of the Saw, are, the sawyers, carpenters, joiners, ebonists, stone-cutters, carvers, sculptors, &c. The lapidaries too have their Saw, as well as the workers in mosaic; but these bear little resemblance to the common Saws.

SAWING (*Dict.*)—There are wind-mills and water-mills, which do the office of Sawing wood, with infinitely more expedition and ease than is performed by the hand.

They consist of several parallel saws, which are made to rise and fall perpendicularly, by means of one of the grand principles of motion.—A very few hands are here needed, viz. only to push forward the pieces of timber, which are laid on rollers, or suspended by ropes, in proportion as the Sawing advances. These mills are frequently found abroad, and were lately begun to be introduced in England; but the parliament, in consideration of this, that they would spoil the sawyers trade, and ruin great numbers of families, thought fit to suppress them.

SCABIOUS (*Dict.*)—All the shrubby sorts of Scabious may be propagated by cuttings, which may be taken off during any of the summer-months, and should be planted in a shady border, and duly watered in dry weather, which will promote their taking root; and then they may be potted, and placed in a shady situation, till they have taken new root, after which time they may be placed amongst other hardy exotic plants, in a sheltered situation, where they may remain until the end of October, when they must be moved into shelter. In some favourable seasons these plants will produce good seeds in England, so that the plants may be raised from these, by sowing them in an open border of light earth about the middle of March; and, if the spring should prove very dry, it will be necessary to water the ground now-and-then, which will forward the vegetation of the seed; so that the plants will appear in about three weeks after the seeds are sown. When they come up, they must be kept clear from weeds, and in dry weather duly watered; and, when they are strong enough to transplant, they should be planted in pots, and managed in the same manner as those plants which are propagated by cuttings.

All the sorts of Scabious continue a long time in flower, for which they are regarded; for there is no very great beauty in many of their flowers: but, as most of the hardy sorts produce flowers near three months successively, so they may be allowed a place in the borders of large gardens, because they require very little care to cultivate them. And as the shrubby kinds continue in flower most part of the year, so they make an agreeable variety amongst hardy exotic plants in the winter. *Miller's Gard. Dict.*

SCÆNANTH, or SCHÆNANTH, in the Materia Medica, the dried stalk of a plant brought to us from Arabia.

This plant is called, by the generality of botanists, juncus odoratus and aromaticus; but Linnæus gives it the name of ischæmum.

The stalk is usually eight or ten inches in length, sometimes considerably more; it is smooth and glossy on the surface, and about the thickness of a wheat-straw, but much more rigid and firm. It is very light, yet considerably hard, and is of a fragrant or aromatic smell, in which we may discover something of a mixed scent, between that of the rose and penny royal. Its taste is acrid and bitterish, but not unpleasant.

It should be chosen fresh, sound, and clean, not dusty or decayed, of a good smell and strong and acrid taste. *Hill's Hist. Mat. Med.*

SCALE *of music* (*Dict.*)—That musical intervals are founded on certain ratio's or proportions expressible in numbers, is an old discovery. It is well known, that all musical ratio's may be analysed into the prime numbers two, three, and five; and that all intervals may be found from the octave, fifth, and third major; which respectively correspond to those numbers. These are the musicians elements, from the various combinations of which all the agreeable variety of relations of sounds result. This system is so well founded on experience, that we may look upon it as the ſtandard of truth. Every interval that occurs in muſic is good or bad, as it approaches to, or deviates from, what it ought to be on theſe principles. The doctrine of ſome of the ancients ſeems different. Whoever looks into the numbers given us by Ptolemy, will not only find the primes 2, 3, and 5, but 7, 11, &c. introduced. Nay, he ſeems to think all fourths good, provided their component intervals may be expreſſed by ſuperparticular ratio's. But theſe are juſtly exploded conceits; and it ſeems not improbable, that the contradictions of different numerical hypotheſes, even in the age of Ariſtoxenus, and their inconſiſtency with experience, might lead him to reject their numbers altogether. It is pity he did: had he made a proper uſe of them, we ſhould have had a clearer inſight into the muſic of his times. However, what remains of the writings of this great muſician, joined to my own obſervation and experience, has enabled me, I hope, to throw ſome light upon the obſcure ſubject of the ancient ſpecies of muſic.

By the manner in which Euclid and others find the notes of their Scale, it muſt have been compoſed of tones major and limma's. Hence, the ſeven intervals of one octave would be thus expreſſed in numbers, $\frac{8}{9}$, $\frac{243}{256}$, $\frac{8}{9}$, $\frac{8}{9}$, $\frac{243}{256}$, $\frac{8}{9}$, $\frac{8}{9}$.

Some modern authors have from this inferred the imperfection of the Greek muſic. They alledge we here find the ditonus, or an interval equal to two tones major expreſſed by $\frac{64}{81}$, inſtead of the true third major expreſſed by $\frac{4}{5}$. As there can be no queſtion of the beauty and elegance of the latter, the former therefore muſt be out of tune, and out of tune by a whole comma, which is very ſhocking to the ear. In like manner the trihemitone of the ancients falls ſhort of the third minor by a comma; which is alſo the deficiency of their hemitone or limma, from the true ſemitone major, ſo eſſential to good melody. Theſe errors would make their Scale appear much out of tune to us. This I readily grant; and add, that it appeared out of tune to them; ſince they expreſly tell us, that the intervals leſs than the diateſſaron or fourth, as alſo the intervals between the fifth and octave, were diſſonant and diſagreeable to the ear. Their Scale, which has been called by ſome the ſcala maxima, was not intended to form the voice to ſing accurately, but was deſigned to repreſent the ſyſtem of their modes and tones, and to give the true fourth and fifths of every key a compoſer might chuſe. Now if, inſtead of tones major and limma's, we take the tones major and minor, with the ſemitone major, as the moderns contend we ſhould, we ſhall have a good Scale indeed, but a Scale adapted only to the concinnous conſtitution of one key; and, whenever we proceed from that into another, we find ſome fourth or fifth erroneous by a comma. This the ancients did not admit of. If, to diminiſh ſuch errors, we introduce a temperature, we ſhall have nothing in tune but the octave. We ſee then the Scale of the ancients was not deſtitute of reaſon; and that no good argument againſt the accuracy of their practice can from thence be formed.

It was uſual among the Greeks to conſider a deſcending as well as an aſcending Scale; the former proceeding from acute to grave, preciſely by the ſame intervals as the latter did from grave to acute. The firſt ſound in each was the proſlambanomenos. The not diſtinguiſhing theſe two Scales has led ſeveral learned moderns to ſuppoſe, that the Greeks, in ſome centuries, took the proſlambanomenos to be the loweſt note in their ſyſtem; and, in other centuries, to be the higheſt. But the truth of the matter is, that the proſlambanomenos was the loweſt, or higheſt note, according as they conſidered the aſcending, or deſcending Scale. The diſtinction of theſe is conducive to the variety and perfection of melody; but I never yet met with above one piece of muſic, where the compoſer appeared to have any intelligence of this kind. The compoſition is about 150, or more, years old, for four voices; and the words are, ‘ Vobis datum eſt noſcere myſterium regni Dei, cæ‘ teris autem in parabolis; ut videntes non videant, et audientes ‘ non intelligant’. By the choice of the words, the author ſeems to allude to his having performed ſomething not commonly underſtood.

I ſhall here give an octave only of the aſcending and deſcending Scales of the diatonic genus of the ancients, with the names of their ſeveral ſounds, as alſo the correſponding modern letters.

Aſcending.			Deſcending.	
A		Proſlambanomenos		*g*
	$\frac{8}{9}$		$\frac{9}{8}$	
B		Hypate Hypaton		*f*
	$\frac{243}{256}$		$\frac{256}{243}$	
C		Parhypate Hypaton		*e*
	$\frac{8}{9}$		$\frac{9}{8}$	
D		Lychanos Hypaton		*d*
	$\frac{8}{9}$		$\frac{9}{8}$	
E		Hypate Meſon		*c*
	$\frac{243}{256}$		$\frac{256}{243}$	
F		Parhypate Meſon		*b*
	$\frac{8}{9}$		$\frac{9}{8}$	
G		Lychanos Meſon		*a*
	$\frac{8}{9}$		$\frac{9}{8}$	
a		Meſe		*G*

Where the ſame Greek names ſerve for the ſounds in the aſcending and deſcending Scales.

In the octave here given, four ſounds, viz. the proſlambanomenos, hypate hypaton, hypate meſon, and meſe, were called ſtabiles, from their remaining fixed throughout all the genera and ſpecies.

The other four ſounds being the parhypate hypaton, lychanos hypaton, parhypate meſon, and the lychanos meſon, were called mobiles, becauſe they varied according to the different ſpecies and varieties of muſic.

I come now to determine the queſtion, What theſe different genera and ſpecies were? We know, that by genus and ſpecies was underſtood a diviſion of the diateſſaron, containing four ſounds, into three intervals. The Greeks conſtituted three genera, known by the names of enharmonic, chromatic, and diatonic. The chromatic was ſubdivided into three ſpecies, and the diatonic into two. The three chromatic ſpecies were the chromaticum molle, the ſeſquialterum, and the toniæum. The two diatonic ſpecies were the diatonicum molle, and the intenſum; ſo that they had ſix ſpecies in all. Some of theſe are in uſe among the moderns, but others are as yet unknown in theory or practice.

I now proceed to define all theſe ſpecies, by determining the intervals, of which they ſeverally conſiſted; beginning by the diatonicum intenſum, as the moſt eaſy and familiar.

The diatonicum intenſum was compoſed of two tones, and a ſemitone: but to ſpeak exactly, it conſiſts of a ſemitone major, a tone minor, and a tone major. This is in daily practice; and we find it accurately defined by Didymus, in Ptolemy's Harmonics publiſhed by Dr. Wallis.

The next ſpecies is the diatonicum molle, as yet undiſcovered, as far as appears to me, by any modern author. Its component intervals are, the ſemitone major, an interval compoſed of two ſemitones minor, and the complement of theſe two to the fourth, being an interval equal to a tone major, and an enharmonic dieſis.

The third ſpecies is the chromaticum toniæum. Its component intervals are, a ſemitone major, ſucceeded by another ſemitone major; and, laſtly, the complement of theſe two to the fourth, commonly called a ſuperfluous tone.

The fourth ſpecies is the chromaticum ſeſquialterum, which is conſtituted by the progreſſion of a ſemitone major, a ſemitone minor, and a third minor. This is mentioned by Ptolemy, as the chromatic of Didymus. Examples among the moderns are frequent.

The fifth ſpecies is the chromaticum molle. Its intervals are two ſubſequent ſemitones minor, and the complements of theſe two to the fourth; that is, an interval compounded of a third minor, and an enharmonic dieſis. This ſpecies I never met with among the moderns.

The ſixth and laſt ſpecies is the enharmonic. Salinas and others have determined this accurately. Its intervals are, the ſemitone minor, the enharmonica dieſis, and the third major. Examples of four of theſe ſpecies may be found in modern practice. But I do not know of any theoriſt who ever yet determined what the chromaticum toniæum of the ancients was: nor have any of them perceived the analogy between the chromaticum ſeſquialterum and our modern chromatic. The enharmonic, ſo much admired by the ancients, has been little in uſe among our muſicians as yet. As to the diatonicum intenſum, it is too obvious to be miſtaken.

Ariſtoxenus and others often mention the tone as divided into four parts, and the ſemitone into two; thereby making ten diviſions or dieſes in the fourth. And this is true, if we conſider theſe ſounds in one tenſion; that is, either aſcending or deſcending: but, accurately ſpeaking, when we conſider all the dieſes or diviſions of the fourth, both aſcending and deſcending, we ſhall find thirteen; five to each tone, and three to the ſemitone major. But then it is to be obſerved, that ſome of theſe diviſions will be leſs than the enharmonic dieſis: for, if we divide the ſemitone major into the ſemitone minor, and enharmonic dieſis, aſcending, for inſtance, E, ♯ E, F, and then divide in like manner deſcending, F, ♭ F, E, we ſhall have the ſemitone major divided into three parts thus, E ♭ F, ♯ E, F; where the interval between ♭ F and ♯ E is leſs than the enharmonic dieſis between E and ♭ F, and between ♯ E and F, as is eaſily proved.

Now, if we ſuppoſe theſe ſmall intervals equal, by increaſing the leaſt diviſion, and diminiſhing the true enharmonic dieſis, we ſhall then have a fourth divided into thirteen equal parts; and, conſequently, the octave divided into thirty one ſuch equal parts; which gives us the celebrated temperature of Huygens, the moſt perfect of all.

From this it appears, that the diviſion of the octave into thirty-one parts was neceſſarily implied in the doctrine of the ancients. The firſt of the moderns who mentioned ſuch a diviſion was Don Vincentino, in his book intitled L'Antica Muſica ridotta alla moderna Prattica, printed at Rome, 1555, folio. An inſtrument had been made according to his notion: which was condemned by Zarlino and Salinas, without ſufficient reaſon. But Mr. Huygens, having more accurately examined the matter, found it to be the beſt temperature that could be contrived. Though neither this great mathematician, nor Zarlino,

lino, Salinas, nor even Don Vincentino, feem to have had a diftinct notion of all thefe thirty-one intervals, nor of their names, nor of their neceffity to the perfection of mufic.

In Huygens's temperature the tones are all equal: but, in a true and accurate practice of finging, they are not fo. And I muft add, that the tone divided in every fpecies muft be the tone minor; for the divifion of the tone major is harfh and inelegant. So that, in the divifion of the fourth, it is to be obferved, that in every fpecies, the tone major muft either be an undivided interval, or make part of one. *Philof. Tranf.* N°. 481.

SCALES, in natural hiftory. What the naturalifts underftand by Scales, are certain flat and femipellucid bodies, common to the fifh, the ferpent, and the lizard kind; confifting of a fubftance fomewhat analogous to that of the horns and hoof of other animals, as is found by cutting and burning them, and by their fmell.

The Scales in fifhes are of fo many different kinds and fhapes, that they afford, in many cafes, very good characters for the diftinction of the fpecies. The differences of thefe parts of fifh arife from their number, fituation, figure, and proportion, and to fome other qualities peculiar to a few of them. Their differences, in regard to number, are thefe: there are none on feveral kinds of fifh, as on the petromyza, the dolphin, and the whales. Upon fome other fifhes they are but very few in number, as on the conger, the eel, the clariæ, &c. And they are on others found in vaftly great numbers, and placed in clufters one over another, as in the pearch, falmon, &c. Thefe Scales are not fuppofed to be fhed every year, nor during the whole life of the fifh, but to have an annual addition of a new Scale growing over, and extending every way beyond the edges of the former, in proportion to the fifh's growth; fomewhat in the manner as the wood of trees increafes annually, by the addition of a new circle next the bark. And, as the age of a tree may be known by the number of ringlets its trunk is made up of, fo in fifhes, the number of plates, compofing their Scales, denote to us their age. It is alfo probable, that as there is a time of the year when trees ceafe to grow, or have any farther addition to their bulk, the fame thing happens to the Scales of fifhes; and that afterwards, at another time of the year, a new addition, increafe, or growth begins.

Mr. Lewenhoek took fome Scales from an extremely large carp, forty-two inches and a half long, Rynland meafure, which were as broad as a dollar; thefe he macerated in water, to make them cut the eafier, and then cutting obliquely through one of them, beginning with the firft formed, or very little fhell in the center, he by his microfcope plainly diftinguifhed forty lamellæ, or Scales, glewed as it were to one another; whence he concluded the fifh to be forty years old.

It is generally imagined that an eel has no Scales; but, if the flime be wiped clean away, and the fkin then examined by a microfcope, it is found covered with extremely fmall Scales, ranged in a very orderly and pretty manner; and probably very few fifhes, except fuch as have fhells, are truly free from Scales.

The way of preparing Scales for the microfcope, is to take them off carefully with a pair of nippers, wafh them very clean, and then place them between the leaves of a book to make them dry flat; and, when thoroughly dry, they are to be put between two flips of talc. The fnake, viper, and eel afford alfo a very beautiful and very different feries of Scales from thofe of fifhes.

SCA'LLION, or ESCALLION, a fort of onion that never forms any bulb at the root, but is ufed green in fpring, before the other forts fown in July are large enough.

This is however very fcarce in London, the gardeners ufually felling in its place the fhoots of fuch decayed common onions, as have fprouted in the houfe. Thefe they plant in a bed early in the fpring, and they foon grow large enough for ufe, when they pull them out; and, taking off all the old outer coat of the roots, they lay them in bunches, and fell them at market for Scallions.

The true Scallion is eafily propagated by parting the roots in autumn, and planting them three or four together in a hole, at fix inches diftance. Thefe will grow in any foil or fituation, and will multiply very quickly, and in a very great abundance; and their being hardy enough to endure the fevereft weather, and fit for ufe fo early in fpring, makes them worthy a place in all kitchen gardens. *Miller's Gard. Dict.*

SCAL'LOP. — The anatomy of this fifh lets us greatly into the knowledge of the ftructure of the parts of other bivalve fifh.

The Scallop is compofed of two fhells, which, as in many others, are one concave, and the other plane or flat. The cardo, or hinge, is lightly bent from the concave fhell, and thence carried over a part of the plane fhell, and all the way between it is firmly connected to a cartilage. In the middle of the length of the cardo there is placed another fhort, black, and very ftrong cardo.

It is eafy to fee, from hence, to what is owing that remarkable ftrong power, which this creature has of fhutting and opening its fhell; and it is very poffible, that, by means of fo ftrong an apparatus of tendons or ligaments as it has in this part, it may be able to move the plane fhell in fo fwift and regular, as well as forcible and eafy a manner, that it may ufe it in moving from place to place, and poffibly it may make a fort of wing of it, to beat againft the water as the pinion of a bird does againft the air; and what the antients have fo frequently faid of its moving about in a very fwift manner, from place to place, may be true, though we have been wanting in later obfervations to fee it.

When the two fhells are opened, the following particulars offer themfelves to the view. Firft, the mouth; this is covered with a fort of membranous hood, as in the oifter; it does not ftand on the center of the head, but towards the right-hand, and the covering is only an elongation of the branchiæ, or gills of the fifh: thefe are of a membranous nature, and furround the whole body from the mouth to the anus, which ftands towards the left hand from the mouth, where they are connected again.

That branchia of the exterior part, to which the flat or plane fhell adheres, is fixed in its center to an immenfely ftrong mufcle, which grows from the fhell, and is fixed into the body of the fifh at right angles: this branchia is fixed to the upper limb of that mufcle, and the other branchia is, in like manner, connected to the lower limb of the fame ftrong mufcle. Thefe two exterior, or fpurious branchiæ, from this mufcle to a confiderable extent, are formed only of a thin and pellucid membrane, and, being carried to the middle of the valves on each fide, they are fixed down in fuch a manner, that they cannot be removed by any means, without injuring or deftroying them.

The ufe of thefe is to defend the body of the animal from the injuries of the water, and other fubftances let in with it, on the opening of the fhell. From the place of this adhefion there is propagated a ftrong and thick mufcle, of a truly wonderful ftructure; this is a fort of limb or verge to the animal. It is contracted inward when the animal is dead, but, while it is alive, it is expanded, at the creature's pleafure, a great way out beyond the edges of the fhell; and is jagged, and variegated with lines and ftreaks in an amazing and elegant manner.

The ufe of this part feems eafily gueffed, it being, when expanded out of the mouth of the fhell, a fort of net, for the catching whatever the creature chufes to feed upon. It is, at the pleafure of the animal, either laid flat on the furface of the mud or rock, or arched into a part of a circle: when, in any of thefe pofitions, any thing comes in its way which is proper food for the creature, it immediately gathers up like a net round about it, and, withdrawing itfelf into the fhell, takes in the prey with it. In this cafe, the ufe of its being cut, or fringed, is alfo plainly feen; for it can, by means of this ftructure, let out the water taken in with the prey through the jags, and yet retain the prey itfelf. *Philof. Tranf.* N°. 229.

The ufe of this admirable mufcle is not only the ferving as a net for the taking the food, and afterwards as a ftrainer for the feparating the water from it; but its mufcular force is fo great, that it alfo ferves as a weapon of death to the little animal it has feized, by compreffing it to pieces, if neceffary, at leaft by fqueefing it till no life remains. This is a very neceffary article in the preying of an animal which can neither follow or refift an animal in motion, but this is not all. When the prey is brought into the fhell, it might there remain, where firft laid down, without being of any ufe to the Scallop, who cannot turn about her mouth to come at it: in this cafe the fame wonderful mufcle, by its undulatory motion, ferves to convey the prey to a part of the fhell nearer the mouth of the animal; and when there, taking it up between the jags of the fringe, it holds it to the opening of the mouth; in this laft office ferving in the place of a hand. Thefe are the many and neceffary ufes of this part.

But to come to the branchiæ, or gills, properly fo called; the true branchiæ are four in number; they are of a yellowifh colour, and are fringed in a very elegant manner; thefe every way furround the great central mufcle, and ferve as a covering to the uterus of the animal, or its ovary; certainly, however, to the parts of generation, by what ever name they may be called.

The lower part of the body of the Scallop is yellow, and its upper part white, and near its mouth there is very plainly to be difcovered a procefs with a double aperture. It feems probable, from all obfervation, that the Scallop is an hermaphrodite animal, and contains the parts of generation of both fexes in each individual; and it appears that the female part of generation is, on occafion, pufhed out from one of thefe apertures, and the penis, or male part, from the other. The mouth of the Scallop is furnifhed with reddifh lips, refembling the branchiæ, or gills, in their ftructure, but very fhort and fmall; and near the hinge there are two large circular cavities, refembling the eyes of the turbot. Near the head there is a large mafs of blackifh matter towards the left hand, and under that, or rather behind it, is fituated the creature's heart. The pericardium is pellucid, and is of fo fine a ftructure, that the heart is eafily feen through it: it is of a reddifh colour, and its aorta, or large artery, is divided into a great number of branches, which are fent every way round to the gills.

It is fome doubt, however, whether this their membrane, before

fore deſcribed, ſerves alone in the capacity of a pericardium, or whether all this black matter, that lies about it in a ſort of rhombic form, does not alſo, in ſome degree, ſupply that office. The lower part of this gives place to the urinary bladder, and the ſtrait gut ariſes from the baſe of this black ſubſtance, and is thence carried ſtraight over the pericardium, whence it runs on to the branchiæ, and is at length affixed to the great central muſcle.

This central muſcle is of a rounded figure, very ſmooth, and white, and even in the greater part of its bulk, where it is connected to the ſhell; but on the left it is divided, and forms another white and lacerated muſcle, which runs along a part of the ſhell, and ſtrengthens the connection of the body of the fiſh with this part of the plane valve. *Philoſ. Tranſ.* N°. 229.

SCAL'PEL, *ſcalpellum*, in chirurgery, a kind of knife chiefly uſed in diſſections; but which may be occaſionally uſed in many other operations, as in amputations, and to cut off the fleſh and membranes that are between the two bones of an arm or leg, before the limb be ſawed off.

There are two kinds of Scalpels: the firſt cuts on both ſides, and is fixed in an ebony or ivory handle, which, being very flat and thin at the extremity, ſerves to part the membranous and fibrous parts in anatomical preparations.

The other has a back, that is, it only cuts on one ſide; it is crooked, and very commodious for ſtripping the fleſh off the bones in embalming, making ſkeletons, &c.

Scultetus, in his Arſenal, deſcribes ſeveral other kinds of Scalpels; as, a deceitful Scalpel, thus called, becauſe it deceives the patient by hiding its blade. It was much uſed by the ancients, in opening and dilating of ſinews; but as it is apt to deceive the ſurgeon himſelf, and is beſides very ſlow, it is better uſing a ſyringotomus.—A Scalpel, ſharp on both ſides for ſetons.—A little crooked Scalpel for ſeparating the coherence of the eyelids.—A ſharp, double-cutting Scalpel, with a bone-handle, for the cutting off an ægilops.—Scalpels like ſcolopomachærions, &c. Even the ſcolopomachærion itſelf is a kind of Scalpel.

SCA'LPRA *dentalia*, inſtruments uſed by the ſurgeons to take off thoſe black, livid, or yellow cruſts, which infeſt the teeth, and not only looſen and deſtroy them, but taint the breath.

The manner of uſing them is to begin near the gums, ſupporting the blade with the left hand, and ſcraping all along the teeth, till the cruſt is taken off, taking care not to wound the gums, or diſplace the teeth. *Heiſter's Surgery.*

SCAPE-*goat*, in the Jewiſh antiquities, the goat ſet at liberty on the day of ſolemn expiation. For the ceremonies on this occaſion, ſee Levit. XVI. 5, 6, &c.

Some ſay that a piece of ſcarlet cloth, in form of a tongue, was tied on the forehead of the Scape-goat. *Hofm. Lex univ. in voc. Lingua.*

Many have been the diſputes among the interpreters, concerning the meaning of the word Scape-goat, or rather of azazel, for which Scape-goat is put in our verſion of the Bible. Spencer is of opinion that azazel is a proper name, ſignifying the devil or evil dæmon. See his reaſons in his book de Leg. Hebr. Ritual, Diſſert. VIII. Among other things he obſerves that the antient Jews uſed to ſubſtitute the name Samaël for azazel, and many of them have ventured to affirm, that at the feaſt of expiation they were obliged to offer a gift to Samaël to obtain his favour. Thus alſo the goat, ſent into the wilderneſs to Azazel, was underſtood to be a gift or oblation. Some Chriſtians have been of the ſame opinion. But Spencer thinks that the genuine reaſons of the ceremony were, 1. That the goat loaded with the ſins of the people, and ſent to Azazel, might be a ſymbolical repreſentation of the miſerable condition of ſinners. 2. God ſent the goat thus loaded to the evil dæmons, to ſhew that they were impure, thereby to deter the people from any converſation or familiarity with them. 3. That, the goat ſent to Azazel ſufficiently expiating all evils, the Iſraelites might the more willingly abſtain from the expiatory ſacrifices of the Gentiles.

Fracture of the SCA'PULA.—The Scapula is uſually fractured either near its acromion, or head, where it joins the clavicle, or in ſome more diſtant part. If the fracture happens in proceſs of the acromion, the reduction will be eaſily made, by lifting up the arm to relax the deltoide muſcle, and puſhing the arm evenly upwards, making the fractured parts meet together with the fingers: but, notwithſtanding their reduction is ſo eaſy, they eaſily ſlip away again from any ſlight cauſe, and ſo are difficultly agglutinated. They are not in particular very eaſily ſeparated by the weight and motion of the arm, and by the contraction of the deltoide muſcle; inſomuch that there is ſcarce ever an inſtance of a fractured acromion being ſo perfectly cured, as to admit afterwards of a free motion of the arm upwards: all means muſt, however, be uſed to endeavour to keep the replaced bones in their proper ſituation. A compreſs, wet with ſpirit of wine, is to be applied to the fracture; a ball is to be put under the arm-pit to ſupport it; the whole is to be bound up with the bandage commonly called ſpica, and the arm is to be ſuſpended in a ſaſh or ſling hung about the neck. But if the neck of the Scapula, which lies under the acromion or its acetabulum, ſhould be fractured, which is a caſe that indeed very ſeldom happens, and, when it does, is very difficult to diſcover; it is a hundred to one but, from the vicinity of the articulation of the tendons, muſcles, ligaments, nerves, and large veins and arteries, there will follow a ſtiffneſs and loſs of motion in the joint; great inflammation is alſo to be expected, and abſceſſes with the worſt ſymptoms, and ſometimes death itſelf.

SCA'NDAL, * ΣΚΆΝΔΑΛΟΝ, in the ſcripture language, denotes any thing that may draw us aſide, or ſollicit us to ſin.

> * The word is formed from the Greek σκάνδαλον, or the Latin ſcandalum, which, according to Papias, was originally uſed for a ſudden, extemporary quarrel, quæ ſubito inter aliquos ſcandit vel oritur.

In which ſenſe, the word is uſed promiſcuouſly with offence and ſtumbling-block.

Scandal is either active or paſſive.

Active Scandal is a real induction to ſin; paſſive Scandal is the impreſſion which an active Scandal makes on the perſon induced to ſin.

SCANDAL, in the popular language, is ſome action, or opinion, contrary to good manners, or to the general ſenſe of a people.

SCANDAL alſo denotes a diſadvantageous rumour, or report; or an action whereby any one is affronted in public.

SCA'NDIX, *ſhepherd's needle, or Venus-comb*, in botany, a genus of plants, whoſe characters are:

It has a roſe-ſhaped umbellated flower, conſiſting of ſeveral petals, which are ranged orbicularly, and reſt on the empalement, which becomes a fruit conſiſting of two parts, having two ſeeds, which reſemble, when joined.

They may be propagated by ſeeds which ſhould be ſown in autumn, ſoon after they are ripe, in the place where they are deſigned to remain, which ſhould be in a ſhady ſituation; and, when the plants are come up, they will require no farther care, but to keep them clear from weeds. In May the plants will flower, and in the beginning of July they will perfect their ſeeds, and ſoon after decay. But, if the ſeeds are permitted to ſcatter, the plants will come up without any manner of care, and become weeds in the garden.

SCA'PHISM * SCAPHISMUS, in antiquity, a kind of torture or puniſhment formerly in uſe among the Perſians. It conſiſted in locking the criminal cloſe up within the trunk of a tree bored to the dimenſions of his body, only with five holes for his head, arms, and legs to come through. In this ſtate he was expoſed to the ſun, and the parts thus appearing anointed with honey and milk, to invite the waſps and flies.

> * The word is Greek, σκαφισμὸς; formed of σκαφὸς, digging, of σκάπτω, I dig, hollow.

To increaſe the torment, they forced the criminal to eat abundantly, till his excrements, cloſe pent up in the wood, rotted his body. Some authors obſerve, that perſons ordinarily lived forty days in this condition.

This invention is aſcribed to Pariſatis queen of *Perſia*, and mother of Artaxerxes Mnemon, and the young Cyrus. It is added, ſhe firſt ordered it to be practiſed on the perſon who brought the tidings of the death of Cyrus.

SCARABÆ'US, *the beetle*. This is an extremely numerous genus of inſects; and, in order to have a diſtinct idea of the differences of the ſpecies, they are arranged by Liſter into a ſort of method. The firſt general diſtinction is into thoſe which live on land, and thoſe which live in the water; of each of which there is a very great number. Thoſe beetles which live on land have ſome of them antennæ laminated at the end, and others have them ſharp-pointed. The outer wings, or caſes of the wings, in ſome are perfect, in others they ſeem mutilated. Some have the antennæ inſerted into a ſort of promuſcis. Theſe were called by the antients gurguliones, and in ſome there is only one juncture in this, in the middle; in others ſeveral near the end. Some have a ſharp-pointed inſtrument at their head; theſe are called cimices.

SCARABÆUS *tardipes*, the ſlow beetle. We have a very ſingular account of the longevity of this animal, and that without food, given by Mr. Baker from his own obſervation. In the year 1737 he found ſeveral beetles of this kind plunging themſelves in the mud at the bottom of an old ciſtern; theſe were about an inch in length, and of a ruſty black colour, and had long jointed antennæ: they had no wings, but only a thick ſhell, covering the whole body, and divided along the middle with a fiſſure, reſembling the meeting of the two caſe wings in other beetles; the tail turned up a little, and the legs were long, but moved ſlowly. Mr. Baker, chuſing one of the largeſt of theſe, threw it into a cup of ſpirits of wine; in a little time it appeared to be dead, and was ſhut up in a ſmall box, and laid by, but ſome months after it was found alive and well: it was then plunged again into ſpirits of wine, and left a much longer time; and after being taking out as dead, and put in the ſame box again for ſome time, when it was found again come to life. It had now thrice eſcaped from being plunged in ſpirits, and lived three months ſhut up without any ſuſtenance. After this the beetle was kept a month or two without ſuſtenance under a glaſs, and at the end of this time again put into ſpirits of wine, and left there a whole night; after this, however, it again recovered, and ſeemed the next day as well as before. He lived, in the whole, two years and an half, without any viſible food or drink. Several things were at times offered him by way of food, as bread, fruits, &c. and water ſet in his way, but he never touched either. It ſeems very probable that this creature received a ſufficient nouriſhment from the particles floating in the air; and it is very poſſible that lizards, ſnakes, &c. when they live ſo long without any viſible food, are ſupplied in the ſame manner, though at other times they are capable of digeſting more ſolid matters; as doubtleſs was alſo the caſe with the beetle, when in its own natural ſtate. This is an inſtance of a creature's ſubſiſting without viſible food, longer than we have any other account of any kind; but it is poſſible, that, though the larger animals cannot long ſubſiſt without ſupplies of ſolid food, yet many inſects may find nouriſhment enough for their tender bodies in the particles floating in the air, though we want obſervations for the proof of it.

While kept under the glaſs, it did not walk about much, but uſually placed its noſe cloſe againſt one edge of it for the benefit of the air: it was of an agreeable aromatic ſmell, and, when touched, communicated its ſcent to the fingers, which did not go off in a long time. Its ſmell is ſtronger in winter than in ſummer. This creature not only bears the plunging in ſpirits of wine much longer than any other animal, but it bears the exhauſted receiver of an air pump without any injury or uneaſineſs. It has been kept under it half an hour, and would walk about without any concern; only, when the air was let in, it appeared ſtartled, and drew up its legs for about a minute.

SCARABÆ'US *virax*, the cankerworm. This laſt term is uſed, in the tranſlation of our Bibles, to ſignify a very deſtructive inſect, of the nature of the locuſt, and uſually mentioned as its companion. The Septuagint gives it the name βροῦχος, bruchus, a name ſignifying an animal which makes a great noiſe, as this inſect does in eating and in flying. We generally underſtand by this word a reptile, but it certainly means no other than that ſort of beetle, which we call the cockchaffer, or dor; a flying inſect very remarkable for the humming noiſe it makes with its wings when in motion, and which, when it is found in ſwarms ſitting upon the hedges, makes a continual noiſe in eating like the ſawing of wood. This creature deſerves very well to be placed with the locuſt, as a deſtroyer of the fruits of the earth. Our own experience in Norfolk has given a very late proof of this; and the hiſtories of Ireland ſhew that this creature has, in that kingdom, devoured every green leaf from the trees, for whole tracks of land at a time. That we have a wrong tranſlation of the word bruchus in cankerworm, is evident from the ſcriptures themſelves; for the prophet Nathan expreſly ſays it is a fly, and has wings, which cannot agree with any thing of the nature of what we underſtand by the word worm, which always ſignifies with us a reptile, or a creeping animal. This prophet has indeed deſcribed them ſo well, that it is wonderful that ſo obvious a thing ſhould not have been obſerved by the commentators. He ſays, they ſpoil and then flee away; they camp in the hedges in the day, and, when the ſun ariſeth, they flee away, and their place is not known where they are. That is, they then retire again to the hedges, and hide themſelves among the trees, where they lie quiet and concealed till the ſun ſets again. It is plain, by comparing theſe words with the common animal here mentioned, that the bruchus of the Old Teſtament is the ſame with our cockchaffer, and that the prophet has given us the natural hiſtory of the animal he deſcribes in this ſhort account.

SCA'RBOROUGH *Water*. — The water of this medicinal ſpring has been the ſubject of great conteſts and diſputes among the phyſical people; all allowing it conſiderable virtues, but ſome attributing them to one ingredient, others to another. Dr. Witty alledges that its material principles are alum, nitre, and vitriol of iron; but, though this author declares, that theſe principles are all to be ſeparated out of it, Dr. Tonſtall, on the other hand, affirms that it has no vitriol of iron in it, but a ſtone powder and a clay, leaving ſand at the bottom of the veſſel; and therefore that it is apt to breed the ſtone, and is bad in the gout, jaundice, and all other diſeaſes where indurations of the parts, or ſtony concretions in the body, are the cauſe: and this author ſeems to ſpeak very experimentally, when he alledges that he never had any ſymptoms of the ſtone till he drank the Scarborough water, but acquired that diſeaſe during the courſe of it.

Alum ſtone diſſolved in water is always found to yield a purple tincture with galls, and therefore the colouring an infuſion of this, or other vegetable ſubſtances, by the Scarborough water, which is by all allowed to contain this ſtone, is no proof of any vitriol of iron being contained in it, other than ſuch a ſmall portion of it, as is always found in this alum ſtone. All waters, which have diſſolved iron, will yield vitriol as a ſalt from that metal on evaporation. The cliffs about Scarborough yield abundance of ſalt in ſhoots and efferveſcences, plainly owing to the waters of the ſpring; yet all theſe are nitro-aluminous, none of them at all vitriolic. If the Scarborough water is ſet by for ſome days, after it is taken freſh from the ſpring, it precipitates a ſediment; which, being examined, is found not to be of a ferruginous nature, but a mere glebe of alum.

Upon the whole, the virtues of alum and vitriol are ſo far different, that it muſt be eaſy to ſee which of the two ſalts the water partakes moſt of, by its virtues; but as to the ſtony matter, which one of theſe diſputants calls an inſipid clay, and the other a ſandy ſtone, it is no other than ſpar, which is contained in all water; and which has been in general ſo far from being accuſed of breeding the ſtone in the bladder, that the general conſent of mankind has ſeemed to eſteem it a cure for that diſorder. The ſpar, in the form of the lapis Judaicus and oſtracites, and the very waters, which are ſo impregnated with it, as to incruſt every thing with it that is put into them, are given for the cure of this diſeaſe. *Phil. Tranſ.* N°. 85.

SCA'RFED, in the ſea-carpenters language, is the ſame as pierced, or faſtened or joined in; thus they ſay the ſtern of a ſhip is Scarfed into her keel. They alſo imply by it, that the two pieces are ſhaped away ſlanting, ſo as to join with one another cloſe and even; which they call wood and wood.

SCA'RY, in huſbandry, a term uſed by the farmers for a barren land, which has a poor or thin ſward, or coat of graſs upon it. *Plot's Oxford.*

SCATCH-*mouth*, in the manege, a bit-mouth, differing from a cannon-mouth in this, that the cannon is round, whereas a Scatch is more upon the oval. That part of the Scatch-mouth that joins the bit-mouth to the branch, is likewiſe different; a cannon being ſtayed upon the branch by a fonceau, and a Scatch by a chaperon, which ſurrounds the banquet. The effect of the Scatch-mouth is ſomewhat greater than that of the cannon-mouth, and keeps the mouth more in ſubjection. Commonly ſnaffles are Scatch-mouths.

SCENT-*bags*, in natural hiſtory, a name given by Tyſon to thoſe peculiar pouches, or bags, which certain animals, as the civet-cat and muſk animal, have for the receiving the matter of their perfume. Theſe bags are common to more animals than is generally ſuppoſed, and in all have much the ſame qualities, the matter they contain being in moſt of them fœtid and diſagreeable, while contained in the bag, and only becoming ſweet and pleaſant when dried, or taken at leaſt from the animal, and ſmelt in ſmall quantities. The weaſel and pole-cat with us have bags of this kind, and the famous bag, or pouch of the opoſſum, is of the nature of theſe; though it ſerves alſo to the other great purpoſe of receiving and ſheltering the young in time of danger. It contains, like the reſt, a tough and viſcous matter; which ouzes out of the glands, and is of a very offenſive ſmell, while the creature lives; but, as ſoon as it is taken out and dried, the ſmell changes into a fine perfume. The gland of the aper moſchiferus, as Tyſon calls it, is of this kind, containing a glutinous humour of a very offenſive ſmell when freſh, but, when dried, becoming ſweet and perfumed as muſk. *Philoſ. Tranſ.* N°. 239.

SCEP'TICISM (*Dict.*)— The ancient Scepticiſm conſiſted in doubting of every thing, in affirming nothing at all, and in keeping the judgment in ſuſpenſe on every thing. Sextus Empiricus makes Scepticiſm to conſiſt in a faculty of oppoſing all appearances, of making all, even contrary things, equally probable, and of proceeding firſt to an ἐποχὴ, ſuſpenſe of mind, and then to an intire undiſturbedneſs or tranquillity.

Hence theſe great maxims of theirs: Οὐ μᾶλλον τοῦτο ἢ ἐκεῖνο, this no more that: Παντὶ λόγῳ λόγος, &c. every reaſon has another againſt it; and Οὐδὲν ὁρίζω, I determine nothing.

The proper character then of Scepticiſm is an ἀκαταληψία, neutrality, or ſuch a diſpoſition of mind as does not, upon any occaſion, incline to any thing more than the contrary thing.

This heſitancy of the ſceptics is well deſcribed by Ariſtocles in Euſeb. de Præpar. Evan. All things are equally indifferent, uncertain and undeterminate: neither our ſenſes, nor our opinions, give us either truth or falſhood: therefore, neither the one, nor the other, are to be credited; but all things to be left on a level, without admitting any opinion, inclination or motion of the mind at all.—It is added, that the ſceptics carried this ſuſpenſe of theirs ſo far, as to deny, that any thing is either good or evil, juſt or unjuſt, true or falſe, or that any thing is this, more than that.

It is from this acatalepſia of the ſceptics that Des Cartes ſeems to have borrowed his great principle of doubting of all things; as is owned by many of his followers. — It muſt be owned, there is ſome difference between the doubting of the ſceptics, and that of the Carteſians. In phyſical matters, it is true, there does not ſeem a great deal of difference; and Des Cartes, in that reſpect, may, without much injuſtice, be deemed a ſceptic: but this may be ſaid in his favour, that the great Socrates was ſo far a ſceptic himſelf; phyſical and ſenſible things, he held, were all dubious, and, at beſt, but probable.

The origin of Scepticiſm is ſomewhat obſcure. Pyrrho, who lived under Alexander the Great, and made the tour of India in his retinue, is uſually reputed the author; whence Pyrrhonians and ſceptics are ordinarily uſed indifferently.

It muſt be owned, however, that the great dogma of the ſceptics had been countenanced, and even cultivated before Pyrrho, by Democritus, Heraclitus, &c.—Sextus Empiricus ſays,

says, expressly, that all that Pyrrho did, was to improve, illustrate, and inforce the dogma, and form the retainers thereto into a sect.

Democritus's philosophy was near akin to Scepticism; for upon his observing, that honey seemed sweet to some, and bitter to others, he concluded, that it was neither sweet nor bitter; and thereupon, pronounced οὐ μᾶλλον, non magis, which is pure Scepticism.—Yet the same Sextus adds, that Democritus was no sceptic.

Though Plato argues very strenuously against the acatalepsy of the sceptics; yet it is certain that dogma received a great part of its encouragement from Socrates's school, and Plato's academy. Nay, it was a great controversy among the ancients, whether Plato himself were a sceptic or dogmatist? Indeed, Plato's decisive way of speaking, in many cases, seems to leave no great room for such a doubt; but it is certain, his followers of the new academy, founded by Arcesilas, gave much into this way; and Nihil scitu was held by them a principle.

Sextus Empiricus observes, that Socrates himself had a tincture of Scepticism; some even make him the author of it, from that customary saying of his, 'I know nothing but this, that I know nothing.' If this were the origin of Scepticism, it must be owned, it was mightily improved afterwards, before Metrodorus said, 'I know nothing, not even this, that I know nothing.' The same Sextus however adds, that Plato, introducing his master, in his Gymnastic Dialogues, disputing with the sophists, makes him act the part of a sceptic.

Some have even charged Job, and Solomon, with Scepticism, from their proposing a great number of questions, without deciding any of them. The philosopher of Kiel, who has published a dissertation on Scepticism, fetches its origin still higher: he will have the devil the author thereof, who made our first parents doubt of the word of God himself; and drew them in, the first proselytes to Scepticism.

SCE'PTICS *, Sceptici, a sect of ancient philosophers, founded by Pyrrho, whose distinguishing tenet was, that all things are uncertain and incomprehensible; contraries equally true; that the mind is never to assent to any thing, but to keep up an absolute hesitancy or indifference. See SCEPTICISM.

* The term Sceptic, in its original Greek, σκέπτικος, properly signifies considerative and inquisitive; or a man who is ever weighing the reasons on one side and the other, without ever deciding between them: it is formed from the verb σκέπτομαι, I consider, look about, deliberate.

SCIADE'PHORI, Σκιαδηφόροι, among the Athenians, an appellation given to the stranger women residing in Athens, because they were obliged, at the festival Panathenæa, to carry umbrellas to defend the free women from the weather. *Potter, Archæol. Græc.*

* The word is derived from σκιαδιον, an umbrella, and φέρω, I carry.

SCIAMA'CHIA, the fighting with a person's own shadow, a sort of exercise prescribed by the ancient physicians, in which the motion of the arms, and other parts of the body, were of very great service in many chronic cases.

SCIA'RRI, in natural history, the matter which runs down in burning torrents from the craters of Mount Ætna.

This matter, when cold and hard, is hewed and employed at Catania, and other places. It is chiefly used for the basements and coinage of buildings. It probably contains mineral and metallic particles, being a ponderous, hard, grey stone.

Some of the Sciarri are coarse, and others fine and polished on the surface; some of them are black, others reddish, and others of the colour of iron; and many of them have coverings of pure sulphur over the whole surface, or a part of it. Some very fine and smooth ones, resembling iron, but very light, are found in, or near the mouths of the eruption; and some are very hard and heavy, and of a mixed nature, seeming to be the result of many sorts of minerals melted together. These latter, when the mountains have poured out streams of fire, always remain in the places, and are the substance that was on fire cobled again.

At the time of the most terrible eruptions of this kind, these heaps of Sciarri, which sometimes appear to be solid rocks of metalline matter, are only a sort of covered arches, under which the melted matter yet continues liquid and running, and bursts out, at times, in the several parts of their sides or surfaces. The general appearance of a train of these Sciarri, left after the eruption of such a rivulet of fire, is much like that of the Thames, or some other such large river, in the time of a severe frost, the rocks of Sciarri rising above the general surface, like the clods of ice in that scene; the colour only differing, the great quantities of the Sciarri in these places being of a deep bluish hue.

It is remarkable, that the substance of these Sciarri, even while melted and running in streams down the hill, is so firm and solid, that no weight will sink into it, nor any instrument make its way through the surface, any more than a solid mass of cold metal. It has been supposed by some, that the flowing matter concreted into the common pumice stone, but that is a vulgar error, the pumice being a wholly different substance. *Philos. Trans.* N°. 49.

SCIATHE'RICUM *Telescopium*, a horizontal dial with a telescope, adapted for observing the true time, both by day and night, to regulate and adjust pendulum-clocks, watches, and other time-keepers. It is the invention of the ingenious Mr. Molyneux, who has published a book with this title, containing an accurate description of this instrument, its uses and application.

SCI'LLA, *squills (Dict.)*— Although these roots are imported chiefly for medicinal use, yet are they worthy of being cultivated in every good garden, for the beauty of their flowers, which make a very handsome appearance, when they are strong roots.

The best time to transplant these roots is in May, when their leaves are decayed: and, if their roots are brought from abroad, if they can be procured firm at the season, or a little after, they should be planted in pots of light sandy earth, and placed in the windows of the green-house; where, if they are blowing roots, they will flower the July following.

These plants must be preserved in shelter during the winter-season; because, if their leaves are destroyed by frost in winter, the roots are subject to perish: but, in summer, they should be exposed to the open air, and in dry weather must be frequently watered; especially during the season their leaves are on, or that they are in flower: but, when the roots are in a state of rest, they should have but little moisture; for wet at that time will rot them. They are pretty hardy, and only require to be sheltered from hard frost; but must have as much free air as possible in open weather.

SCI'NCUS, *the skink*, in zoology, the name of a species of lizard, called also by some the land crocodile, crocodilus terrestris, and well known in the druggists shops as an ingredient in several compositions.

It resembles the smaller sort of lizards, being usually about six inches long, and its usual thickness is that of a man's thumb. It is of a silvery greyish colour, scaly, and has a rounded tail; its head is of an oblong figure; its nose sharp; and its feet, as it were, alated, having five toes each, armed with very sharp claws. It is very common in Egypt and Arabia. *Worm. Mus.*

SCIRRHUS *hepatis*, in medicine, a disease consisting in an indurated tumor of the liver, occasioned by a stagnation of the humours which grow thick there, from an exhalation of their more fluid and subtile parts.

This differs from the infarctus hepatis, not only in degree but in its symptoms, for it almost always is attended with a hectic, or with œdemato-hydropic swellings.

Signs of it. These are a tumor and hardness in the right hypochondrium, or region of the liver, always evident to the patient, and often sensibly perceived by any body else, on touching the part. To this are to be added dull tensive pains, and a sense of weight hanging there, and usually asthmatic symptoms, and a dry cough. It becomes painful to lie on the left, or opposite side; and with these a hectic comes on, with a wasting of the upper parts, and swelling of the inferior ones; first of the feet, but afterwards upwards to the belly, which finally become very obstinate and truly ascitic. The urine in this case is small in quantity, and of a deep orange colour, and thick consistence. It has usually a mucid sediment, and sometimes a thick one of a rose colour.

Causes of it. These are usually either an omission of artificial discharges of the blood, by habitual bleedings at spring and autumn, or a suppression of the natural ones, by the menses or hæmorrhoidal vessels: an improper treatment of intermitting fevers with astringents, of quartans with large quantities of bark, and of acute fevers with too cooling a regimen, or a violent quantity of the volatile salts, or a condensation of the humours in a simple infarction, by means of cold external applications. The stopping hæmorrhages, which nature had brought on for her relief in plethoras, have also been sometimes known to occasion a Scirrhus of the liver; as have also external injuries by blows, falls, and the like.

Prognostics. A recent Scirrhus of the liver admits of a cure, but this not without great difficulty, and in a more confirmed one there is very little hope. This tumor has a continual tendency to corruption, either by sphacelation, or by an inflammatory suppuration; neither of which can happen successfully, for the first must occasion instantaneous death, and the latter exulceration, and a succeeding fatal hectic.

A Scirrhus of the liver often follows, and sometimes precedes a jaundice of the most violent kind.

Method of treating it. The bowels are first to be cleansed and relaxed by a clyster, made of a decoction of mallows, camomile flowers, mullein, and fennel seed; after this, bleeding in the foot is to be ordered, and then the nitrous and other resolvent medicines are to be given, such as tartar of vitriol, and the like. After this medicated wines should be drank as the common drink, prepared with bryony and arum roots, centaury, hyssop, and maidenhair leaves, sassafras, senna, black hellebore, and rhubarb; and, externally, plasters of the resolvent and strengthening kinds are to be applied. But, after all directions for the treatment, it is to be acknowledged, that an obdurate and inveterate Scirrhus admits of no remedy. *Junker's Consp. Med.*

SCIU'RUS, *the squirrel*, in the Linnæan system of zoology, makes a distinct genus of animals, the characters of which are: that the creatures have four toes on the fore-feet, and five on the hinder, with palms made for climbing and leaping, and all have woolly tails. *Linnæi System. Natur.*

We have five species of this little animal described to us. First, the common English kind. Secondly, the great grey Virginia one. Thirdly, the black-backed kind of Ceylon. Fourthly, the American flying squirrel. And, fifthly the Barbary kind.

The common English squirrel is well known, and is distinguished from the others by its size and colour. It is something larger than the weasel, but shorter-bodied; its back and sides are reddish, its throat and belly white; and it generally carries its long hairy tail erect over its back, so that it serves it for a shade. It is common in our woods, and feeds on all sorts of fruit, but principally on hazel nuts; which it gathers in the season, and lays up for its winter store. The same species of squirrels with ours is found in Poland and Russia, grey or ash-coloured.

The second, or great grey American squirrel, is very common in Virginia, and is of the size of a rabbet. It is of a dark iron grey, such as some rabbets are of; its fore feet have only four toes, its hinder ones five.

The third, or black-backed squirrel, is found in the island of Ceylon, and called by some rukkaia, from the noise it makes. The hair on its back is sometimes grey.

The fourth, or flying squirrel, is a very small kind; its back is of a dusky mouse-coloured grey; its throat and belly white; its eyes small, black, and prominent, resembling those of the mouse kind; its tail is very long, and very broad and flat. It has a thin and lax skin on each side, which is fixed to the fore and hinder legs, and consequently, on the extending its legs, this skin expands on each side like a sort of a sail: this it always does in leaping, and is by that means carried a great way; and hence has arisen the opinion of its flying. It is very common in New Spain, and is sometimes met with in the colder American countries. It very much approaches to the mouse kind in many particulars, receding from the nature of the squirrel. Its fur is short, like that of the rat or mouse; not long, like the other squirrels. It never erects its tail on its back, nor turns, or twists it round, as the other squirrels do. It has a very beautiful black line on each side the face, near the eyes.

The fifth kind, or Barbary squirrel, is of a mixed colour, between black and reddish, and is very beautifully variegated all down the sides with brown and white longitudinal streaks, laid in a regular alternate order, and each reaching the whole length of the body. These lines are, in some of these creatures, not brown and white, but black and white; and the tail, when in a state rest, is seen elegantly streaked with the same colours, but when the creature erects it, the hairs standing all upright, the beauty of this variegation is hid. The belly of this creature is blue and white. It is smaller than our squirrel, and has shorter ears, which are roundish, and lie close on the head. The whole head has much of the figure of a frog's, in all other respects it is perfectly like our squirrel. *Ray's Synop. Quad.*

SCNIPS, in natural history, a name given by authors to the small species of gnat, always found about the oak-tree feeding on the juices of its leaves, which it sucks by means of its sharp trunk.

SCOLO'PAX, in ichthyography, the name of a sea-fish called in English the trumpet or bellows.

SCLA'REA, *clary*, in botany, a genus of plants, whose characters are:

It is a verticillate plant, with a labiated flower, consisting of one leaf, whose upper lip (or crest) is hooked; but the under lip (or beard) is divided into three parts, the middle segment being hollow and bifid: out of the flower-cup rises the pointal, attended by four embryoes, which afterwards turn to so many roundish seeds inclosed in an husk, which was before the flower-cup.

SCOLOPEN'DRA, in zoology, an insect of a very slender and long body, very smooth, and of a yellowish or reddish colour, furnished with a vast number of legs, and having two long antennæ, and a bifid tail.

It is used by some as a depilatory, being boiled in wine. *Dale's Pharmacop.*

There is a species of this animal, which naturally shines in the dark in the manner of a glow-worm, but with a fainter and more general light. Every part of the body of this animal will emit sparks, if pressed in the dark. It is covered with a soft down, or short and fine hair, much resembling in texture the downy matter which grows on the back of colt's-foot leaves. The two sides of the animal are covered also with two other lists or stripes; these go off from the main stripe at the top, and these are about a quarter of an inch broad; they are covered with a fine and soft hairiness, of more than a quarter of an inch long, of a fine changeable red and green colour, and of prodigious beauty and brightness. Among this long hair of the stripes on the sides, there are set a vast number of long and sharp prickles; they are about the same length with the hair, but they are as stiff as a hog's bristle, and are very sharp at the points, and of a black colour; there are several hundreds of these on the two sides.

The tail, or smaller end, terminates on the back in two scales, which are very bright and fine; under this is the anus, at which the creature voids its excrements. The larger end has no part in the common characters of a head except the mouth; but, as it has this, and stands opposite to the tail, it is properly enough called so in description. It has no horns, no eyes, nor any other of the common organs of insects heads.

The mouth is very wide, in proportion to the size of the creature, and is not placed at the extremity, but somewhat under the belly part; so that, when the back of the creature is viewed, the mouth is not seen. The belly is smooth and flat, and is covered with a thin skin, much paler-coloured than that of the back, and irregularly variegated with a number of brown spots, of different sizes and shapes. Within an inch of the tail there are seen on this under part several marks, like those of the annular divisions of the bodies of insects, but they do not shew themselves on the back.

The legs are placed in two rows, each of the whole length of the body of the fish; they begin from the angle of the mouth on each side, and are continued to the tip of the tail.

Those standing near the mouth are longer than others, which gradually decrease till they are very short at the tail; the longest are about a quarter of an inch in length, and the shortest not a sixth of that length.

The whole number of legs is seventy-two, thirty-six standing on each side. From within the body, through the middle of each leg, there passes a cluster of three or four prickles; these are larger or smaller, according to the size of the leg, and vary also in number, the longest legs having most of them; they give strength and firmness to the legs, serving them in the place of bones, and issuing out beyond the end of the leg, in the way of claws; they serve the creature for the laying fast hold of any thing it pleases. On each side of the upper, or back part of the fish, there are also placed a number of soft, flat, and smooth fins; these stand near the legs, and are placed face to face in such a manner, that each foot has its corresponding fin. The fins are exactly of the same number with the legs, and, like them, are largest towards the head, and go off gradually tapering towards the tail.

These serve the creature in the office of a fish, giving it power to swim in the water, as the others serve it as a reptile to crawl upon the ground at the bottom. The fins on each side are fringed with the same changeable-coloured hair that the stripes on the back are.

On opening the body there appears a muscular organisation, elegantly contrived for working so great a number of legs and fins. This appears in form of one large and broad red muscular congeries, and from this there are propagated on each side thirty-six pair of rays, or oblong and slender muscles, every pair serving for the motion of one leg and one fin. These are distinctly visible, and represent the spine and ribs in some fish. And in this the wonderful care of nature is seen, in regard to this little animal, which, by means of these distinct muscles, is able to move every single leg or fin separately, and consequently can put as many, or as few as it pleases, in motion at a time. It is plain also, from the structure of the body of this creature, that it can at pleasure roll up its body into a round form, and in that case will appear as a globe covered with long and sharp prickles: this is probably its practice, when in danger of being devoured, and may serve it on many occasions. It has been thought by some that Rondeletius means this creature by his physalus; but this does not appear to be the case on a careful examination. *Philos. Trans.* N°. 225.

SCO'LYMUS, *the golden thistle*, in botany, a genus of plants, whose characters are:

The whole plant hath the appearance of a thistle: the flower consists of many half-florets, which rest on the embryoes; each of these are separated by a thin leaf; and on the top of each embryo is fastened a little leaf: these are contained in a scaly empalement, which incloses the seed.

SCO'MBER, *the mackarel*, a well known sea-fish of the thynnus kind, and distinguished from the other fish of that genus by its extremely small and thin scales; by its bluish green colour on the back, variegated with undulated and crooked black lines; by the forkedness of its tail, and the very substance of the fin of it, being almost entirely wanting at the angle of it; and by the largeness of its eye, in comparison of the amia, and other fish of this kind, which most resemble it in other respects. *Willughby's Hist. Pisc.*

SCONCE (*Dict.*) — Some Sconces are made regular, of four, five, or six bastions; other are of smaller dimensions, fit for passes, or rivers; and others for the field.—Such are,

First, triangles with half bastions; which may be all of equal sides, or they may be something unequal. However it be, divide the sides of the triangle into three equal parts, one of these three parts will set off the capitals and the gorges; and the flanks, being at right angles with the sides, make half of the gorge.—Secondly, square, with half bastions; whose sides may be betwixt 100 and 200 feet, and let one third of the sides set off the capital and the gorges, but the flank (which raise at right angles to the side) must be but one half of the gorge or capital, that is, on the sixth part of the side of the square.—Thirdly, square with half bastions and long.—Fourthly, long squares. Fifthly, star redoubt of four points.—Sixthly, star redoubt of five or six points.—Seventhly, plain redoubts, which are either small, or great. The small are fit for court of guards in the trenches, and may be squares of twenty feet to thirty. The middle sorts of redoubts may have their sides from thirty to fifty feet; the great ones from sixty to eighty feet square.

SCORBU'TUS, *the scurvy (Dict.)*—There are some who derive all diseases from the scurvy, which indeed must be allowed to create, or mimic, most other maladies. Boerhaave tells us it produces pleuretic, cholic, nephritic, hepatic pains, various fevers, as hot, malignant, and intermitting; dysenteries, faintings, anxieties, dropsies, consumptions, convulsions, palsies, fluxes of blood; in a word, it may be said to contain the seeds and origin of almost all distempers. A cachexy, or ill habit, is much of the same nature with the scurvy. It is supposed by physicians, that the immediate cause of the scurvy lies in the blood, the fibrous part of which is thick, and the serum too thin and sharp; and that hence arises the great difficulty in the cure, because, in the correcting of one part, regard must be had to the other. It is well known how extremely difficult it is to cure an inveterate scurvy; how many scorbutic patients have grown worse by an injudicious course of evacuations; how many are even rendered incurable by the treatment of inconsiderate physicians; and how difficult, tedious, and uncertain the cure is, in the hands even of the best, who are obliged to use such variety and change of medicines, in the different stages of that malady; which nevertheless may be cured, says the bishop of Cloyne, by the sole, regular, constant, copious use of tar-water. In the cure of the scurvy, the principal aim is to subdue the acrimony of the blood and juices; but as this acrimony proceeds from different causes, or even opposite, as acid and alkaline, what is good, in one sort of scurvy, proves dangerous, or even mortal, in another. It is well known, that hot anti-scorbutics, where the juices of the body are alkalescent, increase the disease; and four fruits and vegetables produce the like effect in the scurvy caused by acid acrimony. Hence fatal blunders are committed by unwary practitioners, who, not distinguishing the nature of the disease, do frequently aggravate, instead of curing it. The bishop says, if he may trust what trials he has been able to make, this water is good in the several kinds of scurvy, whether acid, alkaline, or muriatic; and he believes it the only medicine that cures them all, without doing hurt in any. In a high degree of scurvy a mercurial salivation is looked on by many as the only cure; which, by the vehement shock it gives the whole frame, and the sensible secretion it produces, may be thought to be more adequate to such an effect: but the disorder, occasioned by that violent process, it is to be feared, may never be got over. The immediate danger, the frequent bad effects, the extreme trouble, and nice care attending such a course, do very deservedly make people afraid of it. And, though the sensible secretion therein be so great, yet in a longer tract of time the use of tar-water may produce as great a discharge of scorbutic salts by urine and perspiration; the effect of which last, though not so sensible, may yet be greater than that of salivation; if it be true that insensible perspiration is considerably more than all the rest of the sensible secretions together.

SCO'RDIUM *(Dict.)*—This plant is propagated in our gardens for medicinal use; by parting the roots, or planting slips or cuttings in March, in beds of moist earth, at four or five inches distance, in July they will be in flower, and fit to cut for use. But every other year the bed should be renewed, and that always on a fresh spot of ground, for they do not succeed well on the same. *Miller's Gard. Dict.*

SCO'RIA *(Dict.)*—Some authors call by this name that saline mass, which is produced by melting ores and metals together with saline and reducing fluxes. But the word Scoria is not properly to be understood of all this mass, but only of the vitrified particles which are lodged between, and adhere to the small masses of the salts, and which may be separated from them by water. *Cramer's Art of Assaying.*

SCORIFICA'TION, in metallurgy, is the art of reducing a body either entirely, or in part, into scoriæ.

It is used by metallurgists, in order that any metal, imprisoned in a solid body, may, on account of its weight descend and separate itself therefrom; and, finally, if that be required, be itself wholly or in part converted into scoriæ.

All fixed bodies are subject to this alteration, not totally excepting even gold and silver. There are also, among the volatile bodies, some that may be fixed, and which assume the form of scoriæ, by adding fixed bodies to them.

It is often proper to make this Scorification in a vessel that may absorb the scoriæ, and retain only the metallic part of the mass under trial. In this case the operation is called coppelling, and vessels made of ashes, called tests and coppels, serve for this purpose. It is evident in these processes, that a great attenuation of the scoriæ is necessary, that they may be able to pass through the vessel; nor is there any fitter body to promote this operation than lead, which, by its undergoing itself a like attenuation in the fire, disposes other bodies to be reduced into a subtile scoriæ for the same attenuation.

SCO'RPION, in natural history, an insect frequently found in the hot countries. The opinions of authors are very different as to the sting of this creature, some asserting that there is an opening in it, through which a poisonous liquor is thrown into the wound made by it, as is the case in the tooth of the viper, &c. and others affirming that there is no such opening.

Galen affirms that there is none, but most of the writers of the middle ages assert that there is. But the whole is set in the clearest light by Signior Redi, who took the pains of examining microscopically the stings of the Scorpions brought alive from Tunis, Egypt, and Italy. These he nicely examined by the best glasses in the musæum of the Great duke of Tuscany, and could find no aperture: but, not satisfied with this, he pressed the stings to try if he could make any liquor flow out of them; they were, however, so hard and horny, that squeesing could have no effect on them; and, finally, he caused a Scorpion to strike upon a plate of iron, but no liquid was found thereon; so that he began to conclude Galen's opinion right, when he accidentally discovered an exceedingly small drop of white liquor upon the sting, and this he afterwards found in all the trials he made with several Scorpions. And Mr. Lewenhoek discoverd an opening on each side of the sting of this creature, for the emission of the poison, which he supposes is not discharged, till the sting is buried in the wound. *Baker's Microscope.*

Mr. de Maupertuis, having caused Scorpions to bite several animals, of which very few died, or suffered any more than the pain of the sting, is of opinion, that oil of Scorpions and other vulgar antidotes to the poison of these animals have rather got their reputation from the innocence of the sting of these creatures, than from any considerable virtue in the medicines. *Mem. de l'Acad. Scienc.* 1731.

Water SCORPION, *scorpio palustris*, a name given to a very remarkable species of water insect. It is a very thin and light little creature, yet is but a very slow mover. Its head is very small, and is hard to the touch, and of a paler brown than the rest of the body; and this is terminated by a very fine and sharp proboscis, of the same colour and texture. The eyes are small, but prominent, and very hard and black. The shoulders are broad and flat, they are of the same colour with the head, and are wrinkled on the surface. The triangular spot between the wings is black and shining, the body is of a bright red lead colour on the back, and of a faint dusky brown on the belly, and is composed of six joints, covered with a sort of scales. The outer wings are very hard and firm, and lie very far over one another; they are opake, and of a dark muddy brown, without any variations: the inner wings are of a dusky white veined with a red-lead colour. The two fore-legs are broader and thicker than the rest, and end in short blunt claws; these the creature never walks with, but always uses them as arms: the hinder pair are the longest, and both they and the middle ones end in a sharp claw; they are all of a pale brown, and somewhat transparent. The tail is long and straight; it is composed of two slender bristles, of a pale brown; the creature scarce ever separates these. It lives among the weeds in clear standing waters, and is continually watching for its prey. It feeds on other insects, and is particularly fond of the cicada aquatica, or worm of the great libella. It seizes its prey with the fore-legs, and holds it fast in them, while the proboscis pierces into the body, and sucks the juices.

SCORPION *fly*, in natural history, a name given by Mouffet and other writers to a kind of fly, remarkable for carrying the end of its tail turned up in form of the Scorpion's sting.

There are two very beautiful species of these. The one has silvery wings, variegated with three transverse streaks of black towards the ends; the head is black, and the breast, shoulders, and feet whitish; the rest of the body is black. The tail, which represents a sting, has five joints, three of which are red, and the others black; the end of the tail is also forked, and the forks black, turned up like the sting of a Scorpion.

The other resembles this in many respects, but the end of the tail is thicker, and the forks blunter; the head is dunnish, the mouth long, and each wing variegated with six black spots, of a large size.

SCORPIU'RUS, *caterpillar*, in botany, a genus of plants, whose characters are:

It hath a papilionaceous flower, out of whose empalement rises the pointal, which afterwards becomes a jointed pod, convoluted like a snail, or caterpillar, having a seed in each joint, which is, for the most part, of an oval figure.

SCORZONE'RA, *viper-grass*, in botany, a genus of plants, the characters of which are:

It hath a semi-flosculous flower, consisting of many half florets, which rest upon the embryoes, which are included in one common empalement, which is scaly: the embryoes afterwards become oblong seeds, which are furnished with down.

These plants may be propagated by sowing their seeds in the spring upon a spot of light fresh soil. The best method of sowing them is, to draw shallow furrows by a line about a foot asunder, into which you should scatter the seeds, thinly

covering

covering them over about half an inch thick with the same light earth; and, when the plants are come up, they should be thinned where they are too close in the rows, leaving them at least six inches asunder; and, at the same time, you should hoe down all the weeds to destroy them: and this must be repeated as often as is necessary; for, if the weeds are permitted to grow among the plants, they will draw them up weak, and prevent their growth.

SCRATCH, in the salt works, the name of a calcarious earthy or stony substance, which separates from sea-water in boiling it for salt.

This forms, in a few days, a thick crust on the sides and bottoms of the pans, which they are forced to be at the pains of taking off once in a week or ten days, otherwise the pans burn away, and are destroyed. See SALT.

This is no other than the same substance which crusts over the insides of our tea-kettles, and is truly a spar, sustained more or less in all water, and separable from it by boiling. The shells of sea-fish have great affinity in their substance and nature with this, both being powerful alkalies, and both easily calcining into lime.

The magnesia alba, so celebrated in Germany for its mild purgative and alkaline virtues, seems very nearly allied to this earth; and it is probable, according to Hoffman, that the purging virtues of many springs are owing to the quantities they contain of this substance.

SCRATCH *pans*, in the English salt-works, a name given to certain leaden pans, which are usually made about a foot and half long, a foot broad, and three inches deep, and have a bow, or circular handle of iron, by which they may be drawn out with a hook, when the liquor in the pan is boiling. See SALT.

The use of these pans is to receive a calcarious earth, of the nature of that which incrusts our tea-kettles, which separates from the water in boiling; this substance they call Scratch; and these pans, being placed at the corners of the salt pan, where the heat is least violent, catch it, as it subsides there.

SCROBI'CULUM *cordis*, in anatomy, the pit of the stomach. See STOMACH, *Dict.*

SCROPHULA'RIA, *fig-wort*, in botany, the name of a genus of plants, whose characters are:

It hath an anomalous flower, consisting of one leaf, gaping on both sides, and generally globular, cut, as it were, into two lips; under the upper one of which are two small leaves: the pointal rises out of the flower-cup, which afterwards turns to a fruit or husk, with a roundish-pointed end, opening into two divisions, parted into two cells by an intermediate partition, and full of small seeds, which adhere to the placenta.

The root of Scrophularia is esteemed externally as a remedy for the piles and the king's evil. It is generally made into an ointment for these purposes; but some give it also internally in diet drinks.

This root is of a very singular figure, by which it is easily distinguished at sight from all other medicinal roots. It is usually of the thickness of a man's finger, or more, of an oblong figure, nearly as thick at the one end as the other, and full of protuberances on the surface, resembling a kind of little kernels; and between there are a great many fibres, which strike deep into the ground. The root itself has no great smell, but its taste is somewhat acrid and disagreeable.

SCU'LPTURE *(Dict.)*— To perform any thing in the way of Sculpture, they begin with making a model of earth, or wax.— For earthern models, they use but few instruments: their hands and fingers do almost the whole.— For waxen models, to a pound of wax they put half a pound of colophony; some add turpentine, melting the whole with oil of olive; some add a little vermilion, or other matter, to give it a colour. It is wrought and molded with the fingers, like earthern models.

For Sculpture in wood, which we properly call carving, the first thing required, is, to chuse a wood proper for the particular kind of work.—If it be any thing large, and require a deal of strength and solidity; the hardest and most durable wood is to be chosen, as oak, or chesnut: for smaller works they use pear-tree and service-tree. But, as these woods are very hard, for little delicate works, they use softer woods, only close, and of a fine grain: such is the linden-tree, which the chissel is found to cut more easily, and cleanly, than any other wood.

For large works, if it be only single figures, it is better they consist of several pieces, than of a single one, by reason of the liableness of the latter to warp; for every large piece may probably not be dried to the heart, however it may appear without-side.—Observe, that the wood will not be fit for working, till after it have been cut at least ten years.

SCULPTURE *in marble and stone.*— The first thing they do, is cut of a great block of marble to saw another of the size required, which is performed with a smooth steel saw without teeth, casting water and sand thereon, from time to time: then they fashion it, by taking off what is superfluous with a stubbed point, and a heavy mallet; after this, bringing it near the measures required, they reduce it still nearer with another finer point.—They now use a flat cutting instrument, having two notches in its edge, or three teeth; then a chissel to take off the scratches the former has left.—This last instrument they use with a deal of delicacy, giving thereby a softness and tenderness to their figure; till, at length, taking rasps of different degrees of fineness, by degrees they bring their work into a condition for polishing.— To polish, or make the parts smooth and sleek, they use pumice-stone and smalt; then tripoli, and when a still greater lustre is required, a skin and burnt straw.

When any considerable work is undertaken, as a statue, basso relievo, or the like, they always make a model, beforehand, of clay; but as this shrinks in drying, and easily cracks and breaks, they only use it to make a mould of plaister, or stucco, wherein they make a figure of the same matter, which serves them thenceforth for a model, and by which they adjust all their measures and proportions.

To proceed the more regularly; on the head of the model, they place an immoveable circle, divided into degrees, with a moveable ruler, or index fastened in the center of the circle, and divided likewise into equal parts. From the end of the ruler hangs a thread with a plummet, which serves to take all the points to be transferred thence to the block of marble, from whose top hangs another plummet like that of the model.— See *Plate* XLII. *fig.* 6.

SCU'RVY *grass*, *cochlearia*, in medicine, is a powerful attenuant and resolvent; and on that principle is an excellent medicine in all diseases arising from a viscid state of the fluids, and particularly in the Scurvy. The best way of taking it, is to eat the whole herb by way of sallad.

The Scurvy, however, is a disease so various, that the same medicine cannot be good for all the kinds. Accordingly Scurvy-grass proves hurtful, where the Scurvy is attended with a redness in the face, palpitations of the heart, frequent feverish heats, head-achs, purgings, and the like; in all which, acrid medicines of any kind do harm.

SCUTELLA'RIA, *scull-cap*, in botany, the name of a genus of plants, whose characters are:

The empalement of the flower is of the lip-kind; the upper segment resembling an helmet, and is divided into three segments; the middle being broad and concave; but the other two are narrow and plain: the beard, or lower lip, is divided into two equal segments: the calyx, having a cover, contains a fruit resembling the heel of a slipper or shoe: which character is sufficient to distinguish it from all the other genera of this class.

SCU'TUM, in natural history, the name of a genus sea-shells, the characters of which are: that it is a shell of an irregular figure, which on the lower part represents, in some measure, a shield; on the surface it has the shape of a five-leaved flower; its mouth is in the middle of the base, and the aperture for the anus at the edge.

SCY'TALA *.— The Lacedæmonians invented a secret method of writing by means of the Scytala, which was a wooden roll. Two of these were made of an equal length and thickness; one the ephori, principal magistrates of Sparta, kept at home, the other was given to their general who marched to fight their battles. When these magistrates had a mind to send him secret orders, they took a long narrow slip of parchment, which they rolled exactly round the Scytala they kept for themselves; on this they wrote their intentions, and what they wrote, while the parchment was applied on the Scytala, contained a complete and connected meaning; but, when it was taken off, the writing was disjoined, and the connection of the words separated in such a manner, that no body could understand the meaning, but the general, by applying the parchment on the fellow Scytala which he had in his possession.

* The word is Greek σκυτάλη, a staff.

SCY'THIAN, a word used very often in the old Greek writers on the Materia Medica, to distinguish the peculiar sort of gum, or other drug, brought from that place. The Scythian and Indian drugs have been by many supposed different kinds of the same medicine; but this is an error, for it appears very obvious, on comparing the writings of Galen, Aëtius, Ægineta, and other of the later writers among the Greeks, with those of Dioscorides, Theophrastus, and the other old ones, that the words Scythian and Indian mean the same thing, and that what the old writers have called Indian, these have called Scythian.

The meaning of this is, that those things were called Scythian, which were brought from the country of Indo-Scythia, or that part of Scythia which lay at the coasts of the river Indus: but it is to be observed, that though the later Greek writers mean this by their term Scythian, yet the word is used in a very different sense by the Arabians, Avicenna, Serapio, and others; and that, wherever they mention a drug under the name of Scythian, they mean that it comes from the northern parts of Scythia, on the confines of Europe. These authors having understood, of this Scythia, what the Greek writers have said of the other, have made no small errors in regard to the history of drugs, having given bdellium, and many other gums, the produce of only the Scythia of the Greek medical writers, to the frozen Scythia beforementioned.

SEA (*Dict.*)—The sea differs in faltnefs in different parts; it is, in general, obferved, that in the hotteft climates the water is falteft.

When falt water freezes, it hath been thought to let fall all its falt; the ice of Sea water, and the water melted from it, tafting frefh, and being good for boiling meat and peafe in. Captain Middleton, being in Hudfon's Streights in July 1738, took ice from under the furface of the Sea, which he melted till he got forty quarts of water; thefe he evaporated to drynefs, and out of that quantity had only fix ounces of falt, or about $\frac{1}{213}$. *Phil. Tranf.* N°. 461.

General motion of the SEA. Mr. Daffie of Paris, in a work publifhed about fixty years ago, has been at great pains to prove that the Sea has a general motion, independent of winds and tides, and of more confequence in navigation than is ufually fuppofed. He affirms that this motion is from eaft to weft, inclining towards the north, when the fun has paffed the equinoctial northward, and that during the time the fun is in the northern figns; but the contrary way, after the fun has paffed the faid equinoctial fouthward; adding, that, when this general motion is changed, the diurnal flux is changed alfo: whence it happens, that in feveral places the tides come in during one part of the year, and go out during the other; as on the coafts of Norway, in the Indies, at Goa, Cochinchina, &c. where, while the fun is in the fummer figns, the Sea runs to the fhore; when in the winter figns, from it. On the moft fouthern coafts of Tonquin and China, for the fix fummer months, the diurnal courfe runs from the north with the ocean; but, the fun having repaffed the line toward the fouth, the courfe declines alfo fouthward. *Philof. Tranfact.* N°. 135.

Bafon of the SEA, *fundus maris*, a term ufed by geographers, and other writers, to exprefs the bottom of the Sea in general.

Our honourable Mr. Boyle is the firft who has written any thing on that part of the globe, and he has given us a treatife exprefsly upon it; but this only gives an account of its irregularities, and unequal depths, and is founded on the obfervations communicated to him by mariners, and people of too little curiofity to be depended upon for great difcoveries.

The ingenious Count Marfigli has, fince his time, given us a much fuller account of this part of the globe, in a great part from his own experiments in many places, particularly along the coafts of Provence and Languedoc.

The entire bafon of the Sea is of fuch immenfe extent, and covered in many places with fuch an unfathomable depth of water, that it is not to be expected that it can be traced in every part; but as the whole may be gueffed at, from fome part of it, and as its general figure is of no confequence in a fearch of this kind, the obfervations of this curious author are of great value, in forming a judgment of the whole.

The materials, which compofe the bottom of the Sea, may very rationally be fuppofed, in fome degree, to influence the tafte of its waters; and Marfigli has made many experiments to prove, that foffil coal, and other bituminous fubftances, which are found in plenty at the bottom of the Sea, may communicate in great part its bitternefs to it. We are not, however, to judge haftily, that there are not fo many beds of thefe at the bottom of the Sea, as would be neceffary for fuch a purpofe, or to judge too haftily againft the exiftence of any other fubftances there, becaufe we do not find proofs of them by the plummet, which in founding brings up other fubftances, and not thefe; for the true bottom of the Sea is very often covered and obfcured from us by another accidental bottom, formed of various fubftances mingled together, and often covering it to a confiderable depth.

The entire gulf of Lyons, fituated between Cape Quiez in Roufillon, and Cape Croifit in Provence, forms a bank above the furface of the water at the fhore, of the exact and perfect figure of an arch; and within this there is formed another fuch arch, making the bottom of the Sea in that place for a very great way from fhore, which is of different depths in various places, but ufually between fixty and feventy fathoms.

It is a general rule among failors, and is found to hold true in a great many inftances, that the more the fhores of any place are fteep and high, forming perpendicular cliffs, the more deep the Sea is below; and that, on the contrary, level fhores denote fhallow Seas. Thus the deepeft part of the Mediterranean is generally allowed to be under the height of Malta. The obfervation of the ftrata of earth, and other foffils, on and near the fhores, may ferve to form a very good judgment, as to the materials which are found in its bottom. The veins of falt and of bitumen doubtlefs run on the fame, and in the fame order in which we fee them at land; and the ftrata of rocks, that ferve to fupport the earth of hills and elevated places on fhore, ferve alfo, in the fame continued chain, to fupport the immenfe quantity of water in the bafon of the Sea. It is probable alfo that the veins of metals, and of other mineral fubftances, which are found in the neighbouring earth, are in the fame manner continued into the depths of the Sea. The particles of metals, in this cafe, are probably carried off into deep water, and funk among the fofter matter of the bottom; but fome of the lighter minerals feem to have given colour to thofe beautiful crufts, which are found upon many Sea plants, and which lofe their luftre in the drying. The fubterranean rivers, and currents of water, make great changes in what would be the natural furface of the bottom of the Sea, where they arife, each having a peculiar bafon of its own. We are informed by numerous inftances of fubterranean currents, and, as we fee them break out in rivers on the furface of the earth in fome parts, fo in others we may be well affured thrt they break up the bottom of the Sea, and empty their frefh waters into the falt mafs.

In this cafe, the rufhing up continually of fuch a body of water makes a roundifh cavity, and its running fome one way lengthens and carries on that cavity, till, by degrees it is loft, as the frefh water by degrees becomes blended with the falt. Thus every river, that arifes in the bottom of the Sea, alters the form of its furface, and makes a bafon for itfelf, in which it runs a confiderable way. Many Seas near the fhore, and when the water is tolerably clear, fhew the traces of thefe currents to the naked eye from the furface, and the water taken up from them is found more or lefs frefh. The coral fifheries have given us occafion to obferve, that there are many, and thofe very large, caverns or hollows in the bottom of the Sea, efpecially when it is rocky; and that the like caverns are fometimes found in the perpendicular rocks, which form the fteep fides of thofe fifheries. Thefe caverns are often of great depths, as well as extent, and have fometimes wide mouths, equal to their largeft diameter in any part, but fometimes they have only narrow entrances into large and fpacious hollows. It is the common opinion of the people about the place, that thefe caverns are prepared by nature for the circulating of the Sea water; but that operation, however neceffary, may be performed as well without, as with thefe caverns, and they feem in reality to be only accidental.

We daily meet with immenfe hollows and caverns, naturally made in rocky mountains; and as this part of the bottom of the Sea is almoft all rock, and its fides of the fame nature, it is no wonder that the fame accidents fhould happen, and like hollows be found, though with no particular intent of providence in their ufe. Nay there is this farther reafon to expect them in the rocks buried under the Sea than in thofe in hills, that the latter are in a ftate of reft and quiet, whereas the former are in continual reach of water, which will infinuate itfelf into every crack or crevice nature has left in them, and may be eafily fuppofed to have burrowed its way in a fmall hole made by nature, till it has formed of it a very large one.

It feems plain from the whole, that the bafon of the Sea was at the creation, or at its fecond formation after the univerfal deluge, covered with, or compofed of the fame fubftances, as the furface of the reft of the earth is, that is, of rocks, clay, and fand, and other fuch fubftances. The common obfervations of feamen feem indeed to make againft this opinion, but they may be eafily folved, fo as not to overthrow it. The plummet which they let down in founding, ufually brings up with it a matter compofed of mud, tartarous incruftations, or of dead weeds and broken fhells, or numbers of various bodies of this kind, cemented together into a firm mafs by fome fparry or tartarous matter, depofited from among the water, and agglutinating them together: thefe form an artificial bottom, covering the natural one; but it is eafy to fee, that fuch a cruft or coat as this muft needs have been formed over the true bottom, in places where numbers of animals and vegetables are produced, and decay again, and where the waters being at reft have time to depofit their ftony matter, in the fame manner as the waters of feveral of our petrifying, or rather incruftating fprings do. And that thefe decayed fubftances, and this ftony matter, falling to the bottom together, and there lying undifturbed, muft neceffarily have formed juft fuch a cruft as is found; and the natural bottom of the Sea, whether of ftone, of fand, or of clay, muft be covered by fuch accidental concretions, and that probably to fuch a depth, that it is not eafy now to break through it. There are places however where, by fome accidents, this fort of adventitious cruft either has never been formed, or elfe has been removed. In thefe places we find the natural bottom, as defcribed, that is, of the fame nature with the ftrata in the body of the earth. The fimile the Count Marfigli has made, between the bafon of the Sea and a cafk of wine, is very expreffive and juft. When wine has been a long time kept in a cafk, the whole internal furface of that cafk is fo covered and incruftated over with tartar, that it feems within to be really compofed of it; yet, as we know that this cafk is of wood, we are very certain that the true inner furface of it is of the fame texture and nature with the tree from which it was cut, though we cannot get off the accidental furface formed by the liquor kept in it, and wholly covering it.

We very frequently meet with fine and pure fand at the bottom of the Sea, and in thefe places are apt to believe that we certainly have the true and original bottom, but this

is

is rather to be looked on as a probability than a certainty; and, where the sand is more than ordinarily fine, there is always reason to suspect that the course of some subterranean river has brought it there, by opening into the Sea in this part; and that this is one of those particular basons, which these rivers form to themselves within the bason of the Sea, and which continue only to a small distance from their source.

The bottom of the Sea is covered with a variety of matters, such as could not be imagined by any but those who have examined into it, especially in deep water, where the surface only is disturbed by tides and storms, the lower part, and consequently its bed at the bottom, remaining for ages perhaps undisturbed. The soundings, when the plummet first touches ground on approaching the shores, gives some idea of this. The bottom of the plummet is hollowed, and in that hollow there is placed a lump of tallow; this, being at the bottom of the lead, is what first touches ground, and the soft nature of this fat receives into it some part of those substances, which it meets with at the bottom: this matter, thus brought up, is sometimes pure sand, sometimes a sort of sand made of the fragments of shells, beat to a sort of powder; sometimes it is made of a like powder of the several sorts of corals, and sometimes it is composed of fragments of rocks: but besides these appearances, which are natural enough, and are what might very well be expected, it brings up substances which are of the most beautiful colours. Things of as fine a scarlet, vermilion, purple, &c. as the finest paint could make them, and as yellow as a solution of gamboge, are common; and sometimes, though not so frequently, the matter brought up is blue, green, or of a pure snowy whiteness. These coloured matters sometimes seem to have made up the whole bottom or mass of the surface, but more usually they have been formed upon other things, as upon the mud, or upon larger pieces of shells, corals, and the like, in the manner of tartarous crusts, and those in some degree resembling the crustaceous coats of some of the Sea plants. The colours of these substances are not merely superficial and transient, but many of them are so real and permanent, that they may be received into white wax melted, and poured upon them, or kept in fusion about them; and, when thus examined, they seem as if a proper care might make them of great value, as paints of the finer kinds, where little is to be used.

The same coloured matters that thus coat the substances, found at the bottom of the Sea in these places, are also sometimes found extended over the surface of Sea plants of the harder kind, which grow in deep water. They are always, in this case, in a sort of liquid form, being lodged within, or embodied among a sort of jelly or glue of a transparent substance, which in these cases perfectly coats over the whole plant. In this state it gives the naturalist, who is present at the fishing up his treasures, a transient prospect of a very elegant kind; but this vanishes, while he admires it. A piece of coral, or other hard Sea plant, thus coated over, appears, as it rises to the surface of the water, of a delicate green, blue, or purple; but, when taken above water, it is found that this fine colour is only in the coat of glue or jelly which covers the plant: as soon as this is wiped off, the colour is carried away with it, and the coral shews its own native tinge; and it is to no purpose to attempt the preserving it, by suffering this glue to dry upon the plant, for the colour flies away by degrees, as the moisture evaporates; and the coral or plant, whatever it be, is only so much the less beautiful, than it naturally would have been, as it is covered with a dry yellowish dirty looking horny matter. These are beauties in the submarine plants, therefore, which can be only seen by those who venture out, in order to take them up.

The small quantities of these elegant colours, which we thus find spread over the surfaces of plants and other bodies, as we approach deep water, may give a rational idea of what we should find, were we able to examine the bottoms of the Sea in its deep and unfathomable recesses. It is easy to conceive, that in these places we should find great quantities of the most beautiful substances. *Marsigli, Hist. Phys. de la Mer.*

Dead SEA. Dr. Perry made several experiments on the water of the dead Sea, in order to find what particles it contained. Upon infusing some scrapings of galls in it, it becomes of a bright purple colour, but that not till it has stood a considerable time. On adding oil of tartar per deliquium to it, it becomes turgid, and looks as if globules of fat were fluctuating in it; this unctuous matter, upon its long standing in repose, comes together in form of a sediment at the bottom. On pouring spirit of vitriol into it, it deposits a milk-white greasy sediment, which, after standing twelve hours, occupies about one fifth part of the liquor. On putting a small quantity of saccharum saturni to it, it deposits a small quantity of a greyish powder. Being severally and separately mixed with a solution of sublimate, with spirit of sal armoniac, and with sugar of violets, it neither ferments, nor deposits any sediment, nor changes colour, except with the sugar of violets, with which it becomes green. It is highly saturated with salt, so that it is to common water in specific gravity, as five to four; and it has so acrid and styptic a taste, that, on being held in the mouth, it constringes it in the manner of alum.

From all these experiments it appears, that this water is impregnated with a sort of an acrid and alkaline nature, and a matter partly of a sulphureous, partly of a bituminous nature. *Phil. Trans.* N°. 462.

SEA *adder*, an English name for a Sea fish of the acus kind, called by Willughby the acus lumbriciformis.

It is a small fish of a cylindric shape, without scales, and of a greenish brown colour, with some admixture of a reddish yellow. The snout is long and hollow, and the mouth opens upwards at its end. The eyes are small, and their iris red. The gills are four on each side, but are covered by a membrane, and the whole body divided into rings like the common earth-worm. It is usually about three or four inches long, and of the thickness of a goose quill. It has but one fin, which is situated on the back. The anus is much nearer the head than the tail, and under the snout there is always a fleshy tubercle. The fish is common on the coast of Cornwall. *Willughby, Hist. Pisc.*

SEA *breaches*, a term used by the farmers to express the overflowing of their low lands near the Sea by the Sea water.

Sea salt, moderately used, is a great improvement to all lands, but too much of it kills all sorts of vegetables, except such as nature has intended to live among it. The Sea, breaking in upon lands thus, injures them greatly. The owner is to stop the breach by which it entered with all possible diligence, and then trenches and drains must be cut through all parts of the land, to carry the salt water into some one low place, from which it may be emptied by means of an engine; or, if it be small in quantity, it may be laded out by hand over the bank; or, if yet less, the sun and winds may dry it away: but, in either case, the place where it was suffered to rest must be covered with a large quantity of fresh earth, to take off from the too great saltness of the other; and the whole land should be plowed for three or four years, to let in the rains and air to freshen it. *Mortimer's Husb.*

SEA *bream*, in ichthyology, the English name for the fish called by the generality of authors the pagrus and phagrus. According to the new system of Artedi, it is a species of the spari, and is distinguished by the name of the red sparus with the skin carried into a sinus at the roots of the back fins, and the pinna ani.

SEA *cow*, the English name of the manati, a species of fish so different from all the other of the cetaceous tribe, to which it properly belongs, that Artedi, in his new system of ichthyology, allots it a peculiar generical name, which is thricechus.

SEA *fox*, an English name for a fish of the squalus kind, called also the Sea ape; both names being given on occasion of the length of its tail in proportion to the body.

SEA *plants*. Count Marsigli, who was at indefatigable pains in collecting the various Sea plants of several places, divides all those productions into three classes.

The first class contains the soft, or herbaceous ones; the second, the ligneous ones, or such as are of a woody hardness; and the third, those which are of the hardness of stone. Of the first class are the algas, called Sea wrecks, the fucuses, or Sea oaks, the Sea mosses, or confervas, and the different species of spunges.

Of the second kind are those called lythophyta by the ancients, as if their hardness approached to that of stone. All these consist of two substances, a cortical and an internal: the cortical part, while in the Sea, is soft, but, in drying, it becomes as hard as chalk, or thereabouts, easily crumbling to pieces between the fingers; this is what deceived the ancients into an opinion of its being of a stony nature. The internal substance, properly speaking, seems more of the nature of horn than of wood: if it is burnt, it throws out a spume or froth, like that which horns or feathers of animals yield in the fire, and their smell in burning is of the same kind. The branches of these plants are very pliable, bending in the manner of whale-bone, and they give the same resistance to a knife in the cutting.

The stony plants, which should properly be called the lythophyta, but which never are called so, are the several species of coral, madrepora, and the like. The madrepora differs from the coral, in having its surface pierced with almost innumerable holes.

The algas are the only Sea plants which have any roots, properly so called; these therefore grow out of the soft bottom of the Sea, as other plants out of the earth, but all the other Sea plants, without exception, appear fixed upon hard and solid bodies, incapable of affording them any nourishment; such as stones, shells, pieces of iron, of wood, &c. and sometimes on other plants; and they are not fastened to these substances by fibres passing into, or surrounding them, but merely by a foot or pediment, capable of only fixing them down, not of drawing nourishment from the substances, were there any there. From this observation the author concludes, that all the plants which have no roots may be properly said to be all root, or to perform the office of roots in their whole substance, ftance, or that they take in nourifhment in every part by certain pores, which in many are vifible, and cover the whole furface.

This manner of receiving nourifhment, he alfo obferves, very well fuits their condition, fince they are always furrounded on all fides, with that water by which they are to be nourifhed; whereas the plants, which grow at land, have only a part of them buried in the earth, from whence they are to be fupplied with the proper juices. The roots of land plants, therefore, have only the neceffary organs for receiving fupplies, whereas the Sea plants he finds to be all over covered with fmall glandules, whofe office it is to receive and to convey, into the internal parts of the plant, the proper juices for its nourifhment, and thefe he obferves are, in general, of a glutinous and milky nature. The great difference between the land and Sea plants is feen in this familiar inftance; a land plant will remain frefh for a long time, in all its parts, on one end of the ftalk only being plunged in water; but a Sea plant, if part of it be out of water and part in, will always be frefh and vigorous in that part which is under water, while the part that is dry will wither and decay. It is eafy hence to fee, that the feveral parts of the land plants have connections with, and dependences, on one another; whereas, in the Sea plants, every part takes in its own nourifhment, and lives and flourifhes wholly independent of the reft. After having gone through this general fyftem, the author defcends to feveral remarkable particulars. He mentions an inftance of a fucus, whofe ftalk, when in its growing ftate, is a quarter of an inch in diameter, yet in drying fhrinks up fo much, as to be no thicker than a fingle thread. Another fpecies, called by the fifhermen the Sea orange, from its refemblance to an orange in fhape, he obferves, is properly a fucus; it has neither ftalk nor branches, but confifts wholly of this globular body; it is not a folid fubftance, but a membrane of about one-ninth of an inch in thicknefs, regularly diftended into this fhape, by being filled with Sea water. All over the fides of this cavity there are fixed flender filaments, which traverfe the whole, and probably receive nourifhment from the water contained in the cavity, and diftribute it to the feveral parts of the fides where they are inferted.

Another Sea plant, this author mentions, only appears in the fhape of a bark; it affixes itfelf to the branches of the lythophyta, when they have loft their natural bark, and fometimes, in the fame manner, coats and crufts over the furfaces of ftones. When it is frefh, it is of a lively red, of the confiftence of a mufhroom, and about the thicknefs of the back of a common knife, and its external furface is full of fmall prominences, which contain a glutinous juice; round about thefe alfo there ftand feveral yellow tubercles, which, with the red of the ground of the plant, make upon the whole a very beautiful appearance. Its under furface is perfectly fmooth and gloffy. This feems a much more remarkable plant, as to the manner of its vegetation, than thofe which grow on other plants at land.

The fame author obferves, that feveral of the fpunges, when taken out of the Sea, have a motion of the nature of a fyftole and diaftole, which lafts as long as there remains any of the Sea water in their cavities. Some of the Sea plants, which while growing are as foft as the fucufes, yet when dried are as eafily rubbed to powder between the fingers, as the bark of the lithophytons. There is one of the lithophytons, which carries fo large a quantity of branches, that they make the refemblance of leaves; but, as thefe leaf-like branches are all truly of the fame nature with the reft of the plant, this is no exception to the general rule, that the lithophyta have no leaves. One of the fpecies of lithophyton is naturally deftitute of a bark, and is covered in the place of one with a glutinous fubftance, of the nature of varnifh; this is moft abundant at the foot. The whole plant is full of prickles, and thefe appear the moft plainly on the fummits of the branches, where this glutinous varnifh is more thinly fpread. On this part of the plant, alfo, there appear certain globules of a glutinous matter, when it is taken out of the water, which, when it is again plunged into it, fpread themfelves over the whole furface of the branches.

The madreporæ grow in the fame places with the coral; they often hang pendulous from the hollow rocks, and often grow erect on the flat ones. They ufually change colour, when taken out of the water, and are of very different kinds, and different degrees of hardnefs; many of them are as hard as common ftones, and many others are fo brittle, that it is fcarce poffible to touch them without breaking their branches.

The flowers of the thorny and naked lithophyton appear to be wholly like thofe of coral, and like them they are not found to contain any folid feed. *Mem. de l'Acad. Par.* 1710.

SEA-*ficknefs* is faid to be prevented by drinking Sea-water mixed with wine.

SEA-*fwallow*, the name of a bird of the larus, or gull kind, called by authors fterna, and common on our coafts. See the article STERNA.

SEA-*turtle-dove*, in zoology, the name by which we commonly call the little diver, called by Mr. Ray columba Greenlandica.

It very much refembles the coulterneb or anas arctica of Clufius, only it is much fmaller, and its legs are red, and it has no hinder toe. Its beak is long, not compreffed or flatted fideways, as in that bird, and a little crooked and fharp at the end. It has a large white fpot on each fide of the fore-part of its head, and, excepting that, it is all over black. *Ray's Ornithology.*

SEAL (*Dict.*)— The king's great Seal is that whereby all patents, commiffions, warrants, &c. coming from the king, are fealed. The keeping hereof is in the hands of the lord high chancellor, who is hence alfo denominated lord-keeper. —Indeed, there is fome difference between the lord-chancellor and lord-keeper; not in office, but in the manner of creation, the latter being made by the delivery of the great Seal to him by the king, but the former having likewife a patent.

The king's privy Seal, is a Seal ufually firft fet to grants that are to pafs the great Seal.

The ufe of Seals is very ancient: in Daniel, chap. xiii, we read that Cyrus fet his Seal on the temple of Bel: but Seals are ftill older; for Jezebel, in 1 Kings, chap. xxi, feals the orders fhe fent for Naboth's death with the king's ring.— In effect, as the ancient Seals were all engraven on the collets, ftones, &c. of rings, and as the original ufe of rings, it is afferted, was only to be in a readinefs for the fealing of acts, inftruments, &c. Seals fhould be as ancient as rings themfelves.

Thefe fealing-rings, called annuli fignatorii, figillares, cirographi or cerographi, it is faid in ancient authors, were firft invented by the Lacedæmonians, who, not content to fhut their chefts, armories, &c. with keys, added Seals to them: and to this end, at firft, made ufe of worm-eaten wood, the impreffions whereof they took on wax, or foft earth: but they at length found the art of engraving figures, or rings, the impreffions of which they took in the fame manner.— This, however, muft be granted, that, even in Mofes's time, the art was known of engraving, not only on metals, but alfo on precious ftones.

Indeed, it does not appear that the ring had any other ufe among the primitive Jews befides ornament: but at length it was ufed to Seal inftruments, contracts, diplomas, letters, &c. inftances whereof we have in the third book of Kings, xxi. 8. Efther viii. 10. Xenophon. Hellen. lib. I. Quint. Curt. lib. vi. Juft. lib. xliii. cap. iii. where we learn, the keeping of the emperor's Seal was become a particular office. — Lucian adds, that Alexander gave his to Perdiccas, thereby appointing him his fucceffor.

Pliny obferves, that in his time there were no Seals ufed any where but in the Roman empire: at Rome, he tells us, they were become of abfolute neceffity, infomuch that a teftament was null without the teftator's Seal, and the Seals of feven witneffes: but it does not appear that the Romans had any fuch things as public Seals; nor that their edicts, and contracts, were fealed, not even in the times of the emperors.

In France, the cuftom anciently was, inftead of figning their inftruments, &c. only to Seal them; as appears from an infinity of ancient charters, which are not figned at all: the reafon whereof was, that in thofe days very few people were then able to write; no body could read and write but clerks.

In England, the firft fealed charter we find extant, is that of Edward the Confeffor, upon his founding of Weftminfter-abbey: yet, we read of Seals in the MS. hiftory of king Offa.

Before the time of William the Conqueror, the Englifh did not Seal with wax, but only made a golden crofs on the parchment, and fometimes an impreffion on a piece of lead, which hung to the grant with a filken ftring, and was deemed an abundant authorifing of the grant itfelf, without either figning or witneffes.— The colour of the wax wherewith the king's grants were fealed, was ufually green, to fignify that the act continued for ever frefh, and of force. The ufual impreffion on all laymens Seals, till the year 1218, was a man on horfeback, with a fword in his hand; afterwards, they began to engrave their coats of arms on their Seals: only the archbifhops and bifhops, by a decree of cardinal Otto, who was legate here in 1237, were to bear, in their Seals, their title, office, dignity, and even their proper names.

Du Chefne obferves, that none below the dignity of a knight had any right to a pendent Seal, called authenticum.

The emperors long fealed all their acts of importance with a golden Seal; and the golden bull of Charles IV, for the election of an emperor, takes its name from the gold Seal hanging to it, which is called bull.

The pope has two kinds of Seals: the firft ufed in apoftolical briefs, and private letters, &c. called, the fifherman's ring.— This is a very large ring, wherein is reprefented St. Peter, drawing his net full of fifhes.

The other is ufed in bulls, reprefenting St. Peter's head on the right, that of St. Paul on the left, with a crofs between the two: on the reverfe is fometimes the pope's name, and arms.

The impreffions of the firft Seal are taken in red wax, thofe of the fecond, in lead.

SEASONS (*Dict.*)— *Plate* VII, *fig.* 9, in the Dictionary, reprefents the various Seafons of the year. When the earth is

in

in ♋, it is plain that the rays of the ſun S illuminate the north pole, and that all thoſe who live in north latitude, the days are longer than their nights; and thoſe who live in ſouth latitude the contrary, the ſouth pole being then wholly in darkneſs. And, when the earth is in ♑, the very contrary happens, the north pole then being wholly in darkneſs, and ſouth pole illuminated. When the earth is either in ♈ or ♎, the days and nights are equal in every part of the globe. The figure repreſents the earth in every one of the ſigns, whereby the viciſſitudes of the Seaſons are rendered very conſpicuous.

SE'BESTEN, SEBESTENA, *myxa*, in pharmacy, &c. a fruit reſembling a little plum or prune; which, when ripe, is of a deep red colour, bordering on black; very ſweet, and the fleſh, or pulp, glutinous, or ſticky.

The Syrians make a kind of glue, or birdlime, of the Sebeſtens, called birdlime of Alexandria. The fruit is eſteemed pectoral, cooling, and emollient; though not much uſed in medicine. The ſtone within it is triangular.—It brought its name from Arabia, whence Pliny obſerves it came in his time into Italy.

SEBUÆ'I, a ſect among the ancient Samaritans; whom St. Epiphanius accuſes of changing the time expreſſed in the law, for the celebration of the great annual feaſts of the Jews. Serrarius conjectures, that they were thus called, from their celebrating the feaſt of the paſſover on the ſeventh month, called by the Hebrews ſeba, ſeventh.—Druſius rather takes them to have been denominated from Sebaia, the leader of a ſect among the Samaritans; as the followers of Doſitheus were denominated Doſithei; which two ſects ſome Jewiſh doctors ſuppoſe to have ſubſiſted at the ſame time.—Scaliger derives the name from the Hebrew ſebua, week; as who ſhould ſay, Hebdomadites, becauſe of their celebrating every ſecond day of the ſeven weeks, between Eaſter and Whitſuntide. Yet the ſame Scaliger, in his anſwer to Serrarius, gives a different explication.—In effect, all that has hitherto been advanced, on the point, is mere conjecture.

SEBU'RAI *, SEBURÆI, a name which the Jews give to ſuch of their rabbins or doctors, as lived and taught ſome time after the finiſhing of the talmud.

* The word is derived from סבר, *ſeber*, I think, whence סברא, *ſebara*, opinion, ſentiment; and thence סבראי, *ſebari*, or *Seburai*, opinionative.

The reaſon of this appellation, ſay the rabbins, is that, the Talmud being finiſhed, publiſhed, and received in all the ſchools and ſynagogues, theſe doctors had nothing to do, but diſpute for, and againſt, the Talmud and its deciſions. Others ſay, it was becauſe their ſentiments were not received as laws, or deciſions, as thoſe of the Miſchnic and Gemaric doctors were; but were held as mere opinions. Others, as the author of Scalſcheleth Hakkabala, or Chain of Tradition, tell us, that the perſecution, the Jews underwent in thoſe times, not allowing them to teach quietly in their academies, they only propoſed their opinions on the compoſition of the Miſchna.

The firſt and chief of the Seburai was R. Joſi, who began to teach in the year 787 of the æra of contracts; which, according to R. David Gautz, falls on the year of the world 4236; and who, according to R. Abraham, was 38 years preſident of the Jewiſh academy.

This æra of contracts is the ſame with that of the Seleucidæ, the 787th year whereof falls on the year of Chriſt 476, which, of conſequence, is the æra of the origin of the Seburai; whoſe reign did not hold long: Buxtorf ſays, not above ſixty years; but R. Abraham and others, not fifty. The laſt of them was R. Simona.—They were ſucceeded by the Gaons of Geonim.

SECA'LE, *rye*, in botany, the name of a genus of plants, whoſe characters are:

The flowers have no leaves, but conſiſt of ſeveral ſtamina, which are produced from the flower-cup: the flowers are collected into a flat ſpike, and are diſpoſed almoſt ſingly: from the flower-cup riſes the pointal, which afterwards forms an oblong ſlender ſeed, incloſed in an huſk, which was before the flower-cup; this differs from wheat in having a flatter ſpike, the awn larger, and more naked. See RYE.

SE'CULAR *Games* (*Dict.*)—The Secular games were alſo called Terentine games, ludi Terentini, either by reaſon Manius Valerius Terentinus gave occaſion to their inſtitution; for that, having been warned, in a dream, to dig in the ground in a place near the Campus Martius, called Terentum, he there found an altar inſcribed to Dis, or Pluto and Proſerpine: upon which, as had been foretold him in his dream, three of his children, born blind, recovered their ſight; and he, in gratitude, performed ſacrifices, on the ſame altar, for three days and three nights ſucceſſively.—Or by reaſon here was an altar of Pluto buried deep under ground, becauſe the water of the Tyber terram tereret, eat into the ground in this place.

The Secular games laſted three days, and as many nights; during which, ſacrifices were performed, theatrical ſhews exhibited, with combats, ſports, &c. in the circus.

Their origin, and inſtitution, is delivered at length by Val. Maximus: the occaſion thereof, according to this writer, was, to ſtop the progreſs of a plague. — The firſt who had them celebrated at Rome, was Valerius Publicola, the firſt conſul created after the expulſion of the kings, in the year of Rome 245. — The ceremonies to be obſerved therein were found preſcribed in one of the books of the Sibyls.

At the time of the celebration of the Secular games, heralds were ſent to invite all the world to a ſolemnity no body had ever yet ſeen, nor was ever to ſee again.

Authors are not agreed as to the number of years wherein theſe games returned; partly, becauſe the quantity of an age or ſeculum among the ancients is not known, and partly on other accounts: ſome will have it, that they were held once every hundred years, and that the ſeculum, or age, was our century.—This Varro and Livy ſeem to expreſs in very plain terms; yet others will have it, that ſeculum comprehended 110 years, and that the Secular games only returned in that period, that is, at the beginning of every 111th year; which opinion is countenanced by Horace, in his Secular poem, v. 21.

Be this as it will, it is certain they ſometimes did not ſtay for the 111th, nor even for the 100th year, for the celebration of theſe games. Auguſtus, for inſtance, held them in the year of Rome 736; and Caligula again in the year of Rome 800, and of Chriſt 38, viz. 64 years after the former; and Domitian, again, in ſtill leſs time, viz. in the year of Chriſt 87, at which Tacitus aſſiſted in quality of quindecimvir, as he himſelf tells us, Annal. lib. xi. c. 11. This was the ſeventh time that Rome had ſeen them from their firſt inſtitution.

The emperor Severus exhibited them the eighth time 110 years after thoſe of Domitian: Zoſimus ſays, theſe were the laſt; but he is miſtaken, for in the year of Rome 1000, fifty years after thoſe of Severus, the emperor Philip had them celebrated with greater magnificence than had ever been known.—We find them repreſented on medals.

SE'CUNDANS, in mathematics, an infinite ſeries of numbers, beginning from nothing, and proceeding as the ſquares of numbers in arithmetical progreſſion, as 0, 1, 4, 9, 16, 25, 36, 49, 64, &c.

SECU'NDINES (*Dict.*)— It very often happens that theſe are retained in the womb after child-birth, and great miſchiefs enſue from it. The aſſiſtance of a ſkilful hand is, in many caſes, neceſſary to the getting them out; and this is to be done with great care and ſpeed, before the uterus cloſes itſelf upon them, otherwiſe, they occaſion terrible hæmorrhages, faintings, and often inflammatory and putrid fevers.

The patient herſelf may greatly promote the expulſion of theſe, by any forcible emotion of the body, as by a forced cough, or by ſneezing; the midwife at the ſame time is gently to pull them by the navel ſtring, but this muſt be done very cautiouſly, for fear of its breaking. If this fails, the cautious introducing the hand often ſets all right, or the uſe of gently pellent medicines may be called in; and to theſe may be added broths, with ſaffron in them, and by the uſe of common clyſters great good is often done: but, if after all this care there yet remain ſome fragments of them behind, there uſually ariſes a fever within twelve hours; and, in this caſe, the utmoſt care muſt be taken to prevent putrefaction, and expel the remains of them. To theſe purpoſes medicines prepared with myrrh, amber, ſaffron, and the cortex Eleutherii, are of the greateſt ſervice; and to theſe may be added occaſionally the colliquating and attemperating ſalts, ſuch as tartarum vitriolatum and nitre. *Junker's Conſp. Med.*

SERCUI'DACA, *hatchet-vetch*, in botany, the name of a genus of plants, whoſe characters are:

It has a papilionaceous flower, out of whoſe empalement riſes the pointal, which afterwards becomes an upright, plain, articulated pod, containing in each joint a rhomboid ſeed, having a notch on the inner ſide.

SE'DER *Olam* (*Dict.*)—The great Seder Olam commences at the creation of the world, and comes down as low as the war of the pſeudo-meſſiah Barchochabas, under Adrian, fifty-two years after the deſtruction of the temple of Jeruſalem, and, of conſequence, to the 122d year of Chriſt.—It is almoſt all taken from the ſcripture, excepting the end. It is the work of R. Joſa, ſon of Hhelpeta of Tſippora, who lived in the ſecond century, about the year one hundred and thirty, and was maſter of the famous R. Juda Hakkadoſch, the compiler of the Miſchna.

The leſſer SEDER *Olam* is an abridgment of the former, brought down as far as Mar Sutra, who lived four hundred and fifty years after the deſtruction of the temple of Jeruſalem, or five-hundred and twenty-two years after Chriſt.—F. Morin, continually bent upon diminiſhing the antiquity of the principal books of the Jews, endeavours to prove it to have been wrote about the year of Chriſt one thouſand one hundred and twenty four, as indeed is expreſſed at the beginning: but R. Dav. Gantz. has overthrown this opinion in his Tſemahh David, and ſhewn, that the date, in the beginning, is an interpolation.

The two chronologies were firſt printed at Mantua in one thouſand five-hundred and fourteen, quarto; again, at Baſil, by Frobenius, in one thouſand five-hundred and eighty, octavo: at Venice in one thouſand five-hundred and forty-five, quarto: at Paris, with a Latin verſion of Genebrard, in 12°.—They have been ſince reprinted at Amſterdam, in one thouſand ſeven-hundred and eleven.

SEDI'TION, among civilians, is uſed for an irregular commotion of the people, or an aſſembly of a number of citizens

without

without lawful authority, tending to disturb the peace and order of the society.

SEDR, or SEDRE, the high-priest of the sect of Ali, among the Persians.

The Sedr is appointed by the emperor of Persia, who usually confers the dignity on his nearest relation.

The jurisdiction of the Sedr extends over all effects destined for pious purposes, over all mosques, hospitals, colleges, sepulchres, and monasteries. He disposes of all ecclesiastical employments, and nominates all the superiors of religious houses.—His decisions, in matters of religion, are received as so many infallible oracles: he judges of all criminal matters, in his own house, without appeal, and is, without contradiction, the second person in the empire.

The Sedr, however, has not any indelible character, but frequently quits his post, for another purely secular one.—His authority is balanced by that of the mudsitehid, or first theologue of the empire.

SE'DUM, *houseleek*, in botany, the name of a genus of plants, whose characters are:

The flower consists of several leaves, which are placed orbicularly, and expanded in form of a rose; out of whose flower-cup rises the pointal, which afterwards turns to a fruit, composed, as it were, of many seed-vessels, resembling husks, which are collected into a sort of head full of small seeds.

House-leek is very cooling, and in that intention is often used in outward applications.

SEED (*Dict.*)—The exterior form, and even the internal structure, of the generality of vegetable Seeds have been supposed by some so much alike in the several kinds, and of so little curiosity and beauty in the whole, that they have been little regarded by the curious; but, when nearly examined with the help of microscopes, they are found to be worthy of a greater attention; those which appear most like to one another, when viewed by the naked eye, often proving as different, when thus examined, in their several forms and characters, as the different genera of any other bodies of the creation. If their external forms carry all this variety and beauty about them, their internal structure, when laid open by different sections, appears yet more admirable.

The Seed of the musk scabious is amazing in its shape and structure: it resembles in figure an octagonal vase, with a scalloped brim; the whole is bell-fashioned, having ribs or divisions, which run down from the mouth of the vase, and, thence becoming narrower, form the bottom. Between these ribs, down to the beginning of the narrow part, it is clear, though not wholly transparent, and from thence to the bottom the ribs are hairy. This vase contains a seed, which is like a pestle standing in a mortar. The pestle stands loose in an octagonal case, but the narrowness of the mouth of this vase hinders the pestle's being drawn out, because its extremity within is rounded, and thicker than any other part of it. From its upper end there arise five spiculated aristæ or awns, whose little thorns are directed upwards, and are thereby prepared to cause the Seed to recede from any thing that might injure it on being touched. The bason, from which these aristæ rise, is of a fine green colour, and they are of an elegant shining brown.

The Seed of the angelica is one of the most fragrant in its smell in the world. When the outer husk of this seed is pulled off, the nucleus appears of a brownish colour, and of an elliptical shape. By the help of the microscope we soon discover what it is that produces this charming smell; this is a fine amber-coloured gum, which appears laid in ridges, disposed alternately with others of a brownish colour, longitudinally, all over the seed; and on the flat side there is a white part, which is a sort of theca, which receives a very minute stylus from the pedicle that supports it.

The medicinal Seed, commonly known in the shops under the name of grain of paradise, is one that promises very little from its external appearance, being only a brown Seed of an irregular surface, with many flats and angles, and having an apex like the mouth of a purse, when drawn together with a string; from this unpromising aspect, however, there arises a very wonderful appearance on dissection. In a longitudinal section we see first the edge of the brown cortex, next within that appears a black pitchy substance, and, within that, a very white matter, lodged in a radiated form: this resembles a fine white salt, and is probably a mixture of a volatile salt and a farinaceous matter. Its radiated disposition, and extremely pungent taste, favour also this opinion. But there is in this Seed a yet far more curious particular than these; the center of every Seed is occupied by a small piece of perfect camphor: that is, in all respects, the same with the common camphor sold in the shops, and is always of the figure of a vinegar cruet, having a round large bottom, and a long and narrow neck. This is invariably the appearance in every Seed, and that not only in this, but in other Seeds of the same kind.

The Seed of the great maple, which we commonly, but improperly, call the sycamore-tree, consists of a pod and its wing: two of these grow upon a pedicle with the pods together, which makes them resemble the body of an insect with its expanded wings. The wings are finely vasculated, and the pods are winged with a fine white down, resembling silk: this contains a round compact pellet, covered with a brown membrane, that sticks very closely to it. When this is pulled off, instead of discerning a kernel, as in other Seeds, there appears an entire green plant, folded up in a most surprising manner. The pedicle of this is about two eighths of an inch long, and its feminal leaves of about six eighths each: between these the germina of the next pair of leaves are plainly visible to the naked eye, but with a microscope they are seen with the greatest beauty and perfection.

These, and a number of such other beauties in this part of the creation, are described at large by Dr. Parsons in his work, intitled a Microscopic Theatre of Seeds, to which we refer for the rest. *Phil. Transf.* N°. 474.

Many experiments have been made, in order to prove that the Seeds of plants derive their constituent matter from the woody central parts of the plant. Thus apple-trees, when they grow hollow, will bear good fruit, but with empty and imperfect Seeds. Barberry-trees, when the roots are bored through, are said to bear fruit absolutely without Seeds; and the gardeners say, that, if the woody part of the roots of parsley be cut out, the plant will continue to thrive in all appearance, but that it will never afterwards produce Seeds that will propagate the species. It is to be acknowledged that hollow oaks and elms produce Seed that is as good as that growing on the soundest trees of the same species; but the elm is all timber to the bark, and an oak, when it is putrid to the heart, may still have firm wood enough to convey a proper nourishment from the root to the acorn. The roots may be found, when the body of the tree is very much decayed by water let in at the top of the pollard tree, or at the loppings of the branches; and we see that beans, wheat, and other grain, grow well, if the eyes and parts next adjoining be whole, though the beans be full of great holes in other parts, or the main body of the wheat be cut off with sciffars.

The people who recommend boring the barberry roots, to have fruit without stones, order therefore that the borings be very complete in the roots for that purpose. It is observed, in countenance of this doctrine, that some trees are less fruitful, or even altogether barren, by the excessive growth and hardness of the timber, and these are cured by cross hackings or cuts, done with sharp instruments through the bark, and into the wood: they also do the like injuries to the roots on the same occasion, and often split them lengthwise, putting a stone into the slit, that they may not grow together again. When this remedy is applied both to the stem and roots, it seldom fails of success; but, when only to one, it sometimes misses.

As the heart of the wood, or its more solid substance, are supposed to furnish the matter of the Seeds, the bark is supposed to furnish the matter of the pulp of the fruit. The experiment has been made, by debasing and vitiating its juice, and the fruits have accordingly been debased. Thus if rests be made for water on the body of a Kentish codling tree, and water poured frequently into these cavities, so as always to keep up a supply for the bark, the apples will grow to an immoderate size, and be insipid; part of their pulp will be so relaxed as to look like the pulp of a lemon, and, on hanging but a moderate time on the tree, they will be as rotten, as if laid on heaps, when fully ripe. *Philos. Transf.* N°. 46.

Change of SEED, a term used by the farmers to express the common and, as they suppose, necessary custom, of changing among one another the Seed of their lands, as wheat, and the like; it being a received opinion, that the Seed produced on one land will grow better on another, than on that which produced it, though the same species of plant be sown.

Seeds, in their natural climate, do not degenerate, unless culture has improved them; they then indeed are liable, upon omission of that culture, to return to their natural state again. Whatever benefit arises to the farmer from the changing the Seed of the same species, is from causes which are themselves the effects of different climates, such as heat and moisture, which may vary very much in the same neighbourhood. There is a mountain in the Mogul's country, which on the south side produces Indian plants, and on the north side European ones, from different exposures. Some land retaining water longer is colder, and some letting it pass off quicker is warmer; as it may also be from the nature and figure of its parts, which retain more of the sun's heat than others. Sandy and gravelly grounds are always warmer than others, if they have some hollow and spungy stratum underneath, that will let the water pass off.

The benefit arising from the change of Seed is owing to these changes, not to the change of food; and these causes shew their effects chiefly in the generation of the Seed. Flax Seed, brought from Holland, and sown here, will produce as fine flax as it does there, but, in the next generation, it will degenerate, become coarser; by this means it will continue to degenerate every year, till after two or three years it is no better than our own Seed produces, and yet the land shall be as good for this coarse sort, as when it produced the fine; so also it is, when the Seeds of our own wheat are changed between farmer and farmer. And thus silk-worms hatched and bred in France, of eggs brought from Italy, will make as fine silk as the Italian;

PLATE XL. *Engraved for the Supplement* *Facing* Semifloscular

Printed for J Hinton in Newgate Street but the eggs of those laid in France will produce worms that make no better silk than those produced in France, though their food is all the while the same.

Common barley, once sown in the burning sands in Wiltshire, will for many years after, if sown on indifferent warm ground, be ripe sooner than any other barley by two or three weeks; but, if sown on cold grounds farther north, it will be as late as any other barley, after two or three years. The weeds, which perplex the farmers in every field, grow as strong and troublesome one year as another, and that without any change of Seed at all. These seem therefore to have been the natural produce of our soil, and corn and other useful plants to have been brought from other places, and improved by culture; these will therefore no longer retain their perfection and value, than such culture is continued to them.

Laurembergius has carried this notion of degeneracy and change from the soil, so far as to affirm that wheat will, in some places, degenerate into rye; and in other places, rye will be exalted into wheat by the soil: but those who are acquainted with botany know, that a horse might as soon be changed into a bull by feeding in an improper pasture, as one plant degenerate into another by fault of the soil. *Tull's Husbandry.*

SEE'DY, in the brandy trade, a term used by the dealers to express a fault that is found in several parcels of French brandy, which renders them unsaleable. The French suppose that these brandies obtain the flavour, which they express by this name, from the weeds which grow among the vines, from whence the wine, of which this brandy was made, was pressed.

However it be, the thing is evident, and the taste not of any one kind; but some pieces of brandy taste strongly of aniseed, some of caraway-seed, and some of other of the strong flavoured seeds of plants, principally of the umbelliferous kind; so that it shall be rather taken for aniseed, caraway, or some other water, than for brandy.

The proprietor of such brandies is always at great trouble to get them off, and usually is reduced to the necessity of mixing them in small quantities with pieces of other brandies, so as to drown and conceal the taste; and, where he has not opportunities of doing this, is obliged to sell them on very disadvantageous terms.

The business of rectification of spirits is very little understood abroad, though very much practised with us; and a man in France or Holland, who could take off this taste from these brandies, might get great advantages by it. There is no doubt but that the same means, which we use to rectify malt spirits, that is, to clear it of its nauseous and stinking oil, which always rises with it in the first distillation, would also serve to purify these brandies, and, by leaving these extraneous oils behind, render them as well tasted as any others; since there is no question, but that the oil of malt, which is a principle of the same ingredients with the spirit, is more firmly united to it than flavouring oils in the brandy, which are not the produce of the grape, but of some foreign matter only accidentally mixed with it.

It is a mistake to imagine, that all the brandies made in France are so fine as those which we meet with on the keys of London; on the contrary, there are many hundred pieces made every year, which are as badly flavoured as our coarsest malt spirit: but the case is this, they send the best brandies and the best wines to England, where they can get the best prices for them. In Holland, on the contrary, the mart of goods of all sorts, it is sometimes difficult to pick one piece of good brandy out of fifty, the general run of them being either feedy, musty, oily, or otherwise infected with some unnatural and disagreeable flavour; and these are the sorts which in France they despair of curing by re-distillation, or bringing to the state of three fifths, or trois cinques, as they express their stronger brandies. *Shaw's Essay on Distillery.* See TROIS CINQUES.

SE'GMENTS *of leaves*, are the parts of such leaves of plants as are divided or cut into several threads.

SE'GUL, in Italian music, is often found before aria, allelujah, amen, &c. to shew that those portions or parts are to be sung immediately after the last note of that part over which it is writ. But, if these words se piace, or ad libitum, are joined therewith, it signifies that these portions may be sung, or not, at pleasure.

SEGUE'NZA, in the Italian music, sung in the Roman church, generally in prose. The Sequenza are often sung after the gradual, immediately before the gospel, and sometimes in the vespers before the magnificat. They were formerly more used than at present.

SEI'M, in agriculture, a term used by the farmers of Cornwall to express a certain determinate quantity of sea-sand which they use as manure to their lands.

They dredge this up on the sea coasts, and carry it as far toward the lands, where it is to be used, as they can by water. At the landing-place the farmers bring a train of horses to receive it, each horse carrying a Seim, that is, a sack of it, containing thirteen gallons. The land carriage of this sand, in Cornwall alone, is supposed to cost thirty-two thousand pounds annually; and yet the farmers find abundant encouragement to continue the use of it, it is so rich a manure. *Philos. Trans.* Nº. 103.

SEISA'CHTHEIA, a Σεισάχθεια, in antiquity, a public sacrifice at Athens, in memory of Solon's ordinance; whereby the debts of poor people were either entirely remitted, or at least the interest due upon them lessened, and the creditors hindered from seizing upon the persons of their debtors, as had been customary before that time. *Potter, Archæol. Græc.*

The word is Greek, and literally signifies the shaking off a burden.

SELF-*opens*, a term used by the miners in the north of England to express certain natural cavities or chambers, which are frequently met with, some near the surface, some at very great depths, some small, and others very large.

These are of various figures, and often run into strange sinuses. Dr. Lister, in accounting for the origin of earthquakes, supposes the whole crust of the earth to be more or less hollowed in this manner; which he also argues for, from the streams of waters which arise in large quantities from the sides of mountains, and must have communication with these Self-opens and supplies from them.

The natural hollows the doctor thinks to be the means of continuing and propagating earthquakes; the first cause of which he ascribes to the breath of the pyrites, which he also says is the pyrites itself tota substantia. This he observes takes fire of itself, on being exposed to the air in our sight, and may do so, from various other causes, under-ground. The sulphureous smell of the air and waters, before and after earthquakes, in the places where they happen, seems a proof that they owe their origin to some such sulphureous matter as this stone; and the rolling, and desultory noise of an earthquake, seems also to shew that it is not expanded any way at once, but is propagated through a chain of these subterranean hollows.

It is not necessary that we should suppose a continued chain of them, from the place where the earthquake begins to be felt, to the spot where it ends; but, if there are many of them irregularly scattered about the earth, the force of the explosion will be sufficient to burst through the solid parts between, and open a passage from one to the others, which may continue open no longer than the force continues, and after the shock is over close together again, so as to leave no trace where it was

Our miners not only find the natural caverns, but they also find them often full of what they call fire damps, which are inflammable vapours, of the very nature of those which occasion earthquakes, and, when fired, make the same explosions, and cause the same effects in a certain degree. These sometimes require a candle, or other actual fire, to come in contact, in order to kindle them; but sometimes they are found kindled of themselves, and flaming on the surface of the waters, in the bottoms of the pits, or at the fissures of the coal. *Philos. Trans.* Nº. 157.

SEMIFI'STULAR *flowers*, in botany, are such whose upper part resembles a pipe cut off obliquely; as in bush-wort, &c.

SEMIFLO'SCULOUS, in botany, a term used to express the flowers of a certain class of plants, of which the dandelion, hawkweed, and the like, are kinds.

This sort of flower consists of a number of semiflosculi, which are either disposed into one or more circles, and all comprehended in the same cup, which often becomes inverted, as the flower ripens. These Semifloscules are petals, hollow in their lower part, but in their upper half are flat, and continued in the shape of a tongue. These are often separated from each other by intermediate leaves, and are placed upon the embryo fruit, from which there stands out a slender capillament, divided at the end into two parts; often carried beyond the vagina, supported by five props. The embryo's are placed in the thalamus, or bottom of the cup, and finally become seeds, sometimes winged with down, sometimes naked, sometimes coronated, and sometimes foliated. See *Plate* XL. *fig.* 7. *Tourn. Inst.*

SEMILUNA'RES *cochleæ*, in natural history, the name of a genus of sea snails, so called, from their having semicircular mouths.

The characters of the genus are these: they are univalve shells of a compact body, with a flat, semicircular, and often dentated mouth. Some of the species have exerted apices, and some depressed.

SE'MINAL *leaves*, are two plain, soft, and undivided leaves, that first shoot forth from the greatest part of all sown seeds; which leaves are very different from those which do succeed on the same plant, in size, figure, surface, and position.

SEMINAL *root*, in natural history, a name given by Grew to that part of the seeds of plants, which may otherwise be called the inner body of the seed: this is distributed through the parenchyma of the seed, but is wholly different from it, and distinguished by Dr. Grew from the radicle, which becomes the plant root in its future growth. The parenchyma of the seed is, in some degree, that to the Seminal root, which the mould or earth is to the plant-root, or radicle; and the Seminal root is to the plant-root what the plant-root is to the trunk. *Grew's Anat. of Plants.*

SEMINI'FEROUS, *bearing or producing seed*, in botany, an epithet

epithet applied to those plants which produce large quantities of seed.

SE'MINARIES, in popish countries, are certain colleges, appointed for the instruction and education of young persons, destined for the sacred ministry. The first institution of such places is ascribed to St. Augustin. And the council of Trent decrees, that children, exceeding twelve years of age, shall be brought up, and instructed in common, to qualify them for the ecclesiastical state, and that there shall be a Seminary of such belonging to each cathedral, under the direction of the bishop.

In the Seminaries of France, none are taken in but young persons ready to study theology, and be ordained. And, for the maintenance of these Seminaries, certain benefices are allotted; or else the clergy of the diocese are obliged to maintain them. These colleges are furnished with halls for the public exercises, and little chambers or cells, where each student retires, studies, and prays apart. Such is the Seminary of St. Sulpitius at Paris.

In the reign of queen Elisabeth, the Roman Catholics projected the founding English Seminaries abroad, that from thence they might be furnished with missionaries, to perpetuate and increase their communion. Accordingly, the college of Douay was founded in 1569, at the expence of Philip II. King of Spain; and Dr. William Allen, an Englishman, was made head of it. In the year 1579, a college was founded at Rome, for the same purpose, by Gregory XIII. who settled 4000 crowns per annum for the subsistence of the society. The famous Robert Parsons, an English jesuit, was rector of this college. King Philip founded another of these nurseries at Valladolid in the year 1589, and one at Seville in 1593. The same prince founded St. Omers in Artois, in 1596. In the next century, more Seminaries were established, at Madrid, Louvain, Liege, and Ghent.

The two colleges of Douay and Rome received such great encouragements, that some hundreds of priests were sent off from thence into England.

By the statute of queen Elisabeth it is made a præmunire to contribute to the maintenance of a popish Seminary. And by one of king James I. no persons are to go, or be sent, to popish Seminaries, to be instructed or educated, under divers penalties and disabilities mentioned in the statute.

The Houses of the society de propaganda fide, established for the preparing ecclesiastics for missionaries among infidels and heretics, are also called Seminaries. The principal of these is that at Rome, called the apostolical college, or Seminary, or the Seminary de propaganda fide.

SE'MINARY, in gardening, is a seed-plot, adapted or set apart for the sowing of seeds. These are of different natures and magnitudes, according to the several plants intended to be raised therein. If it be intended to raise timber of fruit trees, it must be proportionably large to the quantity of trees designed; and the soil should be carefully adapted to the various sort of trees. Without such a place as this, every gentleman is obliged to buy, at every turn, whatever trees he may want to repair the losses he may sustain in his orchard, wilderness, or larger plantations; so that the necessity of such a spot of ground will easily be perceived by every one. But as I have already given directions for preparing the soil, and sowing the seeds in such a Seminary, under the article of NURSERY, I shall not repeat it in this place, but refer the reader to that article.

It is also as necessary, for the support of a curious flower-garden, to have a spot of ground set apart for the sowing of all sorts of seeds of choice flowers, in order to obtain new varieties; which is the only method to have a fine collection of valuable flowers; as also for the sowing of all sorts of biennial plants, to succeed those which decay in the flower-garden; by which means the borders may be annually replenished, which, without such a Seminary, could not be well done.

This Seminary should be situated at some distance from the house, and be intirely inclosed either with an hedge, wall, or pale, and kept under lock and key, that all vermin may be kept out; and that it may not be exposed to all comers and goers, who, many times, do mischief before they are aware of it. As to the situation, soil, and manner of preparing the ground, it has been already mentioned under the article of NURSERY; and, the particular account of raising each sort of plant being directed under their proper heads, it would be needless to repeat it here. *Miller's Gard. Dict.*

SEMI'NIUM, a term used by the writers on fossils to express a sort of first principle, from which the several figured stones, or as they are more usually called the extraneous fossils, are supposed to have their origin.

SEMITE'RTIAN, a kind of complex fever, which deserves our careful observation.

It begins with a horror, and goes off with a sweat, yet not so as to leave the patient entirely free from a fever. But, since it is complicated of an intermittent tertian and a continual quotidian, on one day it is more exasperated, and molests the patient with a horror, and frequently with something of a rigor, attended with bilious vomitings or stools, a burning heat, and exhalations of humid vapours. On the other day the patient is rather sensible of a cold than a horror, and is not much afflicted with heat or thirst; the pulse is more moderate, and the fever more gentle on all accounts; besides, on one day may be observed two kinds of fevers, on the other but one. A Semitertian fever is indeed but rare, but, where it is once settled, very dangerous. An exquisite Semitertian is, when the supplies of peccant matter for the intermittent tertian and continual quotidian are nearly equal; otherwise there cannot be a pure Semitertian, and consequently the disease, as it is thought, will the more easily give way to remedies. *Lommii, Med. Obs.*

Among the epidemic fevers of the intermittent and malignant kind, we, in practice, frequently meet with that species which consists of an intermittent tertian and a quotidian of the continual kind, for which reason it is by the Greeks called ἡμιτριταῖος; and by the Latins semitertiana.

This species of fever generally seizes the patient, in the forenoon, with a violent cold and horror, and a contracted pulse. This state is afterwards succeeded by an heat, which lasts for some hours, is accompanied with a frequent pulse, and remits without being totally removed upon the eruption of the Sweat. Towards the evening the heat is rather increased, after a gentle refrigeration; and next day the disorder is milder, and accompanied with thirst, till about the evening, after a slight horripilation, it again becomes more violent. But, on the third day, the horror again seizes the patient, and is succeeded by a more intense heat, whilst the state of the disorder is the same it was on the first day. So that there is always present a kind of growing fever, the exacerbation of which happens towards the evening; and on the third day, in the morning, this exacerbation is most conspicuous, and accompanied with a rigor. Besides, the strength is impaired, the appetite rendered languid, the sleep defective, and the urine thin and crude; whereas, after the paroxysm of a tertian, it is thick and high-coloured. In coughing a small quantity of crude matter is spit up. This species of fever is, also, frequently accompanied with a pain of the back and abdomen, which latter is, also, tumid. Some, upon the approach of the tertian paroxysm, are afflicted with a nausea and cardialgia; others vomit; others fall into deliquiums; and others become absolutely delirious.

This fever is almost unknown in some parts of Europe, the inhabitants of which generally take it for a malignant intermittent fever; but the former greatly differs from the latter, since it is neither contagious, accompanied with exanthematous efflorescences, nor attended with so considerable a loss of strength. Besides, it has every third day a conspicuous exacerbation accompanied with horror.

Others, in like manner, unjustly confound a Semitertian with a continual tertian; for the latter, otherwise than in the former, has its exacerbation only on the third day, but not in the evening; nor is it wholly continual; but, though it at first seizes with a continual heat, yet, on the third day, it generally loses its violence, and passes into an intermittent tertian.

Nor is a Semitertian to be confounded with a double tertian; for, though the latter seizes every day, yet the paroxysms correspond to each other, and the fever itself perfectly intermits; whereas, in a Semitertian, there is absolutely no intermission, but a remission. The paroxysm, also, happens about the evening, and is always double on the third day.

A Semitertian is, therefore, composed of two fevers, and must, therefore, have a double fomes, and a double cause; that is, the source of the continual fever in the mesentery, in consequence of the intercepted circulation of the blood through its structure, and its consequent inflammatory stagnation in the contiguous nervous coats. But the violent paroxysm, happening on the alternate days, has, as well as a tertian, its seat and cause in the intestines, and especially in the duodenum; for to the winding cavity of this intestine the lymphatic, bilious, and corrupted humours, in consequence of the disorder of the mesentery, are conveyed from the glands, the liver and pancreas; as also crude juices from the stomach, which constitute a morbid fomes; which, mixing with the blood, and being conveyed to the nervous membranes of the spine, induces a preternatural febrile motion.

Among the things which have a tendency to generate a Semitertian, we may reckon all those substances and circumstances which render the juices thick and impure, and especially fill the primæ viæ and vessels of the mesentery with sordes. Hence Semitertians are most generally incident to those, who, neglecting a salutary regimen, eat liberally of sweet, acid, fermentable aliments, and farinaceous substances fried with butter, sugar, and eggs; and to those who lead an idle and too sedentary life; who drink too little; who are too great lovers of sweet wines; or who indulge the passions of the mind, especially sorrow. Semitertians are, also, readily incident to persons after a recovery from acute disorders; to those who are costive; to those who frequently use drastic purgatives; and to such as have the menstrual or hæmorrhoidal discharge suppressed. These fevers are, also, less frequent at other seasons than in the autumn, the fruitful source of terrible fevers, on account of the variety and inequality of the weather, which is highly unfriendly to salutary perspiration,

tion. Semitertian fevers, also, frequently happen to those, who, when overheated, greedily drink cold liquors, or who, when sweating, sit down in moist places.

Semitertians are observed to be more frequent in some countries than in others. Thus Galen, Spigelius, and Baglivi, inform us, that they rage more in Italy than in other climates. And certainly, in that part of the world, the heat, during the day, generates many acrid recrementitious sordes, whilst the cold air of the night hinders the exclusion of these; and the cold drink, of which they are so very fond as to prepare it by putting ice into it, occasions, that the juices in the mesentery, where the resistance is small, and the circulation languid, as it were, stand still, and conceive an inflammatory stagnation. And thus a continual fever is generated, which is changed into a tertian, by the corrupted juices falling from the mesentery to the intestines. The like happens in Hungary, where a similar state of the air, and a liberal use of sweet and spirituous wines, frequently excite Semitertians.

Since, therefore, a Semitertian, besides the common cause of intermittents in the primæ viæ, has, for a foundation, an inflammation, and a continual disposition never to admit of a great remission of the symptoms, nor of a due time for recovering the strength, it is of a very dubious nature, and far more dangerous than a simple intermittent.

For this reason, its progress is quick, since, for the most part, it terminates on the ninth or thirteenth day, either in health, some other disease, or death.

When it is long protracted, the inflammation either comes to a suppuration, and the disorder is changed generally into an hectic or slow fever; or, when there is a violent obstruction of the mesentery, it terminates in a dropsy; or, which happens more rarely, when the primæ viæ are filled with sordes, it ends sometimes in a simple, and sometimes in a double intermittent.

But when the sweat not only breaks out in the decline of the paroxysm, but also on the seventh day, which is critical; or if, after this day, the intestines are put into a commotion, and a bilious, pituitous, or even a bloody flux, is produced, it is a good sign, and prognosticates the solution of the disease; or if there happen violent pains of the abdomen, which are increased at certain stated hours, the disorder is resolved by them, or afterwards terminated by a subsequent sanious and purulent diarrhœa, or an evacuation of a large quantity of black blood by stool.

On the contrary, when none of these circumstances happen, but rather a heat about the præcordia, a tension and pain in the whole region of the stomach, a vomiting, a hiccup, a restlessness, a tossing, and a trembling of the hands, are perceived, they are bad prognostics, and indicate that the inflammation has spread itself farther even to the stomach.

Those who die of a Semitertian are taken off under the access of a violent paroxysm, which keeps the type of a tertian, the inflammation, in the mean time, being far diffused and converted into putrefaction. Thus Spigelius, in his Lib. de Semitertiana, cap. 14, informs us, that he always found this to be the cause of the death of such patients, in the following manner: 'When, says he, I reflect upon what I have observed, in dissecting those who died of Semitertians, I can ascribe their death to nothing else but putrid stagnations in the vessels; for, in the carcasses of such persons, I found inflammations formed of bilious and pituitous blood, about the concave part of the liver, in the stomach, in the great and small intestines, in the mesentery, omentum, and spleen, and often in one or more of these parts, and sometimes in them all; and a supervening gangrene or sphacelus, though perhaps small, was found to be the cause of their speedy death.'

The cure. The two principal intentions to be pursued in the cure of a Semitertian, are,

1. With all expedition either to discuss or hinder the farther spreading of the inflammatory stagnation lodged in the coats of the mesentery and intestines, and exposing the patient to imminent danger.

2. To correct and gently evacuate the febrile matter during the intermission, having a due regard, at the same time, to the critical efforts of nature.

The former of these intentions is excellently well answered, by diaphoretic and gently nitrous powders exhibited frequently in small doses. Thus:

Take of the cerus of antimony, of prepared mother of pearl, and crabs eyes, each one drachm; of the solution of crabs eyes and depurated nitre, each half a drachm; reduce them to a powder, of which, every three hours, fifteen grains may be exhibited in a decoction prepared of two ounces of the roots of vipers-grass, one ounce of the shavings of hartshorn, one ounce of currans, and half an ounce of the roots of succory, boiled for half an hour in four quarts of water.

The same intention is answered, by exhibiting every three hours a spoonful or two of the resolvent and diaphoretic mixtures, prepared of the pectoral and analeptic waters of lily of the valley, galangals, carduus benedictus, vipers-grass, and black cherries, with the distilled vinegar of crabs eyes, diaphoretic antimony, the mixtura simplex, and the syrup of carduus benedictus.

By means of these, the sordes of the primæ viæ, which produce the disorder, being corrected and diluted, are best evacuated by solutions of manna, with a due portion of cream of tartar, rhubarb, raisins, and sal polychrestum; for these, without any commotion of the blood, irritation of the nervous parts, or loss of strength, cleanse the intestines, and greatly contribute to remove the infarctions of the mesentery. This intention is, also, answered by balsamic pills, prepared of bitter extracts, resinous and balsamic gums, and depurated aloes, together with the precipitating nitrous powder, moderately but frequently used. If the more subtile parts of the sordes are, by an increased perspiration, to be eliminated through the cutaneous pores, the essence of scordium mixed with an equal quantity of the anodyne mineral liquor, is of all other medicines the most safe and efficacious.

All cures are to be so managed, as never to disturb or interfere with the critical efforts of nature, but rather to assist them when defective, and moderate them when excessive.

Hence, it is highly prejudicial to exhibit purgatives, especially in the beginning of a Semitertian, since, by that means, the unprepared matter is agitated, the inflammation increased, and the disease disposed to a speedy, though a fatal event.

Saline detersives, exhibited by themselves, are not to be used in a Semitertian, especially in large doses, except antimoniated nitre, to which, and the sal polychrestum, Baglivi justly ascribed so much; for these are possessed of an aperient, diuretic, and gently laxative quality, and may sometimes be commodiously exhibited to the dose of fifteen grains, in a sufficient quantity of some proper decoction.

But if a Semitertian seizes a person who is costive, or if he is long costive during it, his body is only to be rendered soluble, by clysters prepared of paregoric and emollient substances, the carminative seeds, and Venice soap, that thus the primæ viæ may be freed from the excrementitious sordes; for, if this is neglected, nature seeks a way upwards, and excites a vomiting, especially when the biliary ducts in the liver are turgid with an acrid bile.

In the decline of the fever, the physician is to follow the tendency of nature, which often terminates the disorder by a flux, so that on this occasion the above-mentioned laxatives and balsamic pills are commonly used.

In a Semitertian, the physician is to be very cautious in exhibiting emetics, lest he should create a vomiting, or hiccup, or dispose the stomach to an inflammation: but if the peccant matter is to be evacuated by vomit, in consequence of the tendency of nature that way, the intention is sufficiently answered by drinking tepid water with salt, or a very gentle antimonial stimulus.

In a Semitertian, venesection is not proper, except there is a violent plethora, and an intense heat in persons as yet vigorous, and labouring under a suppression of critical hæmorrhages; for, in this case, venesection is absolutely necessary, in order to prevent a mortal inflammation of the intestines; but it is to be used in the very beginning, since, the sooner a proper quantity of blood is taken away, the sooner the cure is accomplished.

The patient is, also, carefully to avoid all hot substances, alexipharmic essences, bezoardic tinctures, a hot regimen, and large quantities of hot liquors; for, by means of these, the heat is increased, the critical discharge of the fomes of the disease through the intestines is disturbed, and the strength impaired by profuse sweats.

Astringent, too fixed, earthy, testaceous powders, and Peruvian bark, are not to be used in a Semitertian; for Baglivi observes, that, by means of these, either mortal inflammations, or slow and hectic fevers, have been brought on.

Though the patient should be afflicted with an exquisite pain of the abdomen, and frequent stools, he is nevertheless to abstain from sedatives, and is only to be relieved by anointing his abdomen with spirituous and corroborative liniments, whilst the tumult and commotion is to be checked by an internal exhibition of diaphoretics.

For ordinary drink, the most proper is the decoction beforementioned; as, also, a decoction of oats prepared in the following manner:

Take of clean washed oats, one pound; of the roots of succory, sarsaparilla, and vipers-grass, each one ounce; of the flowers of red poppy, six pugils; of antimoniated nitre, half an ounce; leaves of scabious, half an handful; and of pure nitre two drachms; boil them in five quarts of common water, to a consumption of a third part, and edulcorate with syrup of carduus benedictus, wild poppy, or citron juice.

In Semitertians, I have, also, found happy effects produced by decoctions of chamomile flowers, and the tops of yarrow, or by extracts prepared from these; for such decoctions and extracts safely alleviate the pains, especially of the hysteric and complicated kind, and, at the same time, by their bitterness, prove excellent antiscorbutic medicines, and restore the due tone of the parts.

As no fever more readily recurs than a Semitertian, so the patient is, after it, carefully to avoid the things already enumerated, as the procatarctic causes of the disorder. All things are to be used temperately; the body is to be kept soluble by mild laxatives; the increase of crudities is to be prevented by stomaftomachics; and, which is of all other circumftances the moft important, the perfpiration is carefully to be kept free and unobftructed; for as in all fevers, fo, alfo, in thofe of the Semitertian kind, the relapfes are far worfe and more obftinate than the original diforder.

Thefe are the general precepts, founded on reafon, and fupported by the indications of nature, by the obfervation of which the cure may be judicioufly attempted, and fuccefsfully performed. But the particular method is to be fuggefted by the fagacity of the phyfician, which is to direct him to the order, dofe, time, and ufe of proper medicines, which, being the fame with thofe employed in the cure of continual quotidian, tertian, and quartan intermittents, may be feen under thefe articles. *Frederic Hoffman.*

SE'MITONE (*Dict.*)— There are three degrees, or leffer intervals, by which a found can move upwards and downwards fucceffively from one extreme of any concord to the other, and yet produce true melody; and, by means whereof, feveral voices and inftruments are capable of the neceffary variety in paffing from concord to concord.— Thefe degrees are the greater and leffer tone, and the Semi-tone. The ratio of the firft is 8 : 9; that of the fecond 9 : 10.

The ratio of the Semi-tone is 15 : 16, its compafs is five commas; which interval is called a Semi-tone, not that it is geometrically the half of either of the tones, for it is more; but becaufe it comes fomewhat near it. It is alfo called the natural Semi-tone, and the greater Semi-tone, becaufe greater than the part it leaves behind, or its complement to a tone, which is four commas.— The Italians alfo call it feconda minore, or a leffer fecond.

Every tone of the diatonic fcale is divided into a greater and lefs, or a natural and artificial Semi-tone. Mr. Malcolm obferves, it was very natural to think of a divifion of each tone, where 15 : 16 fhould be one part in each divifion, in regard this, being an unavoidable and neceffary part of the natural fcale, would readily occur as a fit degree, and the more, as it is not far from an exact half-tone. In effect, the Semi-tones are fo near equal, that, in practice, at leaft, on moft inftruments, they are accounted equal, fo that no diftinction is made into greater or lefs.

Thefe Semi-tones are called fictitious notes, and, with refpect to the natural ones, are expreffed by characters called flats and fharps.

Their ufe is to remedy the defects of inftruments, which, having their founds fixed, cannot always be made to anfwer to the diatonic fcale.

By means of thefe we have a new kind of fcale, called the

SE'MI-TONIC *fcale*, or the *fcale of Semi-tones*: a fcale or fyftem of mufic, confifting of twelve degrees, or thirteen notes, in the octave, being an improvement on the natural or diatonic fcale, by inferting, between each two notes thereof, another note, which divides the interval or tone into two unequal parts, called femi-tones.

The ufe of this fcale is for inftruments that have fixed founds, as the organ, harpficord, &c. which are exceedingly defective on the foot of the natural or diatonic fcale.— For, the degrees of the fcale being unequal, from every note to its octave there is a different order of degrees; fo that from any note we cannot find any interval in a feries of fixed founds: which yet is neceffary, that all the notes of a piece of mufic, carried through feveral keys, may be found in their juft tune, or that the fame fong may be begun indifferently at any note, as may be neceffary for accommodating fome inftruments to others, or to the human voice, when they are to accompany each other in unifon.

The diatonic fcale, beginning at the loweft note, being firft fettled on an inftrument, and the notes thereof diftinguifhed by their names *a . b . c . d . e . f . g*; the inferted notes, or Semi-tones, are called fictitious notes, and to take the name or letter below with a ♯ as *c* ♯ called *c* fharp; fignifying, that it is a femi-tone higher than the found of *c* in the natural feries; or this mark ♭ called a flat, with the name of the note above, fignifying it to be a femi-tone lower. See FLAT and SHARP, in the *Dict.*

Now $\frac{15}{16}$ and $\frac{128}{135}$ being the two femi-tones the greater tone is divided into; and [illegible] and [illegible], the Semi-tones the lefs tone is divided into; the whole octave will ftand as in the following fcheme, where the ratio's of each term to the next are wrote fraction-wife between them below.

Scale of SEMI-TONES.

c . c ♯ *. d . d* ♯ *e . f . f* ♯ *. g . g* ♯ *. a . b*♭ *. b . cc*

[illegible]

For the names of the intervals in this fcale it may be confidered, that as the notes added to the natural fcale are not defigned to alter the fpecies of melody, but leave it ftill diatonic, and only correct fome defects arifing from fomething foreign to the office of the fcale of mufic, viz. the fixing and limiting the founds: we fee the reafon why the names of the natural fcale are continued, only making a diftinction of each into a greater and lefs.— Thus an interval of one Semi-tone is called a leffer fecond; of two Semi-tones, a greater fecond; of three Semi-tones, a lefs third; of four, a greater third, &c.

A fecond kind of femitonic-fcale we have from another divifion of the octave into Semi-tones; which is performed by taking an harmonical mean between the extremes of the greater and lefs tone of the natural fcale, which divides it into two Semi-tones nearly equal.— Thus the greater tone 8 : 9 is divided into 16 : 17, and 17 : 18; where 17 is an arithmetical divifion, the numbers reprefenting the lengths of chords; but, if they reprefent the vibrations, the lengths of the chords are reciprocal, viz. as 1 : $\frac{16}{17}$: $\frac{8}{9}$, which puts the greater Semi-tone [illegible] next the lower part of the tone, and the leffer [illegible] next the upper, which is the property of the harmonical divifion.— After the fame manner the leffer tone 9 : 10 is divided into the two Semi-tones 18 : 19 and 19 : 20, and the whole octave ftands thus:

c . c ♯ *. d . d* ♯ *e . f . f* ♯ *. g . g* ♯ *. a . b*♭ *. b . c*

[illegible]

This fcale, Mr. Salmon tells us, in the Philofophical Tranfactions, he made an experiment of, before the royal fociety, on chords, exactly in thefe proportions, which yielded a perfect concert with other inftruments, touched by the beft hands.— Mr. Malcolm adds, that, having calculated the ratio's thereof, for his own fatisfaction, he found more of them falfe than in the preceding fcale; but their errors were confiderably lefs, which made amends.

SE'NATE (*Dict.*)— The Senate's authority in the Roman republic was very confiderable; they decided what was to be done in matters of peace and war, without faying any thing to the people, to whom the fentiments of the faid body were communicated in thefe terms: Senatus decrevit, populus juffit. It was the Senate's right to give the firft audience to foreign ambaffadors, to difpofe of provinces, appoint triumphs, and receive letters from the generals of their armies concerning the fuccefs of the republic's arms. Their power came fomewhat to be leffened under the emperors; for Auguftus conftituted to himfelf a privy-council, confifting of a certain number of Senators, with whom he confulted concerning the moft important affairs of ftate. Tiberius endeavoured by little and little to affume the power into his own hands. Nero on the contrary ordered, that the Senate fhould retain their ancient rights and privileges; but we may fay with Tacitus, that all this was but a fpecious pretence, wherewith he was minded to colour his ufurpations. All authors are agreed, that the Senate of Rome was of great dignity and authority, but had not a full power nor an abfolute dominion, they having none to command, and much lefs to execute their orders, as Dionyfius of Halicarnaffeus has well obferved; we alfo meet with divers paffages in Livy to this purpofe; Senatus decrevit, populus juffit; that is, the Senate have thought it good, and the people commanded it: and, in fhort, the leaft tribune, that oppofed the Senate, could obftruct all their decrees; and the Senate gave out their orders to the confuls and prætors, no otherwife than if it pleafed them, fi eis ita videtur.

All the great magiftrates had a right to enter into the Senate, but not to give their opinions there, unlefs they were Senators: The fenators children had alfo the fame right, that they might betimes ufe themfelves to the affairs of the republic: the tribunes of the people at firft ftood at the door of the Senate, to know their deliberations, and to oppofe them, in cafe they were contrary to the rights of the people; but they were afterwards admitted in: the confuls, dictators, tribunes of the people, and the governor of Rome, in the conful's abfence, had a right to call the Senate together.

The Senate ufually met three times a month, viz. on the calends, nones, and ides, according to Suetonius: and this ftated affembly was called legitimus fenatus; and all the fenators were obliged to be prefent, under the penalty of a fine. They might be extraordinarily called together any day in each month; and this they called fenatus indictus, or edictus. Thefe affemblies might be held from morning to evening, in three places in the city, appointed for this purpofe, viz. in the temple of Concord, between that place and the capitol, at the gate Capena, and in the temple of Bellona, where they gave foreign ambaffadors audience, before they were introduced into the city. There were alfo a great many more places appointed for this purpofe, as, Curia Hoftilia, Pompeia, and Julia, which the augurs firft confecrated, according to Aulus Gellius and Varro.

The affembly of the Senate began with a facrifice offered to the gods; but Auguftus altered this cuftom, and ordered every fenator to offer a facrifice of wine and incenfe upon the altar of the god, in whofe temple the Senate met, before he took his feat, or could confult about any bufinefs, as Suetonius in his Life, c. 35, informs us. After which he was obliged to take an oath, by touching the altar, and calling the gods to witnefs, that he would give his opinion with fincerity, and without flattery. This being done, the fenators took their places, when the conful, or he who fat as prefident, propofed both the public and private bufinefs, which they were to confult about.

SE'NATOR (*Dict.*)— Romulus inftituted the firft hundred Senators at Rome, which made up the king's council: in order to be a Senator, a man muft be a citizen of Rome, or of the municipal cities that had the fame privileges or freedom: refpect was had to their manners, birth, and eftate: for

for a Senator ought to have a revenue of 4000 pounds for the maintenance of his dignity; but Auguftus required he fhould have 300000 crowns. He was to be at leaft thirty years old before he was made a Senator.

We are not without inftances of children affranchifed, and of perfons yet of a meaner condition, and even ftrangers, who have arrived at the dignity of Senators; but this was brought about either by intrigue, or the emperor's authority. The choice of Senators belonged at firft to the kings; the confuls afterwards were invefted with this power; and, laftly, the cenfors, being obliged every five years to take an account of them, fubftituted others in the room of thofe that were dead, or had been degraded: but, in the decaying time of the republic, the emperors arrogated this power to themfelves, and made as many Senators, and of what quality they pleafed.

The number of Senators varied according to various times: Romulus at firft created a hundred of them, which he called patres; and, after the alliance made with the Sabines, increafed their number to a hundred more. Tarquinius Prifcus, according to Livy, or, as others will have it, king Servius, added alfo an hundred, which he named Patres minorum gentium, becaufe they were not of fo noble an extract as the former. This number of 300 Senators continued to the time of C. Gracchus, tribune of the people; who, oppofing the nobles, made the people add 300 Roman knights to the reft, in order to counterbalance the number of the 300 Senators: thus the number of 600 Senators lafted to the time of Julius Cæfar, who being willing to gratify a great many brave men, who had faithfully ferved him in his wars againft Pompey, increafed the number to 1000 of all forts of people, without diftinction. But Auguftus, to purge this body that was in an ill habit, reduced it to the former number of 600. And fo, of the 300 Senators, the 200 created by Romulus were called Patricii majorum gentium, and the other 100 Adlecti, or Confcripti, a name which afterwards continued to be given to the whole fenate.

Among thefe Senators, there were fome who had a decifive vote, and fpoke their fentiments in the matters that were propofed; and others who did no more than follow thofe fentiments which to them appeared moft reafonable; and this made them be called Pediarii Senatores, who did not declare their own opinions, but fided with thofe whofe opinions they approved of: Aulus Gellius rejects this interpretation, and feems to follow that of Q. Baffus, who fays in his Commentaries, that thofe of the Senators who had never bore the office of curule magiftrate, went a foot to the fenate, and for that reafon were called Pedarii Senatores.

The Senators wore a very large purple tunicle with broad edges called lati-clavii; they had a right to fit or be carried in the curule chair, to affift at plays and fhews in the Orcheftra, and likewife at feafts and the banquet confecrated to Jupiter, in the capitol. The cenfors took an account of them every five years, calling them with a loud voice; and thofe whom they paffed over were degraded from the order of Senators, which were called præterire: but, if the perfon who was paffed over was minded to oblige the cenfor to tell the reafon of it, he was under an obligation to do it, fays Lipfius, and then he was degraded with the greateft ignominy and fhame; this being called ejicere fenatu. He, who was thus degraded, had the remedy of appealing to the people, who, in fpite of the cenfor, did many times re-eftablifh him.

SENEKA, *rattle-fnake-root.* See POLYGALA.

SENNA (*Dict.*)—The feeds fhould be fown early in the fpring, upon a good hot-bed; and, when the plants are come up, and are ftrong enough to tranfplant, they fhould be each planted in a fmall pot filled with light rich earth, and plunged into a frefh hot-bed, in order to bring the plants forward: for, as this is an annual plant, unlefs the plants are brought on in the fpring, they will not flower in this country: therefore, they muft be conftantly kept in the hot-bed all the fummer, obferving to admit plenty of air in warm weather; by which method I have frequently had this plant in flower, but it is very rare that they perfect their feeds in England.

If the feeds of this plant were fent to South Carolina, the plants might be propagated there, fo as to furnifh plenty of the leaves, to fupply the confumption of Great-Britain.

In the Weft-Indies, the inhabitants make ufe of the leaves of feveral fpecies of caffia, inftead of this plant; and, alfo, of thofe of the poinciana, or flower-fence, which is frequently called by them the true Senna.

SENSATION (*Dict.*)— To conceive the manner wherein Senfation is effected, obferve, that all the organs confift of little filaments, or nerves which have their origin in the middle of the brain, are diffufed thence throughout all the members which have any fenfe, and terminate in the exterior parts of the body; that when we are in health, and awake, one end of thefe nerves cannot be agitated or fhaken, without fhaking the other, by reafon they are always a little ftretched; as in the cafe of an extended chord, one part of which cannot be ftirred without a like motion of all the reft.

Obferve, further, that thefe nerves may be agitated two ways, either at the end out of the brain, or that in the brain.— If they be agitated from without, by the action of objects, and their agitation be not communicated as far as the brain; as frequently happens in fleep, when the nerves are in a ftate of relaxation; the foul does not then receive any new Senfation.— But if the nerves happen to be agitated in the brain, by the flux of the animal fpirits, or any other caufe; the foul perceives fomething, though the parts of thofe nerves, that are out of the brain, diffufed through the feveral parts of the body, remain at perfect reft: as likewife is frequently the cafe in fleep.

Laftly, obferve, that experience tells us, we may fometimes feel pain in parts of the body that have been entirely cut off, by reafon the fibres in the brain correfponding to them, being agitated in the fame manner, as if they were really hurt; the foul feels a real pain in thofe imaginary parts.

All thefe things feem to fhew, that the foul refides immediately in that part of the brain wherein the nerves of all the organs of fenfe terminate: we mean, it is there it perceives all the changes that happen with regard to the objects that caufe them, or that have been ufed to caufe them; and that it only perceives what paffes out of this part, by the mediation of the fibres terminating in it.

Thefe things premifed, it will not be difficult to explain how Senfation is performed: the manner whereof may be conceived from what follows. When the point of a needle, for inftance, is thruft againft the hand, that point ftirs and feparates the fibres of the flefh, which fibres are extended from that place to the brain, and when we are awake, are in fuch a degree of tenfion, as that they cannot be ftirred without fhaking thofe of the brain. If then the motion of the fibres of the hand be gentle, that of the fibres of the brain will be fo too; and, if the firft be violent enough to break any thing in the hand, the laft will be ftronger and more violent in proportion.— In like manner, if the hand be held to the fire, the little particles of the wood it throws off in great numbers, and with a great deal of violence, ftriking againft thefe fibres, and communicating a part of their agitation thereto; if the action be moderate, that of the extremities of the fibres of the brain, correfponding to thofe of the hand, will be moderate likewife: if it be violent enough to feparate any of the parts of the hand, as it happens in burning; the motion of the fibres in the brain will be proportionably more violent. This is what befals the body, when objects ftrike upon it.— We are now to confider how the mind is affected.

The mind, we have obferved, refides principally, if we may be allowed to fay fo, in that part of the brain where all the fibres of the nerves terminate. It attends here, as its fenfory, or office, to look to the prefervation of all the parts of the body; and, of confequence, muft be here advertifed of all the changes that happen, and muft be able to diftinguifh between thofe agreeable to the conftitution of the body, and thofe hurtful thereto. Any other abfolute knowledge, without a relation to the body, were ufelefs.— Thus, though all the changes in our fibres do, in reality, confift in motions, which ordinarily only differ as to more and lefs; it is neceffary the foul fhould confider them as changes effentially different; for, though in themfelves they differ but very little, yet, with regard to prefervation of the body, they are to be looked on as effentially different.

The motion, for inftance, which caufes pain, frequently differs exceeding little from that which occafions a pleafing titillation: it is not neceffary there fhould be an effential difference between thefe two motions; but it is neceffary there be an effential difference between the pain and the tickling, which thofe two motions occafion in the foul; for the agitation of the fibres, which accompanies the titillation, informs the foul of the good ftate of the body, that it is able to refift the impreffion of the objects, and that it need not apprehend its being hurt: but the motion which occafions pain, being fomewhat more violent, is capable of breaking fome of the fibres of the body; wherefore it is neceffary the foul be advertifed hereof by fome difagreeable Senfation, that it may provide againft it.

Thus, though all the motions which pafs in the body only differ in themfelves, as to more or lefs, yet, when confidered with regard to the prefervation of life, they may be faid to be effentially different: for this reafon it is, that the foul does not perceive the fhakes, or motions themfelves, which objects excite in the fibres of the flefh: it would be ufelefs to perceive them; and fhe would never be able, thence, to learn whether the objects were capable of doing hurt or good. But fhe perceives herfelf affected with Senfations, which differ effentially, and which fhewing precifely the qualities of the objects, as they regard the body, make her perceive diftinctly, whether or no thofe objects are capable of hurting it.

In effect, from a ftrict examination of the feveral fenfes, it appears, that fenfible objects act no otherwife upon the body, for the producing of Senfation, than by exciting a change in the extreme furface of the fibres of the nerves: the quality of which change depends on the figure, bulk, hardnefs, and motion of the object; fo that, according to all appearance, the moft different objects, which fhould agree in thefe four circumftances, would produce the fame Senfation.

From the various texture of the object, the diverfity of the nerve

nerve affected, the different fabric of the organ of fenfe, the different place in the medulla of the brain where the nerve arifes, and the different degree of motion wherewith the action of the object is applied, arife various Senfations, and ideas, in the mind; none of which reprefent any thing in the action of the object, on in the paffion of the organ. And yet the fame action of the fame object, on the fame organ, always produces the fame Senfation or idea: and the fame ideas neceffarily follow the fame difpofition of the fame fenfible organ, in the fame manner as if the idea perceived were the natural and neceffary effect of the action on the organ.

SENSE (*Dict.*)—Some ufe the word Senfe in a greater latitude; and define it a faculty whereby the foul perceives ideas or images of objects, either conveyed to it from without, by the impreffion of objects themfelves, or excited within by fome effort of the foul of the fenfory itfelf.

Under which notion, Senfe becomes diftinguifhable into two kinds, external and internal: correfponding to the two feveral manners wherein the images of the objects perceived are occafioned, and prefented to the mind, viz. either immediately from without, or from within; that is, either by what we commonly call the five external Senfes, hearing, feeing, &c. or by the internal ones, imagination, memory, and attention; to which fome add hunger and thirft.

But thefe internal Senfes are not ordinarily confidered in the notion of Senfes, nor implied under the word Senfe; but are thus only denominated by analogy.

The means, on the part of the mind, are always the fame; it being one and the fame faculty, whereby we fee, hear, &c.— The means, on the part of the body, are different; as different as are the objects we are concerned to perceive: for, the being and well-being of the animal being the end, nature had in view in giving him any perception of external bodies, by this, the meafure and manner of that perception is regulated: and we have fo many ways of perceiving, and of perceiving fo many things, as the relation we bear to external bodies renders neceffary for the prefervation, &c. of our being.

Hence thofe feveral organs of Senfe, called eye, ear, nofe, palate, and the univerfal one cutis; each of which is fo difpofed as to give fome reprefentation and report to the mind of the ftate of external things, the nearnefs, convenience, hurtfulnefs, and other habitudes; and each of them a different one, according to the degree, and immediatenefs, &c. of the danger, or conveniency. And hence the feveral exercife of thofe organs, hearing, feeing, fmelling, tafting, and feeling.

A late excellent author gives us a more ingenious, extenfive, and philofophical notion of Senfe.—On his principle, Senfe is defined a power of perception, or a power of receiving ideas; if what is abfolutely paffive may be properly called a power.

On fome occafions, inftead of power, he chufes to call it a determination of the mind to receive ideas.—The ideas thus perceived, or raifed in the mind, he calls fenfations. Senfe he confiders, either as natural or moral: and the natural, either as external or internal: though the diftribution is chiefly founded on the common ways of conceiving; for, in reality, they appear to be all natural and neceffary: fome reafons, however, for the diftinction, will be fhewn under the feveral articles thereof.

External SENSES, then, are powers of perceiving ideas, upon the prefence of external objects.—On fuch occafions, we find the mind is merely paffive, and has not power directly to prevent the perception, or idea, or to vary it at its reception; as long as the body is continued in a ftate fit to be acted upon by the external object.

When two perceptions are intirely different from each other, or agree in nothing but the general idea of fenfation; the power of receiving thofe different perceptions is called different Senfes. Thus feeing and hearing denote the different powers of receiving the ideas of colours and founds. And though colours, as well as founds, have vaft differences amongft themfelves; yet is there a greater agreement among the moft oppofite colours, than between any colour and a found: and hence all colours are deemed perceptions of the fame Senfe.

All the feveral Senfes feem to have their diftinct organs, except feeling, which is, in fome degree, diffufed over the whole body.

Internal SENSES (*Dict.*)— Of thefe there are two different fpecies, diftinguifhed by the different objects of pleafure, viz. pleafurable or beautiful forms of natural things, and pleafurable or beautiful actions, or characters of rational agents: whence the internal Senfes become divifible into natural and moral; though what we call the internal natural Senfe, our author calls fimply, and by way of eminence, the internal Senfe.

In reflecting on our external Senfes, we plainly fee, that our perceptions of pleafure, and pain, do not depend directly on our will. Objects do not pleafe us according as we incline they fhould: the prefence of fome objects neceffarily pleafes us, and the prefence of others as neceffarily difpleafes us; nor can we, by our will, any otherwife procure pleafure, or avoid pain, than by procuring the former kind of objects, and avoiding the latter. By the very frame of our nature, the one is made the occafion of delight, and the other of diffatisfaction. In effect, our fenfitive perceptions are pleafant and painful, immediately, and without any knowledge of the cafe of this pleafure and pain, or of the manner how they excite it, or are occafions of it, or without feeing to what further advantage, or detriment, the ufe of fuch objects might tend. Nor would the moft accurate knowledge of thefe things vary either the pleafure, or the pain, of the perception; however it might give a rational pleafure diftinct from the fenfible; or might raife a diftinct joy, from profpect of further advantage in the object, or averfion, from apprehenfion of evil. There is fcarce any object, which our minds are employed about, but is conftituted the neceffary occafion of fome pleafure or pain. Thus we fhall find ourfelves pleafed with a regular form, a piece of architecture, or painting, a compofition of notes, a theorem, an action, an affection, a character; and we are confcious that this pleafure naturally arifes from the contemplation of the idea then prefent in the mind, with all its circumftances, though fome of thofe ideas have nothing of what we call fenfible perception in them; and, in thofe which have, the pleafure arifes from fome uniformity, order, arrangement, imitation; and not from the fimple ideas of colour, or found, or mode of extenfion feparately confidered.

It feems hence to follow, that, when inftruction, education, or prejudice of any kind, raife any defire or averfion towards an object, this defire, or averfion, is founded on an opinion of fome perfection, or deficiency, in thofe qualities, for perception whereof we have the proper Senfes. Thus, if beauty be defired by one who has not the Senfe of fight; the defire muft be raifed by fome apprehended regularity of figure, fweetnefs of voice, fmoothnefs, foftnefs, or fome other quality perceivable by the other Senfes, without relation to the ideas of colour.

The only pleafure of Senfe, which our philofophers feem to confider, is that which accompanies the fimple ideas of fenfation; but there are vaftly greater pleafures in thofe complex ideas of objects, which obtain the names of beautiful and harmonious.— The power, then, whereby we receive ideas of beauty and harmony, has all the characters of a Senfe. It is no matter, whether we call thefe ideas of beauty and harmony perceptions of the external Senfes of feeing and hearing, or not: we fhould rather chufe to call thefe ideas an internal Senfe, were it only for the convenience of diftinguifhing them from other fenfations of feeing and hearing, which men may have without perception of beauty and harmony.

Moral SENSE (*Dict.*)— This moral Senfe of beauty, in actions and affections, may appear ftrange at firft view: fome of our moralifts themfelves are offended at it in my lord Shaftfbury, as being accuftomed to deduce every approbation, or averfion, from rational views of intereft. Our gentlemen of good tafte can tell us of a great many Senfes, taftes and relifhes for beauty, harmony, imitation in painting and poetry; and may we not find, too, in mankind, a relifh for a beauty in characters, in manners? The truth is, human nature does not feem to have been left quite indifferent, in the affair of virtue, to form to itfelf obfervations concerning the advantage or difadvantage of actions, and accordingly to regulate its conduct. The weaknefs of our reafon, and the avocations arifing from the infirmity and neceffities of our nature, are fo great, that very few of mankind could have framed thofe long deductions of reafon, which may fhew fome actions to be, in the whole, advantageous, and their contraries pernicious. The author of nature has much better furnifhed us for a virtuous conduct, than our moralifts feem to imagine, by almoft as quick and powerful inftructions, as we have for the prefervation of our bodies; he has made virtue a lovely form, to excite our purfuit of it, and has given us ftrong affections, to be the fprings of each virtuous action.

SE'NSITIVE *Plant* (*Dict.*)—The ftructure of the Senfitive plant is this: from the large ftems, or main branches of the whole, there part off feveral other leffer ones, and from thefe there go off others ftill lefs, which, by way of diftinction, may be called the ribs of the leaves, as they ferve to fupport a number of leaves arranged on each fide, and ftanding on fhort pedicles in pairs over-againft one another. Several other plants have this fort of compound leaves, as the caffia, colutea, and the like; and all thefe fhut their leaves together at night, and open them again in the morning, in the fame manner as the Senfitive plant does. This periodical opening and fhutting of the leaves is therefore common to many plants, not peculiar to the Senfitive plant; but the wonder in this is, that, befides having this motion periodical and regular, it is to be brought on at other times, and by accidents, there requiring no more than the touching the plant to make it clofe its leaves at any time of the day, which it foon afterwards naturally opens again. This is peculiar to this plant, and refembles the action of an animal which had been injured or frightened. A clofe obfervation alfo of the manner, in which this is performed, will give many hints towards the finding its caufe.

It is a very difficult thing to touch the leaf of a vigorous Sensitive plant so lightly, as not to make it close. Its sensation is extremely delicate; and its large rib or nerve, which runs along its middle, is as it were a hinge, on which the two halves of the leaf move, when they turn upon being touched, till they stand erect, and by that means meet one another. The slightest touch imaginable gives this motion to the side of the leaf which is touched, which is communicated immediately to the other side or half, and they move together; and, if the touch hath been a very little rougher, the opposite leaf on the same rib receives the impression, and closes up in the same manner with that which was actually touched.

Nor is this all; for, when the two sides of each of these leaves move upwards, the pedicle of each half moves upwards at the same time, and by this means they, in some measure, approach towards each other, and make the angles of their pedicles with the main rib, or stalk of the composite leaf, less than before; and the total motion of each leaf is composed of these two motions.

If the touch be still rougher, the whole arrangement of leaves on the same rib feel its influence on each side, and all close in the same manner with the single pair in the preceding instance; and, if the touch be yet stronger than this, the rib itself feels it, and attempts to close in its way, moving itself upwards towards the branch from which it is produced, just as the single pedicles of the leaves did towards it; and, if the touch be yet more hard and rough, the very branches have the sensation propagated to them, and apply themselves to the main stem or trunk of the shrub, as the simple leaves did before to their rib, and that rib to the branch; so that the whole plant in this state forms itself, from a very complexly-branched figure, into a sort of straight cylindric one. The motion which has, of all others, the greatest effect upon this plant, is a shaking one.

These three motions of the plant are performed by means of three distinct and sensible articulations; the first, that of the single leaf to its pedicle; the second, that of the pedicle to its branch; the third, that of the branch to the trunk. The primary motion of all which is the closing of the two halves of the leaf upon this rib, which ought also to be performed in a similar manner, and by a similar articulation: this, however, is much less visible than the others.

These motions are wholly independent on one another, as may be proved by experiment. It should appear, that, if the stalks are moved and collapse towards the branches, or these towards the trunk, that the leaves, whose motion is usually primary to these, should be affected also; yet experiment proves, that it is possible to touch the branches in such a manner, as to affect them only, and make them apply themselves to the trunk, while the leaves feel nothing of the touch: but this cannot be, unless the branches are so disposed, as that they can fall to the trunk without suffering their leaves to touch any other part of the plant in their passage; because, if they do, they immediately become affected. Winds and heavy rains cause the Sensitive plants to shut up their leaves, while easy showers do not at all affect them: it is plain from hence, that the agitation of the plant by the wind, and the strokes given by the large and hasty drops of rain, are what cause the contraction.

By whatever accident the plant has been made to close its leaves, it always regularly opens them again afterwards. This, however, requires different times, according to several circumstances, as the time of the day, the season of the year, and the more or less vigorous and healthy state of the plant: sometimes this is done in ten minutes, sometimes it requires half an hour. And the manner is not less different than the time; for sometimes the leaves unfold themselves first, and sometimes the branches; whereas sometimes all is done at once, and the whole plant seems in motion at a time.

In endeavouring to account for the motions of this plant, Mess. Du Fay and Du Hamel have conjectured, that they are performed by means of a sort of very nice and fine hinges, which communicate one with another by means of very minute and slender cords, which occasion them to act as we see when the plant is sufficiently disturbed, and these cords shaken; and what gives a strong probability to this conjecture is, that the decayed and dying leaves of this plant perform this motion as regularly and vigorously, as those which are fresh and full of juice. It seems plain, that, while the juices are evaporating, and the parenchymatous substance of the leaves drying up, these more solid parts, the lines and cordages, retain their figure; and, consequently, if it is by means of these that the motion is always performed, it will be as well performed in these as in the fresher leaves; which could not be the case, were it owing to the juices.

The natural opening and shutting of the leaves of this plant, at night and morning, are not so fixed but that they are variable also, according to circumstances of place, temperature, &c. In the month of August, a Sensitive plant was carried in a pot out of its usual place into a dark cave; the motion that it received in the carriage shut up its leaves, and they did not open for twenty-four hours afterwards. At this time they became moderately open, but afterwards subject to no changes at night or morning, but remained three days and nights with their leaves in the same moderately open state. At the end of this time they were brought out again into the air, and there recovered their natural periodical motions, shutting every night, and opening every morning, as naturally and as strongly as if it had not been in this forced state; and, while in the cave, it was observed to be very little less affected with the touch, than when abroad in the open air.

Repeated experiments have proved, that it is not the light of the day that opens these plants, nor the darkness of the night that closes them; neither is it the alternate warmth of the day, and cold of the night, that have this effect, since it shuts in nights that are much warmer than the days often are, in which it opens; and the increasing the heat of the place in which it is kept, and marking the increase or decrease on the thermometer, have not been found to have the least effect, as to its sooner or later opening or shutting its leaves.

The most probable conjecture seems, that it is not great heat, or great cold, such as it can bear, that brings on this effect, but the sudden change from one to the other; and this is confirmed by this experiment: that, if one of these plants be raised under a glass bell or case, and the bell or covering be taken off, it immediately closes, even though it be in the middle of the day; and this is also observed, that, the more open or exposed the plant stands, the more strong and lively are its shutting and opening; and that they are most observable in summer, and much less so, when it is kept in a close stove in winter.

The great heats of summer, when there is open sunshine at noon, affect the plant in some degree like cold, causing it to shut up its leaves a little, but never in any great degree. The plant, however, is least of all affected about nine o'clock in the morning, and that is, consequently, the properest time to make experiments on it. A branch of the Sensitive plant, cut off and laid by, retains yet its property of shutting and opening in the morning for some days; and it holds it longer, if kept with one end in water, than if left to dry more suddenly.

The leaves only of the Sensitive plant shut up in the night, not the branches; and, if it be touched at this time, the branches are affected in the same manner as in the day, shutting up, or approaching to the stalk or trunk, in the same manner, and often with more force. It is of no consequence what the substance is with which the plant is touched, it answers alike to all; but there may be observed a little spot, distinguishable by its paler colour in the articulations of its leaves, where the greatest and nicest sensibility is evidently placed.

SENTENCE, in grammar (*Dict.*)—In every Sentence there are two parts necessarily required; a noun for the subject, and a definite verb; whatever is found more than these two, affects one of them, either immediately, or by the intervention of some other, whereby the first is affected.

Again, every Sentence is either simple or conjunct: a simple Sentence is that consisting of one single subject and one finite verb.—A conjunct Sentence contains several subjects and finite verbs, either expressly or implicitly.

A simple Sentence needs no point or distinction; only a period to close it: as, 'A good man loves virtue for itself'.—In such a Sentence, the several adjuncts affect either the subject or the verb in a different manner. Thus the word 'good' expresses the quality of the subject, 'virtue' the object of the action, and, 'for itself,' the end thereof.—Now none of these adjuncts can be separated from the rest of the Sentence: for, if one be, why should not all the rest? And, if all be, the Sentence will be minced into almost as many parts as there are words.

But, if several adjuncts be attributed in the same manner either to the subject or the verb, the Sentence becomes conjunct, and is to be divided into parts.

In every conjunct Sentence, as many subjects, or as many finite verbs as there are, either expressly, or implied, so many distinctions may there be. Thus, 'My hopes, fears, joys, pains, all center in you:' and thus Cicero, 'Catilina abiit, excessit, evasit, erupit.'—The reason of which pointing is obvious; for, as many subjects or finite verbs as there are in a Sentence, so many members does it really contain. Whenever, therefore, there occur more nouns than verbs, or contrariwise, they are to be conceived as equal. Since, as every subject requires its verb, so every verb requires its subject, wherewith it may agree: excepting, perhaps, in some figurative expressions.

Indeed, there are some other kinds of Sentences which may be ranked amongst the conjunct kind, particularly the absolute ablative, as it is called: Thus, 'Physicians, the disease once discovered, think the cure half wrought:' where the words, 'disease once discovered', are equivalent to, 'when the cause of the disease is discovered.'— So also in nouns added by apposition; as, 'The Scots, a hardy people, endured it all': so also in vocative cases and interjections; as, 'This, my friend, you must allow me:' And, 'What, for heaven's sake, would he be at!'

The case is much the same, when several adjuncts affect either the subject of the Sentence, in the verb, in the same manner; or at least something, whereby one of them is affected: as, 'A good, wise, learned man, is an ornament to the commonwealth:' where the several adjectives, denoting so many qualities of the subject, are to be separated from one another.—

 Again,

Again, when I say, 'Your voice, countenance, gesture terrified him': the several nominative cases denote so many modes of the verb, which are likewise to be distinguished from each other. The case is the same in adverbs; as, 'He behaved himself modestly, prudently, virtuously'.—In the first example, the adjuncts immediately affect the subject; in the third, the verb; in the following one, another adjunct: as, 'I saw a man loaden with age, sickness, wounds.'

Now, as many such adjuncts as there are, so many several members does the Sentence contain; which are to be distinguished from each other, as much as several subjects, or finite verbs: and that this is the case in all conjunct Sentences, appears hence, that all these adjuncts, whether they be verbs or nouns, &c. will admit of a conjunction copulative, whereby they may be joined together.—But, where-ever there is a copulative, or room for it, there a new member of a Sentence begins.

SE'PTICS, among physicians, an appellation given to all such substances as promote putrefaction.

From the many curious experiments made by Dr. Pringle to ascertain the Septic and antiseptic virtues of natural bodies, it appears that there are very few substances of a truly Septic nature. Those commonly reputed such by authors, as the alcaline and volatile salts, he found to be no wise Septic. However, he discovered some, where it seemed least likely to find any such quality; these were chalk, common salt, and the testaceous powders. He mixed twenty grains of crab's eyes, prepared with six drachms of ox's gall, and an equal quantity of water. Into another phial he put an equal quantity of gall and water but no crab's-eyes. Both these mixtures being placed in the furnace, the putrefaction began much sooner, where the powder was, than in the other phial. On making a like experiment with chalk, its Septic virtue was found to be much greater than that of the crab's-eyes: nay, what the doctor had never met with before, in a mixture of two drachms of flesh with two ounces of water and thirty grains of prepared chalk, the flesh was resolved into a perfect mucus in a few days.

To try whether the testaceous powders would also dissolve vegetable substances, the doctor mixed them with barley and water, and compared this mixture with another of barley and water alone. After along maceration by a fire, the plain water was found to swell the barley, and turn mucilaginous and sour; but that with the powder kept the grain to its natural size, and though it softened it, yet made no mucilage and remained sweet.

Nothing could be more unexpected, than to find sea-salt a hastener of putrefaction, but the fact is thus: one drachm of salt preserves two drachms of fresh beef in two ounces of water, above thirty hours, uncorrupted, in a heat equal to that of the human body; or, which is the same thing, this quantity of salt keeps flesh sweet twenty hours longer than pure water. But then half a drachm of salt does not preserve it above two hours longer. Twenty-five grains have little or no antiseptic virtue, and ten, fifteen, or even twenty grains manifestly both hasten and heighten the corruption. The quantity, which had the most putrefying quality, was found to be about ten grains to the above proportion of flesh and water.

Many inferences might be drawn from this experiment. One is, that since salt is never taken in aliment beyond the proportion of the corrupting quantities, it would appear that it is subservient to digestion, chiefly by its Septic virtue, that is, by softening and resolving meats: an action very different from what is commonly believed.

It is to be observed that the above experiments were made with the salt kept for domestic uses. *Pringle's Observ. on Dis. of the Army.*

SEPTIFO'LIOUS *Plants*, they are such has have but seven leaves.

SERJA'NIA, a name given to a genus of plants by father Plumier, who discovered them in America, in honour to the reverend father Philip Sergeant, who was of the order of the Minims, and a person well versed in the knowledge of botany and physic.

The characters of the genus are:

It hath a rose-shaped flower, consisting of four or more leaves, which are placed in a circular order: from whose flower-cup arises the pointal, which afterwards becomes a fruit composed of three cells having three wings, and each cell containing one round seed.

SE'RIES (*Dict.*)—The doctrine of Series is of extensive use in mathematics, and has been carried far, though not so far as could be wished. It would far exceed the limits of our design to enter into a detail of the discoveries relating to this subject.

A Series being proposed, one of the principal questions concerning it, is, to find the law of its continuation. For this no universal rule can be given; but it often happens, that the terms of the Series, taken two and two, three and three, or in greater numbers have an obvious and simple relation, by which the Series may be determined and produced indefinitely. Thus, if unity be divided by $1-x$, the quotient will be a geometric progression, any term of which will be to the next antecedent term as x to 1. And by this property the Series $1+x+x^2+x^3+$ &c. may be distinguished and produced ad infinitum. In like manner, in other cases of division, other Series's will arise, the terms of which will have a constant relation to each other, and this relation recurring always throughout the Series, they have been called recurring Series by Mr. de Moivre, who first considered them, and applied them to the solution of several intricate problems.

In many cases, the relation of the terms of a Series is not constant, as it is in those arising from division. Yet this relation often varies according to a certain law obvious upon inspection. Thus in the Series $1+\frac{1}{2}x+\frac{3}{8}x^2+\frac{5}{16}x^3+\frac{35}{128}x^4+$ &c. the terms may be continued indefinitely by the continued multiplication of these fractions $\frac{1}{2}$, $\frac{3}{4}$, $\frac{5}{6}$, $\frac{7}{8}$, &c. And the following Series. $1+\frac{1}{6}x+\frac{3}{40}x^2+\frac{5}{112}x^3+\frac{35}{1152}x^4+$ &c. may be continued by the multiplication of the fractions $\frac{1\times1}{2\times3}$, $\frac{3\times3}{4\times5}$, $\frac{5\times5}{6\times7}$, $\frac{7\times7}{8\times9}$, &c.

Series's of this kind may be defined by differential equations. The equation defining a Series is that which assigns the relation of the terms generally by their distances from the beginning. To do this Mr. Stirling conceives the terms of the Series to be placed as so many ordinates on a right line given by position, and he, for the sake of simplicity, takes unity as the common interval of these ordinates. The initial terms of the Series he denotes by the initial letters of the alphabet, A, B, C, D, &c. A being the first, B the second, C the third, &c. And he denotes any term in general by the letter T, and the rest following it in order, T′, T″, T‴, T⁗, &c. He denotes the distance of the term T from any given term, or from any given intermediate point between two terms, by the indeterminate quantity z: so that the distances of the terms T′, T″, T‴, &c. from the said term or point, will be, $z+1$, $z+2$, $z+3$, &c. for the increment of the absciss is the common interval of the ordinate, or terms of the Series applied to the absciss.

These things being premised, let this Series be proposed, 1, $\frac{1}{2}x$, $\frac{3}{8}x^2$, $\frac{5}{16}x^3$, $\frac{35}{128}x^4$, &c. in which the relations of the terms are $B=\frac{1}{2}Ax$, $C=\frac{3}{4}Bx$, $D=\frac{5}{6}Cx$, $E=\frac{7}{8}Dx$, &c. The relation in general will be defined by the equation, $T'=\frac{z+\frac{1}{2}}{z+1}Tx$, where z denotes the distance of T from the first term of the Series. For, by substituting 0, 1, 2, 3, 4, &c. successively in the place of z, the relations of the terms of the proposed Series will arise. In like manner, if z be the distance of T from the second term of the Series, the equation will be $T'=\frac{z+\frac{3}{2}}{z+2}Tx$, as will appear by substituting the numbers -1, 0, 1, 2, 3, 4, &c. successively for z. Or, if the indeterminate z denotes the place of the term T in the Series, its successive values will be 1, 2, 3, 4, &c. and the equation will be $T'=\frac{z-\frac{1}{2}}{z}Tx$.

It appears therefore that innumerable differential equations may define one and the same Series, according to the different points from whence the origin of the abscissa z is taken. And, on the contrary, the same equation defines innumerable different Series's by taking different successive values of z. For in the equation $T'=\frac{z-\frac{1}{2}}{z}Tx$, which defines the Series abovementioned, when 1, 2, 3, 4, &c. are the successive values of the abscissæ; if $1\frac{1}{2}$, $2\frac{1}{2}$, $3\frac{1}{2}$, $4\frac{1}{2}$, &c. be successively substituted for z, the relations of the terms arising will be $B=\frac{2}{3}Ax$, $C=\frac{4}{5}Bx$, $D=\frac{6}{7}Cx$, &c. from whence the Series A, $\frac{2}{3}Ax$, $\frac{8}{15}Ax^2$, $\frac{16}{35}Ax^3$, $\frac{128}{315}Bx^4$, &c. will arise, which is different from the former. But the equation will always determine the Series from the given values of the abscissa and of the first term, when the equation includes but two terms of the Series; as in the last example, where the first term being given, all will be given. But, when the equation includes three terms, two must be given; and three must be given, when it includes four, and so forth.

If the Series x, $\frac{1}{6}x^3$, $\frac{3}{40}x^5$, $\frac{5}{112}x^7$, $\frac{35}{1152}x^9$, &c. be proposed, where the relations of the terms are, $B=\frac{1\times1}{2\times3}Ax^2$, $C=\frac{3\times3}{4\times5}Bx^2$, $D=\frac{5\times5}{6\times7}Cx^2$, &c. the equation defining this Series will be $T'=\frac{2z-1\times2z-1}{2z\times2z+1}Tx^2$, or $T'=\frac{4zz-4z+1}{4zz+2z}Tx^2$, where the successive values of z are 1, 2, 3, 4, &c. *Stirling's Methodus differentialis, in the Introduction.*

This may suffice to convey a notion of these differential equations, defining the nature of Series's. But, as to the application of these equations in finding the sums of Series's, it would require a treatise to explain it. We must therefore refer the curious to that excellent one just quoted, as also to Mr. de Moivre's Miscellanea Analytica, and several curious papers by Mr. Euler in the Acta Petropolitana.

A Series often converges so slowly as to be of no use in practice. Thus, if it were required to find the sum of the Series $\frac{1}{1.2}+\frac{1}{3.4}+\frac{1}{5.6}+\frac{1}{7.8}+\frac{1}{9.10}+$ &c. which lord Brounker

found

found for the quadrature of the hyperbola true to 9 figures, by the mere addition of the terms of the Series, Mr. Stirling computes that it would be neceſſary to add a thouſand millions of terms for that purpoſe; for which the life of man would be too ſhort. But by that gentleman's method the ſum of the Series may be found by a very moderate computation.

Recurring SERIES, is uſed for a Series which is ſo conſtituted, that, having taken at pleaſure any number of its terms, each following term ſhall be related to the ſame number of preceding terms according to a conſtant law of relation.

Thus in the following Series,

A B C D E F

$1 + 2x + 3xx + 10x^3 + 34x^4 + 97x^5 +$ &c. in which the terms being reſpectively repreſented by the capitals A, B, C, D, &c. we ſhall have

$$D = 3Cx - 2Bxx + 5Ax^3$$
$$E = 3Dx - 2Cxx + 5Bx^3$$
$$F = 3Ex - 2Dxx + 5Cx^3, \text{ \&c.}$$

Where it is evident, that the law of relation between D and E is the ſame as between E and F, each being formed in the ſame manner from the three terms which precede it in the Series.

The quantities $3x - 2xx + 5x^3$ taken together and connected with their proper ſigns is what Mr. de Moivre calls the index or the ſcale of relation. Sometimes the bare coefficients $3 - 2 + 5$ are called the ſcale of relation. And this ſcale of relation ſubtracted from unity is called the differential ſcale. Thus in the foregoing Series the ſcale of relation being $3x - 2xx + 5x^3$, the differential ſcale will be $1 - 3x + 2xx - 5x^3$.

A recurring Series, with its ſcale of relation, being given, the ſum of that Series continued in infinitum will alſo be given. For inſtance, ſuppoſe a Series $a + bx + cxx + dx^3 + ex^4 +$ &c. where the relation of the coefficient of any term to the coefficients of any two preceding terms may be expreſſed by $f - g$; that is, $e = fd - gc$; and $d = fc - gb$, &c. Then will the ſum of the Series continued in infinitum be, $\frac{a + bx - fax}{1 - fx + gxx}$

To facilitate the intelligence of this rule by a particular example, aſſume any Series whereof the two firſt coefficients are given, ſuch as 2 and 5, and ſuppoſe f and g to be reſpectively 2 and 1; then we ſhall have the following Series, $2 + 5x + 8xx + 11x^3 + 14x^4 + 18x^5 +$ &c.

And the ſum $= \frac{2 + 5x - 4x}{1 - 2x + xx} = \frac{2 + x}{\overline{1-x}^{\,2}}$

For the proof divide 1 by $\overline{1-x}^{\,2}$

$1 - 2x + xx)\,1\,(1 + 2x + 3xx + 4x^3 +$ &c. which

multiplied by $2 + x$

$2 + 4x + 6xx + 8x^3 +$ &c.

gives $+ x + 2xx + 3x^3 +$ &c.

the product $= 2 + 5x + 8xx + 11x^3 +$ &c. $=$ the given Series.

Analogous rules might be derived for more complex caſes; and Mr. de Moivre's general rule is,

Firſt, take as many terms of the Series as there are parts in the ſcale of relation. Secondly, ſubtract the ſcale of relation from unity, the remainder is the differential ſcale. Thirdly, multiply the terms taken in the Series by the differential ſcale, beginning at unity, and ſo proceeding orderly, remembering to leave out what would naturally be extended beyond the laſt of the terms taken. Then will the product be the numerator, and the differential ſcale will be the denominator of a fraction expreſſing the ſum required.

But we muſt here obſerve that, when the ſum of a recurring Series extended ad infinitum is found by Mr. de Moivre's rule, it ought to be ſuppoſed, that the Series converges indefinitely, that is, that the terms may become leſs than any aſſigned quantity. For, if the Series diverges, that is, if its terms continually increaſe, it is not true, that the rule gives the ſum. For the ſum in ſuch caſes is infinite, or greater than any given quantity, whereas the ſum exhibited by the rule will often be finite. The rule therefore in this caſe only gives a fraction, the reduction of which into a Series gives the propoſed Series.

Thus $\frac{1}{\overline{1-x}^{\,2}}$, reduced to an infinite Series gives the recurring Series $1 + 2x + 3xx +$ &c. whoſe ſcale of relation is $2 - 1$ and its ſum by the rule will be $\frac{a + bx - fax}{1 - fx + gxx} = \frac{1 + 2x - 2x}{1 - 2x + xx} = \frac{1}{\overline{1-x}^{\,2}} =$ the quantity from which the Series aroſe. But this quantity cannot in all caſes be deemed equal to the infinite Series $1 + 2x + 3xx$, &c. For, ſtop were you will, there will always be a ſupplement required to make the product of the quotient by the diviſor equal to the dividend. When the Series, indeed, converges infinitely, the ſupplement diminiſhing continually, it becomes leſs than any aſſigned quantity, and is therefore, without error, reputed nothing; but, in diverging Series, this ſupplement becomes indefinitely great, and the Series deviates indefinitely from the truth.

A recurring Series being given, the ſum of any number of the terms of that Series may be found. This is prob. III. p. 73. Miſcel. Analyſ. and prop. V. p. 196. of the Doctrine of Chances. One ſolution of the ſimpleſt caſe will be ſufficient to give an idea of the method there uſed.

Let there be a geometric progreſſion $a + ax + ax^2 + ax^3 +$ &c: it is required to find the ſum of a number n of its terms. Then will the laſt term be ax^{n-1}. Suppoſe the progreſſion continued ad infinitum, and we ſhall have two infinite progreſſions, the firſt beginning with a, and the ſecond with ax^n. Now the difference of the ſum of theſe two muſt be the ſum of the number n of terms. By the rule the ſum of the firſt infinite progreſſion will be $\frac{a}{1-x}$; and the ſum of ſecond will be $\frac{ax^n}{1-x}$. But $\frac{a}{1-x} - \frac{ax^n}{1-x} = \frac{a - ax^n}{1-x}$, which will therefore be the ſum of a number n, of terms.

This quantity $\frac{a - ax^n}{1-x}$ is equal to $\frac{ax^n - a}{x - 1}$, which laſt expreſſion, calling $ax^{n-1} = l$, will be equivalent to this, $\frac{lx - a}{x - 1}$, which is the common rule for finding the ſum of any geometric progreſſion of which a, the firſt term; x, the ratio; and l the laſt term are given.

The Series reſulting from the diviſion of unity by $\overline{1-x}^{\,p}$ or $\frac{1}{\overline{1-x}^{\,p}} = \overline{1-x}^{\,-p}$ is $1 + px + p \times \frac{p+1}{2}xx + p \times \frac{p+1}{2} \times \frac{p+2}{3}x^3 +$ &c. And the ſum of any number of terms expreſſed by n of this Series will be $\frac{1 - x^n}{\overline{1-x}^{\,p}} - \frac{nx^n}{\overline{1-x}^{\,p-1}} - \frac{\frac{n}{1} \times \frac{n+1}{2}}{\overline{1-x}^{\,p-2}}x^n - \frac{\frac{n}{1} \times \frac{n+1}{2} \times \frac{n+2}{3}}{\overline{1-x}^{\,p-3}}x^n -$ &c. which is to be continued till the number of terms $= p$.

This theorem is of uſe in finding the ſums of progreſſions of figurate numbers, and others.

Suppoſe, for inſtance, it were required to find the ſum of any number n of terms of the geometric progreſſion $1 + x + xx + x^3 +$ &c. generated by $\frac{1}{1-x}$. Here $p = 1$. And the ſum will conſequently be $= \frac{1 - x^n}{\overline{1-x}^{\,p}} = \frac{1 - x^n}{1 - x}$.

Again, if the ſum of a number n of terms of the Series $1 + 2x + 3xx + 4x^3 +$ &c. were required. The Series is generated from $\frac{1}{\overline{1-x}^{\,2}}$. Then $p = 2$. And the ſum $= \frac{1 - x^n}{\overline{1-x}^{\,2}} - \frac{nx^n}{1-x}$. Suppoſe $x = 1$, then will the ſum be $\frac{nn + n}{2} = n \times \frac{n+1}{2}$ which is the ſum of the arithmetical progreſſion $1 + 2 + 3 + 4 +$ &c. continued to the number n of terms. But it is to be obſerved that it requires a particular artifice to derive the ſum from the general rule: for at firſt ſight the ſum appears under this form $\frac{1 - 1}{\overline{1-1}^{\,2}} - \frac{n}{1-1}$ which determines nothing.

In like manner, the ſum of a number n of terms of the Series of triangular numbers will be found to be $n \times \frac{n+1}{2} \times \frac{n+2}{3}$, as in Miſcel. Analyſ. p. 168.

By the like methods the ſum of any number of ſquares, cubes, &c. of the natural Series of numbers may be found. Which may alſo be done by Sir Iſaac Newton's differential method.

3° In a recurring Series any term may be obtained whoſe place is aſſigned. For, after having taken ſo many terms of the Series, as there are terms in the ſcale of relation, the Series may be protracted till it reach the place aſſigned. But, if that place be very diſtant from the beginning of the Series, the continuation of the terms will prove laborious: other methods have therefore been contrived.

Theſe queſtions have been reſolved in many caſes, beſides thoſe of recurring Series. But, as there is no univerſal method for the quadrature of curves, neither is there one for the ſummation of Series; there being a great analogy between theſe things, and ſimilar difficulties ariſing in both.

SERMONES, the title Horace gives to his Satires.

The critics are divided about the reaſon of the name. The opinion of father Boſſu ſeems well grounded; a mere obſervation of feet and meaſure, ſuch as we find in Plautus, Terence, and in Horace's Satires, he thinks, is not ſufficient to conſtitute verſe; to determine the work to be poetical, or diſtinguiſh it from proſe; unleſs it have ſome farther air or character

racter of poetry, ſomewhat of the fable, or ſublime. Hence it is that Horace calls his Satires proſe Sermones. *Dict. de Trevoux.*

SERMONS, orations or diſcourſes delivered by the clergy of the Chriſtian church, in their religious aſſemblies.

In the ancient church, immediately after the reading of the pſalms, and leſſons out of the ſcriptures, before the catechumens were diſmiſſed, followed the Sermon, which the biſhop, or ſome other, appointed by him, made to the people. This, being done in the preſence of the catechumens, was therefore reckoned a part of the miſſa catechumenorum, or ante-communion ſervice. Such diſcourſes were commonly termed homilies, ὁμιλίαι, which ſignifies indifferently any diſcourſe of inſtruction to the people. Among the Latins they were frequently called tractatus, and the preachers, tractatories.

Preaching, anciently, was one of the chief offices of a biſhop; inſomuch that, in the African churches, a preſbyter was never known to preach before a biſhop in his cathedral church, till St. Auſtin's time. In the eaſtern church, preſbyters were indeed allowed to preach before the biſhop; but this was not to diſcharge him of the duty, for ſtill he preached a Sermon at the ſame time after them. In the leſſer churches of the city and country, the office of preaching was devolved upon the preſbyters; but deacons never were allowed to perform it. There are numberleſs paſſages in the writings of the fathers, which ſpeak of preaching as a duty indiſpenſably incumbent on a biſhop. Many canons of councils either ſuppoſe, or enjoin it: and, in the imperial laws, there are ſeveral edicts of the ſecular power to the ſame purpoſe.

It has been a queſtion, whether laymen were ever allowed by authority to make Sermons to the people. It is certain, they did it in a private way, as catechiſts, in their catechetic ſchools at Alexandria, and other places; but this was a different thing from public preaching in the church. Sometimes the monks, who were only laymen, took upon them to preach; but this was cenſured, and oppoſed, as an uſurpation of an office that did not belong to them. Yet, in ſome caſes, a ſpecial commiſſion was given to a layman to preach; as in the caſe of Origen, who was licenſed by Alexander, biſhop of Jeruſalem, to preach and expound the ſcriptures in the church, before he was in orders. As to women, whatever gifts they could pretend to, they were never allowed to preach publicly in the church; agreeably to the apoſtolic rule, Let your women keep ſilence in the churches, &c. But they might teach thoſe of their own ſex, as private catechiſts, and prepare them for baptiſm. And this was the office of the deaconeſſes. The Montaniſts were a noted ſect for giving the liberty of preaching to women, under the pretence of inſpiration by the ſpirit; for they had propheteſſes, women-biſhops, and women-preſbyters.

Next to the perſons, the manner, in which the office of preaching was executed, comes to be conſidered. And firſt it is obſervable, that they had ſometimes two or three Sermons preached in the ſame aſſembly, firſt by the preſbyters, and then by the biſhops. When two or more biſhops happened to be preſent in the aſſembly, it was uſual for ſeveral of them to preach, one after another, reſerving the laſt place for the moſt honourable perſon. In ſome places, they had Sermons every day, eſpecially in Lent, and the feſtival days at Eaſter. In many places, they had Sermons twice a day, for the better edification of the people. But this is chiefly to be underſtood of cities and large churches: for in the country pariſhes there was not ſuch frequent preaching.

The next thing to be obſerved is, their different ſorts of Sermons, and different way of preaching. Theſe are diſtinguiſhed into four kinds: 1. Expoſitions of ſcripture. 2. Panegyrical diſcourſes upon the ſaints and martyrs. 3. Sermons upon particular times, occaſions, and feſtivals. 4. Sermons upon particular doctrines, or moral ſubjects. There are examples of all theſe kinds in St. Chryſoſtome's and St. Auſtin's homilies, the two great ſtandards of preaching, in the Greek and Latin churches. But, though moſt of theſe were ſtudied and elaborate diſcourſes, penned and compoſed before-hand, yet ſome were alſo extempore, ſpoken without any previous compoſition, and taken down in ſhort-hand from the mouth of the preacher. Origen was the firſt that began the way of extempore preaching in the church.

Upon this account it was uſual for the preacher to uſher in his diſcourſe with a ſhort prayer, for divine aſſiſtance. In this ſenſe we are to underſtand St. Chryſoſtome, when he ſays, We muſt firſt pray, and then preach. Sometimes, before they began to preach, they uſed the common ſalutation, Pax vobis, Peace be with you; to which the people anſwered, And with thy ſpirit. And ſometimes they prefaced the Sermon with a ſhort form of benediction, eſpecially in times of calamity and diſtreſs, or of happy deliverances out of them. Sometimes they preached without any text, and ſometimes upon more texts than one. Neither did they entertain their auditory with light and ludicrous matters, or fabulous and romantic ſtories, ſuch as thoſe with which preaching ſo much abounded in the age before the reformation.

And, as they were careful in the choice of their ſubject, ſo were they in the manner of dreſſing it up, and delivering it, that they might anſwer the true ends of preaching. St. Auſtin has laid down excellent rules, for the practice of Chriſtian eloquence; and, if we will take his character of the ancient preachers, it was, in ſhort, this: that their diſcourſes were always upon weighty and heavenly matters, and their ſtyle anſwerable to the ſubject, being plain, elegant, majeſtic, and nervous; fitly adapted to inſtruct and delight, to convince and charm their hearers. It was no part of the ancient oratory to raiſe the affections of the auditory, either by geſticulations, or the uſe of external ſhews and repreſentations of things in their Sermons, that is now very common in the Romiſh church. As to the length of their Sermons, ſcarce any of them would laſt an hour, and many not half the time. And among thoſe of St. Auſtin there are many, which a man may pronounce diſtinctly, and deliver decently, in eight minutes. They always concluded their Sermons with a doxology to the Holy Trinity. And it is farther obſervable, that the preacher uſually delivered his Sermon ſitting, and the people heard it ſtanding; though there was no certain rule about this, but the cuſtom varied in different churches.

It was a peculiar cuſtom in the African church, when the preacher chanced to cite ſome remarkable text, in the middle of his Sermon, for the people to join with him in repeating the cloſe of it. St. Auſtin takes notice of this in one of his Sermons, where, having begun thoſe words of St. Paul, The end of the commandment is — the people all cried out, Charity, out of a pure heart. But it was a much more general cuſtom for the people to teſtify their eſteem for the preacher, and approbation of his Sermon, by public applauſes, and acclamations in the church. Thus, we are told, the people applauded St. Chryſoſtome's Sermons, ſome by toſſing their garments, others moving their plumes, others laying their hands upon their ſwords; and others waving their handkerchiefs, and crying out, Thou art worthy of the prieſthood, &c. Many of the auditors practiſed the art of notaries, and took down the Sermons of the moſt eminent preachers, word for word, as they delivered them. By this means ſome of their extempore diſcourſes were handed down to poſterity, which elſe would have died with the ſpeaking.

The Roman catholics call the Sermon, the prone. After the goſpel, the preacher goes to the bottom of the ſteps of the altar, on the epiſtle ſide, where he kneels down, and offers prayers to God for the action he is going about. Then he aſcends the pulpit; where he firſt bows to the croſs, and then to the chief of the congregation. He likewiſe croſſes himſelf; and, whenever he pronounces the name of Jeſus and Mary, he takes off his cap, and bows. In Italy, he does the ſame thing, whenever the reigning pope is named in the Sermon. Before the biſhop, or when the holy ſacrament is ſolemnly expoſed on the altar, it is uſual to preach bare-headed.

The manner of preaching in Italy is very indecent, the behaviour of the preachers being like that of ſtage-dancers: they are extravagant in their geſtures, they ſtrike with their hands and feet, roll their eyes, and walk from one end of the pulpit (which is very long and wide) to the other, with immoderate and ridiculous vivacity. Their fineſt Sermons (ſays a celebrated traveller) are thoſe that raiſe the moſt laughter. 'The Capuchins (adds he) never preach, but on terrible ſubjects; they ſeize their own beards, clap their hands, and ſcream enough to fright one. The other day, I heard a Carmelite, who was preaching to the repentant nuns of the holy croſs, on the ſubject of Mary Magdalen. In order to raiſe a more exalted idea of the ſacrifice his penitent had made of the pleaſures of the world, he ſpent a whole quarter of an hour in painting her out as the moſt charming creature under heaven: not one feature, in the moſt perfect body, was omitted; and he talked more like a moſt accompliſhed painter, than a preacher.' In Italy, there are ſeldom any Sermons, but in the time of Advent and Lent. The friars preach in their convents upon topics, which we may call eternal; for they ſeldom loſe ſight of their founders, or of ſome particular practices, which they are fond of, ſuch as the roſary, and ſcapulary, and St. Francis's girdle. In ſome cities of Italy, are itinerant preachers, who carry about with them little moveable pulpits.

In Spain they often preach in the public ſquares and high ſtreets, and ſeldom fail of a numerous audience. The preachers take great pains to affect their hearers, and to this end they frequently ſtrike their breaſt or face, and the whole congregation does the ſame thing. They who draw moſt tears are thought the beſt preachers.

The Greek Chriſtians ſeldom have any Sermons. Preaching, as Tournefort aſſures, is ſo far aboliſhed, that there is ſcarce a pulpit to be ſeen in all their churches: however, when a father does attempt to mount the roſtrum, he delivers himſelf in the moſt awkward manner imaginable; and has two crowns for his diſcourſe, which conſiſts only of a tedious train of empty words, without the leaſt order or coherence, and which the preacher himſelf (ſays our author) underſtands no more than the people.

SERPENT, *ſerpens*, in zoology, the name of a genus of animals, which Mr. Ray defines to be creatures breathing by means of lungs, having only one ventricle in the heart, having no feet, and having a long body, covered with ſcales.

To which he adds, that in cold seasons they can bear hunger a long time. The greater part of the Serpent class are poisonous, and dangerous in their bite, leaving a mischievous liquor in the wound, made by their tooth, which, mixing by this means immediately with the blood, is of fatal consequence; though the whole creature may be eaten with safety, or even the poisonous liquor, which does this mischief in the wounded, tasted without hurt.

Notwithstanding that Serpents respire by means of lungs, they do not take in and discharge their breath by such short intervals as other animals, but what they have once inspired will serve them a long time; for as they are of a cold nature, and therefore their necessary warmth very small, they do not require such an eternally renewed supply of that pabulum of vital heat, as those which have more of it; and as with us they lie half the year torpid, and half dead, their vital warmth at that time, like fire smothered under ashes, barely exists, and needs perhaps no more air than what the creature took in at one inspiration, before its laying itself down for the season, which serves it till the life-renewing spring returns.

Serpents, according to Mr. Ray, may be divided into the poisonous and the harmless; the first having long dentes exerti, with poisonous liquors contained at their bottom, which on biting they discharge into the wound: the others wanting these teeth, and this poison.

They may also be divided, in regard to their generation, into the oviparous and viviparous; but this is a less firmly founded distinction than may be supposed, since all Serpents are truly and properly produced of eggs; and the only difference is, that some deposit their eggs in dung-hills, and the like places, to be hatched by accidental heat; while others retain those eggs to be hatched in their own bodies, and so bring forth living young ones. Of the first kind is the common snake, of the latter the viper. *Ray's Syn. Quad. et Serp. p.* 284. *See Plate* XLIII. *fig.* 1.

SERPENS *bubalinus.*—Mr. Cleyer has given a very remarkable account, in the German Ephemerides, of the prodigious size and voracious appetite of this Serpent, and its manner of feeding. This gentleman assures us that they grow to the length of five feet, and are surprisingly daring in attacking large creatures for prey. Their neck, he observes, is so small, in proportion to the creatures they seize, that it is a wonder that they can swallow them whole, which yet experience shews they certainly do, having no power of tearing them to pieces. This gentleman saw a complete stag taken out of the belly of one of these snakes, with all its limbs remaining on: and at another time a wild goat which had been swallowed in the same manner, and from another a complete porcupine, a very troublesome morsel; and there was once an instance, in the Molucca islands, of a woman big with child being thus sucked down whole by one of these creatures. *Ray's Syn. An.*

The method of their managing their prey is this: when thoroughly lank, lean, and hungry, the Snake lies in wait for any thing it can seize; he darts out upon the prey, and, seizing it with his mouth, winds his body round that of the creature; and this he is able to do with such force, that he will often, in twisting himself firmly round the creature, break the bones within its skin. This he continues, and at the same time is biting, with his terrible mouth, all the tender parts of the creature, till he has destroyed it; or, if it be an animal too strong to be killed by these simple folds, it will drag it to some neighbouring tree, and, tying it fast against that, draw its body so forcibly round it, as to crush all its bones to pieces by the help of that solid resisting body. The part it usually seizes with its teeth, at the same time, is the creature's nose, which he bites so forcibly as not only to stop the breath, but to occasion a discharge of blood, which helps to forward its destruction.

But the most singular attack, ever known to have been made by this creature, is that recorded by the same author, of its seizing a buffalo; which it destroyed in the manner above described, though it was a long time about it, and was obliged to have recourse to the method of tying it up to a tree, against which it broke its bones severally, with a noise that was heard to a great distance. When the creature had thus destroyed its prey, it continued breaking of the bones, till there was not one left whole in the body, and the whole resembled a shapeless mass of matter.

The jaws and throat of this, and of the other Serpent-kind, though small and narrow, are prodigiously extensible, and made so by nature, for the swallowing these morsels. The Snake, when the prey lay in this state before it, licked it all over, and covered it thick with its saliva, and that so regularly, that the whole carcase looked as if daubed over with glue. This done, it opened its jaws to a monstrous extent, and sucked in the head of the prey, and, continuing incessantly sucking, at length drew down the whole body.

This is a work of time, and very often two or three days are employed in it. And, when the animal is thus got down, the snake is swelled and bloated up all over with it, and is no longer in a state of offending, or even of defending itself, or so much as running away; and the people of the places where this species is common, well know this, and find it an easy thing to destroy them in this state, and are very happy when they catch one, as their flesh is a very delicate food. *Ephem. Germ. Ann.* 12. *Obs.* 7.

SERPENT, in music, a wind-instrument, serving as a bass to the cornet, or a small shawm, to sustain a chorus of singers in a large vessel. It had its name Serpent from its figure, as consisting of several folds or wreaths, serving to take off its length, which would otherwise be six or seven feet; it is usually covered with leather, and consists of three parts, a mouth-piece, neck, and tail. It has six holes, by means whereof they give it the compass of two octaves.

SERPENT-*stones*, a name given by some to the cornua ammonis, a beautiful fossil shell, which resembles a Serpent coiled up.

These are frequent in many parts of the world, besides the plenty we have of them in England, and elsewhere. The accurate observer, Mr. Harenberg, found prodigious numbers of them on the banks, and among the sand of a river in Germany. He traced this river through its several windings for many miles, and among a great variety of belemnitæ, cornua ammonis, and cochlitæ, of various kinds. He found also great quantities of wood, of recent petrifaction, carrying in it at that time the plain marks of the axe, by which it had been cut from the trees then growing on the shore. The water of this river he found, in a dry season, and when the supplies of its natural springs were not diluted with rains, to be considerably heavier than common water; and many experiments shewed him that it contained ferrugineous, as well as stony particles, in great quantity, whence the petrifactions in it appeared the less wonderful, though many of them of recent date.

Of the cornua ammonis, or Serpent-stones, he there observed more than thirty different species, and doubts not but there are many more yet unobserved. They lie immersed in a bluish fossil stone, of a soft texture, and fatty appearance. They lie in this in prodigious numbers, and of a great variety of sizes, from the larger known sorts, down to such as could not be seen without very accurate inspection, or the assistance of a microscope. Such as lie in the softest of these stones are soft, like their matrix, and easily crumble to pieces; others are harder. In a piece of this stone, of the bigness of a finger, it is common to find thirty, or more, of these fossils; and often they are seen only in form of white specks, too minute to shew their figure, till examined by the microscope. But what is most observable of the cornua ammonis of this place is, that they are often found growing not only to, but into one another, in such a manner, that they cannot be supposed ever to have been inhabited by any living fish, especially the specimen which is pierced by the other. This author is of opinion that they grow, and are formed where they are; and attempts to prove it by affirming, that they have an actual increase in size there in a little time, and that not only if left in their beds, but if taken out, and put into a glass of the water. This is an opinion wholly different from the received one at present in the world, and perhaps will be found erroneous on farther trials. *Act. Erudit.* 1727.

SERPENTS *tongues.* The island of Malta abounds with glossopetræ, or the petrified teeth of sharks, which, from their resemblance to a tongue, are by the vulgar supposed to be the tongues of Serpents turned into stone by some miracle of St. Paul, when he was there. This island abounds not only with these, but with bufonitæ, and vast numbers of other remains of sea productions. These things, notwithstanding their perfect resemblance of the same bodies now found recent in mouths of living fishes, &c. are by some supposed never to have been real parts of fishes, but to have been formed where they now lie by some lusus of nature, or plastic seeds. This, however, is an idle and absurd opinion; and Agustino Scilla, who has written at large on the fossils of this island, gives a very rational account of their being the real remains of animals, which, according to his system, it is no way wonderful to find there. The universal deluge has doubtless been of power to bring all the fossils we find into the places where we now see them buried, even in the midst of quarries of stone, in the middle of inland countries; but in regard to the island of Malta, which so abounds with them at this time, he supposes that, long since the time of the creation, and even without the assistance of the general deluge, it may have been formed out of the sea, and that it appears plainly to have been at first no other than a mass of soft mud, with an immense number of sea shells, teeth of fishes, and other remains of sea animals, mingled among it; and that these, subsiding as low as they could among that thickening matter, have made the island what we now find it, that is, a heap of earth with these things, in vast quantities, buried in it, and that at different depths, but principally not far from the surface.

That this collection of matter was occasioned by a flood of some kind, is highly probable; but it is not necessary to have recourse to Noah's flood for it, though that might as well cause it as any other; but it might also be formed by an irruption of the ocean into the Mediterranean, or by an inundation of the Tuscan sea driven by vehement winds, or any other means, that way: and, when the origin of this island is thus allowed, it is not to be wondered at, that an immensity of the refuse parts of animals, inhabitants of those waters, should be left in the places where they had time to subside. And though there are found among these teeth, &c. in the island of Malta, great quantities of ſhells, of ſuch ſpecies as are not natives of thoſe ſeas, this is no objection to the opinion; ſince it is well known that the winds when violent, as they probably were about the time of the formation of that iſland, will bring ſuch light bodies as ſhells a vaſt way in water.

It is a common obſervation, that the eaſt and ſouth-eaſt winds bring to the coaſt of Calabria great quantities of beautiful ſhells, none of which are found living in the ſeas thereabout. The bufonitæ, or toadſtones of Malta, are plainly the grinder teeth of the lupus and ſargus dentex, as alſo of the aurata, and ſeveral other fiſh, which have ſuch round teeth in the hinder part of their jaws. The ſhells found in this iſland, and other places, are ſo plainly thoſe of once living animals, that the remains of the body of the fiſh is plainly to be diſtinguiſhed in ſome of them: and in others the lamellæ are laid together, and coated over one another, in the very ſame manner as in the recent ſhell fiſh.

It is objected, that theſe ſhells are produced in the places where they lie, becauſe they are found in great cluſters together, all of the ſame kind; but this is no material objection, but is eaſily ſolved upon the common principles: for, if we ſuppoſe a number of diſſimilar bodies, ſeveral of every kind, to be ſuſpended in the ſame quantity of water, and that water be put in motion, we ſhall ſee them all confuſedly blended together, while the motion is violent, but they will, as that becomes more calm, ſeparate themſelves, and thoſe of the ſame nature will, in a great meaſure, get together, and ſubſide in parcels ſeparately from the reſt. Thus, if ſtraws, ſticks, egg-ſhells, pebbles, and common cockle-ſhells, were to be thus ſhook together, the conſequence would be, that in a large tub of water they would naturally each parcel ſubſide together in different parts of the bottom; and, though in the neighbourhood of one another, yet the ſtraws would not be mixed with the pebbles, nor the egg-ſhells with the cockles, any more than it is really found, that the different ſpecies of ſhells are mingled in the earth.

It is alſo to be added, that theſe ſhells have ſubſided, not in water, but in a thicker fluid, compoſed of mud and water, and this has kept them more aſunder than common water alone would have done; and we ſhall find, on examining the bowels of the earth, that, though the ſhells, in the ſame maſs of earth, or ſtone, are generally principally of one kind, yet they are neither always ſo, nor perfectly ſo, but that often they are confuſedly blended among other kinds, and more often have ſome few of other ſpecies blended among them; as a few cockle-ſhells might be among the pebbles, in the familiar inſtance mentioned above, and by ſome particular accidents, even in that caſe, the whole ſet of bodies, excepting the very lighteſt, might happen to be blended together.

The mountains of Sicily afford ſome few gloſſopetræ, or ſnakes-tongues, but they are few in number, and worſe prepared than thoſe of the iſland of Malta; which is probably owing to the high ground of thoſe mountains being leſs likely to receive the refuſe of the ſea, and its ſoil, which is ſandy, being leſs fitted to preſerve them when there, than the marl, of which the iſland of Malta conſiſts.

The echini marini, or ſea eggs, and their ſpecies, which are very frequent among the Serpents-tongues of Malta, all lie upon the ſurface of the ground, or near it; whereas the gloſſopetræ lie deeper, though at no great depth. This is a plain effect of all theſe things having been really animal bodies, and having floated in the mud, of which that iſland was formed; for in this it could not be otherwiſe, but that the gloſſopetræ, or Serpents-tongues, being heavy, would ſubſide in the water, while the light ſhells of theſe other animals would float on, or near the ſurface.

The opinion of theſe bodies growing from ſeminal principles is alſo greatly weakened by the ſituation of them in the earth. If they grew from ſeeds as plants, we ſhould doubtleſs ſee them, like plants, all bending one way, the points of all upwards, and their roots downwards; but on the contrary, both in the iſland of Malta and elſewhere, theſe things are found in the moſt different directions imaginable; ſome with their bottoms upwards, ſome downwards, ſome horizontal, and others in all the intermediate angles. Some have ſuppoſed the gloſſopetræ, in particular, to grow from roots in the earth, becauſe they uſually have roots different from the other parts, and becauſe they ſtick very firmly in the earth at theſe roots, but are very eaſily looſened in any other part. It is certain, indeed, that theſe parts, at the bottom of the gloſſopetræ, are their roots, and that their ſpungy texture was intended for their taking in nouriſhment; but this was their uſe when in the head of the fiſh, not when in the earth; and the reaſon of their adhering more firmly to the earth in this, than in any other part, is only that they are more ſpungy and porous here, and that, in other parts where they are ſmooth and even, the earth can have no hold of them; but, where they are thus rough, as they ſubſided with a moiſt earth like mud about them, they naturally become connected ſtrongly to it in drying, as part of it was received into their pores, and not broken from the reſt, till by forcing them out afterwards. *Philoſ. Tranſ.* N°. 219.

Some affirm that the gloſſopetræ are natural cryſtalliſations of ſalt, and that to this their regular figure is owing; but it is to be anſwered, that their figure is not ſo regular as theſe objectors ſeem to ſuppoſe, but that there are as many different ſhapes of them, as there are of teeth, in the different parts of the jaw of the ſame ſhark, or in the jaws of different ſpecies of ſharks now found living; and, if they were cryſtalliſations of ſalt, the whole cryſtalliſation would be of one and the ſame ſurface and texture; which is not the caſe, ſince the root, as before obſerved, is always very different from the body of the tooth, and the ſubſtance different in even the various parts of the body. Salts are ſalts throughout, and a ruby, a cryſtal, or a diamond, is the ſame in all its parts; but this is not the caſe in the gloſſopetræ, but they are compoſed of a cortical and a medullary part, like the teeth of living ſharks: and it is to be obſerved, that, when any of theſe gloſſopetræ are found broken, as they frequently are, the fracture is found raw and unaltered, which ſhews that it has happened before they came to the place where they are now found, and that they have no growth or vegetation there, to heal or cover it; for, if there were, it would be ſkinned over, as the wounds of plants and animals always are, when in a perfect ſtate and living.

Whenever the gloſſopetræ are taken carefully up out of the earth in Malta, the marl or earth, which ſerved for their bed, is found to contain all their minuteſt traces and lineaments, like wax from a ſeal. This is a proof that the marl was as ſoft as melted wax when they were put into it, and that they were of their full ſize and growth when placed there, not having grown, or had any increaſe, in that place.

The apophyſes, or proceſſes in the gloſſopetræ, are alſo a ſtrong proof of their being no other than real ſharks teeth, ſince they exactly anſwer to thoſe in the teeth of recent ſharks, by which every tooth is received or inſerted into its neighbour in the jaw. Nay, whereas ſharks teeth are mortiſed into one another in ſuch a manner, that a man may eaſily tell which belong to each ſide, which lie near the throat, and which near the front of the mouth; and whereas, in a ſhark's mouth, the teeth on the left ſide will not fit on the right, nor thoſe above ſerve below, but that on ſeeing a recent tooth, a perſon of judgment will be able to ſay what part of the mouth it belonged to; ſo in the foſſil ſhark's teeth, or gloſſopetræ, there is not any one which may not be referred to the particular part of the mouth of the living animal, and could have belonged to no other. *Auguſtino Scilla, de Petrifac.*

SE'RPYLLUM, *mother-of-thyme*, in botany, the name of a genus of plants, whoſe characters are:

It hath trailing branches, which are not ſo woody and hard as thoſe of thyme, but in every other reſpect is the ſame.

There are but two of theſe ſpecies, commonly cultivated in gardens, viz. the lemon-thyme, and that with ſtriped leaves; the firſt for its agreeable ſcent, and the other for the beauty of its variegated leaves. Theſe were formerly planted to edge borders; but as they are very apt to ſpread, and difficult to preſerve in compaſs, they are diſuſed at preſent for that purpoſe. All theſe propagate themſelves very faſt by their trailing branches, which ſtrike out roots from their joints into the earth, and thereby make new plants; ſo that from a root of each there may be ſoon a large ſtock increaſed. They may be tranſplanted either in ſpring or autumn, and love an open ſituation, and a dry undunged ſoil; in which they will thrive and flower exceedingly, and continue ſeveral years.

It may not be improper here to take notice of a common miſtake, which generally prevails concerning this plant; which is, that the ſheep which feed upon this plant, afford the ſweeteſt mutton; whereas it is very certain, that the ſheep will not eat it; nor, ſo far as I have been capable of obſerving, is there any animal that will, it being extremely bitter to the taſte.

SERRA'TULA, *ſaw-wort*, in botany, the name of a genus of plants, whoſe characters are:

It hath a floſculous flower, conſiſting of ſeveral florets, divided into many parts reſting on the embryo, and contained in a ſcaly empalement, like to the greater centaury; from which this differs in having ſmaller heads; and from the knap-weed in having the borders of the leaves cut into ſmall ſharp ſegments, reſembling the teeth of a ſaw.

SE'RUM *aluminoſum*, *alum-whey*, a form of medicine preſcribed in the late London Pharmacopœia, made of a pint of milk boiled to whey with a quarter of an ounce of alum. *Pemberton's Lond. Diſp.*

SE'SAMUM *oily-grain*, in botany, the name of a genus of plants, whoſe characters are:

The flowers are produced from the wings of the leaves, without any foot-ſtalk; the flower-cup conſiſts of one leaf, divided into five long ſlender ſegments: the flower is of one leaf, in ſhape like thoſe of the fox-glove: the pointal, which riſes in the middle of the flower, afterwards becomes an oblong four-cornered pod, divided into four diſtinct cells, which are replete with eſculent ſeeds.

In England, theſe plants are preſerved in botanic gardens as curioſities. Their ſeeds muſt be ſown in the ſpring upon an hot-bed; and, when the plants are come up, they muſt be tranſplanted in a freſh hot-bed, to bring them forward. After they have acquired a tolerable degree of ſtrength, they ſhould be planted into pots filled with rich light ſandy ſoil, and plunged into another hot-bed, managing them as hath been directed for amaranthus's; to which I ſhall refer the reader, to avoid

avoid repetition: for, if these plants are not brought forward thus in the former part of the summer, they will not produce good seeds in this country; though, after they have flowered, if the season is favourable, they may be exposed in a warm situation, with other annual plants. When these plants have perfected their seeds, they decay, and never continue longer than one season.

SE'SELI-*seed*, in the materia medica, the name of the seed of a plant, called also by some libanotis, and growing three or four feet high, with leaves like fennel, but of a paler green. It is a native of warm climates. The seed ought to be chosen moderately large, of a longish shape, heavy, clean, and of a greenish colour, fresh, and of a grateful smell. It affords, by distillation, a very large quantity of an essential oil, and is hot and dry. It incides, opens, and discusses, and is cephalic, neurotic, pectoral, and nephritic. It is good against epilepsies, apoplexies, vertigoes, and all disorders of the head and nerves. *Lemery's Dict. of Drugs.*

SETS, a term used by the farmers to express the young plants of the white thorn, and other shrubs, which they use to raise their quick, or quick-set hedges.

The white thorn is the best, of all trees, for this purpose, and under proper regulations, its Sets seldom fail of answering the farmers utmost expectations.

The first thing to be considered by the person, who is about to plant a quick-set hedge, is what nature the land is of where it is to stand, as whether it is clay, sand, or gravel. It is always proper to take the Sets from a worse land, than that they are to be planted on, otherwise they will never grow well. The Sets are about the thickness of a man's thumb, and cut within four or five inches of the ground. If the quick is intended only for a hedge, without a bank or ditch, let the Sets be planted almost perpendicular in two rows, at about twelve inches distance from each other; and, if there is to be a ditch and a bank, that is to be first provided. The ground is to be marked out with a line, and a ditch dug three feet wide at the top, one foot wide at the bottom, and two feet deep. When the ditch is digging, on that side where the quick is to stand, let the turf be laid evenly on the ground, with the grassy side downwards: upon this some fine mould is to be laid, to bed the quick Sets in, and they are to be laid upon it with their ends inclining upwards, and at about twelve inches asunder. They must be carefully gathered, and such as are straight, smooth, and well rooted, are only to be chosen. At every thirty feet there should be planted with the Sets a young oak, ash, or some other such tree, to grow up along with the hedge. When a complete row of the Sets is thus laid, cover them with a layer of fine mould, and lay over that another layer of the turf; and upon this a third layer of mould, so deep, that its surface may be a foot above the row of Sets: on this bed place another row of the like Sets at the same distances, but placed between the others; cover this as the other, and then make up the bank with the earth dug out of the bottom of the ditch, and on its top set the dry, or dead hedge: this will shade the under plantation, and will be a defence till the Sets are grown up into a live hedge. The stakes for the dead hedge are to be driven into the bank so low as to reach the firm ground, and are to be placed at two feet and a half distance from one another.

Oak-stakes are the best for this purpose, and sallow and black thorn are esteemed next to these. The small bushes cut from them must be laid below, but not too thick, that they may shade the young plantation without smothering it, and defend its young shoots from the biting of cattle: the long bushes are to be laid at top to bind in the stakes by interweaving them. To add a farther strength to the hedge, it may be eddered as the farmers call it: this is binding the tops of the stakes with some small long poles, or sticks on each side. When this is all done, the stakes should be new drove a little, because the making the hedge, and the eddering it, are apt to loosen them a little.

The young plants must be constantly weeded, and great care must be taken to preserve them from the bitings of cattle, especially of sheep. If they have been cropped, or are not found to grow well, it is a good custom among the farmers to cut them down to the ground, or within an inch of it, for after this they usually send out new roots, and shoot very vigorously. *Mortimer's Husbandry.*

SETA'CEUS *Vermis*, in natural history, a name given by Dr. Lister to that long and slender water-worm which so much resembles a horse-hair, that it has been supposed by the vulgar to be an animated hair of that creature.

SETTEE', a vessel, very common in the Mediterranean, with one deck, and a very long and sharp prow. They carry, some two masts, some three, without top-masts. Their yards and sails are like the misen. The least of them are of sixty tons burthen. They serve to transport cannon, and provision for ships of war and the like.

SE'TTING, the term used by sportsmen to express a manner of attacking partridges, in order to the taking them, by means of a dog peculiarly trained to that purpose. The setting-dog generally used is a long land-spaniel, taught by nature to hunt partridges more than any other game, and, in his untaught state, running over the fields in search of them, with an alacrity that is truly wonderful; yet by art this creature is brought under such excellent command, that he will, in the midst of his highest career, attend to the least hem from his master, and stand still to look in his face, and take his orders by the slightest signals; and, when he is so near his game, that it is almost in his mouth, he will stand stock still, or lie down on his belly, till his master arrive, and he receives his directions.

The Setting-dog, being taken to the haunt of the partridges, is to be cast off, and sent to range; but he must be made to keep near the sportsman, and not to run wildly on, but to beat all the ground regularly. On being reproved for ranging too wildly and too far, he will keep close the whole day, and at times look up in his master's face to know if he does right or wrong. If in the dog's ranging he stops of a sudden, the sportsman is to make up to him, and as there is certainly game before him, he must be ordered to advance; if he refuse this, and look back and shake his tail, it is a signal that they are close before him, and the sportsman is then to make a circumference, and look with a careless eye before the dog's nose to see where they are, and how they lie; then going up, and staking down one end of the net, he is to command the dog to lie still, and to draw the net gently over the birds; then making in with a noise, he is to spring them, and they will be entangled and taken, as they rise. It is a rule with fair sportsmen, when they take a covey in this manner, always to let the cock and hen go.

SE'VENTH, *(Dict.)* — In thorough basses the Seventh, whether double, simple, major, or minor, is marked by a figure of 7; but, if it be accidentally flat, or minor, thus, 7♭, or ♭7. If sharp, or major, thus, ♯7, or 7♯. Again, if, when it is naturally minor, it be marked with a flat, it must be diminished.

SE'WEL-*coronde*, a name given by the natives of Ceylon to a species of cinnamon, which, when chewed, is of a mucilaginous nature, like the cassia; this dries well, and is very firm and hard, and has the appearance of a very fine cinnamon, but it has very little taste, and a disagreeable smell. The natives take advantage of the handsome appearance of this kind of cinnamon, and are very apt to mix it with the good kind, to the great detriment of the buyer. *Philos. Trans.* N°. 409.

SEXA'NGLE, in geometry, a figure having six sides, and consequently six angles.

SEXUALI'STÆ, among botanical authors, those who have established the classes of plants upon the differences of the sexes, and parts of fructification in plants, according to the modern method, as Linnæus, &c. See the article *Sexes of* FLOWERS.

SHAD, *alausa*, in zoology, the name of a sea-fish of the herring kind, called also the mother of herrings, and by some authors clupea and trissa, and by the ancients trichis, or trichias.

It is very common in many seas, and in some of our large rivers which lie near the sea. They run up these in great numbers in the months of March and April, and are then very fat; in May they become lean, and then go down to the sea again. They usually swim in large shoals together. *Willughby's Hist. Pisc.*

SHAGGE, in zoology, a name by which we commonly call a water fowl, common on the northern coasts, and called by Mr. Ray corvus aquaticus minor, or the lesser cormorant, being properly a bird of the cormorant kind.

SHA'KER *Pigeon*, a kind of pigeons, of which there are two sorts, the broad-tailed, and the narrow-tailed. The first is the finest, and most valued. It has a beautiful long thin neck, which bends like the neck of a swan, leaning towards the back. It has a full breast, and a very short back, and a tail consisting of a great number of feathers, seldom less than four and twenty, which it spreads in an elegant manner, like the tail of a turkey-cock, and bends it up so, that it meets the head. It is commonly all white, but sometimes is red, yellow, or blue-pied. The longer the neck of this bird is, the more it is valued.

The second, or narrow-tailed Shaker, has a shorter and thicker neck, and a longer back. It is esteemed by many a different species, but seems only a mixed breed with some other pigeon. They are called Shakers, from a tremulous motion which they have in their necks, when courting. *Moore's Columbarium.*

SHA'MBLE, in mining, a term used to express a sort of nich, or landing-place, left at certain distances in the adits of mines. The method of digging the tin mines in Devonshire, and some parts of Cornwall, is this: they sink their way in such a breadth, as is sufficient for them to stand and work, and at every fathom they leave a square place vacant, to which the ore is to be thrown up with shovels, as it is dug. This they do from cast to cast; that is, as far as a man can conveniently throw up the ore with his shovel. Thus the ore, as it is dug by the beelmen, is thrown up by the shovelers, who follow them from Shamble to Shamble, till it comes to the top of the mine. This, however, is but an inconvenient way, and the use of these Shambles is generally supplied by a winder at the opening of the mine, which manages two buckets, the one of which is sent down empty, while the other is sent up full; and one man employed below to load, and another above to empty. *Philos. Trans.* N°. 69.

SHAMBRIE'R, in the manege, is a long thong of leather,

made

made faſt to the end of a cane, in order to animate a horſe, and puniſh him, if he refuſes to obey the rider.

SHA'MMY (*Dict.*) — Beſides the ſoftneſs and warmneſs of the leather, it has the faculty of bearing ſoap without damage, which renders it very uſeful on many accounts.

In France, &c. ſome wear the ſkin raw, without any preparation: it is alſo uſed for the purifying of mercury; which is done by paſſing it through the pores of this ſkin, which is very cloſe.

The true chamoiſe leather is counterfeited with common goat, kid, and even ſheep-ſkin; the practice of which makes a particular profeſſion, called by the French chamoiſure. The laſt, though the leaſt eſteemed, is yet ſo popular, and ſuch vaſt quantities prepared, eſpecially about Orleans, Marſeilles, and Tholouſe, that it may not be amiſs to give the method of preparation.

Manner of SHAMOISING, *or of preparing ſheep, goat, or kid-ſkins in oil, in imitation of* SHAMMY. — The ſkins being waſhed, drained, and ſmeared over with quick-lime on the fleſhy ſide, are folded in two, length-wiſe, the wool outwards, and laid on heaps; and ſo left to ferment eight days; or, if they had been left to dry after fleaing, fifteen days.

Then they are waſhed out, drained, and half dried; laid on a wooden leg, or horſe, the wool ſtripped off with a round ſtaff for the purpoſe, and laid in a weak pit, the lime whereof had been uſed before, and had loſt the greateſt part of its force.

After twenty-four hours they are taken out, and left to drain twenty-four more; then put in another ſtronger pit. This done, they are taken out, drained, and put in again, by turns; which begins to diſpoſe them to take oil: and this practice they continue for ſix weeks in ſummer, or three months in winter; at the end whereof they are waſhed out, laid on the wooden leg, and the ſurface of the ſkin on the wool-ſide peeled off, to render them the ſofter; then, made into parcels, ſteeped a night in the river, in winter more; ſtretched, ſix or ſeven over one another, on the wooden leg; and the knife paſſed ſtrongly on the fleſh-ſide, to take off any thing ſuperfluous, and render the ſkin ſmooth.

Then they are ſtretched, as before, in the river; and the ſame operation repeated on the wool-ſide; then thrown into a tub of water with bran in it, which is brewed among the ſkins till the greateſt part ſtick to them; and then ſeparated into diſtinct tubs, till they ſwell, and riſe of themſelves above the water.

By this means, the remains of the lines are cleared out: they are then wrung out, hung up to dry on ropes, and ſent to the mill, with the quantity of oil neceſſary to ſcour them: the beſt oil is that of ſtock-fiſh.

Here, they are firſt thrown in bundles into the river for twelve hours, then laid in the mill-trough and fulled without oil till they be well ſoftened; then oiled with the hand, one by one, and thus formed into parcels of four ſkins each, which are milled and dried on cords a ſecond time, then a third; then oiled again and dried.

This proceſs is repeated as often as neceſſity requires: when done, if there be any moiſture remaining, they are dried in a ſtove, and made up into parcels wrapped up in wool: after ſome time they are opened to the air, but wrapped up again as before, till ſuch time as the oil ſeems to have loſt all its force, which it ordinarily does in twenty-four hours.

The ſkins are then returned from the mill to the chamoiſer, to be ſcoured; which is done by putting them in a lixivium of wood-aſhes, working and beating them in it with poles, and leaving them to ſteep till the lye have had its effect; then they are wrung out, ſteeped in another lixivium, wrung again, and this repeated till all the greaſe and oil be purged out. When this is done, they are half dried, and paſſed over a ſharp-edged iron inſtrument, placed perpendicular in a block, which opens, ſoftens, and makes them gentle: laſtly, they are thoroughly dried, and paſſed over the ſame inſtrument again, which finiſhes the preparation, and leaves them in form of Shammy.

Kid and goat ſkins are ſhamoiſed in the ſame manner as thoſe of ſheep; excepting that the hair is taken off, without the uſe of any lime; and that, when brought from the mill, they undergo a particular preparation, called ramalling; the moſt delicate and difficult of all the others.

It conſiſts in this, that, as ſoon as brought from the mill, they are ſteeped in a lixivium; taken out, ſtretched on a round wooden leg, and the hair ſcraped off with a knife; this makes them ſmooth, and, in working, caſt a kind of fine nap; the difficulty lies in ſcraping them evenly.

SHANK, or SHANK-*painter*, in a ſhip, is a ſhort chain faſtened under the fore-maſt ſhrouds, by a bolt, to the ſhip's ſides, having at the other end a rope faſtened to it. On this Shank-painter the whole weight of the aft part of the anchor reſts, when it lies by the ſhip's ſide. The rope by which it is haled up, is made faſt about a timber-head.

SHARE, the name of that part of the plough which cuts the ground, and the wood to which it is fixed. The extremity of the iron forwards is called the point of the Share, and the end of the wood behind is called its tail.

The length of the whole Share, from point to tail, ſhould be three feet nine inches; at the top of the iron it has an upright piece called the fin, and, near the iron at the other end, there is an oblong ſquared hollow, called the ſocket; the uſe of which is to receive the bottom of the ſheat. Near the tail there is a thin plate of iron, well riveted to the wood; by means of this plate the tail of the Share is held firmly to the hinder ſheat of the plough by a ſmall iron pin, with a ſkrew at the end, and a nut ſkrewed on it, on the inner or right ſide of the ſheat.

The point of the Share is that part in which it does not run up into the fin: this point is generally made of three inches and a half in length, and ſhould be flat underneath, and round at the top, and the lower part of it muſt be of hard ſteel. The edge of the fin ſhould alſo be well ſteeled, and ſhould make an acute angle with the Share.

The ſocket is a ſort of mortiſe; it ſhould be a foot long, and about two inches deep: the fore-end of it muſt not be perpendicular, but oblique, conformable to the end of the ſheat which enters into it. The upper edge of the fore-part muſt be always made to bear againſt the ſheat; but, if this end of the ſocket ſhould not be quite ſo oblique as the ſheat, it may be helped, by paring off a ſmall part of the wood at the point. *Tull's Huſbandry.* See the article PLOUGH.

SHARK.—We know two different fiſh under the ſame name of Shark, with the addition of their colour, blue and white.

The blue Shark is that ſpecies of ſqualus called glaucus, and galeus glaucus, by authors, and diſtinguiſhed by Artedi by the name of the ſqualus with a triangular dent or furrow in the extremity of the back, and with no foramina about the eyes like the galeus.

The other is the lamia, or canis carcharias of authors, commonly called by us ſimply the Shark. This is diſtinguiſhed by Artedi by the name of ſqualus with a flat back, and with numerous teeth, ſerrated at the edges. See the article SQUALUS.

The white Shark, or lamia, is a very dreadful and voracious fiſh, the largeſt of all the Sharks. They have been ſeen of four thouſand weight, with throats capable of ſwallowing a luſty man whole; nay, men have been found in them whole, when opened. Some have, for this reaſon, imagined this, and not the whale, to have been the fiſh in whoſe belly the prophet Jonah lay.

Its teeth are very ſharp and terrible; they are diſpoſed in ſix rows, and are all triangular, and notched like a ſaw on their edges. Theſe are, in the whole, a hundred and forty-four in number, and are placed in various directions. Their number is not exactly determinate. Its back is ſhort and broad, in compariſon of the other fiſh of this kind, and its tail compoſed of two fins of a cubit in length each. Its ſkin is rough, and its eyes large and round. It is found both in the ocean and Mediterranean, and is of all fiſh the moſt voracious of human fleſh.

SHEA'RING. The beſt time for Shearing of ſheep is about the middle or the latter end of June, becauſe it is good for them to ſweat in the wool before it is cut. They muſt be very well waſhed before the Shearing, for this is a great addition to the price of the wool: after the waſhing, let them go three or four days in a clean dry ground. When they are cut, the ſhearer muſt be very careful not to wound their ſkins, becauſe this gives occaſion to the flies to teaze the poor creature in a terrible manner. Some ſhear their lambs, the firſt year eſpecially, behind; but, before the doing of this, they ought to be carefully tagged, as it is called, that is, their tails and thighs behind ſhould be well cleared of wool, that the dung may not hang there, which would elſe make them ſore, and ſubject them to the flies, which would blow them, and make them full of maggots.

In Glouceſterſhire they houſe their ſheep every night, and litter them with clean ſtraw. Their dung makes this a very good manure for the land, and the wool of the ſheep is rendered ſo much finer by it, that the farmers have a double advantage from the practice.

In Middleſex, and about London, they have Way-hill ſheep: theſe come from Hampſhire, Wiltſhire, &c. and lamb very early, before Chriſtmas. *Mortimer's Huſbandry.*

SHEAT *of a plough*, a word uſed by our farmers to expreſs a part of a plough paſſing through the beam, and faſtened to the ſhare. The Sheat, or, as it is ſometimes called, the fore-Sheat, there being another timber behind it, called the hinder Sheat, ſhould be ſeven inches wide, and is faſtened to the beam by the retch, a piece of iron with two legs, and by a wedge driven, with it, into the hole in the beam.

The angle made by the Sheat, with the beam of the plough, ſhould be forty-two, or forty-three degrees. *Tull's Huſbandry.* See the article PLOUGH.

SHEATS, in a ſhip, are ropes bent to the clews of the ſails, ſerving in the lower ſails to hale aft, or round off the clew of the ſail; but in top-ſails they ſerve to hale home, as the word is, or to hale the clew of the ſail cloſe to the yard-arm.

SHEA'THING, *of a ſhip*, (*Dict.*)— It is very well worth the trying what the new ſtone-pitch will do in this caſe; if it will defend from the worm, as perhaps it may, a ſhip might be paid with it cheaper than with the crown-pitch; and it will not

not crack nor scale off, as that will do, but keeps always soft and smooth. It has been found to continue on thirteen months, and to remain very black and soft all the time.

SHEEP, *ovis*, in zoology, a well known kind of cattle, that is kept at the least expence of any to the farmer, and will thrive upon almost any ground, and for this reason many prefer them before the larger cattle.

The best sort of Sheep for fine wool are those bred in Herefordshire and Worcestershire, but they are small and black-faced, and bear but a small quantity.

Warwick, Leicestershire, Buckingham, and Northamptonshire breed a large-boned Sheep, of the best shape, and deepest wool we have got. The marshes of Lincolnshire breed a very large kind of Sheep, but their wool is not good, unless the breed be mended by bringing in Sheep of other countries among them, which is a scheme of late very profitably followed there.

The northern counties in general breed sheep with long, but hairy wool; and Wales breeds a small hardy kind of Sheep which has the best-tasted flesh, but the worst wool of all.

The farmer should always buy his Sheep from a worse land than his own, and they should be big-boned, and have a long greasy wool, curling close and well. These Sheep always breed the finest wool, and are also the most approved of by the butcher for sale in the market.

For the choice of Sheep to breed, the ram must be young, and his skin of the same colour with his wool, for the lambs will be of the same colour with his skin. He should have a large long body, a broad forehead, round, and well rising, large eyes, and straight and short nostrils. The polled Sheep, that is, those which have no horns, are found to be the best breeders. The ewe should have a broad back, a large bending neck, small, but short; clean and nimble legs, and a thick deep wool covering her all over. To know whether they be sound or not, the farmer should examine the wool, that none of it be wanting, and see that the gums be red, the teeth white and even, and the brisket skin red, the wool firm, the breath sweet, and the feet not hot. Two years old is the best time for beginning to breed, and their first lambs should not be kept too long, to weaken them by suckling, but be sold as soon as conveniently may be. They will breed advantageously, till they are seven years old.

The farmers have a method of knowing the age of a Sheep, as a horse's is known, by the mouth. When a Sheep is one shear, as they express it, it has two broad teeth before; when it is two shear, it will have four; when three, six; when four, eight; after this, their mouths begin to break. The difference of land makes a very great difference in the Sheep. The fat pastures breed straight tall Sheep, and the barren hills and downs breed square short ones; woods and mountains breed tall and slender Sheep, but the best of all are those bred upon new plowed land, and dry grounds. On the contrary, all wet and moist lands are bad for Sheep, especially such as are subject to be overflowed, and to have sand and dirt left on them. The salt marshes are, however, an exception to this general rule, for their saltness makes amends for their moisture; any thing of salt, by reason of it drying quality, being of great advantage to Sheep.

As to the time of putting the rams to the ewes, the farmer must consider at what time of the spring his grass will be fit to maintain them and their lambs, and whether he has turneps to do it till the grass comes; for very often both the ewes and lambs are destroyed by the want of food; or, if this does not happen, if the lambs are only stunted in their growth by it, it is an accident that they never recover. The ewe goes twenty weeks with lamb, and according to this it is easy to calculate the proper time. The best time for them to yean is in April, unless the owner has very forward grass, or turneps, or the Sheep are field Sheep where you have not inclosures to keep them in, then it may be proper they should yean in January, that the lambs may be strong by May-day, and be able to follow the dam over the fallows, and water furrows; but then the lambs, that come so early, must have a great deal of care taken of them, and so indeed should all other lambs at their first falling, else, while they are weak, the crows and magpies will peck their eyes out.

When Sheep are turned into fields of wheat or rye to feed, it must not be too rank first, for, if it be, it generally throws them into scowerings. Ewes that are big should be kept but bare, for it is very dangerous to them to be fat at the time of their bringing forth their young. They may be well fed indeed, like cows, a fortnight before-hand, to put them in heart. *Mortimer's Husbandry.*

The feeding Sheep with turneps is one great advantage to the farmers, from the crops they raise of them: they soon fatten upon them, but there is some difficulty in getting them to feed on them; the old ones always refuse them at first, and will sometimes fast three or four days, till almost famished; but the young lambs fall to at once.

The common way, in some places, of turning a flock of Sheep at large into a field of turneps, is very disadvantageous, for they will thus destroy as many in a fortnight, as would have kept them a whole winter. There are three other ways of feeding them on this food, all of which have their several advantages.

The first way is to divide the land by hurdles, and allow the Sheep to come upon such a portion only at a time, as they can eat in one day, and so advance the hurdles farther into the ground daily, till all be eaten. This is infinitely better than the former random method, but they never eat them clean even this way, but leave the bottoms and outsides scooped in the ground; the people pull up these indeed with iron crooks, and lay them before the Sheep again, but they are commonly so fouled with the creature's dung and urine, and with the dirt from their feet, that they do not care for them; they eat but little of them, and what they do, does not nourish them like the fresh roots.

The second way is by inclosing the Sheep in hurdles, as in the former; but in this they pull up all the turneps they suppose the Sheep can eat in one day, and daily remove the hurdles over the ground, whence they have pulled up the turneps: by this means there is no waste, and less expence, for a person may in two hours pull up all those turneps; the remaining shells of which would have employed three or four labourers a day to get up with their crooks out of the ground, trodden hard by the feet of the Sheep; and the worst is, that as, in the method of pulling up first, the turneps are eat up clean; in this way, by the hook, they are wasted, the Sheep do not eat any great part of them, and when the ground comes to be tilled afterwards for a crop of corn, the fragments of the turneps are seen in such quantities on the surface, that half the crop at least seems to have been wasted.

The third manner is to pull up the turneps, and remove them in a cart or waggon to some other place, spreading them on a fresh place every day; by this method the Sheep will eat them up clean, both roots and leaves. The great advantage of this method is, when there is a land not far off which wants dung more than that where the turneps grow, which perhaps is also too wet for the Sheep in winter, and then the turneps will, by the too great moisture and dirt of the soil, sometimes spoil the Sheep, and give them the rot. Yet such ground will often bring forth more and larger turneps than dry land, and when they are carried off, and eaten by the Sheep on plowed land in dry weather, and on green sward in wet weather, the Sheep will succeed much the better; and the moist soil, where the turneps grow, not being trodden by the Sheep, will be much fitter for a crop of corn, than if they had been fed with the turneps on it. The expence of hurdles, and the trouble of moving them, is saved in this case, and this will counterbalance at least the expence of pulling the turneps, and carrying them to the places where they are to be eaten. They must always be carried off for oxen. *Tull's Horsehoeing Husbandry.*

The use of salt preserves Sheep from the rot. The animals must be made to take a small handful of it two or three times in a few days, without permitting them to drink any thing for some hours afterwards. *Boyle's Works.*

SHEEP's *dung*.— This is one of the best manures we know. It succeeds better upon cold clayey lands, than any other dung whatever; but, as it is not so conveniently to be collected as the dung of larger animals, it is commonly conveyed to the land it is intended for, by folding the Sheep upon it. The urine, as well as the dung, is thus given to the land, and is of very great advantage; but the farmer always should plow in this sort of manure as soon as he can, for the sun soon robs it of a great part of its virtue.

In Northamptonshire they begin to fold the Sheep upon the lands that they would dung by them, after the month of July, and, the drier the lands are, the later they fold them. In Flanders they make many thousand loads of manure annually from their Sheep: they cover the bottom of the folds considerably deep with some light and spungy earth, and, when this has received the dung and urine of the animals for seven or eight days, they remove it, and lay fresh in its place: the earth, thus impregnated, becomes an excellent improvement to land, and they raise large crops by means of it, in places where very little could be expected without it.

In England we have a contrivance like this, which is the covering the bottoms of the folds deep with sand, and changing it once in a week, or thereabouts: this is a kind of manure finely calculated for clayey lands, both the sand, and this peculiar kind of dung, being appropriated things for it.

SHEEP-*nose-worms*, in natural history, a species of fly-worm, found in the noses of sheep, goats, and stags, and produced there from the egg of a large two-winged fly.

The frontal sinuses above the nose in Sheep, and other animals, are the places where these worms live, and attain their full growth. These sinuses are always full of a soft white matter, which furnishes these worms with a proper nourishment, and are sufficiently large for their habitation; and when they have here acquired their destined growth, and come to the state in which they are fit to undergo their changes for the fly-state, they leave their old habitation, and, falling to the earth, bury themselves there; and, when these are hatched into flies, the female, when she has been impregnated by the male, knows that the nose of a Sheep, or other animal, is the only place for

for her to deposit her eggs, in order to their coming to good. *Reaumur's Hist. Inf.*

SHEERS, aboard a ship, a name the seamen give to two mast's yards, or poles, set up and seized across each other aloft, near the top. This pair of Sheers, as they call it, is placed below on the chain-wales of the shrouds, and lashed fast to the ship's side, to keep them steady aloft. Their use is to set in, or take out a mast; for which end there is fastened, at the place where they cross one another, a strong double block with a strap. They serve also to hoise in or out, of boats that have masts, such goods as are wanted to be taken in or out.

SHEER-*water*, in zoology, an English name for a bird common on our coasts, and not known by any of the common authors, nor honoured with a Latin name. It is nearly of the size of a duck. Its head, which is large, neck and back, are of a brownish black; its throat, breast, and belly, white; its legs are red. Its three fore toes are connected by a membrane, but its hinder one is loose. Its wings are very long, and, when folded, reach to the end of the tail. Its beak is strong and sharp, and is hooked at the end. It flies very swiftly along the surface of the water, whence it has its name. *Ray's Ornithology.*

SHEIK, in the Oriental customs, the person who has the care of the mosques in Egypt; his duty is the same as that of the imams at Constantinople. There are more or fewer of these to every mosque, according to its size or revenues. One of these is head over the rest, and answers to a parish priest with us, and has under him, in large mosques, the readers, and people who cry out to go to prayers; but in small mosques the Sheik is obliged to do all this himself. In such it is their business to open the mosque, to cry to prayers, and to begin their short devotions at the head of the congregation, who stand rank and file in great order, and make all their motions together. Every Friday the Sheik makes an harangue to his congregation. *Pocock's Egypt.*

SHEIK-*bellet*, the name of an officer in the Oriental nations.

In Egypt the Sheik-bellet is the head of a city, and is appointed by the pasha. The business of this officer is to take care that no innovations be made, which may be prejudicial to the port, and that they send no orders which may hurt the liberties of the people. But all his authority depends on his credit and interest, not his office: for the government of Egypt is of such a kind, that often the people of the least power by their posts have the greatest influence; and a caia of the Janizaries, or Arabs, and sometimes one of their meanest officers, an oda-basha, finds means, by his parts and abilities, to govern all things. *Pocock's Egypt.*

SHE'KEL (*Dict.*)—In the Bible, the Shekel is sometimes rendered solidus, and sometimes stater.

The Jewish doctors are in great doubt about the weight of the Shekel: and it is only by conjecture, and by the weight of the modern Shekel, that the ancient one is judged equal to four Attic drachmas.

Father Souciet has described several of these Shekels, in his dissertation on the Hebrew Medals. By the way he observes, that the third and fourth parts of a Shekel, described by Waserus de Ant. Num. Heb. are counterfeits of that author.

The Hebrew Shekel, according to F. Mersenne, weighs 268 grains, and is composed of 20 oboli, each obolus weighing 16 grains of wheat. This, he says, is the just weight, as he found by weighing one in the French king's cabinet. He adds, that such as come short of this weight have been filed or clipped. Bishop Cumberland tells us, he has weighed several, and always found them near the weight of a Roman semuncia, or half-ounce.

Some are of opinion, that the Hebrews had two kinds of Shekels: the common or prophane Shekel, called didrachma; and the Shekel of the sanctuary, which last they will have to be double the former.—By this expedient they think we may get clear of some difficulties occurring in scripture, where things are mentioned as of incredible weight; particularly that passage where it is said, that every time Absalom cut off his hair, the weight whereof used to incommode him, he cut off the weight of 200 Shekels.

But Villalpandus will not hear of such a distinction; nor do bishop Cumberland, M. Morin, &c. take the opinion to have any foundation. The prophane Shekel, or Shekel of four drachmas, they agree, was the same with the sacred Shekel; and it was only called by this last name, in regard the standard thereof was kept, in the sanctuary, by the priests. It is maintained by several, that the Jews had also a gold Shekel, siclus aureus, of the same weight with the silver one, and valued at 1 l. 16 s. 6 d. sterling.

The Shekel is supposed to have been first struck in the desart, on the footing of 100 to the Attic mina, weighing 160 grains of wheat, and current for 10 geratis or oboli. But afterwards they were struck of double that weight.

Some will have the Shekel to be the oldest piece of money in the world, as being in use in Abraham's time; but this was not coined, or stamped; nor had any other value besides its intrinsic worth.

Xenophon mentions Shekels, as current in Arabia: Du Cange speaks of others struck and current in England.

SHELF (*Dict.*)—What the miners mean by this term is, that part of the earth which they find lying even, and in an orderly manner, and evidently having retained its primitive form and situation unmoved by the waters of the general deluge, while the circumjacent and upper strata have plainly been removed, and tossed about.

It is evident to reason, that there must have been a very violent concussion of the superficial part of the earth, in the time of its being covered by the waters of the deluge; and experience as much evinces this as reason. Before this concussion it appears probable that the uppermost surface of mineral veins, or loads, did in most places lie even with the then surface of the earth. The remains of this surface, found at different depths in digging, the miners express by the word Shelf.

In this concussion of the waters covering the whole earth, its natural surface, together with the uppermost surface of those mineral veins, were then in many places loosened, and torn off; and the earth, and with it the mineral nodules, called shoad-stones, were carried down with the descending waters from hills into the adjacent valleys, and sometimes into the streams of rivers; by which they were washed to yet greater distances from their original place.

On this depends the method of training mines. *Philos. Transf.* N°. 69.

SHELLS (*Dict.*)—The world has for a long time wanted a regular method of classing of Shells, which a late author of the French nation has attempted upon a new and very laudable plan. In this, he throws aside the vulgar distinction of Shells into the sea, fresh-water, and land kinds, and very judiciously arranges all under the same class, which have the same general characters.

The Shells are all naturally to be arranged under three principal classes; these will contain all the species, and are afterwards to be divided into a number of families, or genera, and under these the several species regularly recounted; and, at the end of each description, the varieties may be added. The first general class of Shells contains those which are found all of one piece, or have only one Shell, not a pair. These have been called by the Greeks monothyræ, and by the Latin authors univalviæ, univalves.

The second general class contains those Shells which are of two pieces, called bivalves, such as oysters, cockles, and the like.

The third class contains those which are composed of more than two pieces. These are called multivalves; and of this kind are the pholas and balanus.

This method takes in the fresh-water Shells, as well as those of the sea; and, as those hitherto known are all of one or other of the first classes, their several species will be comprised among, or after the sea Shells of each of those classes.

The land Shells are of two kinds, the recent and the fossil; the first kind, as far as hitherto known, are all univalves, and the latter are of all the three classes.

As each of these general classes contains a very great number of species, it may seem difficult to enter on this study, from the multiplicity of the bodies; but method renders all this easy, and it is no way difficult, in the following manner, to find of what class, what family, and what genus, any given Shell is, from a bare inspection.

Bivalve SHELLS.—The former are all the genera of the Shells composed of one piece, and thence called univalves: and, as any given Shell may, by the characters given of each, be easily referred to that to which it belongs, so, in regard to the bivalves, the task is not more arduous, when entered on upon the same principles; and it is the easier in this respect, that the families of this class are much less numerous than those of the other, these being only six.

The first genus or family of the bivalves is that of the oister, ostreæ. The variety of this one genus is almost infinite, and is extremely agreeable. Some are echinated so as to represent the echini; others have excrescences of parts in undulatory, or jagged forms, representing the ears of animals, or the comb of a cock; and others form themselves into very remarkable figures, by adhering and growing to trees, stones, corals, and other substances, either naturally growing in the sea, or such as have accidentally fallen into it. Sometimes, also, the upper Shell in an oister is smaller and flatter than the under one. These, however, are all trifling varieties, and the Shells are still of the oister kind.

When the bivalve Shells, under examination, differ from the oister kind, in being more elevated in the middle, and equally convex, or nearly so, in both Shells, then it belongs to the family, under the name of chamæ. These differ also from oisters, in that they are more smooth on the surface, and they often do not close so evenly and regularly at the mouth, whence some have called them conchylia ore patulo et hianti.

The third family is that of the muscles. These are all of the general shape of the common muscle, and are thence easily known. It is to be observed, however, that some of them are equal at both ends; these are called tellinæ: and some others are extremely long at one end, and broad and short at the other; these are called pinnæ marinæ.

The fourth genus, or family, is the cordiform kind, called in French cœurs. The essential character of this family is, that the

the Shells are of a roundish elevated figure, and that they have no ears, as the pectens have, and they always represent the figure of a heart, in whatever view they are taken; though this is sometimes of a triangular figure. Most of the species of this family, as well as of the following one of the pectens, are striated.

The fifth family of the bivalves is that of the pectens or scallop Shells. Among these, some have two ears at the head of the Shell; others have only one ear; and others have none at all. Some species are deeply furrowed, and others are full of small protuberances. The general character of the pectens is to have the upper Shell plain, and the under one somewhat hollow; and the ears are also a very obvious character in those that have them.

The sixth, and last family of the bivalves, is the solen or rasor-fish, called by the French manche de couteau. These are very easily known by their figure which resembles that of a knife-haft, and therefore need no other mark of distinction.

Multivalve SHELLS. These are not less easily distinguished, than the other two general classes, into their separate families. Of these, also, there are six families. The first is that of the echini marini, called, in English, sea-eggs, and by the French oursins, boutons, and herissons des mer. These carry a very obvious distinction, in their being covered with spines or prickles; and if we meet with them in a state, when these are fallen off, they are still easily known by the marks of their insertion. This, and their general figure which is alike in all, and in all unlike to all other species, is such a distinction, as cannot suffer them to be mistaken.

The second family of these is that of the vermiculi marini particularly charactered in the species called the sea-organ. These are usually of a beautiful red colour, and are of a very elegant structure. These generally are found in very large clusters, and are easily distinguished from all other genera.

The third family of the multivalves consists of the balani marini, called by the French glands de mer. These are all so like one another, that they are easily known from all the other genera, by their all resembling the common balanus, a Shell too well known to need description.

The fourth family is that of the pollicipedes, or, as the French call them, the pousSepieds. These are so easily known by their perfect resemblance to one another, that there needs no other character than referring to their figure in *Plate* XLIII. *fig.* 2.

The fifth family of the multivalves is that of the conchæ anatiferæ. These were once supposed to produce a bird of the goose kind; and these are all so like to one another, that the referring to the figure of the common species, in *Plate* XLIII. *fig.* 3. will shew the characters of all the species.

Finally, the sixth genus of the multivalves is that of the pholas. These Shells are easily distinguished by their figure, which is usually oblong, and their colour, which is simply white in all the species. These Shells are often found inclosed in stone in the sea, and some of them are composed of five valves.

Fossil SHELLS.— The number and variety of sea Shells which are found far from seas buried at great depths in the earth, and often immersed in the hardest stones, is an object of great wonder.

Of these some are found remaining almost entirely in their native state, but others are variously altered by being impregnated with particles of stone, and of other fossils; in the place of others there is found mere stone or spar, or some other native mineral body, expressing all their lineaments in the greatest nicety, as being formed wholly from them, the Shell having been first deposited in some solid matrix, and thence dissolved by very slow degrees, and this matter left in its place, on the cavities of stone and other solid substances, out of which Shells have been dissolved and washed away, being afterwards filled up less slowly with these different substances, whether spar or whatever else: these substances, so filling the cavities, can necessarily be of no other form than that of the Shell, to the absence of which the cavity was owing, though all the nicer lineaments may not be so exactly expressed. Besides these, we have, also, in many places, masses of stone formed within various Shells; and these, having been received into the cavities of the Shells while they were perfectly fluid, and having therefore nicely filled all their cavities, must retain the perfect figures of the internal part of the Shell, when the Shell itself should be worn away, or perished from their outside.

The various species we find of these are, in many genera, as numerous as the known recent ones; and as we have in our own island not only the Shells of our own shores, but those of many other very distant ones; so we have also many species, and those in great numbers, which are, in their recent state, the inhabitants of other yet unknown or unsearched seas and shores. The cockles, muscles, oisters, and the other common bivalves of our own seas are very abundant: but we have also an amazing number of the nautilus kind, particularly of the nautilus Græcorum, which, though a Shell not found living in our own, or any neighbouring seas, yet is found buried in all our clay-pits about London, and elsewhere; and the most frequent of all fossil Shells in some of our counties are the conchæ anomiæ, which yet we know not of in any part of the world in their recent state. Of this sort, also, are the cornua ammonis and the gryphitæ, with several of the echnatæ and others.

The exact similitude of the known Shells recent and fossil, in their several kinds, will by no means suffer us to believe, that these, though not yet known to us in their living state, are, as some have idly thought, a sort of lusus naturæ. It is certain, that, of the many known shores, very few, not even those of our own island, have been yet carefully searched for the Shell-fish that inhabit them; and, as we see in the nautilus Græcorum an instance of Shells being brought from very distant parts of the world to be buried here, we cannot wonder that yet unknown shores, or the unknown bottom of deep seas, should have furnished us with many unknown Shell-fish, which may have been brought with the rest; whether that were at the time of the general deluge, or the effect of any other catastrophe of a like kind, or by whatever other means; to be left in the yet unhardened matter of our stony and clayey strata. *Hill's Hist. of Foss.*

The vast beds of fossil Shells, buried in many parts of the world, are not useless matter, but will serve to one of the greatest purposes of husbandry, the manuring of barren lands. The people of many parts of France, and in some places in our own country, dig up the masses of broken Shells, connected into a sort of strata by marly, or other earths, for this purpose; and, spreading them upon the lands as dung, they soon moulder away, and are found extremely beneficial to the earth. Mr. Reaumur, desirous of knowing in what manner these fragments of Shells fertilised land, at first conjectured that they did the same as the various species of marls, dissolving wholly away in time, and entering into, and fattening the earth; and carried it so far, as to believe that the common marls were a sort of earth, which owed its origin merely to such fragments of Shells more perfectly dissolved; and consequently, that the rain and air, in some sort, converted these Shells into marl upon the earth. But he was soon convinced of the error of this opinion, by the experience of the peasants, from whom he found that there was marl in the same pits whence they dug these Shells, and that they used it also as manure, but to lands of a very different kind; those which received benefit from the marl being always injured by the Shells, and, on the contrary, those which were meliorated by the Shells receiving no benefit from the marl. It might naturally enough be supposed that the salts, contained in these fossil Shells, helped to fertilise the earth, in the same manner with the salts of the common sea-plants, which are used as manure in many places. It is not impossible, but that the salts may indeed have their use in the whole, but the great good these shelly fragments do to the lands they are used on, is to be explained in a much easier manner, when the nature of the lands, on which they are employed, is considered.

These are usually cold clayey lands, on which nothing can grow but heath, and a few useless weeds, the common plants not shooting in any strength or perfection upon them; and they are always very wet upon the surface after any little rain, their texture being so close and compact, that the water cannot penetrate into them, as it does into the spungy texture of the common fertile lands. This sort of manure, which is very light, and is no other than a mass of broken, and, as it were, half calcined Shells, mixing with this earth, breaks its particles, and occasions a multitude of voids and little cavities in it, which reduce it to something like the common state of other earth, and the rain penetrates it as it does other mould.

The effects of this sort of manure are very lasting; a land well strewn with these Shells is manured for twenty years, and the rain no longer wets its surface only, but penetrates its substance, and moistens the roots of plants sown in it. These find also an easier passage, and penetrate to a proper depth; while the plowman finds no less the benefit; his plough now easily turning up an earth, which before it was scarce able to cut. Some have imagined, indeed, that all these effects are owing to the salts in the Shells operating in the manner of those of dung, and by that means breaking the connections of the more minute molecules; but ocular examination will shew the Shells act, in this case, merely as particles of hard matter of that size and hardness, and do no more than fragments of stone of the same size would do; and the peasants are well acquainted with this, as they find it necessary to dung those lands, which they have before manured with Shells, in the same manner as they do any others.

There are in many foreign countries, as well as in our own, lands of such a nature, that they never will become fertile, unless a large quantity of sand is dispersed over them. These lands are all of the same nature with those on which the farmers find their manure of Shells to take effect. The sand, and this manure of Shells, evidently act upon the same principle, in meliorating land, which is only by dividing its parts, when naturally too compact; but the Shells are qualified to do it greatly the better of the two, because they are in themselves so considerably lighter. Somewhat analogous to this sort of manure is that of the throwing pebbles and rough fragments of stone on some earths, which are naturally tough and compact in a great degree. It is the general practice in husbandry to take off all the stones, as far as it can be done, from the lands; but these soils are apt to crack, and burst open in dry seasons, and, the more stones are mixed in them, the less they are observed to crack, and what cracks they have, are always the smaller and the shorter. The earth is, by these stones, divided into so many separate parcels, that no very large and continued cracks can be formed; and always is the more fruitful, the more stones it has upon it, provided that they be not too large.

The manure of Shells, upon these lands, does not produce nearly so great an effect for the two first years, as it does in the succeeding ones; the reason of which is, that it is not then sufficiently mixed, but in succeeding time it breaks itself into a number of very small particles, and these all become intimately blended with the molecules of earth, and produce their effect more perfectly.

It is well known, that the Shells of the common garden snails always become calcined, as it were, in some degree, by lying in the earth; this becomes very friable, and may be mouldered to powder between the fingers: and the case is just the same in regard to these sea-shells; they, by their long abode in the earth, are thus calcined, and, happily for the farmer, are reduced to a sort of coarse powder, the particles of which are just of such a size, as may properly serve for the dividing and breaking the little clods of earth, and forming in the whole certain voids and spaces, just as large as they could be wished, in order to give roots, and moisture to swell them, an easy passage. And as these pieces of Shells are not expected to act as bodies containing active principles, but merely as inert particles of matter, so long as they retain their form, that action will not be impeded; and notwithstanding all the rude shocks they receive from the plough, and other instruments of husbandry, they retain this their form without any great alteration for a long time, and therefore the operation of strewing them on any piece of land needs not to be repeated in twenty, or sometimes in thirty years.

The manner in which the effects of this Shell-manure wear off at length, will be easily seen, if parcels of earth, manured with it at different distances of time, be examined, by washing away the earth with water; the fragments of Shells, left from the washing of earths of different years from the time of their being added to them, will be found growing smaller and smaller every year, till at length they make only a fine powder, mixing every way equally with the earth, and no longer opening its texture, or dividing its molecules; and it is then that these lands require a fresh quantity of it.

This breaking of the particles of the Shells is not to be determined by any regular rule, as to time, but differs from a number of accidents; and, accordingly, the farmer cannot say when he ought to renew the work, till he finds that the fertility it occasioned decreases. The size of the fragments in their original beds makes a great difference, the largest usually, and as might naturally be supposed, lasting the longest; but, besides this, they are more or less durable, as they were more or less calcined in the earth, and even according to the nature of that earth, upon which they are laid.

Mr. Reaumur concludes this useful account of these substances, by observing, that it is much more easy to account for the manner of their acting upon land, than for the manner of their coming where they are found. It has been the favourite system of our Dr. Woodward, that all these Shells were the remains of the universal deluge, which, having overflowed the whole earth, might easily leave them in all places; but Mr. Reaumur has much more rationally accounted for their coming to those parts of France, where they are found at this time in such vast abundance, by carefully tracing the course of the beds of them, so far as known there, and easily proving, that all that extent of country, under which they are found, may have been once overflowed by the sea, without a deluge; it being the very track that a large body of waters, let in at one part of the kingdom, must have taken, in order to getting out at another. *Mem. de l'Acad. Par.* 1720.

Arabian SHELL, a name given by some to a species of porcelain Shell, not because it is found on the coast of Arabia, but because its lines and variegations are supposed to represent the figures of Arabic characters.

Aurora SHELL, in natural history, a very remarkable species of Shell-fish, found in cabinets of the curious. It is of the figure of a bird, having a head, wings, and tail, and is of a flame-colour. It owes much of its beauty, however, to art and accident. The Shell is an oister of a peculiar variation of figure from the common one; the head of the bird is the cardo or hinge; the wings are the body of the Shells; and the tail is a peculiar process, like that of the marteau, only single. It is naturally of a dusky brown on the outside, and pearly within, but, when its rough coat is taken off, it appears of this beautiful flame-colour.

Center SHELL, in natural history, a name given to the balanus marinus, a kind of sea Shell, of the multivalve kind, with an open mouth, frequently found fixed to the bottoms of ships, and other things covered with sea-water.

China-letter SHELL, in natural history, a name given by many to that species of chama, usually called, by authors, the chama Arabica. It is of a pale brownish ground, and is variegated with a great number of black lines, which are as slender as the strokes of a pen, and are of such odd figures, that they represent some of the Arabic, or, as others fancy, Chinese characters.

Guinea SHELL, the English name for a very beautiful variegated species of voluta, called by the French la speculation.

Helmet SHELL, in natural history, the name of a kind of murex, of which there are several species. They all approach somewhat towards a triangular figure, and are free from any long spines.

Leopard SHELL, in natural history, the English name of the pardus, a kind of voluta; so called, from its spots resembling those of a leopard. There are three kinds of this, one spotted with black, another with yellow, and another with red.

Leveret SHELL, in natural history, a name given by many to a species of porcelain, resembling a young hare in colour.

Lightning SHELL, in natural history, a name given by some authors to a species of murex with variegations on its body, resembling the pictures we commonly see of flashes of lightning.

Map SHELL, in natural history, the name given by some to a peculiar species of porcelain Shell, the figures on which represent the lines of a map.

Saddle SHELL, in natural history, the name of a species of oister, which in some degree represents a saddle in its shape.

St. James's SHELL, in natural history, a name given by writers on Shells to a very beautiful species of variegated pecten.

St. Michael's SHELL, in natural history, a name given by authors to a species of pecten, or scallop Shell. It is of a bright yellow colour.

Scorpion SHELL, in natural history, the name of a species of murex, very much approaching to the nature of the spider Shell. This is a common Shell in cabinets. It is of a yellow colour, and very deeply ridged, and full of tubercles; there arise from the lip of the Shell five large spines, or, as they are usually called, fingers, and two others, which are very much bent, the one from the head, the other from the tail: these are very elegantly radiated with white and a fine violet colour on the lips.

Screw SHELL. See the article TURBO.

Small-pox SHELL, in natural history, a name given to a remarkable kind of concha venerea, or porcelain Shell, the protuberances on the surface of which are supposed to represent the pustules of the small-pox. There are two species of this Shell, the one white, with flattish protuberances; the other greenish, with more elevated ones.

Snake-SHELL, in natural history, the name given by many to that beautiful species of porcelain Shell, the spots of which represent those of a snake's skin.

Spider SHELL, the name of a kind of murex.

Strawberry SHELL, in natural history, the name given by collectors of Shells to a very beautiful species of cordiformis, spotted with small round red spots.

Swallow SHELL, in natural history, the name given by authors to a species of oister, which in some degree represents the figure of a small bird flying.

Tiger SHELL, in natural history, the name of a species of porcelain, or concha venerea, supposed to represent the spots on a tiger's skin.

Trumpet SHELL. See the article TRUMPET *Shell*.

Turban SHELL. See TURBAN *Shell*.

Turnep SHELL. This is a species of sea Shell, by others called the radish Shell. It is exactly of the shape of a turnep, and is of the dolium, or concha globosa kind. Those who have called it the radish Shell allude to the great black round-rooted radish, not to our common radish.

SHELL-*apple*, in zoology, an English name for the loxia or crossbill; given from his manner of splitting an apple, and feeding on the kernels, leaving the Shell of the pulp untouched. *Ray's Ornithology*.

SHELL-*drake*, in zoology, a common English name for the tadorna.

SHELL-*fish*. These animals are in general oviparous, very few instances having been found of such as are viviparous. Among the oviparous kinds, anatomists have found that some species are of different sexes in the different individuals of the same species, but others are hermaphrodites, every one being in itself both male and female: in both cases their increase is very numerous, and scarce inferior to that of plants, or of the most fruitful of the insect class. The eggs are very small, and are hung together in a sort of clusters by means of a glutinous humour, which is always placed about them, and is of the nature of the jelly of frogs spawn; by means of this they are not only kept together in the parcel, but the whole cluster is fastened to the rocks, Shells, or other solid substances, and thus they are preserved from being driven on shore by the waves, and left where they cannot succeed. *Langius, Method. Testac.*

SHELL-*gall insect*, an insect of the gall-insect class, somewhat resembling those which are called the boat-fashioned ones, but differing in this, that, as the two ends of that species are not very different in form, in this kind one of the ends is sharp and pointed in comparison with the other. It has its name of Shell-insect, from the resemblance it bears to a muscle Shell; as it is, in its whole form, not unlike one of the two Shells, in which the common sea-muscle is inclosed; but the pointed end of this insect is much more extended in length, than the smaller end of this Shell.

SHETLIE,

SHE'LTIE, the name of a small, but strong kind of horse, found in the Island of Zetland, commonly called Shetland. In the country, the price of one of these horses is about a guinea. *Phil. Transf.* N°. 473.

SHE'RIF, in the Egyptian orders, the relations of Mahomet, the same tribe of persons called emir by the Turks.

SHIELD (*Dict.*)—People have at all times thought this honourable piece of armour the properest place to engrave or figure on the signs of dignity of the possessor of it; and hence, when arms came to be painted for families in after times, the heralds always chose to represent them upon the figure of a Shield, but with several exterior additions and ornaments, as the helmet, supporters, and the rest. *Nisbet's Herald.*

The form of the Shield has not only been found different in various nations, but even the people of the same nation, at different times, have varied its form extremely; and among several people there have been Shields of several forms and sizes in use, at the same period of time, and suited to different occasions. *Baron's Heraldry.*

The most antient and universal form of Shields, in the earlier ages, seems to have been the triangular. This we see instances of in all the monuments and gems of antiquity: our own most early monuments shew it to have been the most antique shape also with us, and the heralds have found it the most convenient for their purposes, when they had any odd number of figures to represent; as if three, then two in the broad bottom part, and one in the narrow upper end, it held them very well; or, if five, they stood as conveniently at three below, and two above. The other form of a Shield, now universally used, is square, rounded and pointed at the bottom: this is taken from the figure of the Samnitic Shield used by the Romans, and since copied very generally by the English, French, and Germans. The Spaniards and Portuguese have the like general form of Shields, but they are round at the bottom without the point; and the Germans, besides the Samnite Shield, have two others pretty much in use: these are, 1. The bulging Shield, distinguished by its swelling or bulging out at the flanks; and, 2. The indented Shield, or Shield chancrée, which has a number of notches and indentings all round its sides. The use of the antient Shield of this form was, that the notches served to rest the lance upon, that it might be firm while it gave the thrust; but, this form being less proper for the receiving armorial figures, the two former have been much more used in the heraldry of that nation.

Besides this different form of the Shields in heraldry, we find them also often distinguished by their different positions, some of them standing erect, and others slanting various ways, and in different degrees. This the heralds express by the word pendant, hanging, they seeming to be hung up not by the center, but by the right or left corner. The French call these ecu pendant, and the common antique triangular ones ecu ancien. The Italians call this scuto pendente, and the reason given for exhibiting the Shield in these figures in heraldry is, that, in the antient tilts and tournaments, they who were to just at these military exercises, were obliged to hang up their Shields, with their armories or coats of arms on them, out at the windows and balconies of the houses near the place; or upon trees, pavilions, or the barriers of the ground, if the exercise was to be performed in the field.

Those who were to fight on foot, according to Columbier, had their Shields hung up by the right corner, and those who were to fight on horseback, had theirs hung up by the left. This position of the Shields, in heraldry, is called couché by some writers, though by the generality pendant. It was very frequent, in all parts of Europe, in arms given between the eleventh and fourteenth centuries. But it is to be observed, that the hanging by the left corner, as it was the token of the owners being to fight on horse-back, so it was esteemed the most honourable and noble situation, and all the pendant Shields of the sons of the royal family of Scotland and England, and of our nobility at that time, are thus hanging from the left corner. The hanging from this corner was a token of the owner's being of noble birth, and having fought in the tournaments before; but no sovereign ever had a Shield pendant any way, but always erect, as they never formally entered the lists of the tournament.

The Italians generally have their Shield of arms of an oval form: this seems to be done in imitation of those of the popes, and other dignified clergy; but their herald, Petro Sancto, seems to regret the use of this figure of the Shield, as an innovation brought in by the painters and engravers, as most convenient for holding the figures, but derogatory to the honour of the possessor, as not representing either antiquity, or honours won in war, but rather the honours of some citizen, or person of learning. Some have carried it so far, as to say that those, who either have no antient title to nobility, or have sullied it by any unworthy action, cannot any longer wear their arms in Shields properly figured, but were obliged to have them painted in an oval, or round Shield. In Flanders, where this author lived, the round and oval Shields are in the disrepute he speaks of; but in Italy, besides the popes and dignified prelates, many of the first families of the laity have them. The secular princes, in many other countries, also retain this form of the Shield, as the most antient, and truly expressive of the Roman clypeus. *Nisbet's and Compe-mille's, Herald.*

SHI'NGLING, in the iron-works in many parts of England, is the operation of hammering the sow, or cast-iron, into blooms. The tongs, used for holding the iron in this operation, are called Shingling-tongs, and the iron to be thus wrought is called a loop. *Ray's English Words.*

SHIP (*Dict.*) It is highly necessary, to the health of seamen, that Ships should be cleared of foul air; for it has been found by frequent experience, that air shut up, and confined in a close place, without a succession and fresh supply of it, becomes unwholesome, and unfit for the use of life. This is more sensibly so, if any stagnating water be pent up with it. But it grows still worse, if such an air as this is made use of in respiration; that is, becomes moister and hotter, by passing and repassing through the lungs. These bad effects in different degrees, according to the different manner in which air is inclosed, are observed in many cases; particularly in deep wells and caverns of the earth; in prisons, or close houses, where people are shut up with heat and nastiness: but most of all in large Ships, in which, with the stench of water in the hold, many men being crouded up in close-quarters, all the mentioned circumstances concur in producing greater mischiefs than would follow from any of them single.

Mr. Sutton did therefore, a few years ago, propose, in order to clear the holds of Ships of the bad air they contain, that the fire-place and ash-place of the copper or boiler should be both closed up with substantial and tight iron doors; and that a copper, or leaden pipe, of sufficient size, should be laid from the hold into the ash-place, for the draught of air to come in that way to feed the fire. And thus, from the natural elasticity of the air, it seems plain, that there will be from the hold a constant discharge of the air therein contained: and consequently, that the air so discharged must be as constantly supplied by fresh air below the hatches, or such other communications as are open into the hold; whereby the same must be continually made free, and its air rendered more wholesome, and fit for respiration. And if into this principal pipe, so laid into the hold, other pipes are let in communicating respectively either with the well, or lower decks, it must follow that part of the air, consumed in feeding the fire, must be respectively drawn out of all such places, to which the communication shall be so made. *Philos. Transf.* N°. 462.

SHIP, in the salt-works, is a large cistern, out of which the salt-pans are supplied for boiling.

This cistern is close built to the saltern, and is made either of wood, brick, or clay; and it ought always to be covered with a shed, that the sea-water, contained in it, may be kept clean from soot and other impurities, and not mixed with fresh water in rains; and it must be always placed so high, that the water will easily run out of it into the pans to supply them for boiling.

SHIP-*building*, the art of designing, constructing, and forming Ships.

Shipwrights, in delineating the models of ships, make use of three planes, which they call the sheer-plane, the floor-plane, and the body.

The sheer-plane is the same with that of elevation, being a section of a Ship supposed to be cut by a plane passing through the middle line of the keel stem and stern-post.—The floor plane is the same with the horizontal, and is that on which the whole frame is erected.—The body is the same with the profile; being a section supposed to cut the Ship through the broadest place, and is perpendicular to the sheer and floor planes.

The length of the keel, extreme breadth, depth in the hold, heighth between decks, and in the waist, and sometimes the heighth of the wing transom, are agreed on by contract in the merchants service, from which dimensions the builder is to form a draught suitable to the trade the ship is designed for. The first thing that is generally done, is to lay down the keel, stem, and post, upon the sheer planes: then to determine the proper station of the mid-ship timber, where a perpendicular is erected: it is generally about ⅓ of the keel before the post. On this line the given depth of the hold is set off from the upper side of the keel; to obtain which point, the thickness of the timber and plank must be added to that agreed on by contract. This, being fixed, will enable us to determine the upper heighth of the extreme breadth at that place, which sometimes is the very point itself. The lower heighth of the breadth must likewise be determined at this place. Then we may form the two main heighths of the breadth lines which nearly unite abaft and afore. Abaft these curves end at the wing transom, or above it; and, afore, they are carried up sometimes as high as the hawse holes. The heighth of the breadth line of the top timber must likewise be formed. This is generally done by a bow, which makes nearly an arch of a circle. It is limited in mid-ships by contract, afore and abaft only by the fancy and judgment of the artists, according to what sheer he designs; we must also form a line for the rising of the floor; for which purpose we must determine the dead rising, which is that of the mid-ship timber. This limits it at that place, and, in the whole moulding, it is pretty near parallel to the lower heighth of the breadth lines. These lines must absolutely be drawn on the sheer

sheer plane, and corresponding to the main and top timber heighths of breadth lines; there must be two half breadth lines formed on the floor plane.

The main half breadth at the mid-ship timber is agreed on by contract, only observing that the thickness of the timber and plank must be deducted out of it, because it is the extreme breadth from outside to outside of the plank that is contracted for. Those in the draughts are called moulded half breadths. Then the breadth at the wing transom, if a square stern, is limited; it is generally about two thirds of the extreme breadth, but this is just as the artist shall think proper. He also fixes the breadth of the top timber, and then describes the two half breadth lines. In the due formation of these curves on the sheer and floor planes, the whole art of drawing chiefly consists; which must be acquired by practice, so that it will be scarce possible for one, that is not very well acquainted with drawing, to form them, without having recourse to some other draughts. After these are formed, the stations of the timbers are fixed; if the room and space, and the breadth of the mid-ship timber, are agreed on by contract, this will determine the station of all the timbers; observing that the timbers abaft the mid-ships must be set off from the foreside of the midship timber; and the timbers before the midship from the aft side of it. At every third or fourth timber there must be perpendiculars drawn on the sheer and floor planes, to the line that represents the lower edge of the keel, which is the common section of these two planes; though sometimes the half breadth lines are described on the sheer plane, when there is not space to produce the perpendiculars till they be of sufficient length to contain the heighth of the breadth and half breadth.

After the timbers are stationed, and the perpendiculars for the frames drawn on the sheer and floor planes; we proceed to the body plane, and draw a line equal in length to the whole breadth moulded. This line may be called the base of the body plane. A perpendicular is erected at each end of it, and one in the middle, which may be produced at pleasure. The next thing to be done, is to form the midship frame: the limits of it are had from the sheer and floor planes; the lower, upper, and top timber heights of the breadth are taken from the sheer plane at the perpendicular, representing the midship frame, and set off on the middle line of the body plane from the base. Through these points, lines are drawn parallel to the base, and the respective half breadths, corresponding to each, are set off on these lines from the middle line in the body plane. The lower and upper main half breadths are limited by the perpendiculars already drawn at each end of the base. The half breadth of the top timber is had from the floor plane on the perpendiculars representing the midship frame. The heighth of the dead rising is likewise taken from the sheer plane, and set up from the base upon the middle line in the body plane, through which point a line parallel to the base must be drawn, and upon this line the half breadth of the floor is set off from the middle line; at which point a perpendicular is erected. The center of the floor sweep is in this line, from which a circle must be described that shall just touch the rising line. A proper radius for the under breadth sweep is next to be found: the center of it is in the lower breadth line, from which it is described to pass through the point which limits the half breadth. After which the radius, and center of a reconciling sweep to join the floor and under breadth sweeps, is found, and the circle described; and, to compleat the frame below the breadth, the half breadth of the keel is set off from the middle line on the base; from which point, a straight line is drawn to touch the back of the floor sweep.

By this way of forming the frame, it is plain the centers and radii of the sweeps are arbitrary, but they must be determined before any of the other timbers can be formed; if by no other means, by repeated trials, till they are made to please the fancy and judgment of the artist. But there are various other ways of forming this frame; so that, though several ships may be of the same breadth, depth in the hold, and dead rising, they may all differ in the form of their timbers. After this midship timber is formed, a pattern or mould is made to fit exactly to the curve, and the dead rising line. By this, and a hollow mould, all the timbers are formed, so far as the rising line and lower heighth of the breadth line are parallel to one another in the sheer plane.

Having explained what the Ship-wrights call whole moulding, we shall proceed to shew the method of forming the body by sweeps.

In Ships of war the general dimensions are established by the authority of those appointed by the government for that purpose. The sheer and floor planes are laid down in this, exactly in the same manner as in that of the whole moulding. We may have a sufficient number of points from the dimensions settled by authority to determine the heighths of the breadth and half breadth lines. A rising of the floor line must likewise be formed on the sheer draught. We may then go to the body plane, and form the midship bend or frame timber; the limits of which we have from the sheer and floor planes, and it must be formed in the same manner as before directed in whole moulding, either by two, three, or more sweeps, as the artists shall think most suitable to the service the ship is designed for. The lower, upper, and top timber heighths of breadth, and risings of the floor are set up on the middle line in the body plane, as in whole moulding, and lines drawn through these points parallel to the base upon which the half breadths are set off. A mould may then be made for the midship frame as before, and laid upon the several risings in the same manner as in whole moulding, with this difference, that here an under breadth sweep is described to pass through the point which limits the half breadth of the timber; the center of which will be in the breadth line of that timber. The proper centers for all the frames being found, and the arches described, the bend mould must be so placed on the rising line of the floor, that the back of it may touch the back of the under breadth sweep. But the general practice is to describe all the floor sweeps with compasses as well as the under-breadth sweeps, and to reconcile these two by a mould which is an arch of a circle; its radius being the same with that of the reconciling sweep, by which the midship frame was formed. It is usual for all the floor sweeps to be of one radius; and, in order to find their centers, a line is formed on the floor plane for the half breadth of the floor: this, as was before observed, is only an imaginary one; for it cannot be described on the surface of the ship: instead of it some make use of a diagonal in the body plane, to limit the half breadth of the floor upon every rising line, and erect perpendiculars at the several intersections in the same manner as for the midship frame, as in the draught; where it is very plain the floor sweep constitutes no part of the after timbers abaft the square body. After the sweeps are all described, we must have recourse to moulds, or some such contrivance, to form the hollow of the timbers, much in the same manner, as in whole moulding; and, when we have thus formed all the timbers, they must be proved by ribband and water-lines, as before directed; and altered, if needful, to make these lines fair: hence it is obvious, that the form of the ribband lines must be determined, before we can with certainty have the true form of the timbers. But there will be a necessity of determining, at least, the form of three timbers, viz. the midship, foremast, and aftermost, before we can form a ribband line. These will give three points, through which the curve of each ribband must pass. The points in the intermediate timbers may be found by forming timbers as before directed; but by repeated trials, altering them till they make fair ribbands; for it is by them that the whole structure is regulated, when every frame is erected into its proper place.

The ingenious Mr. Mungo Murray has invented a new sector, by which the difficulties attending laying down ships is greatly facilitated, the construction of which the reader will find under the article SHIP WRIGHT'S SECTOR. Its uses are as follows:

The general dimensions being determined, and a scale adapted to the draught, take the half breadth with a pair of compasses, and placing one foot in the proper point for the half breadth of ⊕, which will be found in number V. open the sector till the other foot reaches to the same point in the corresponding line on the other leg.

The sector being thus set, it will be indifferent whether we begin with the body or sheer plane: let it then be the sheer.

First, draw the line X Z (*Plate* XLI. *fig.* 4.) to represent the upper edge of the keel, and length of the gun-deck; but it may be produced to the aft side of the wing transom, and fore part of the stem.

Secondly, erect a perpendicular to the line X Z, upon which set up the heights of the wing transom to W; taken from N°. IV. on the sector.

Thirdly, take the rake of the post from number VII. on the sector, and set it forward from the perpendicular of the wing transom to the point 7, where a perpendicular must be erected, which will be the station of that timber.

Fourthly, take the distance of the frames from number III. on the sector, and set it off from 7 to 8; and erect a perpendicular at that point for timber 8. Draw also a line from 8 to the wing transom, to represent the fore-part of the post.

Fifthly, take the heighth and rake of both counters, also the rake of the stern timber, from number II. The heighth of the stern timber is on number I, and by these form the counters, and upright of the stern.

Sixthly, station the timbers, by taking the distance between the perpendiculars at 7 and 8; which at eight times will reach to ⊕; and erect perpendiculars at 5, 3, and ⊕. Then, for stationing the timbers in the forebody, we must turn the sector, and take the distance of the frames from number III, which, set eight times from ⊕, will reach to H. Erect perpendiculars at C, E, G, and H; and from G set off the distance of the gun-deck before G. It is in number I. on the sector, which will reach to Z; at which point erect a perpendicular, and set off the height of the gun-deck, taken from the sector; and from the gun-deck set up the height of the head of the stem, also its distance before G; both taken from number I. We may then form the stem. The center of the sweep is in the perpendicular of timber F, and the radius of the sweep is upon the sector between numbers III. and IV, which, set up from the point F, will give the center: so the sweep will just touch the upper edge of the keel in the point F. And, as the sweep will not reach to the gun-deck, we must make use of a mould to break in fair with the back of the sweep.

Seventhly,

Seventhly, fet up the heighths of the lower, upper, and top timber breadth lines upon the perpendiculars erected for the ftations of the feveral timbers. The points, correfponding to each, are on their proper lines on the fector.

Having thus finifhed the fheer plane, we may then go to the floor plane; and, producing all the perpendiculars for the timbers, we may upon them fet off the main and top timber half breadths. The points correfponding to each are on their proper lines upon the fector; which muft be fet off from the line W K, reprefenting the lower fide of the keel, and may be produced both ways, as far as fhall be needful. We muft in the next place form all the ribband lines, which are the dotted ones in the draught; beginning with the fourth ribband. But it will be more expeditious, firft, to draw all the diagonals in the body plane.

Let A B be the whole breadth, on the middle of which erect the perpendicular K O; fo fhall A K, or K B, be the half breadth. Upon the line K O, fet up the feveral heighths of the breadth lines, taken from the fheer plane, and draw lines parallel to the bafe, as has been already directed; and likewife fet off the half breadths correfponding to each, taken from the floor plane. We may alfo fet off the heighth and half breadth of the wing tranfom; all which may be done without the fector; but we muft have recourfe to it for the dead rifing. This is in number III, in the after body, and muft be fet off upon the line K O, from the lower heighth of breadth to *i*. Through *i* draw the line *r i s*, parallel to the bafe, and fet off the one half breadth of the floor from *i* to *r*, and from *i* to *s*: it is upon number VII. on the fector. Then, taking *r i*, fet it up from *i* upon the line K O, to which point draw the dotted diagonal marked R 1ft. This regulates all the other diagonals: for, if one line be drawn from the point of this interfection, with the middle line, to the half breadth of the wing tranfom; and another from the point *r*, its interfecting with the rifing line, to the point ⊕, at the lower heighth of breadth; each of thefe may be divided into four equal parts by the dotted diagonals 2^d R^d, 3^d R^d, 4^{th} R^d.

Note, the lines from the ends of the firft diagonal to the lower heighth of breadth, and to the wing tranfom, were drawn only with a black lead pencil, and wiped out after the diagonals were drawn. The diagonals being thus drawn, we may form the midfhip frame, for which purpofe we muft find a point in each diagonal, through which the curve of the timber muft pafs. Thefe points we have from the fector; which muft be fet off from the interfections of the diagonals with the line K O. That in the firft diagonal is in number I. The point in the fecond diagonal is in number VI. The point in the third diagonal is in number V. And the point in the fourth diagonal is between numbers I and II. This laft muft be doubled, becaufe the fector will not contain the whole length. The midfhip frame being formed, we muft in the next place form the after and foremoft timber; which the fector does, by giving the diftance on every diagonal between thefe timbers, and the midfhip frame now formed: fo that we fhall have a point in each diagonal, through which the curve of the timber muft pafs. To find the point in the firft diagonal for the after timber, extend 1ft, from ⊕ R in number V, to the correfponding point on the other leg. Set off this diftance from ⊕ on the firft diagonal: do the fame upon the fecond, third, and fourth diagonals. The point on the fecond diagonal is in number IV. That on the third in number VI. And that on the fourth in number VII. The curve muft pafs through thefe points, and likewife through the point for the half breadth, which was before fet off from the fheer and floor planes; by which means we have determined the form of the after timber; and the foremoft timber is to be formed by the fame method. Thefe two timbers being formed, we may find points in the diagonals for all the intermediate timbers. Thus, to find the point for timber 3 in the firft diagonal, extend from the point 3 in the inner part of the line number V. to its correfponding point on the other leg. Set off this in the firft diagonal from the after timber, already formed; which will give the point through which timber 3 muft pafs; and, to find the point in the fecond diagonal, we muft extend from 3 in the inner part of the line number IV, and fet off this diftance in the fecond diagonal from the after timber. The fame method muft be ufed to find the points in the third and fourth diagonals. In like manner we may find a point in each diagonal for the timbers 5 and 7, which will be fufficient for the after body: and the fame procefs muft be ufed to find points in each diagonal for the timbers in the fore body.

Having now found the points, before we form the timbers, it may be proper, by them, to form the ribbands: for now we may take the diftance of each point in the diagonal, from its interfection with the middle line K O, and transfer it to the floor plane upon the perpendiculars that reprefent the planes of the timbers, as before directed. In order to limit the ends of the ribband lines on the floor plane, we muft fet off half the thicknefs of the poft, on one fide of the middle line K O, and half the thicknefs of the ftem on the other fide of it, on the body plane; firft deducting the depth of the rabbet out of it. We muft likewife determine the inner part of the rabbet on the ftem, and upon the poft in the fheer plane. In the ftem, it is generally in the middle between the lines that reprefent the outfide of the rabbet. It may be alfo fo on the poft, from the wing to the lower tranfom; and from thence the line may be continued fair to interfect the line that reprefents the after fide of the rabbet, at the upper edge of the keel; for there the rabbet is cut fquare into the poft.

Now, it is obvious that, when the plane of any diagonal ribband is in its proper place and pofition, the line W K will be in the fheer plane, parallel to the upper fide of the keel; and its heighth will be the fame with that of the point where the diagonal interfects the middle line in the body plane. But by reafon of its inclination, and of the half thicknefs of the ftem and poft, the heighth of the plane of the ribband upon the poft and ftem will be in the point where the diagonal interfects the line that reprefents the rabbet in the body plane. This then muft be transferred from the body to the fheer plane, and fet up from the upper edge of the keel upon a perpendicular that will interfect the line that reprefents the infide of the rabbet at that heighth. This perpendicular may be produced into the floor plane; and, if that part of the diagonal intercepted between the middle line, and the line that reprefents the infide of the rabbet, in the body plane, be fet off upon the perpendicular, it will give the proper point for the end of the ribband line, as may be feen in the plate; where all the ribbands are dotted lines, and they are marked 1ft D R, 2d D R, &c.

Note, the fcale in the plate is fo fmall, that we have taken the outfide of the rabbet to limit the end of the ribband.

The ribbands being thus formed, we may from them form all the timbers below the breadth.

The next thing to be done, is to form the top timbers. We have the heighth and half breadth of each from the fheer and floor planes; and the timbers below the breadth are carried up by a fweep, which forms the lower part of the top timber. The center of this fweep is in the upper heighth of the breadth line of the timber, and may be taken from the fector: it is on number III. after body. The midfhip top timber has generally a hollow, which is left intirely to the artift; for fome, efpecially fmall Ships, have none. The general practice is to make a mould for this hollow, either by a fweep, or fome other contrivance, and produce it confiderably above the heighth of the top timber in a ftraight line, or very near one. The midfhip timber is formed by this mould, and fo placed, that it breaks in fair with the back of the upper breadth fweep. All the other timbers are likewife formed by the fame mould; obferving to place it fo that the ftraight part of it may be parallel to the ftraight part of the midfhip timber; and moved up or down in that direction till it juft touches the back of the upper breadth fweep. Some begin at the after timber after the mould is made for the midfhip one, becaufe they think it eafier keeping the ftraight part of the mould parallel this, than to the midfhip timber; and by this means the top fide is kept from winding. Others again make a mark upon the mould where the breadth line of the midfhip timber croffes it, and with the fame mould they form the after timber. This will occafion the mark that was made on the mould, when in midfhips, to fall below the breadth line of the after timber; and fo another mark is made at the heighth of the breadth of the after timber.

The next thing to be done, is to lay the ftraight part of the mould obliquely acrofs the breadth lines of the top timbers in fuch a manner that it may interfect the breadth line of the midfhip timber at one of thefe marks, and the breadth line of the after timber at the other mark. Then the feveral interfections of the breadth lines of the timbers are marked upon the mould. The mould, being thus marked, muft be fo placed in forming each timber, that the proper mark may be applied to its proper breadth; and the mould be turned about fo as juft to fweep the upper breadth fweep. Any of thefe methods may make a fair fide; but it may be eafily proved by forming another half breadth line.

Hitherto, we have confidered the timbers, as having their planes perpendicular both to the fheer and floor planes. Thefe are called fquare timbers; and, when they are all formed, we may from them form as many ribband and water lines as fhall be neceffary to form the cant timbers. Their planes are inclined to the fheer, but perpendicular to the floor planes. The reafon of canting thefe timbers is that they may nearly be equally fpaced at the breadth ribband: for, if the poft has a confiderable rake, and the timbers all fquare, there will be a great fpace at the breadth ribband, between timber 8 and the wing tranfom: befides, the timber may be fo canted, that it may be fquare to fome of the ribbands; whereas, if they were perpendicular to the fheer plane, they would interfect the ribband lines fo as to form very oblique angles; which would occafion very great bevelling. Another advantage that attends canting the timbers, is that they will not require fuch compafs timber.

It is ufual to begin the cant timbers from the aftermoft floor timber, and fpace them near equally on the breadth line to the wing tranfom: and, in order to fpace them upon the keel, the cant of the fafhion piece muft be determined. Now, if we fuppofe the plane of the fafhion piece to interfect the fheer and floor planes in the point F, it muft interfect the floor plane in the line F P, becaufe the point P is fuppofed to be the end of the wing tranfom. So the angle *s* F P will be its inclination to the ſheer plane. It will interſect the ſheer plane in a perpendicular erected from the point F; and, if the ſpace between the point F and the foremoſt cant timber upon the keel, be divided into the ſame number of equal parts, that the ſpace between the ſame timber, and the wing tranſom upon the breadth line, is divided into; this will determine the cant of all the timbers only by drawing lines from all points in the line W K, to the correſponding points in the breadth line, in the ſame manner as the line F P determines the cant of the faſhion piece.

It would be needleſs to draw all theſe lines in the plate, the only intent of drawing them being to ſhew how to form the timbers by them: and as one method ſerves for all the cant timbers, which are ſuppoſed perpendicular to the floor plane, it will be ſufficient to ſhew the formation of the faſhion piece.

Before any of the cant timbers can be formed, there muſt be a ſufficient number of water lines, or diagonal and horizontal ribband lines, formed from the ſquare timbers; and, when theſe are abſolutely determined, we may, with certainty form all the cant timbers, either by water, or ribband lines.

If we make uſe of the diagonal ribbands, which are diſtinguiſhed by the dotted curves in the floor plane, we muſt form an horizontal ribband correſponding to each. We have only laid down one of theſe horizontals in the plate, viz. that correſponding to the third diagonal: it is marked 3ᵈ H R. To form this ribband, fix one foot of the compaſſes in the point where the third diagonal interſects the midſhip frame in the body plane; and extend the other foot to touch the middle line K O; ſo that, if a line were drawn from one foot of the compaſſes to the other, it would be perpendicular to the line K O: this diſtance ſet off from the line W K, upon the perpendicular that repreſents ⊕ in the floor plane, will give the point thro' which the curve muſt paſs at that place. The ſame method muſt be uſed for finding the points on all the other timbers.

Now, though the diagonal and horizontal ribbands ſeem to be quite different curves in the plates, they will make but one line upon the timbers; for the one interſects them in a direction perpendicular to the ſheer plane, and the other is ſo inclined as to interſect the timbers in the very ſame points. The horizontal one is too ſhort upon the plate, but the true length of it might eaſily be had by transferring to the ſheer plane the ſeveral heighths at which the diagonal interſects the timbers in the body plane. By theſe we might form a heighth of breadth line to correſpond to this horizontal ribband, which is only a half breadth line; and the length of this heighth of breadth line may be taken by a penning batten, and all the timbers marked upon it. Now, when the batten is applied to a ſtraight line, and all the timbers transferred to this line from the batten, we may erect perpendiculars at each, and ſet off the ſame half breadths as before; by which means we may have the true length of the horizontal ribband: but, as this will be of no manner of ſervice, we ſhall omit forming it. We only mention it, becauſe ſeveral imagine theſe two curves to be as different on the ſurface of the Ship as they are upon the draught. The horizontal ribband correſponding to the firſt diagonal one is formed to timber 7, and marked 1ſt H R; but the horizontals for the ſecond and fourth diagonals were formed by a black-lead pencil, and only the point in which they interſect the line F P, is in the plate; which is ſufficient for our purpoſe.

There are likewiſe five water lines formed, four of which are repreſented by level lines in the body plane, and by lines parallel to the keel in the ſheer plane: three of them repreſent the planes of the tranſoms in the ſheer plane, viz. Dᵏ. 1ſt, 2ᵈ: but the plane of the third tranſom is perpendicular to the poſt. The lower water line is drawn parallel to the keel from the ſtem to the poſt, and produced into the body plane, as in the plate, where it is marked M N: the plane of the third tranſom interſects the timbers at different heighths, which are transferred from the ſheer to the body plane, where it forms a curve.

The water lines being now drawn in the ſheer and body plane, our next buſineſs is to form them in the floor plane, where they will be curves. The points through which the curve of the lower water line is to paſs, are had by transferring the ſeveral portions of the level line, intercepted between the line K O, and the curve of each timber, from the body plane to the correſponding perpendiculars in the floor plane, where it is marked *Watʳ* L. It muſt be obſerved that the line K O, in the body plane, repreſents the ſeveral perpendiculars that are drawn in the ſheer plane to repreſent the planes of the timbers: for the ſpaces in the body plane, contained between the line K O and the curves of each timber, are ſo many different planes; and, when in their proper places, they will be parallel to one another, if perpendicular to the ſheer and floor planes. Thus the plane contained between the line K O, and the curve of timber ⊕ is (when in its proper place) ſuppoſed to be erected perpendicular to the ſheer plane, in the line which repreſents the plane of ⊕; and the like may be ſaid of all the reſt.

The planes of the cant timbers will not be parallel to one another, becauſe they are differently inclined to the ſheer plane; but, as they are perpendicular to the floor plane, they will interſect the ſheer plane in a line perpendicular to the keel: ſo the plane of the faſhion piece interſects the ſheer plane in the dotted perpendicular, erected from the point F, which is the ſame with the line K O, in the body plane. We thought it neceſſary to take notice of this, becauſe ſome who are learning to draw, miſtake the line K O; for they imagine it only repreſents the poſt or ſtem.

Another error which they frequently fall into, is about forming the water lines when their planes are not parallel to the keel. They imagine that the half breadths muſt be ſet off from the line W K which repreſents the lower edge of the keel; whereas it is indifferent what ſtraight line they are ſet off from, ſo the timbers be exactly ſpaced, and perpendiculars drawn to repreſent their planes. Now, when the water lines are ſuppoſed parallel to the keel, the timbers are properly ſpaced, and the perpendiculars ready drawn to the line W K; which is the reaſon it is uſed in ſuch caſes: Though, when the plane is in its true place, the line W K will be in the line M N. But the caſe will be quite different when the water lines are not parallel to the keel; for then their planes will interſect the ſheer plane in a ſtraight line, forming oblique angles with the planes of the timbers; this is the caſe in the plane of the third tranſom. The diſtances between the timbers will be more in this line than in the line W K; ſo the half breadths cannot be ſet off from the line W K, upon the perpendiculars that repreſent the planes of the timbers, unleſs they be properly ſpaced at the ſame diſtance they are upon the line that repreſents the plane of the third tranſom in the ſheer plane; upon which account we have made uſe of that line to ſet off the half breadths from, and drawn the dotted perpendiculars at the points where it interſects the planes of the timbers 8, 7, and at the point where it interſects the lower heighth of breadth line. The heighths of the points of interſection are transferred from the ſheer to the body plane; and the half breadths, at theſe heighths, transferred from the body plane to the dotted perpendiculars before drawn: the half breadth to be ſet off upon the perpendicular where it interſects the lower height of breadth line, is had from the floor plane, and the dotted perpendicular *a a* will ſhew the place where the half breadth muſt be taken: this perpendicular, if produced, will interſect the plane of the third tranſom in the lower height of breadth.

Having now formed four diagonal ribbands with their correſponding horizontals, and alſo two water lines; we may, by theſe, form the faſhion piece, either upon the body plane or ſheer plane; but, as the plane of the faſhion piece is parallel to neither of theſe, it will require two operations.

Now the line F P will interſect all the ribband and water lines; but, becauſe the diagonal ribbands are not in their proper poſition, the line F P will not interſect them in the point where the plane of the faſhion piece interſects them. The firſt thing then to be done, is to find the true place of the faſhion piece on each diagonal ribband: and firſt, to find its place upon the fourth diagonal ribband, from the point *t*, where the fourth horizontal ribband interſects the line F P, let fall a perpendicular to the point *s*, and produce it to interſect the diagonal ribband in *r*; ſo ſhall *r* be the true place of the faſhion piece upon that ribband; that part of the perpendicular between *t* and *s* is not drawn in the plate to avoid the confuſion of too many lines. The reaſon of this will be very evident, if we ſuppoſe the whole plane of the ribband to be turned round upon the axis W K; for then the point *r* will always be right over ſome point of the perpendicular *r t s*; and, when the ribband is in its proper inclination, a perpendicular from *r* will fall into the point *t*, and the plane of the faſhion piece will interſect the floor plane in the line *t* F, and the plane of the diagonal ribband in a ſtraight line drawn from *r* to F: for it muſt be obſerved that, when the ribband is in its proper place, the line W K will be in the ſheer plane, in a line parallel to the keel; the height of which may be had from the body plane. In this caſe it will be the diſtance between K and *r*, but it will be needleſs to draw this line in the plate.

Having now found the place of the faſhion piece on the fourth diagonal ribband, we muſt by the ſame method find its place on the other diagonals, as in the plate, where lines perpendicular to W K are drawn to the points *o*, *o*, *o*, in the diagonal ribbands, from the points where the line F P interſects the correſponding horizontal ribbands.

Theſe points being now found, we may take the neareſt diſtance of each point to the line W K, and ſet off thoſe diſtances on the proper diagonals in the body plane. Thus, for the fourth ribband, place one foot of the compaſſes in the point *r*, and the other in the point *s* in the floor plane; and ſet off that diſtance from *r* to S, on the fourth diagonal in the body plane: do the ſame by all the reſt of the diagonals; and a curve interſecting the diagonals in theſe points would be the projection of the faſhion piece in the body plane, but we have not drawn this in the plate; for, as the plane of the faſhion piece is not parallel to that of the body plane, its projection will be leſs than the original: however this may be found by the following method:

Firſt, draw a perpendicular to the line K O, in the body plane, to paſs through the point S to F.

Second, take the diſtance from *r* to F, in the floor plane, and ſet it off from *r* to F, in the body plane. In like manner draw perpendiculars to the line K O, in the body plane, through the points before found on the diagonals, as in the plate, where only

only that part of the perpendicular is drawn which lies without the diagonal; and take the several distances between the points *o* and F, in the floor plane, and set them off from the intersections of their corresponding diagonals, with the line K O, to the points *o*, *o*, in the body plane: so we have the points *o*, *o*, F, through which the curve must pass.

Thirdly, to find the point P in the body plane, through which the curve must pass, transfer the point P in the floor plane, to the point P, in the sheer plane, by a perpendicular to the line W K, to intersect the height of breadth line in the point P; and set off this height upon the line K O, in the body plane, which will be a little above W, the height of the wing transom: draw a perpendicular at this point, to the line K O; take the line F P, in the floor plane, and set it off upon this perpendicular, from the line K O, to the point P: so shall the curve P F *o o* be the form of the fashion piece.

These points may all be found without the diagonal ribbands, by half breadth lines and water lines, formed on the floor plane; as, for instance, to find the point F, place one foot of the compasses in *t*, the point where the horizontal ribband intersects the plane of the fashion piece, and the other in *s*; *t s* being perpendicular to W K: with that extent, move the compasses with one point in the line K O, and the other point perpendicular to it, till it intersect the fourth diagonal, in the point S; through which draw the perpendicular *t* F. Then take the distance from *t* to F, in the floor plane, which set off from *t* to F, in the body plane; so shall F be the point required, as before: in like manner the points *o*, *o*, may be found: but this, as well as the other method, requires two operations; whereas, if several water lines were formed, with their planes parallel to the keel, we might find the points by one operation. Thus, suppose it was required to find a point in the level line, that represents the plane of the water line formed in the floor plane, which is marked *Wat.^r* L, fix one foot of the compasses in the point *f*, where the line F P intersects the water line in the floor plane, and the other foot in the point F. Set off this upon the level line in the body plane, from the line K O to *f*, which will be the point required. All the other cant timbers, both in the fore and after body, are formed after the same manner as the fashion piece. We have formed but one more in the plate, which is abaft the fashion piece, to assist us in forming the transoms.

The transoms are fastened to the stern post, in the same manner that the floor timbers are to the keel; and, as the floor timbers have a rising, so likewise have the transoms, which is called the flight; and besides this flight, the wing transom has a round aft, and a round up, both which are arbitrary: the deck transom has a round up, the same with that of the beams: but, in forming the transoms, there is no regard had to the round up; for that may be done by the beam mould, after the transom is properly hewed the moulding way.

In forming the transoms, the first thing to be done, is to assign each its proper place upon the post, and then to determine the position of their planes with respect to the floor plane; for their planes are always perpendicular to the sheer plane. In the plate there are five transoms: their upper sides upon the post are in the points W, D^k, 1^st, 2^d, and 3^d: the planes of the wing, deck, first and second transoms, are supposed parallel to the floor plane, and represented in the sheer plane by lines drawn parallel to the keel from the post, till they intersect the lower height of breadth line; and the plane of the third is represented by a line perpendicular to the post, as in the plate. So it will not be parallel to the floor plane.

The height and position of the transoms being determined, we have no more to do, but to form water lines for each. That for the third we have already formed: the rest, being supposed parallel to the floor plane, may be formed in the same manner as the water line there laid down: the only difficulty will be to find a sufficient number of points to determine their forms; because, in the deck and first transoms, their planes intersect the breadth; so that we could only have a point in timber 8, if the fashion piece and a timber abaft it had not been formed by the ribbands; but, now they are formed, we may have likewise a point in each of their planes, through which the curves of the water lines shall pass.

We shall begin with the wing transom. First, determine the round aft which suppose the line W T, in the floor plane: take its height from the sheer plane, and set it up in the body plane from K to W, and draw the line W T: then take this line W T, and set it off on the floor plane, on the line F P, which will reach to the point *n*. A curve drawn through the point *n*, to break in fair with the breadth line, as in the plate, will intersect the line W T in T; so shall W T *n* be the aft side of the wing transom. Next, for the deck transom, draw a level line in the body plane at the point D^k to timber 8. Set off this distance upon timber 8, in the floor plane, from the line W K; which will give us a point through which the curve must pass: then take the distance in the level line, between the line K O and the curve of the fashion piece; which set off from the point F, upon the line F P, in the floor plane; and this will give another point through which the curve must pass: again, take the distance in the same level line, between the line K O and the curve of the timber abaft the fashion piece; which set off from the point G upon the line G *g*, in the floor plane; and we shall have a third point through which the curve must pass. Lastly, let fall a perpendicular to the line W K, from the point D^k upon the post, and produce it into the floor plane, upon which set off half the thickness of the post, allowing for the rabbet, which will limit the end of the water line that forms the deck transom. After the same manner are the first and second transoms formed, by drawing level lines in the body plane, at their heights upon the line K O.

Now some are apt to mistake these level lines for the lengths of the transoms: the reason, as was before observed, is because they imagine the line K O to be the stern post; whereas it is the perpendicular in which the plane of the fashion piece intersects the sheer plane; and so these lines are drawn upon the plane of the fashion piece.

All that now remains, is to determine the length of each transom; and this is done by the line F P, in the floor plane, which intersects the wing, deck, first and second transoms, to their proper lengths. But, before we can find the length of the third, the plane of the fashion piece must be projected upon the sheer plane: thus, take the nearest distance between any perpendicular in the floor plane, and the point where the line F P intersects the water line; and set that off from the same perpendicular upon the line that represents the same water line in the sheer plane. Now the curve P F will be found to be the projection of the aft side of the fashion piece upon the sheer plane: for the distance between the perpendicular of timber 8, and the point *f*, where the line F P intersects the lower water line in the floor plane, is equal to the distance between the same perpendicular and the curve P F, taken in the line M N. The distance between the perpendicular of timber 8, and the point where the line F P intersects the second water line in the floor plane, is equal to the distance between the same perpendicular and the curve P F, taken in the line that represents the second transom in the sheer plane. And by the same method, we find points in the lines that represent the deck and first transoms. The point P is transferred from the half breadth line in the floor plane, to the height of breadth line in the sheer plane. The curve, being thus drawn, will intersect the line that represents the plane of the third transom, in the point *z*: from which point draw the perpendicular *z* F, to the curve of the dotted water line; so shall 3^d *z*, F, be the true form of the third transom; and a line drawn from F to P will be the plane of the fashion piece. It must be observed that the ends of the transoms are let into the fashion piece; for which there must be a proper allowance left without the lengths found by the line F P. We have in the plate only laid down the half of each transom. Those who incline to lay down the whole transoms, may easily transfer the halfs already described to the other side of the line W F.

Having now formed all the timbers, both square and cant, in the after body; we shall proceed to the fore body. The cant timbers are laid down in the same manner as those in the after body, by the diagonal and horizontal ribbands; where the dotted line K T represents the plane of the knuckle timber, canted upon the floor plane; from whence it is transferred to the body plane, and represented by the dotted curve between timber H and G.

The hawse pieces are seldom laid down in the loft; it being the general practice to make moulds for them after the other timbers are put up, and the harpins are brought about.

As the harpins are leveled across, they will be formed by the section of a plane perpendicular to the sheer plane: but there is no necessity for these sections to be parallel to the keel. In the plate we have drawn only a straight line to represent the plane of the harpin above the wale. It is drawn from the stem to timber E, and marked harpin. Now, in order to form the curve of this harpin, it would be proper to form timber F, in the body plane: also to draw perpendiculars to the several points where the plane of the harpin intersects the planes of the timbers E, F, G, and H, in the sheer plane; and upon these to set off the half breadths corresponding to each, taken from the body plane. This would give us the points through which the curve must pass, which would be a water line. But, as this is performed exactly in the same manner as the water line that represents the third transom, we judge it unnecessary to form it in the plate.

The rails of the head are projected on the sheer plane, according to their true hangings; and, in order to find their true lengths, draw the dotted line S T, parallel to the keel at the height of the rails, upon the head. We must then determine the station of the cat-head upon the floor plane; and likewise the thickness of the head at the rail; and let fall a perpendicular from the point T, where the line S T intersects the cat-head in the sheer plane, to the point T in the floor plane; and likewise a perpendicular from S in the sheer, to S in the floor plane; and draw the line T S: S S, in the floor plane, being half the thickness of the head of the figure at the rail; so shall T S, in the floor plane, be the true length of the rail. Let the line T S, in the sheer plane, be divided into any

any number of equal parts: ſuppoſe into the points *x*, *y*, *z*; from which points draw perpendiculars to the line T S, to be limitted by the rail. Divide the line T S, in the floor plane, into the ſame number of equal parts, in the points *x*, *y*, *z*. Draw perpendiculars to theſe points, and make them equal to the correſponding ones in the ſheer plane; ſo we ſhall have the points through which the curve of the rail muſt paſs.

We have now ſhewn different ways of forming all the timbers; where it muſt be obſerved that we have always ſuppoſed every timber to be one intire piece of wood from the keel to the top of the ſide; whereas, in reality, they are in ſeveral different pieces; the head of the lower piece being cut ſquare to join to the heel of the next above it: and, in order to ſupport theſe joinings, another ſet of pieces are cut, and joined together in ſuch a manner, that, if both the ſets were faſtened together, the joinings in one ſet would be nearly againſt the middle of the pieces in the other ſet. In this manner are all the frames faſtened and erected, as if each was one piece of wood. The pieces laid acroſs the keel, to which they are faſtened, are called floor timbers: the other pieces are called futtocks, except that which goes to the top of the ſide, which is called a top timber. Hence it is plain that the mould which ſerves for the floor timber, will ſerve for the lower part of the correſponding futtock. The mould for the upper part of the firſt futtock will be the ſame with that for the lower part of the ſecond; and the mould for the lower part of the top timber will be the ſame with that of the upper part of the correſponding futtock. It is alſo of great importance, in building, to give proper ſcarph to the timbers. *Murray on Ship-building.*

SHIPWRIGHT'*s ſector*, the name of an inſtrument, invented by Mr. Mungo Murray, for forming the plane of a ſhip called the body.

This ſector has ſeven lines on each leg, meeting at the center of the joint, numbered I, II, III, IV, &c. ſo that every line upon one leg has a correſponding one upon the other, both divided and numbered alike. The after body is upon one ſide, and the fore body on the other.

The lines for the after body are as follows. See *Plate* XLII. *fig.* 7.

I. Has five diviſions, viz. ⊕, 4, 1ſt dl, 8, ſt[n]; and marked at the end H B T[r], denoting the heighth of the top timber breadth line at four timbers; ſt[n] is the ſtern timber, and 1ſt dl, the firſt diagonal in the body plane.

II. Has eight diviſions, viz. $\frac{L^r C,}{U, A,}$ $\frac{U^r C^r,}{A, U,}$ St[n], 8, 4, ⊕, and marked at the end ½ B T[r], denoting the half breadth of the top timber at three timbers. L[r] C[r] ſignifies the lower counter, and U[r] C[r] the upper counter; U denotes the heighth, and A the rake of the counters, both taken from the wing tranſom; St[n] is the rake of the ſtern timber, which is likewiſe taken from the wing tranſom at the heighth of the ſheer rail.

III. Has eight diviſions, viz. *d*[n], u[r] S. R *i s*, ⊕, 3, 5, 7, 8: it is marked at the end L H B, for the heighth of the lower breadth line for five timbers: *d*[n] is for the diſtance between the frames, and R *i s*, for the diſtance between the lower breadth line, and the dead riſing in the body plane: u[r] S. is the radius of the upper breadth ſweep.

IV. Is in two parts. The innermoſt has four diviſions, viz. 7, 5, 3, ⊕, expreſſing the points where theſe timbers interſect the ſecond diagonal in the body plane: it is marked at the end 2 R for the ſecond ribband.

The outermoſt part has ſix diviſions, viz. ⊕, 3, 5, 7, 8, W T, and marked at the end U H B for the heighth of the upper breadth line at five timbers, and at the wing tranſom denoted by W T.

V. Is likewiſe in two parts. The innermoſt has four diviſions, viz. 7, 5, 3, ⊕, expreſſing the points where theſe timbers interſect the firſt diagonal: it is marked 1[ſt] R for the firſt ribband.

The outermoſt part has eight diviſions, viz. T, 8, 7, 5, 3, ⊕, *k l*, and then marked M ½ B[th], for the main half breadth of five timbers; T for that at the wing tranſom, and *k l* for the half breadth of the keel in midſhips; without which, there is another diviſion marked 3[d] dl for the third diagonal.

VI. Has four diviſions, viz. 7, 5, 3, ⊕, for the points where thoſe timbers interſect the third diagonal: it is marked 3d R, denoting the third ribband; without which, there is another diviſion marked 2d dl, for the ſecond diagonal.

VII. Has five diviſions, viz. 7, ½ B F l, 5, 3, ⊕. ½ B F l, denotes the half breadth of the floor: the other four are for the points where thoſe timbers interſect the fourth diagonal: it is marked 4[th] R, denoting the fourth ribband; without which there is another diviſion for the rake of the poſt marked R[k] P.

The heighth of the gun-deck is between N°. IV and V. G D ⊕ for that in midſhips, and G D *a* for that at the poſt. There is likewiſe another diviſion between N°. I and II for the fourth diagonal: it is marked ½ 4[th] dl, which muſt be doubled, becauſe the length of the ſector will not contain the whole.

The Lines for the Fore Body are.

I. Has three diviſions, viz. H[t] ſtem, $\frac{G^d,\ H^d}{\text{rake } ſ^t\ G}$ denoting the heighth of the ſtem; and its rake from timber G at the gun-deck and head.

II. Has four diviſions, viz. *d*, *b*, and theſe marked H[r], T[r], for the heighth of the top timber line at theſe timbers; and again *d*, *b*, for the ½ breadth of thoſe timbers; and the line marked ½ B T[r].

III. Has four diviſions, viz. d[n] F for the diſtance between the frames, and *c*, *e*, *g*; it is marked L H B, denoting the heighth of the lower breadth line at theſe timbers.

IV. Is in two parts. The innermoſt has four diviſions, viz. *g*, *e*, *c*, ⊕, for the points of interſection of theſe timbers with the ſecond diagonal: it is marked 2[d] R for the ſecond ribband.

The outermoſt part has three diviſions, viz. *c*, *e*, *g*: it is marked U H B, denoting the heighth of the upper breadth line at theſe timbers.

V. Is in two parts. The innermoſt has four diviſions, viz. *g*, *e*, *c*, ⊕, for the points of interſection of theſe timbers with the firſt diagonal: it is marked 1[ſt] R for the firſt ribband.

The outermoſt part has four diviſions, viz. *g*, *e*, *c*, ⊕: it is marked M ½ B[th] for the main half breadth at theſe timbers.

VI. Has four diviſions, viz. *g*, *e*, *c*, ⊕, for the points of interſection of theſe timbers with the third diagonal: it is mark- 3[d] R for the third ribband.

VII. Has four diviſions, viz. *g*, *e*, *c*, ⊕, for the points of interſection of theſe timbers with the fourth diagonal: it is marked 4[th] R for the fourth ribband. The ſweep of the ſtem is between N°. III and IV; and the heighth of the gun deck between IV and V.

The uſe of this inſtrument we have already given under the preceding article. *Murray's Treatiſe on Ship-building.*

SHIVERY *Salt*, a name given by the ſalt-workers to a ſort of ſalt very little different from the common brine ſalt. See SALT.

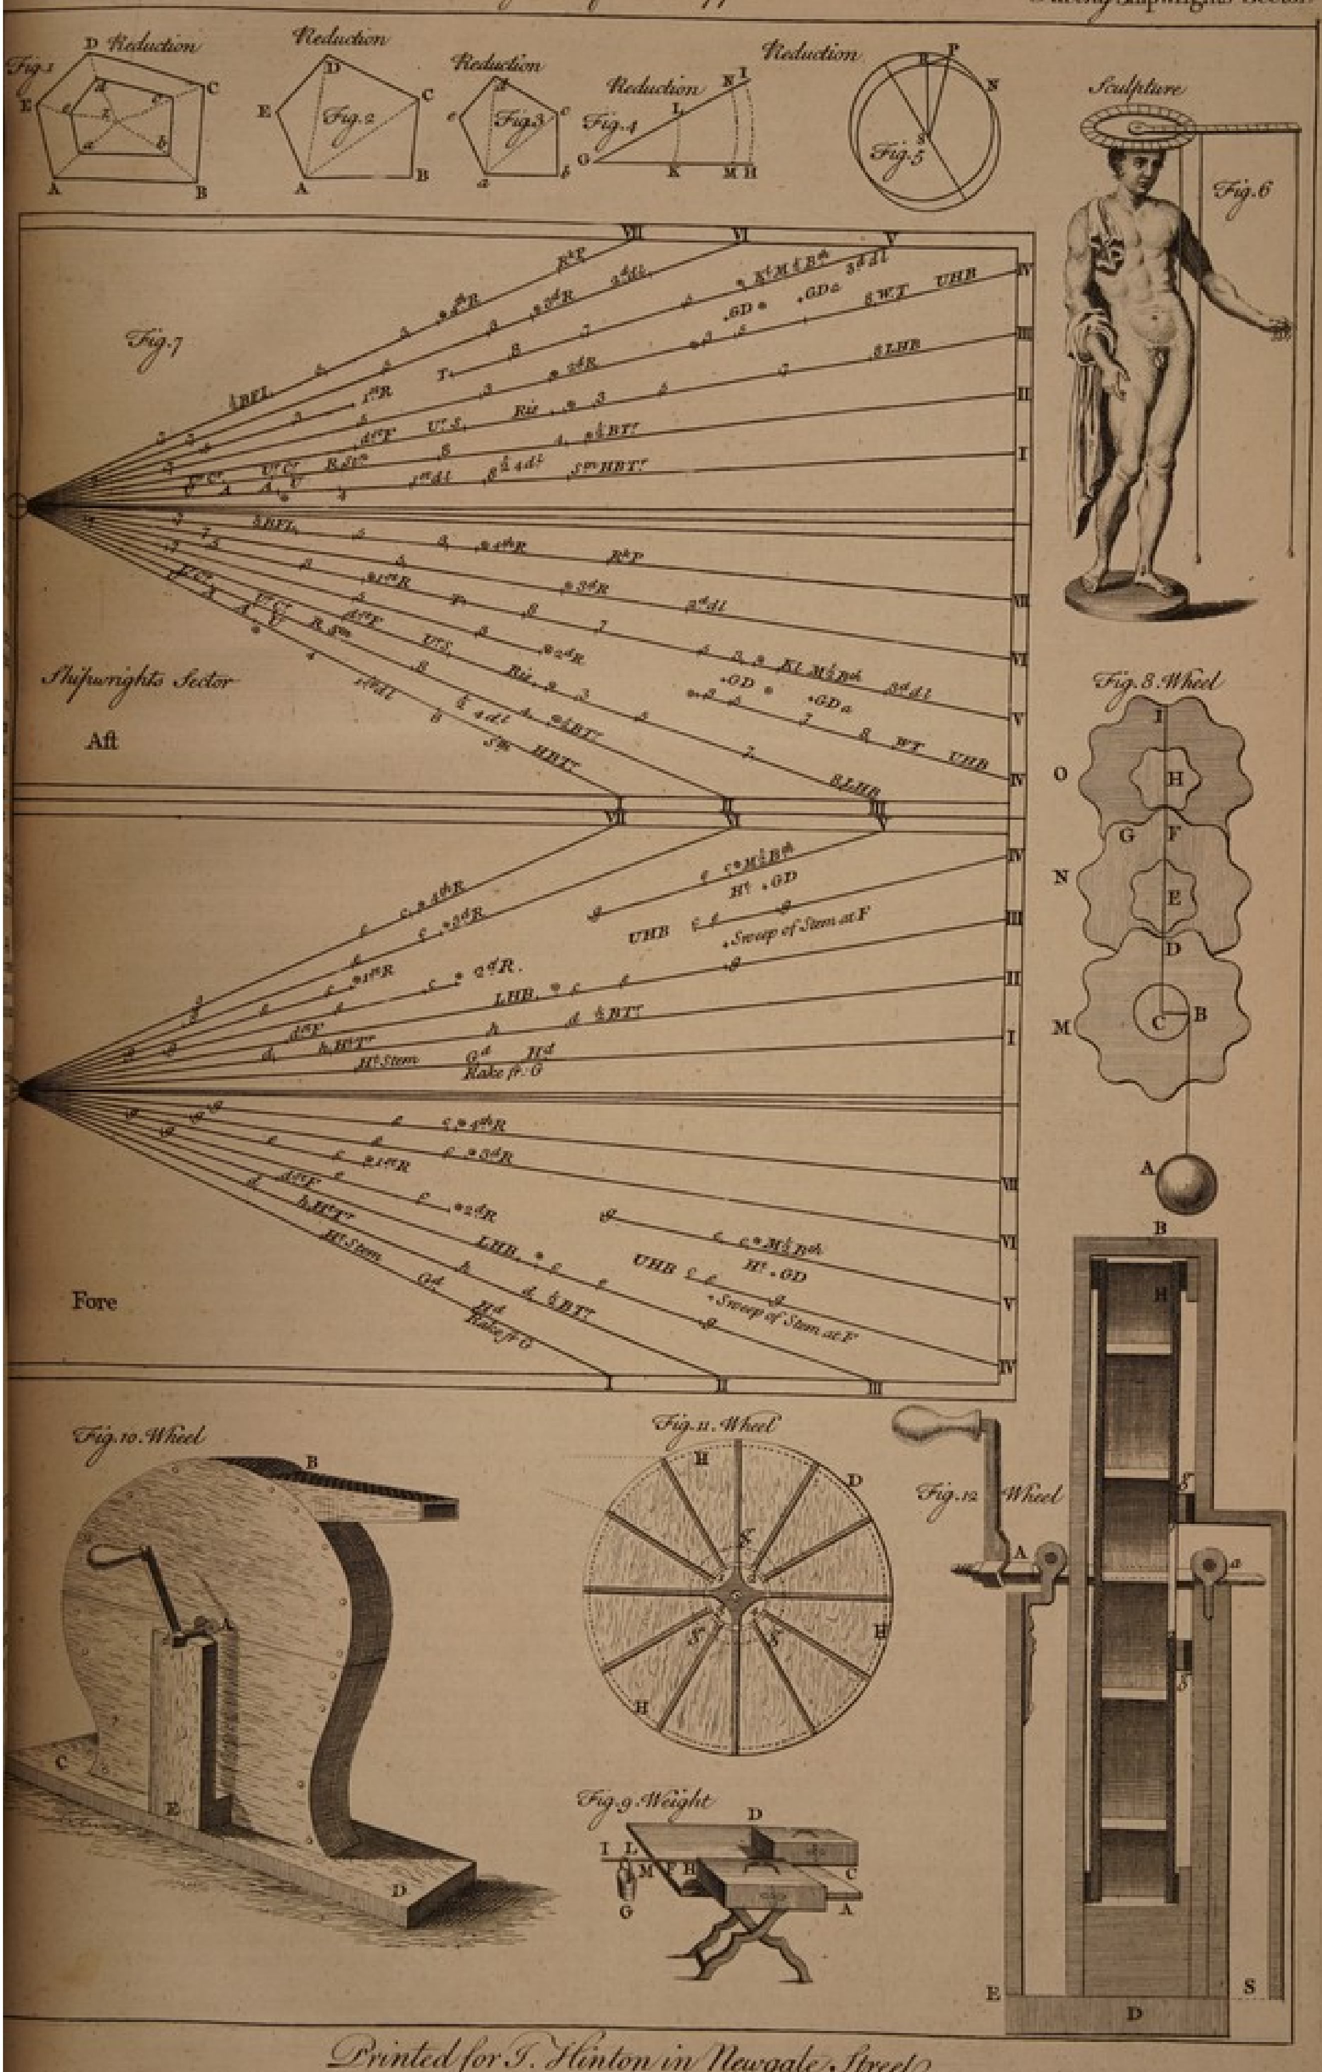
SHOAD, in mining, a term for a train of metalline ſtones mixed with earth, ſometimes lying near the ſurface, ſometimes at conſiderable depths; but always ſerving to the miners as a proof, that the load or vein of the metal is thereabouts. The deeper the Shoad lies, the nearer uſually the vein is. *Ray's Words.*

SHOAD-*ſtones*, a term uſed by the miners of Cornwall, and other parts of this kingdom, to expreſs ſuch looſe maſſes of ſtone as are uſually found about the entrances into mines, ſometimes running in a ſtraight courſe, from the load or vein of ore, to the ſurface of the earth.

SHOT (*Dict.*)— *Plate* XXXV, *fig.* 13, is that ſpecies of Shot called chain Shot; its chief uſe is to deſtroy the rigging of the enemy. *Fig.* 18. repreſents a pile of Shot, in the manner they are placed in magazines, &c.

SICYO'NIUM *ſimplex*, the name of a medicine thus prepared: take of the root of wild cucumber two ounces, and put them into an Italian ſextary, or pint of oil, and boil the ſame in a double veſſel.

SIDERI'TIS, *iron-wort*, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts of one leaf, and is of the labiated kind. The upper lip is erect,



Printed for T. Hinton in Newgate Street.

erect, the lower divided into ſeveral ſegments. The piſtil ariſes from the cup, and is fixed in the manner of a nail into the hinder part of the flower, and ſurrounded by four embryo's, which afterwards become ſo many ſeeds ripening in an open capſule, which was the cup of the flower. To theſe marks it may be added, that in all the Siderites the flowers grow in circles round the ſtalks, at the joinings of the leaves.

SI'GATI-*guſh*, in zoology, the name of a Perſian animal, of the lynx kind, and no way differing from the lynx itſelf, but in that it has no ſpots. Its ears have the fine velvety black pencil of hairs at their top, which are the diſtinguiſhing character of the lynx; and theſe creatures differ ſo much in the variations and different diſpoſitions of their ſpots, that probably this is no other than an accidental variety of the ſame ſpecies. *Ray's Syn. Quad.*

SIGMOI'DES, a word uſed by medicinal writers to expreſs any thing that is in the ſhape of the letter ſigma. The valves of the heart have this epithet applied to them; the coracoide proceſs of the ſcapula is alſo expreſſed by the ſame word; the ſemicircular cavity of the cubit, at the articulation of the forearm with the humerus, is ſometimes alſo called the ſigmoidal cavity; and the cartilages of the ſigmoide circles of the aſpera arteria, or wind-pipe, have their denomination from the ſame occaſions.

SI'GNAL (*Dict.*)— Signals have been in uſe in all ages. The ancients who had no regular couriers or poſts, made uſe thereof to convey intelligence of what paſſed at a great diſtance. For which purpoſe they placed centinels on the eminences, from ſpace to ſpace; ſome mention whereof we find made by Homer himſelf, Iliad. σ. v. 553, &c. Odyſſ. ξ. v. 261. Thoſe people, thus diſpoſed, lighted fires, or flambeaux, in the night-time. In the Agamemnon of Æſchylus, that prince, at his departure for Troy, promiſes Clytemneſtra, that, the very day the city ſhould be taken, he would apprize her of his victory by fires lighted expreſs. He keeps his word, and tidings are brought the princeſs, that Troy is taken, and that Agamemnon's Signals are ſeen. Frontinus obſerves, they were in uſe among the Arabs; and Bonaventura Vulcanius, in his Scholia on Ariſtotle's book de Mundo, adds, that while the Moors were maſters of the greateſt part of Spain, they built, on the tops of the mountains, an infinity of turrets, or watch-houſes, called, in the Arabic, atalayas, a word the Spaniards ſtill retain; whence, by fires, they could immediately alarm the whole kingdom. Indeed the cuſtom was much more ancient than the Moors in Spain. Q. Curtius obſerves, it was very frequent among the Aſiatics, in the time of Alexander. Livy and Cæſar both mention it as uſed among the Romans. Polydore Virgil ſhews it of great antiquity in England; and Bœthius adds, that, in ſeveral places in England, there are the remains of huge poles that have ſerved for this purpoſe.

SIGNALS *at ſea*, are ſigns made by the admiral or commander in chief of a ſquadron of ſhips, either in the day or by night, whether for ſailing, for fighting, or for the better ſecurity of the merchant ſhips under their convoy.

Theſe Signals are very numerous and important; being all appointed and determined by order of the lord high admiral, or lords of the admiralty; and communicated in the inſtructions ſent to the commander of every ſhip of the fleet or ſquadron before their putting out to ſea.

SIGNALS *by day.*— When the commander in chief would have them prepare for ſailing, he firſt looſes his fore-top-ſail, and then the whole fleet are to do the ſame. When he would have them unmoor, he looſes his main-top-ſail, and fires a gun, which in the royal navy is to be anſwered by every flag-ſhip. When he would have them weigh, he looſes his fore-top-ſail, and fires a gun, and ſometimes hawls home his ſheats: the gun is to be anſwered by every flag-ſhip, and every ſhip to get to ſail as ſoon as it can. If with the leeward-ſide, the ſtern-moſt ſhip is to weigh firſt. When he would have the weather-moſt and head-moſt ſhips to tack firſt, he hoiſts the union-flag at the fore-top-maſt-head, and fires a gun, which each flag-ſhip anſwers; but, if he would have the ſtern-moſt and leeward-moſt ſhips to tack firſt, he hoiſts the union-flag at the mizen top-maſt-head, and fires a gun; and, when he would have all the whole fleet tack, he hoiſts an union, both on the fore and mizen-top-maſt-heads, and fires a gun. When, in bad weather, he would have them wear, and bring to the other tack, he hoiſts a pendant on the enſign-ſtaff, and fires a gun: and then the leeward-moſt and ſtern-moſt ſhips are to wear firſt, and bring on the other tack, and lie by, or go on with an eaſy ſail, till he comes a-head: every flag is to anſwer with the ſame Signal. If they are lying by, or ſailing by a wind, and the admiral would have them bear up and ſail before the wind, he hoiſts his enſign and fires a gun, which the flags are to anſwer: and then the leeward-moſt ſhips are to bear up firſt, and to give room for the weather-moſt to wear, and ſail before the wind with an eaſy ſail, till the admiral comes a-head. But if it ſhould happen, when the admiral hath occaſion to wear and ſail before the wind, that both jack and enſign be abroad, he will hawl down the jack, before he fires the gun to wear, and keep it down till the fleet is before the wind. When they are ſailing before the wind, and he would have them bring to, with the ſtar-board tacks abroad, he hoiſts a red flag at the flag-ſtaff, on the mizen-top-maſt-head, and fires a gun. But if they are to bring to, with the lar-board tack, he hoiſts a blue flag at the ſame place, and fires a gun, and every ſhip to anſwer the gun. When any ſhip diſcovers land, he is to hoiſt his jack and enſign, and keep it abroad, till the admiral or commander in chief anſwers him, by hoiſting his; on ſight of which, he is to hawl down his enſign. If any diſcovers danger, he is to tack and bear up from it, and to hang his jack abroad from the main-top-maſt croſs-trees, and fire two guns: but, if he ſhould ſtrike or ſtick faſt, then, beſides the ſame Signal with his jack, he is to keep firing, till he ſees all the fleet obſerve him, and endeavour to avoid the danger. When any ſees a ſhip or ſhips more than the fleet, he is to put abroad his enſign, and there keep it, till the admiral's is out, and then to lower it, as often as he ſees ſhips, and ſtand in with them, that ſo the admiral may know which way they are, and how many; but if he be at ſuch a diſtance, that the enſign cannot well be diſcovered, he is then to lay his head towards the ſhip or ſhips ſo deſcried, and to brail up his low ſails, and continue hoiſting and lowering his top-ſails, and making a waſt with his top-gallant ſails, till he is perceived by the admiral. When the admiral would have the vice-admiral, or he that commands in the ſecond poſt of the fleet, to ſend out ſhips to chace, he hoiſts a flag, ſtriped white and red on the flag-ſtaff, at the fore-top-maſt head, and fires a gun. But, if he would have the rear-admiral do ſo, he then hoiſts the ſame Signal on the flag-ſtaff, at the mizen-top-maſt-head, and fires a gun. When the admiral would have any ſhip to chace to windward, he makes a Signal for ſpeaking with the captain, and he hoiſts a red flag in the mizen-ſhrowds, and fires a gun: but, if to chace to leeward, a blue flag; and the ſame Signal is made by the flag, in whoſe diviſion that ſhip is. When he would have them give over chace, he hoiſts a white flag on his flag-ſtaff at the fore-top-maſt-head, and fires a gun: which Signal is to be made alſo by that flag-ſhip which is neareſt the ſhip that gives chace, till the chacing ſhip ſees the Signal. In caſe of ſpringing a leak, or any other diſaſter, that diſables their ſhip from keeping company, they are to hawl up their courſes, and fire two guns. When any ſhip would ſpeak with the admiral, he muſt ſpread an Engliſh enſign, from the head of his main, or fore-top-maſt, downwards on the ſhrowds, lowering his main, or fore-top-ſail, and firing guns, till the admiral obſerve him; and if any ſhip perceive this, and judgeth the admiral doth not, that ſhip muſt make the ſame Signal, and make the beſt of his way to acquaint the admiral therewith, who will anſwer by firing one gun. When the admiral would have the fleet to prepare to anchor, he hoiſts an enſign, ſtriped red, blue, and white on the enſign-ſtaff, and fires a gun, and every flag-ſhip makes the ſame Signal. If he would have the fleet moor, he hoiſts his mizen-top-ſail, with the clew-lines hawled up, and fires a gun. If he would have the fleet cut or ſlip, he looſes both his top-ſails, and fires two guns; and then the leeward ſhips are to cut or ſlip firſt, to give room to the weathermoſt to come to ſail. So if he would have any particular ſhip to cut or ſlip, and to chace to windward, he makes the Signal for ſpeaking with that ſhip, hoiſts a red flag in the mizen ſhrowds, and fires a gun: but, if the ſhip is to chace to leeward, he hoiſts a blue flag as before. If he would have the fleet exerciſe their ſmall arms, he hoiſts a red flag on the enſign-ſtaff, and fires a gun; but, if the great guns, then he puts up a pendant over the red flag.

SIGNALS *by night.*— To be obſerved at an anchor, weighing anchor, and ſailing, are as follow. When the admiral would have the fleet to unmoor, and ride ſhort, he hangs out three lights, one over another in the main-top-maſt ſhrowds, over the conſtant light in the main-top, and fires two guns, which are to be anſwered by flag-ſhips; and each private ſhip hangs out a light in the mizen-ſhrowds. Note, That all guns, fired for Signals in the night, muſt be fired on the ſame ſide, that they may make no alteration in the ſound. When he would have them weigh, he hangs a light in the main-top-maſt ſhrowds, and fires a gun, which is to be anſwered by all the flags, and every private ſhip muſt hang out a light in his mizen-ſhrowd. When he would have them tack, he hoiſts two flags on the enſign-ſtaff, one over another, above the conſtant light in his poop, and fires a gun, which is to be anſwered by all the flags; and every private ſhip is to hang out a light extraordinary, which is not be taken in, till the admiral takes in his. After the Signal is made, the leeward-moſt and ſtern-moſt ſhips muſt tack as faſt as they can, and the ſtern-moſt flag-ſhip, after he is about on the other tack, is to lead the fleet, and him they are to follow, to avoid running foul of one another in the dark. When he is upon a wind, and would have the fleet veer, and bring to on the other tack, he hoiſts up one light at the mizen-peek, and fires three guns, which is to be anſwered by the flag-ſhips, and every private ſhip muſt anſwer, with one light at the mizen-peek. The ſtern-moſt and leeward-moſt ſhips are to bear up as ſoon as the Signal is made. When he would have them, in blowing weather, to lie a try, ſhort, or a hull, or with the head-ſails braced to the maſt, he will form lights of equal height, and fire five guns, which are to be anſwered

by

by the flag-ships, and then every private ship must shew four lights: and after this, if he would have them to make sail, he then fires ten guns, which are to be answered by all the flags, and then the head-most and weather-most ships are to make sail first. When the fleet is sailing large, or before the wind, and the admiral would have them bring to, and lie by with their star-board tacks aboard, he puts out four lights in the fore-shrowds, and fires six guns; but if with the lar-board tacks aboard, he fires eight guns, which are to be answered by the flag-ships; and every private ship must shew four lights. The wind-most ships must bring to first. Whenever the admiral alters his course, he fires one gun, without altering his lights, which is to be answered by all the flag-ships. If any ship hath occasion to lie short, or by, after the fleet hath made sail, he is to fire one gun, and shew three lights in his mizen-shrowds. When any one first discovers land, or danger, he is to shew as many signs as he can, to fire one gun, and to tack, or bear away, from it: and, if any one happen to spring a leak, or any be disabled from keeping company with the fleet, he hangs out two lights of equal height, and fires guns till he is relieved by some ship of the fleet. If any one discovers a fleet, he is to fire guns, make false fires, put one light out on the main-top, three on the poop, to steer after them, and to continue firing of guns, unless the admiral call him off, by steering another course, and fire two or three guns; for then he must follow the admiral. When the admiral anchors, he fires two guns, a small space of time one from the other, which are to be answered by the flag-ships; and every private ship must shew two lights. When the admiral would have the fleet to moor, he puts a light on each top-mast-head, and fires a gun, which is to be answered by the flag-ships, and every private ship is to shew one light. If he would have them lower their yards and top-masts, he hoists one light upon his ensign-staff, and fires one gun; which is to be answered by the flag-ships, and every private ship must shew one light. And when he would have them hoist their yards and top-masts, he puts out two lights, one under the other, in the mizen-top-mast-shrowds, and fires one gun; which is to be answered by the flag-ships, and each private ship must shew one light in the mizen-shrowds. If any strange ship be discovered coming into the fleet, the next ship is to endeavour to speak with her, and bring her to an anchor, and not suffer her to pass through the fleet. And if any one discovers a fleet, and it blow so hard that he cannot come to give the admiral notice timely, he is to hang out a great number of lights, and to continue firing gun after gun, till the admiral answers him with one. When the admiral would have the fleet to cut or slip, he hangs out four lights, one at each main-yard-arm, and at each fore-yard-arm, and fires two guns, which are to be answered by the flag-ships, and every private ship is to shew one light.

SIGNALS *used, when a fleet sails in a fog.*—If the admiral would have them weigh, he fires ten guns; which every flag-ship is to answer. To make them tack, he fires four guns, which are to be answered by the flag-ships; and then the lee-ward-most and stern-most ships must tack first, and, after they are about, to go with the same sail they tacked with, and not to lie by, expecting the admiral to come a-head: and this is to avoid the danger of running foul of one another in thick weather.

When the admiral brings to, and lies with his head-sails to the mast; if with the star-board tack abroad, he fires six guns; but, if with the lar-board tack, he fires eight guns, which the flag-ships are to answer. And after this, if he makes sail, he fires ten guns, which the flag-ships must answer, and then the head-most and weather-most ships are to make sail first. If it grow thick and foggy weather, the admiral will continue sailing, with the same sail set that he had before it grew foggy, and will fire a gun every hour, which the flag-ships must answer, and the private ships must answer, by firing of muskets, beating of drums, and ringing of bells. But if he be forced to make either more or less sail than he had, when the fog began, he will fire a gun every half-hour, that the fleet may discern, whether they come up with the admiral, or fall a-stern of him; and the flags and private ships are to answer as before. If any one discovers danger, which he can avoid, by tacking and standing from it, he is to make the Signal for tacking in a fog; but if he should chance to strike and stick fast, he is to fire gun after gun, till he thinks the rest have avoided the danger. When the admiral would have the fleet to anchor, he fires two guns, which the flags are to answer; and after he hath been half an hour at an anchor, he will fire two guns more, to be answered by the flags, as before; that all the fleet may know it.

SIGNALS *for calling officers on board the admiral.*—When the admiral puts aboard an union-flag in the mizen-shrowds, and fires a gun, all the captains are to come aboard him: and if, with the same Signal, there be also a waft made with the ensign, then the lieutenant of each ship is to come on board. If an ensign be put aboard in the same place, all the masters of the ships of war are to come on board the admiral. If a standard on the flag-staff be hoisted at the mizen-top-mast-head, and a gun fired, then all the flag-officers are to come aboard the admiral. If the English flags only, then a standard in the mizen-shrowds, and fire a gun: if the flags and land general officers, then the admiral puts aboard a standard at mizen-top-mast-head, and a pendant at mizen-peek, and fires a gun. If a red flag be hoisted in the mizen-shrowds, and a gun fired; then the captains of his own squadron are to come aboard the admiral; and if, with the same Signal, there be also a waft with the ensign, the lieutenant of each ship must come aboard. If he hoists a white flag, as before, then the vice-admiral, or he that commands in the second post, and all the captains of his squadron, are to go on board the admiral: if a blue flag, &c. then the rear-admiral, and the captains of his squadron, must come on board; and if a waft, as before, the lieutenants. When a standard is hoisted on the ensign staff, and gun fired, the vice and rear-admirals must come on board the admiral's ship. When the admiral would speak with the captains of his own division, he will hoist a pendant on the mizen-peek, and fire a gun; and if with the lieutenants, a waft is made with the ensign, and the same Signal: for whenever he would speak with the lieutenants of any particular ship, he makes the Signal for the captain, and a waft also with the ensign. When the admiral would have all the tenders in the fleet come under his stern, and speak with him; he hoists a flag, yellow and white, at the mizen-peek, and fires a gun. But if he would speak with any particular ship's tender, he makes a Signal for speaking with the captain she tends upon, and a waft with the jack. If all the pinnaces and barges are to come on board, manned and armed, the Signal is a pendant on the flag-staff, hoisted on the fore-top-mast-head, and a gun fired; and if he would have them chace any ship, vessel, or boat, in view, he hoists the pendant, and fires two guns. The Signal for the long-boats to come on board him, manned and armed, is the pendant hoisted on the flag staff, and the mizen-top-mast-head, and a gun fired; and if he would have them chace any ship, vessel, or boat, in open view, without coming on board him, he hoists the pendant, as aforesaid, and fires two guns. When the admiral would have all the boats in the fleet come on board him, manned and armed, he hoists a pendant on the flag-staff, both on the fore-top-mast, and mizen-top-mast-head, and fires one gun; but if he would have them chace, he hoists his pendants, as before, and fires two guns. When the admiral would speak with the victualler, or his agent, he puts an English ensign in the mizen-top-mast-shrowds; and when with him that hath the charge of the gunner's stores, he will spread an ensign at his main-top-sail-yard-arm.

SIGNALS *for managing a sea-fight.*—When the admiral would have the fleet form a line of battle, one ship a-head of another, he hoists an union-flag at the mizen-peek, and fires a gun; and every flag-ship does the like. But when they are to form a line of battle, one a-breast of another, he hoists a pendant with the union-flag, &c. When he would have the admiral of the white, or he that commands in the second post, to tack, and endeavour to gain the wind of the enemy, he spreads a white flag under the flag at the main-top-mast-head, and fires a gun; and when he would have the vice-admiral of the blue do so, he doth the same with the blue flag. If he would have the vice-admiral of the red do so, he spreads a red flag from the cap, on the fore-top-mast-head, downward on the back-stay; if the vice-admiral of the blue, he spreads a blue flag, &c. and fires a gun. If he would have the rear-admiral of the red do so, he hoists a red flag at the flag-staff, at the mizen-top-mast-head; if the rear-admiral of the white, a white flag; if the rear-admiral of the blue, a blue flag, and under it a pendant of the same colour, with a gun. If he be to leeward of the fleet, or any part of it, and he would have them bear down into his wake or track, he hoists a blue flag at the mizen-peek, and fires a gun. If he would be to leeward of the enemy and his fleet, or any part of it to be to leeward of him; in order to bring these ships into the line, he bears down with a blue flag at the mizen-peek, under the union-flag, which is the Signal for battle, and fires a gun; and then those ships, that are to leeward of him, must endeavour to get into his wake or track, according to their station in the line of battle. When the fleet is sailing before the wind, and he would have him, who commands in the second post, and the ship of the star-board quarter to clap by the wind, and come to the star board tack, he hoists a red flag at the mizen-top-mast-head: but a blue one, if he would have ships of the lar-board quarter come to the lar-board tack, with a gun. If the van are to tack first, he spreads the union-flag at the flag-staff, on the fore-top-mast-head, and fires a gun, if the red flag be not abroad; but if it be, then he lowers the fore-top-sails a little; and the union-flag is spread from the cap of the fore-top-mast downwards; and every flag-ship doth the same. If the rear be to tack first, he hoists the union-flag on the flag-staff, at the mizen-top-mast-head, and fires a gun; which all the flag-ships are to answer. If all the flag-ships are to come into his wake or track, he hoists a red flag at his mizen-peek, and fires a gun; and all the flag-ships must do the same. If he would have him that commands in the second post of his squadron to make more sail, though he himſelf ſhorten ſail, he hoiſts a white flag on the enſign-ſtaff. But, if he that commands in the third poſt be to do ſo, he hoiſts a blue flag, and fires a gun, and all the flag-ſhips muſt have the ſame Signal. Whenever he hoiſts a red flag on the flag-ſtaff at the fore-top-maſt-head, and fires a gun; every ſhip in the fleet muſt uſe their utmoſt endeavour to engage the enemy, in the order preſcribed them. When he hoiſts a white flag at his mizen-peek, and fires a gun; then all the ſmall frigates of his ſquadron, that are not of the line of battle, are to come under the ſtern. If the fleet be failing by a wind in the line of battle, and the admiral would have them brace their head ſails to the maſt, he hoiſts up a yellow flag, on the flag-ſtaff, at the mizen-top-maſt-head, and fires a gun; which the flag-ſhips are to anſwer: and then the ſhips in the rear muſt brace firſt. After this, if he would have them fall their head-ſails, and ſtand on, he hoiſts a yellow flag on the flag-ſtaff of the fore-top-maſt-head, and fires a gun, which the flag-ſhips muſt anſwer, and then the ſhips in the van muſt fall firſt, and ſtand on. If, when this Signal is made, the red flag at the fore-top-maſt-head be abroad, he ſpreads the yellow flag under the red. If the fleets being near one another, the admiral would have all the ſhips to tack together, the ſooner to lie in a poſture to engage the enemy; he hoiſts an union-flag on the flag-ſtaves at the fore and mizen-top-maſt-heads, and fires a gun; and all the flag-ſhips are to do the ſame. The fleet being in a line of battle, if he would have the ſhip that leads the van, hoiſt, lower, ſet, or hawl up any of the ſails, he ſpreads a yellow flag, under that at his main-top-maſt-head, and fires a gun, which Signal the flag-ſhips are to anſwer; and then the admiral will hoiſt, lower, ſet, or hawl up the ſail, which he would have the ſhip that leads the van, do; which is to be anſwered by the flag-ſhips of the fleet. When the enemies run, and he would have the whole fleet follow them, he makes all the ſail he can after them himſelf, takes down the Signal for the line of battle, and fires two guns out of his fore-chaſe, which the flag-ſhips anſwer; and then every ſhip is to endeavour to come up with, and board the enemy. When he would have the chace given over, he hoiſts a white flag at the fore-top-maſt-head, and fires a gun. If he would have the red ſquadron drawn into a line of battle, one a-breaſt of another, he puts abroad a flag, ſtriped red and white, on the flag-ſtaff at the main-top-maſt-head, with a pendant under it, and fires a gun: if the white or ſecond ſquadron is to do ſo, the flag is ſtriped red, white, and blue: if the blue or third ſquadron is to do ſo, the flag is a Genoeſe enſign and pendant: but if they are to draw into a line of battle, one a-head of another, the ſame Signals are made without a pendant. If they are to draw into the line of battle one a-ſtern of another, with a large wind, and he would have the leaders go with the ſtar-board tacks, a-board by the wind; he hoiſts a red and white flag at the mizen-peek, and fires a gun: but if they ſhould go with the lar-board tacks aboard, by the wind, he hoiſts a Genoeſe flag at the ſame place; which Signals, like others, muſt be anſwered by the flag-ſhips.

SI'LEX, *flint*, in natural hiſtory, the name of a genus of ſemipellucid ſtones, the matter of which is a cryſtal, debaſed by an admixture of a peculiar and appropriated earth, which is of a blackiſh grey; always free from veins, but, according to the different quantity and diſpoſition of the earth in its compoſition, ſubject to clouds of a darker or paler colour, and naturally inveſted with a thin whitiſh cruſt.

Naturaliſts, in general, have accounted various ſpecies of flint, but erroneouſly; nature has eſtabliſhed it into a genus of itſelf, and allowed no other ſpecies than one, which is ever compoſed of the ſame matter, and differs only in the proportions of its admixture. When cryſtalline matter is debaſed by earths of other colours, or clouded and veined, it ceaſes to be flint, and becomes the pebble, the agate, or the onyx; and the not attending to this diſtinction has made many deſcribe theſe variouſly-coloured bodies twice over: one under the name of coloured flints, and a ſecond time under that of Engliſh agates, &c.

The characters of genuine flint are, that it is a ſtone of an extremely fine and even texture; of a very uncertain ſurface, ſometimes rough, ſometimes ſmooth; of a colour always, in ſome degree, between blackiſh and whitiſh, unleſs accidentally tinged, as all other foſſils are ſubject to be; very readily giving fire with ſteel; not fermenting with acids. *Hill's Hiſt. of Foſſils.*

SI'LIQUA, in botany, the name of a genus of trees, the characters of which are theſe: the flower is of the apetalous kind, being compoſed only of a number of ſtamina, which ariſe from the ſegments of the cup, the middle of which is occupied by a piſtil, which finally becomes a flatted pod of a fleſhy ſubſtance, and containing flat and roundiſh ſeeds.

SILIQUA'STRUM, *judas-tree*, in botany, the name of a genus of trees, the characters of which are theſe: the flower is of the papilionaceous kind; the wings, however, ſtand over the vexillum, and the carina is compoſed of two leaves. The piſtil ariſes from the cup, and is ſurrounded by ſtamina; this finally becomes a flat membranaceous pod, filled with ſeeds of a kidney-like form. To this it is to be added, that the leaves ſtand alternately.

SILK-*worm*, *bombyx*. This inſect conſiſts of eleven rings, and each of theſe of a great number of other ſmaller ones, joined to each other; and the head, which terminates theſe rings, is furniſhed with two jaws, which work and cut the food, not by a perpendicular, but a lateral action. The humours, found in the body of this creature, all ſeem approaching to the nature of the Silk which it ſpins, for on being rubbed in the hands, they leave a hard or ſolid cruſt behind them. Under the ſkin there is always found a muſcous roſy-coloured membrane, enveloping the animal, and ſuppoſed to be the new ſkin in which it is to appear, on throwing off the old one. The heart of this creature reaches from the head to the tail, running the whole length of the body: it is indeed rather a ſeries of many hearts connected together, than one. The motion of ſyſtole and diaſtole is very evident in this whole chain of hearts; and it is an elegant ſight to obſerve the manner of the vital fluids paſſing from one of them to the other. The ſtomach of this animal is as long as the heart, reaching, like it, from one end of the body to the other. This large receptacle for food, and the ſudden paſſage of it through the animal, are very good reaſons for its great voracity.

In the ſides of the belly, all about the ventricle, there are depoſited a vaſt number of veſſels, which contain the ſilky juice; theſe run with various windings and meanders to the mouth, and are ſo diſpoſed, that the creatures can diſcharge their contents at pleaſure at the mouth; and according to the nature of the juices, that they are ſupplied with, furniſh different ſorts of ſilk from them, all the fluid contents of theſe veſſels hardening in the air into that ſort of thread, that we find the web of balls of this creature conſiſt of.

Theſe creatures never are offended at any ſtench of whatever kind, but they always feel a ſouthern wind, and an extremely hot air always makes them ſick. *Malpighi de Bombyce.*

SI'LVERING.—To ſilver braſs: fine ſilver is diſſolved in aqua-fortis in a broad-bottomed veſſel of glaſs, or glazed earth, and the aqua-fortis being afterwards evaporated, and the operation repeated as often as there is occaſion; the fire being increaſed towards the latter end, ſo as to leave a perfectly dry and white calx, which will be thus tolerably freed from the aqua-fortis. Of this calx take one part, and an equal meaſure, not weight, of common ſalt, and of the cryſtals of tartar, and mix them together into a fine powder; then, having firſt plunged the ſcowered braſs into fair water, rub ſome of the powder upon it with your wet fingers, till the cavities of its ſurface be ſufficiently filled therewith. Laſtly, waſh the metal well in water, and give it a gloſs by rubbing it hard with a dry cloth.

This waſhing, Mr. Boyle obſerves, is expeditious, cheap, requires no quick-ſilver, and may be made to laſt ſome years, and is eaſily renewable, when it begins to wear. *See his Works Abr. Vol. Iſt.*

SINA'PI, *muſtard*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is compoſed of four leaves, and is of the cruciform kind. The piſtil ariſes from the cup, and finally becomes a long pod, divided by an intermediate membrane into two cells, and containing roundiſh ſeeds; the pod alſo uſually terminates in a fungoſe horn, which has ſome ſeeds in it. To this it is to be added, that theſe plants have all a hot, acrid, and biting taſte.

SI'REN (*Dict.*)—Artedi ſuppoſes it to conſtitute a peculiar genus of the plagiuri, or cetaceous fiſhes. The characters he gives of it are theſe: it has no pinnated tail; the head, neck, and breaſt, down to the navel, repreſent thoſe of the human ſpecies; there are only two fins on the whole body, and thoſe ſtand on the breaſt. Bartholine, in his hiſtory of Curioſities, deſcribes ſuch a fiſh as this, under the name of Syrene, and Barchewitz under the name of homo marinus. This author ſays that he ſaw one at ſea, and that it is wholly different from the manati, and from all other fiſhes. The Philoſophical Tranſactions alſo contain an account of a ſea-man ſeen in the American ſeas, and ſeveral other writers of credit give countenance to the ſtory. Their deſcriptions tell us, that from the navel to the tail it is one ſhapeleſs maſs of fleſh, without any appearance of finny tail, or any other part of the ſtructure of a fiſh. The pectoral fins reſemble hands, and are compoſed of five bones, or fingers, joined by a membrane. With theſe it ſwims. It were much to be wiſhed, that ſome accurate ichthyologiſt might have an opportunity of ſeeing and examining this creature, if it really exiſts different from the other animals of the ſea. Artedi ſeems to doubt the truth of the accounts, but thinks it better not to judge of a thing not yet ſeen, than to pronounce any thing raſhly againſt the accounts of creditable authors. *Artedi, Geſner. Piſc.*

SKIN, in commerce. The Indians in Carolina and Virginia dreſs buck and doe ſkins in this manner: the felt being taken off, they ſtrain them with lines, or otherwiſe, much like the clothiers racks, in order only to dry them. When the hunting time is over, the women dreſs the ſkins, by putting them in a pond, or hole of water, to ſoak them well; then with an old knife, fixed in a cleft ſtick, they force off the hair, whilſt they remain wet. This done, they put them into a kettle, or earthen-pot, and a proportion of deers brains, dried and preserved for this purpose, is put in along with them; this vessel is set on the fire till they are more than blood-warm, which will make them lather and scour clean; after this, with small sticks, they wrest and twist each skin, as long as they find any wet to drop from them, letting them remain so wrested for some hours; and then they untwist and stretch each of them in a sort of a rack, so that every part is extended: and, as the skin dries, they take a dull hatchet, or some such instrument, and rub them well over to force all the water and grease out of them, till they become perfectly dry, and then their work is done.

In this manner one woman (for the men never employ themselves in this work) will dress eight or ten skins in a day, that is, begin and finish them. *Phil. Transf.* N°. 194.

SKI'NUS *cnide*, a name given by the antient naturalists to the lentisk-tree, and also to a peculiar species of the squill, or scilla, which was not nauseous and emetic as the common squill, but esculent and pleasant to the taste.

SKY-*colour*. To give this colour to glass, set in the furnace a pot of pure metal of frit from rochetta, or barillia, but the rochetta frit does best; as soon as the metal is well purified, take for a pot of twenty pounds of metal six ounces of brass calcined by itself, put it by degrees, at two or three times, into the metal, stirring and mixing it well every time, and diligently scumming the metal with a ladle: at the end of two hours the whole will be well mixed, and a proof may be taken; if the colour be found right, let the whole stand twenty-four hours longer in the furnace, and it will then be fit to work, and will prove of a most beautiful sky-colour. *Neri's Art of Glass.*

SLABS *of tin*, the lesser masses, which the workers at the tin mines cast the metal into: these are run into moulds made of stone. *Ray's English Words.*

SLA'CKEN, in metallurgy, a term used by the miners to express a spungy and semivitrified substance, which they use to mix with the ores of metals, to prevent their fusion. It is the scoriæ or scum, separated from the surface of the former fusions of metals. To this they frequently add lime-stone, and sometimes a kind of coarse iron ore, in the running of the poorer golden ores.

SLAU'GHTER-*skins*, a term used by our curriers and leather-dressers for the skins of oxen, or other beasts, when fresh, and covered with the hair: such as they receive them from the Slaughter-houses where the butchers flea the carcase.

SLEDGE, in the mechanic arts, is a large smith's hammer, to be used with both hands: of this there are two sorts, the uphand-sledge, which is used by under workmen, when the work is not of the largest sort; it is used with both the hands before, and they seldom raise it higher than their head. But the other which is called the about-sledge, and which is used for battering or drawing out the largest work, is held with both the hands, and swung round over their heads, at their arms end, to strike as hard a blow as they can. *Moxon's Mechanic Exercises.*

SLEE'PERS, in natural history, a name given to some animals which sleep all the winter: such are bears, marmotes, dormice, bats, hedge-hogs, swallows, &c. These do not feed in winter; have no sensible evacuations, breathe little, or not at all, and most of the viscera cease from their functions. Some of these creatures seem to be dead, and others to return to a state like unto that of the fœtus before birth. In this condition they continue, till by length of time maturating the process, or by new heat, the fluids are attenuated, the solids stimulated, and the functions begin where they left off. See *Dr. Stevenson in Med. Ess. Edinb.* Vol. V. *Art.* 77.

Sleepers, in the glass trade, are the large iron bars crossing the smaller ones, and hindering the passage of the coals, but leaving room for the ashes. *Neri's Art of Glass, Appendix.*

Sleepers, in a ship, timbers lying before and aft in the bottom of a ship, as the rung-heads do; the lowermost of them is bolted to the rung-heads, and the uppermost to the futtocks, in order to strengthen and fasten the futtocks and rungs.

SLICH, in metallurgy, the ore of any metal, particularly of gold, when it has been pounded, and prepared for farther working.

SLOTH, in natural history, the name of an animal remarkable for its slow motion. This creature is so very tedious in all its motions, that it will be three or four days in climbing up and coming down a tree, and does not go the length of fifty paces upon even ground in a day.

SLOE-*worm*, in natural history, the name of an insect found on the leaves of the Sloe, or black-thorn, and sometimes on those of the garden-plum.

SLOW-*worm*, the English name of the cæcilia, called also the blind-worm, and by some the deaf adder: it is very venomous, and its bite often fatal.

SLUDS, a term used by the miners in Cornwal for half-roasted ores.

SMALL-*stones*, among jewellers, denote diamonds under the weight of a carrat. *Jeffreys on Diamonds.*

Small-*work*, among jewellers, is used to denote the star and shell-facets of diamonds. *Jefferys on Diamonds.*

SMALT (*Dict.*)— Some cobalt yields Smalt before roasting, even better than it would afterwards; this is a peculiar kind of cobalt, that is so like the rest, that it cannot be distinguished by the eye, but experiment alone shews this property in it. Though cobalt in general requires roasting, in order to fit it for yielding the Smalt, yet its different kinds require some more, and some less roasting; and the degree can never be judged of by the inspection of the mineral, but is only known by the experienced artist in the process. Hence it is, that expert and intelligent persons are necessary in the Smalt-works more than in almost any other branch in this sort of business. The addition of a small quantity of arsenic, or of the arsenical flowers, during the time that the Smalt is in fusion, adds greatly to the beauty of the colour: this is a practice kept secret by the workmen of some places; and by this means their Smalt is always rendered better than that of their neighbours. It is easy to see from this, that the roasting of the cobalt is the necessary beginning of the Smalt-work, not the divesting it of its arsenic, which only happens accidentally in that process; and it would be much better if it did not happen, since we find the arsenic added afterwards exalts the colour. From hence it is evident, that those cobalts which will make Smalt without previous roasting, must, as they are found to do, make the very finest Smalt, because their arsenic is yet left in them in great part: and from this also appears the necessity of having expert workmen for the Smalt-making; since the knowing the degree of fire necessary to the ore is a most essential article, and, after the roasting has been carried to a sufficient degree, every moment's heat, divesting it of more of its arsenic than was necessary, makes the colour of the Smalt to be made afterwards so much the worse. From this also appears the reason why the blue, made by precipitation from a solution of cobalt, is so much superior to the common Smalt made by fire; because in this the arsenic is all preserved, whereas, in the common way of preparing it by fire, it is driven off. *Philos. Transf.* N°. 396.

SME'CTIS, in natural history, a name used by several authors for the common fuller's earth, more commonly called cimolia purpurascens.

SMELL, is used as the name of a particular sort of wine, of which there are two species; the one sort is very fragrant, muscatelline, and aromatic; this is called simply the Smell-wine; but the other, which is very rank and offensive to the nose, is called by the Germans Smel-bruntzer. Many have been the conjectures about the occasion of the rank Smell of this wine, it not being owing to the grape it is made from, those of the same vineyard often affording the aromatic, and often the rank wine: some have imputed the strange difference to the vessel, others to the vine, and others to the earth it grows in; but the first of these is too trifling a cause for such an effect, and the others are confuted by experience of the same vine, in the same place, yielding both. The opinion of Portzius is, that the rankness of the Smell of some of this wine is owing to some irregularities in the working; this is certain, that it never is perceived before the working. The Smell is truly urinous, and is that of a volatile alkali; which not being embodied in, or subdued by the acid of the grape, in this imperfect fermentation, shews itself in this rank manner. It is evident that the Smell is of a volatile nature, for it is often lost in the drawing the wine several times out of one vessel into another, evaporating during the time of the drawing it out. *Portzius, de Vin. Rhen.*

SMELT, *aqua phalerica*, in ichthyology, the name of a well known fish.

These fish will live almost any where, but they are very apt to degenerate. They are common in the rivers of New-England, and are as large as with us, often weighing two ounces and a half; but, a pail-full of these being taken from one of their rivers, and put into an adjoining pond, they all degenerated in such a manner, that they were afterwards found so small, that the largest did not weigh more than five penny-weights. Though thus small, however, they are much valued, and are better tasted than the others. They are very transparent, and of a beautiful shining pearl colour. *Philos. Transf.* N°. 374.

SME'LTING-*house*, a house where they run and smelt the ore into lead: one of these will run a ton in ten or twelve hours; a fodder is their usual day's work, that is, twenty-two hundred and an half weight. *Houghton's Compl. Min. in the Explan. of the Terms.*

SMI'LAX, in botany, the name of a genus of plants, the characters of which are these: the flower is of the rosaceous kind, being composed of several petals arrayed in a circular form. The pistil finally becomes a soft roundish berry, containing a roundish or oval seed.

SMUT, in husbandry, a disease in corn, in which the grains, instead of being filled with flower, are full of a black stinking powder.

Many things have been suspected as the causes of this distemperature in corn; but Mr. Tull seems convinced by experiment, that it is caused only by too much moisture, the several plants of corn, which he had taken up by the roots and planted in troughs of very moist earth, all bringing forth smutty ears,

ears, while very few such were found in the corn of the field from whence these plants were taken. It is observable, also, that those ears, the grains of which are to be smutty, never send up any flowers at all.

The two things, recommended by writers of husbandry as remedies or preventions of this disease are brining and changing the seed. The first of these methods was accidentally discovered about a century ago: a ship loaded with wheat was, about autumn, sunk near Bristol, afterwards the wheat was taken up at the ebbs at several times, after being thoroughly soaked in sea-water. When the wheat was all taken up, it was found unfit to make bread of; but a farmer, trying some of it for sowing, found it answer very well, and himself, and the neighbouring farmers, bought it all up at a small price; the country all about was sown out of this cargo. It happened that smuttiness in the wheat-corn was a reigning distemper in all parts of the kingdom at that time, but it was remarkable, that all the fields sown with this salt wheat were absolutely free from the mischief: this easily introduced the practice of soaking wheat, before sowing, in a brine of salt and water, to prevent it in other places, and it has succeeded well. Mr. Tull gives an instance of the certainty of its effect, in the case of two farmers whom he personally knew, and whose farms lay intermixed: these men bought the same seed between them from a very good change of land, and parted every land between them in the field; the oldest farmer believed the brining to be a fancy, and sowed his seed unbrined; the other brined all his seed, and the consequence was, that the old farmer had a great deal of Smut in his corn, while the other had not one smutty ear.

When wheat is intended for drilling, it must be soaked in no other brine than that of pure salt and water; for, if there be any grease among it, it will never be dry enough for this manner of sowing. If seed wheat be soaked in urine, it will not grow; and, if it be only sprinkled, it will most of it die, unless it be planted presently. The most expeditious way of brining wheat for drilling, is to lay it in a heap, and wash it with a strong brine sprinkled on it, stirring it up with a shovel, that it may be all equally brined or wetted with it: after this, sift on some fine lime all over the surface, and stir it up, still sifting on more in the same manner till the whole is dusted with the lime; it will then be soon dry enough to be drilled without farther trouble. It must be quick-lime, in its full strength, that is used on this occasion.

Bad years will cause Smut in corn, and good years will prevent it: it is, however, observable, that the crops in which there is smutty corn, will, if used for seed, be liable to produce smutty corn again, rather than other seed. The brining is a defence against bad years, and against the mischiefs attending the sowing corn among which there has been Smut.

The other method of changing the seed is by many held effectual, to prevent smuttiness in the crop; several, who have tried this with due care, have found perfect success from it; and it is to be observed, as to the great success of the drowned wheat at Bristol, that it was a change of seed to the lands on which it was sown, as well as brined seed.

Seed-wheat should be brought from the crop on a strong clay land, whatever kind of land it is to be sowed upon. A white clay is a good change for a red clay, and a red clay for a white; but whatever the land be, from which the seed is taken, it may be infected, if that be not changed there the preceding year; and then there may be danger, though it be had from ever so proper a land. It is a rule among the farmers, never to buy seed-wheet from a sandy soil; they express their dislike of this by the coarse rhime, Sand is a change for no land.

A crop of wheat, very early planted, is not so apt to be smutty, as one planted less early; and the farmers have observed, that the largest and plumpest ground fat wheat is more liable to be smutty than the small ground wheat. *Tull's Horse-hoeing Husbandry.*

SMY'RNIUM, *Alexanders*, in botany, the name of a genus of the umbelliferous plants, the characters of which are these: the flower is of the rosaceous kind, consisting of several petals, arranged in a circular order on a cup, which afterwards becomes a fruit of a sort of globular figure, composed of two thick, and, in some degree, lunated seeds, being gibbose and striated on one side, and flat and smooth on the other.

SNAILS, are great destroyers of fruit in our gardens, especially of the bitter sorts of wall-fruit. Lime and ashes, sprinkled on the ground where they most resort, will drive them away, and destroy the young brood of them. It is a common practice to pull off the fruit they have bitten; but this should never be done, for they will eat no other till they have wholly eat up this, if it be left for them.

The Romans were fond of Snails, and had them fed on purpose for their tables. Their taste is not delicious, but rather disagreeable; but this they disguised by means of good sauces, and had other reasons for the receiving them into the lists of foods.

They used them as provocatives or inciters to venery, and with this intent they eat only the necks, as the part in which the parts of generation of the creature were placed; and they had the greater opinion of the efficacy of these, as the parts of generation were double in each individual, that is, the male and female parts both situated in the neck of every Snail.

Aristotle, and the old Greeks, had no idea of the generation of these insects, in the manner of other animals, but supposed them produced spontaneously; but the Romans shew, by many passages in their writings, that they had got over this error, and even seem, by the preference they give to the neck of this animal, in this intention, to have understood the hermaphrodite structure of this insect, which much later ages have pretended to make a new discovery.

The eastern nations at present run much into the opinions of the Romans of old, as to provocatives; they use, as the others did, every thing that serves to the purposes of generation in other animals, and every thing that has but the resemblance of the external figure of the parts subservient to it. The orchis roots, which resemble the testicles of animals in shape, and contain a white and slimy, or viscous liquor, have introduced themselves into use on this plan, and so of many other things. *Phil. Trans.* N°. 50.

Oat SNAIL, a name given by Dr. Lister, in the Philosophical Transactions, to a small Snail, which he observed under the loose bark of old willows, elms, and other trees, and which is of a very singular structure; the shell resembling an oat-corn, whence the name and its volutæ, or wreaths, running contrary to the direction of them in other Snails, that is, east and west, as the philosophers express it, referring it to the motion of the sun; but these shells, to use that language, have the turns west and east, or, more plainly, they have the turns running from the right-hand to the left, not from the left to the right as other Snails. *Phil. Trans.* N°. 250.

SNAKE, *anguis*, in natural history, the name of a well-known reptile, of the serpent kind.

SNAKE with two heads, a kind of Snake in Brazil, having a swelling at his tail, which, at a distance, has the appearance of a head.

The Portuguese call it Snake with two heads; their fear of this creature, for the bite of which they pretend there is no remedy, having prevented their examining into the truth. They also pretend that it is dangerous to meddle with these Snakes after they are dead, and that barely touching them will give the itch. Mr. Couplet was, notwithstanding, bold enough to flea several of them, but found himself, after having performed this operation on two or three, all covered with pustules filled with a reddish water. These remained on him a considerable time, and he was not quite well in three months.

The country of Brazil abounds with large Snakes, the bite of which is venomous, but the natives and blacks make no scruple of eating them. *Mem. de l'Acad. des Sciences*, 1700.

SNA'PDRAGON, *antirrhinum*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf of a tubular form, personated, and having two lips, the upper of which is bifid, and the lower trifid. The pistil arises from the cup, and is fixed, in the manner of a nail, in the hinder part of the flower; and afterwards becomes a seed-vessel, of the shape of the head of a hog, divided into two cells, and usually filled with small seeds fixed to a placenta.

Many of the species of this plant are very beautiful, and much esteemed in gardens, and are all easily propagated from seeds, which must be sown in a dry soil, not too rich, in April or May. In July the plants may be planted out into large borders, where they will flower the spring following; or they may be sown early in the spring, and they will then flower in the next autumn; but then they are not so likely to stand the winter, and, if the autumn proves not kindly, they will hardly produce a perfect thin seed. They all grow very well on old walls, where they have happened to sow themselves. *Miller's Gard. Dict.*

SNATCH-*block*, in a ship, is a great block with a shiver in it, having a notch cut through one of its cheeks, for the more ready receiving in of any rope; for by this notch the middle part of a rope may be reeved into this block, without passing it in endways. This ready block is commonly fastened with a strap about the main-mast, close to the upper deck, and is chiefly used for the fall of the winding tackle, which is reeved into this block, and then brought to the capstan.

SNIPE, in zoology.— These birds are easily taken, by means of lime-twigs, in this manner: take fifty or sixty birchen twigs, and lime them all very well together; take these out into places where there are Snipes, and, having found the places which they most frequent, which may be seen by their dung, set the twigs in these places, at about a yard distance one from another. Other places are those where the water lies open in hard frosty and snowy weather: in these places also, and wherever they are suspected to come to feed, let more lime-twigs be placed in the same manner. The twigs are not to be placed perpendicularly in the ground, but sloping, some one way and some another; the sportsman is then to retire to a distance, and watch the coming of the birds to these places. When they fly to them, they naturally take a sweep round the earth, and by this means they will almost always be caught by one or other of the twigs. When a first Snipe is taken, the sportsman is not to run to take it up, for it it will feed with the twig under its wings, and this will be a means of bringing down more of them to the place. When three or four are taken, they may be taken up, only leaving one faſt to entice others; and thus the ſport may be continued, as long as there are any birds of this kind about the place. It may be very proper, when the twigs are planted, to go about, and beat all the open and watery places near, that they may be raiſed from thence, and fly to thoſe places where the twigs are placed to receive them.

SNOW-*drop-tree*, a very beautiful American tree, which bears the cold of our climate in the open air; but it is very difficult to encreaſe, the layers being two years before they take root, nor will they ever take root at all, except the branches are very young, and are ſlit in the joint, as in the laying carnations. When thoroughly rooted, they may be tranſplanted into ſmall quarters of flowering-ſhrubs, where, among thoſe of a middling growth, they add much to the variety. *Miller's Gard. Dict.*

SNOW-*ſtone*, in natural hiſtory, a name given by ſome to a very beautiful ſtone found in America; of which the Spaniards are very fond, making it into tables, and other ornaments in their houſes. Alonſo Barba, who had ſeen much of it, tells us, that it is found in the province of Atocama, and is uſually found in pieces of four feet long, and four or five inches broad; ſo that it is forced to be joined in the working. Its general thickneſs is about two inches. It has a great variety of colours, which form clouds and variegations of a very beautiful kind. The principal colours are, red, yellow, green, black, and white. The white is generally formed into ſpots on the very blackeſt parts of the maſs, and is ſo beautifully diſpoſed, that it repreſents Snow falling in all its whiteneſs upon a jetty ſurface. *Alonſo Barba, of Metals.*

SOAL, in ichthyology, the Engliſh name of the fiſh, called by the generality of authors the buglofſus, by ſome ſolea.

It is, according to the new ſyſtem of Artedi, a ſpecies of the pleuronectes, and is of that kind which have the eyes placed on the left ſide. Some authors call it the linguacula.

Almond SOAP, *amygdalinus*, a new form of medicince got much into uſe of late in nephritic caſes, and made to ſupply the place of the common hard Soap for internal uſes, in a more determinate manner for the phyſician, and a more cleanly one for the patient.

It is thus made:—Take any quantity of freſh oil of almonds, and thrice its quantity of Soap lees; digeſt them together in ſuch a heat as will make them but juſt boil; within a few hours the oil and lees will be united, and the liquor will ſoon after become ropy, and ſomething tranſparent, and will cool into the conſiſtence of a jelly; then throw in ſea-ſalt till the boiling liquor has loſt its ropineſs; continue the boiling till, drops of the liquor being received upon a tile, the water is ſeen to ſeparate freely from the coagulated Soap; then take away the fire, and the Soap will riſe to the top of the water, and is to be taken off for uſe. *Pemberton's College Diſp.*

SOAP-*earth* (*Dict.*)— The people of Duraclea make Soap with this earth in the following manner: they mix three-fourths of this earth with one fourth of lime, and then poor boiling water upon the mixture; they ſtir this with a ſtick, and there ariſes to the top a thick browniſh ſubſtance, which they ſcum off; they ſave this in veſſels by itſelf. They uſe both this and the clear liquor in making Soap, but this is much ſtronger than the liquor. They put fifty kintals of oil into a large copper furnace, and, kindling a large fire under it, they let the oil boil a little, and then throw in, by little and little, firſt the ſcum of the ley, and afterwards the liquor itſelf; though ſometimes they uſe only the one, or only the other. They continue adding more and more of theſe till the oil acquires the conſiſtence of Soap, which is often ſeveral days. The fire muſt be all this time kept up very ſtrong. The ſcum of the lye, and the ſtronger part of the ley itſelf, mix with the oil in the boiling, and the weaker part, unmixing itſelf, ſinks to the bottom, and is let out by a cock prepared for that purpoſe. This is not thrown away, but is let run upon freſh lime and earth, to make a ley for future uſe; and, when the Soap is perfectly made, it is ladled out, and put upon a brick or lime floor to harden.

The common proportion, in the making the Soap, is two loads of earth of five kintals each, to fifty kintals of oil, and the produce is between ſeventy and eighty kintals of Soap. The earth is bought at a dollar a load, and the Soap at ſix-pence half-penny a kintal. There are employed annually, in making Soap at Smyrna, at leaſt ten thouſand kintals of oil. The bringing the Soap earth to Smyrna employs a thouſand or fifteen hundred camels, for eight months of the year, the four ſummer months being too hot for camels to travel in. A common Soap-houſe produces, at a medium, a thouſand dollars a year clear profit. *Phil. Tranſ.* N°. 220.

There is great reaſon to believe that, when we know the proper manner of working, this will, one way or other, make a great ingredient in our porcelain manufactures.

The Chineſe have of late diſcovered a ſort of earth which they call hoache. They ſay that this is hard, ſmooth, and ſoft to the touch, like Soap; theſe, and its other qualities, ſeem to prove it to be the ſame with our Soap-rock, and this, with them, makes a ſort of porcelain, ſuperior to the common kind in beauty, and in the compactneſs of its texture, but it is more apt to crack. They uſe it ſeveral ways, ſometimes alone, ſometimes with the petunſe, which is a ſtone; and ſometimes they make a varniſh, by diſſolving this in water, with which they coat over the common China, covering it finally with the other varniſh. All theſe ways of uſing it produce very beautiful wares, and it will be extremely worth our while to try them all round, before we give up the uſe of ſo valuable a thing. *Obſerv. ſur les Coutumes de l'Aſie.*

SOIL (*Dict.*)— The land of England, as conſidered by the farmer, is reduced into nine ſorts of Soils; the ſandy, the gravelly, the chalky, the ſtony, the rocky, the hazely, the black earth, the marſh, and the clay land. Of this kind there are four varieties, diſtinguiſhed by their colours; the black, the blue, the yellow, and the red. In many places theſe Soils are mixed and blended together, and where it is ſo, it is much better than where they are ſeparate or ſingle; eſpecially where the mixtures happen to be of a right kind, as thoſe of the hot and dry Soils blended with the cold and the moiſt. Nature does this often, and art may imitate it. All ſands are hot, and all clays are cold; and therefore the laying clay upon ſandy lands, or ſand upon clayey lands, is the beſt of all manure: this alters and changes for the better the very nature of the land itſelf, whereas dung only improves it for a time, and after that leaves it as bad as it was before. Mixed Soils, that tend to the clayey kind, are the beſt of all others for corn. It is not only the natural Soil we are to conſider, but the depth of it, and what Soil is underneath; for the richeſt Soil, if it be only eight or ten inches deep, and lies upon a cold clay, or upon ſtones, will not be ſo fruitful to the farmer as the leaner Soils that lie upon better under-ſtrata. Gravel or ſand are the beſt under-ſtrata, of all others, to make the land above prolific.

Cold and wet clays are much more fruitful in the ſouthern parts of England, than in the north. The climates, therefore, are to be conſidered, and the quantities or proportions of the different kinds in the mixed Soils. The natural produce of the land, as to weeds or graſs, is alſo to be greatly regarded by the perſon who intends to improve upon it.

What is the effect of plowing is next to be enquired into, and experiment muſt ſhew what kind of corn agrees beſt with it.

All land that moulders into duſt with froſt, with all ſorts of warm lands, black mould, yellow clays, if not too ſpewy when wet, and all that turn black after rain, are in general good lands for corn. Land that produces large trees, as alſo ſuch as produces black-thorn, weeds, thiſtles, rank graſs, and the like, and that lies in bottoms open to the eaſt or ſouth, being well ſheltered from the other winds, may be always eſteemed to bid fair for good land. Thyme, ſtrawberries, betony, and wild ſage, direct to the places where wood will thrive beſt; and camomile is always an indication of a land being diſpoſed to bear corn in large crops.

All land that binds after froſt and rain, all that turns white, and is full of worms, or is very moiſt and cold, or that is too hot and dry, and that lies open to the north on the ſides of hills, expoſed to cold winds and froſts in winter, and to the ſun's ſcorching heat in ſummer; and all that bears naturally holly, box, ivy, juniper, fern or brakes, furzes, broom, and heath; and lands that bear moſſes, ruſhes, yarrow, and wild tanzy, with flags, and other ſuch weeds, which betoken a cold and damp ground; are leſs fit for corn, though other things may ſucceed on it. Where plants appear blaſted, ſhrubby, and curled, theſe are diſtempers in them occaſioned by ſudden changes of wet and cold, and a dry heat. All theſe lands are, by their natural produce, to be judged leſs fruitful than the others. Blackiſh, dun, or yellow land, and very hot ſtony gravel, are generally eſteemed very unfruitful. Chalky lands are naturally cold, and therefore they require warm compoſts; and this is the reaſon why chalk itſelf is ſo good a manure for hot and dry land. Sandy land, well manured with marl, will bear turneps, or white or blue peaſe, to great advantage. *Mortimer's Huſbandry.*

The ſupply of freſh vegetable matter, in the place of that which was drained away by the ſucceſſive growths of plants, is done by ſeveral ways, but by none ſo well, as by letting it lie fallow for ſome time; in this caſe the rain falling upon it, the vegetable earth, which this water contains, is depoſited in ſufficient quantity, and this is alone ſufficient to give nutriment to new crops; and it is proved by this, that the rain water, as well as other water, does contain ſuch earth as is neceſſary to vegetation. The other means of giving a ſupply to the exhauſted earth are the manures laid on it by the farmer, and theſe are, all of them, ſome animal or vegetable remains, and their uſe is to drain into the earth thoſe particles from themſelves, which may be again received into the bodies of new productions of the ſame kinds. Blood, urine, the excrements of animals, with their ſeveral parts, as horns, hoofs, hair, feathers, calcined ſhells, and vegetable bodies in an altered ſtate, ſuch as lees of wine and beer, aſhes of burnt vegetables, leaves, ſtraw, roots, ſtubble, and the like, when in a decaying ſtate, turned

under

under the earth again by plowing, there become disunited into their component parts, and these again are carried up into other new plants.

If we take off our thoughts from the fields, and look among the gardens, we there meet with farther confirmations of the same thing: the trees, shrubs, and herbs cultivated in these, after they have continued in one station, till they have derived thence the greater part of the matter fitted for their increase and nourishment, will either decay, or degenerate, unless they have a new supply of manure added to the earth about their roots, or are themselves translated into other earth, not so drained of that particular matter out of which they are to be fed.

The older trees have some more supplies of fit matter than the younger, by means of the length of their roots, which, when they have drained one spot of ground, usually are carried much farther into another, and reach a very great way; but at last they can reach no farther, and all fails, unless such a supply of manure, or the being removed into fresh earth, supply that nourishment they can no longer have where they stand. The gardeners, when they transplant trees, cut off these long roots; but, though they only do this to prevent the trouble of opening a larger hole than necessary for their reception, yet there is in nature this good reason for it, that they have, when brought to a fresh Soil, no occasion for those long roots to draw nourishment from afar off, when there is enough of it every-where about them. What is to be learned from the whole of this, is, that the modern system is erroneous, which says that water is the only thing that gives nourishment and increase to plants; since, if this was the case, there could be no need of manures, nor any need of altering the crop, in order to its succeeding, or of transplanting trees to make them thrive. It is plain that some sort of terrestrial matter, taken from among the Soil, is what gives increase and bulk to plants; for, where it is only water, the rain falling in all places alike, all would alike be at all times suited to produce all plants; and, if the earth, according to Lord Bacon's system, served to no other purpose to plants and trees, but to keep their roots firm, and to defend them from these uses as another, and the same earth would do as well for over-heat, and over-cold, one earth would do as well for the same plant as a different earth. *Phil. Transf.* N°. 253.

Brickish SOIL, a term used by our farmers to express a kind of hazely earth or land, with a reddish cast. It is frequent in Essex, and some other counties, and approaches to the nature of a loam. It has no stones in it, and does not bind after wet as clay does, but lets all the water in that comes, and has no slates in it; whereas all clays hold the water till the sun exhales, and, after rain, with a frost, moulder into dust.

These loams are an excellent mixture for other earths, being a happy medium between two extremes, uniting what is too loose, cooling what is too hot, and entertaining a moderate share of moisture.

The best produce of the brick earth is rye; if well dunged, it will bear white oats, turneps, barley, wheat, buckwheat, and pease. The natural produce, in weeds, is broom, fern, quick-grass, and the like. If it be well dunged, it will produce large crops of clover, but it soon wears out of it, and should therefore be sowed mixed with rye-grass. The best manure for these lands is chalk, mixed with coal-ashes: marl makes a great improvement in them, and there is a stiff yellow kind of clay, that moulders with the frost, that answers the same purpose. Whatever amendment is bestowed upon this sort of land by dung, and other enriching things, that do not absolutely alter the nature of the earth, lasts but a little while. These lands bind very much after rain, and turn whiter; no frost will dissolve the clod, and if they are newly plowed up, and never so much rain comes on them, people may walk or ride over them almost as firm as over gravel. If they are not frequently plowed, they are very subject to worms, which destroy the winter corn. They yield but poor crops in wet years; the weeds are generally very rank, and the wheat runs all into straw. Plowing is a great improvement of them, they always grow well the year after it. These lands are to be ordered for corn in the same manner with the clay land, only as they are rank, and carry the crop much into straw, it is best to dung them on the etch crop, and to sow them with barley, and never to dung the fallows. Where the farmer has not a mind to plow them, but keep them for grass, they should be mowed one year, and then kept short fed with sheep, which will in time sweeten them very much.

The red sandy lands in Northamptonshire are of this kind; they will not hold manure, so they plow but once for the year's crop, which is just before the sowing-time, and manure just before they plow it; for if they plow it oftener, and manure it sooner, they find a great quantity of the best mould washed away below the surface, and out of the reach of the roots of the corn.

In Oxfordshire they have a sort of red land, which they begin fallowing as soon in the year as they can, before the sun is too high: if it is moderately moist, when fallowed, they esteem it the better, but it should not be too wet. They seldom give it a second stirring, and they reckon that, if it is too fine and light, it runs to weeds. *Mortimer's Husbandry.*

SOLA'NUM, *night-shade*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, and is of a rotated form, and divided into several segments. The pistil arises from the cup, and is fixed in the manner of a nail to the middle part of the flower, and finally changes into a roundish or oval berry, or soft succulent fruit, which contains many seeds, usually of a flatted form.

SOLDANE'LLA, *sea bind-weed*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, formed into the shape of a bell, and jagged or fimbriated at the edges in most species; from the cup of this flower rises a pistil, which perforates the bottom of the flower, and is fixed like a nail to its hinder part; this afterwards ripens into a cylindric fruit, which opens at the top and is filled with seeds fixed to a placenta.

SOLU'TION (*Dict.*)— No phænomenon in nature is more universally known, than the Solution of salts in common water; but the world has not yet attended to all that might be learned from the observations on it.

Mr. Lemery, who examined into this point with great assiduity, has observed, 1. That the first effect of water upon a salt is the reducing it into an inexpressibly fine powder. 2. That it is merely the consequence of this pulverisation carried greatly farther, that every particle of salt which, while in larger moleculæ, subsided to the bottom of the water, according to the known laws of hydrostatics, becomes capable of being elevated and suspended in the water, though in itself greatly heavier than that fluid; that, while in a proper state of separation in this manner, they remain imperceptible in all the water, and when by certain accidents they again approach one another, they form concretions like their original ones, and again subside in that fluid, in which they floated while in form of this imperceptible powder.

In the Solutions of salts, the same author observes, that all the particles of water do not serve to the same purpose; some officiating only in the keeping the saline particles suspended, others in the keeping them asunder, and, as barriers, preventing their reunion.

The quantity of water, necessary to sustain the particles of all salts in Solution, is the same; but the quantity, required to keep those particles from joining again, is different, in regard to every salt. Hence though a quantity of water, equal to the weight of the salt, be sufficient to the suspension of its particles, yet every salt requires its own appropriated quantity of water to keep it in a state of solution, that is, to keep its particles from cohering together again. In such salts, the particles of which are not subject to form hard concretions, such as the fixed salt of tartar, and the like, there requires no more water for a Solution than is necessary to suspend the particles of the salt; but in those which readily form solid concretions, such as common salt, nitre, borax, and the rest, there requires a large quantity besides to act as a barrier.

The more the particles of any salt are disposed to re-unite, the more water they require to keep them in a state of Solution; and hence follows a very remarkable phænomenon, which is the Solution of several salts successively in the same water: this is known to be possible, and the reason of the whole is this, that when a given salt, requiring a large quantity of water for its Solution, is dissolved in that water; the greater part of that water, which in this Solution serves only to the second purpose of keeping the particles of the salt asunder, is still at full liberty to act as water upon another salt that shall be thrown into it.

This, however, can be only the case in regard to salts which do not naturally ferment with one another, because the whole process is disturbed by such a fermentation, and, in consequence of it, there is a third salt formed, which is not the same with either of the two; and the consequence of the formation of this salt is the precipitation of the metallic or earthy matter, which was the base of one of the other salts. Thus an alkaline salt, added to a Solution of alum, or saccharum saturni, takes up the acid of either of these salts, and becomes, by its mixture with that acid, a new concrete salt, and at the same time throws down, in precipitation, the terrestrial base of the alum, and the metallic one of the salt of lead.

To return to those salts which excite no fermentation with one another. In regard to these, when a quantity of water has dissolved as much as it can retain of one, it will readily take in and dissolve a second; and the particles of this, not fermenting with those of the salt first dissolved, will remain suspended, and the water which dissolves them, and which in the first Solution served only as an intermedium to keep the particles of that salt asunder, serve as well to that purpose, now they are impregnated with this new salt, as they did before.

It is well known that salt of tartar does not ferment with saltpetre, nor does it take any thing from this salt, or at all alter by being mixed with it, which is quite different from the effect on mixing it, as before obſerved, with alum, or ſaccharum ſaturni; on this principle, and on the known property of ſalt of tartar being diſſolved in a ſmaller quantity of water than any other ſalt; or, in other words, of water's diſſolving more ſalt of tartar than any other ſalt, Mr. Lemery reſolved on the trial, whether water, which had already diſſolved as much nitre as it could contain, would not, on the addition of ſalt of tartar, diſſolve a larger quantity of freſh nitre, than on the addition of ſal armoniac, or any other ſalt: but what appeared very ſtrange was, that after two days ſtanding of a Solution of nitre, with about a fourth part of the quantity of ſalt of tartar added, there was found a white powder at the bottom. The liquor, being examined on this, was found to be a lixivium of ſalt of tartar, and the powder, at the bottom, ſalt-petre.

On adding freſh quantities of ſalt of tartar, new precipitations were afterwards formed, and, in fine, all the ſalt-petre which had been diſſolved was ſeparated. The ſalt-petre being examined, by all trials proved true ſalt-petre, as pure and unmixed as when put in; and the liquor being evaporated, the ſalt of tartar was found equally pure. Salt of tartar tried afterwards in the ſame manner with Solutions of other ſalts, with which it does not raiſe any fermentation, was found to have the ſame effect, precipitating all equally out of the Solution.

In the common precipitations of ſalts, ſuch as alum and ſugar of lead, by means of an alkali, the alkali ſeizes upon the acid of thoſe ſalts, and by that means effects the thing, and therefore itſelf becomes changed into another ſalt, and the precipitate, robbed of that acid, is no longer the ſalt it was, but merely its baſe: but here the ſalts, both alkali and neutral, remain the ſame they were before, both pure and unmixed, and the whole proceſs ſeems only one of them taking the place of the other.

The ſalts which are capable of ſucceſſive Solutions in the ſame water, and of remaining ſuſpended together in it, muſt be all of the neutral kind; that is, they muſt be ſalts compoſed of acids, engaged in ſuch manner in the pores of their baſes, as to fill the whole, and leave no void ſpaces for the penetration of other acids. But this is by no means the caſe with ſalt of tartar, which, being wholly ſpunge-like in its ſtructure, readily admits all ſorts of acids, and ferments with them; and therefore is very capable of diveſting other ſalts of that, on the preſence of which their natural ſtate, as ſalts of a particular kind, depends.

Every alkali ſalt is, as it were, an eſſential ſalt, in part decompounded; that is, it is the earthy part of ſuch ſalt, the acid parts of which have been driven off by fire, and when there is only ſo much left, as may give the whole a ſaline form; for, if all the acids were to be driven off, the remainder would not be an alkali, nor yet a ſalt, but a mere ſimple earth; as is the caſe in the caput mortuum of ſpirit of nitre diſtilled by a retort, the reſiduum from this diſtillation being a mere dead earth, indiſſoluble in water, and altogether different from the fixed alkali produced by burning the ſame nitre with charcoal. What proves, alſo, that theſe alkalies are only the matrix of the compound ſalts diveſted of their acids, is, that if ſpirit of nitre be poured upon the alkali ſalt of nitre made with charcoal, true nitre is regenerated. *Mem. Acad. Par.* 1724.

SO'NCHUS, *ſowthiſtle*. Theſe are moſt of them weeds in England, and are not planted in gardens; for if their ſeeds are once permitted to ſcatter upon the ground, they will ſoon ſtock it with plants; for which reaſon, they ſhould always be extirpated; not only thoſe in the garden, but alſo thoſe in the parts near it; becauſe their ſeeds being furniſhed with down, are wafted in the air to a conſiderable diſtance, where falling on the ground, they ſoon come up, and prove troubleſome.

SO'PHIST (*Dict.*)—The term Sophiſt, which is now reproachful, was anciently honourable; and carried a very innocent idea. St. Auguſtin obſerves, it ſignified a rhetor, or profeſſor of eloquence: ſuch as were Lucian, Athenæus, Libanius, &c.

Suidas, and after him, Olar, Celſius, in an expreſs diſſertation on the Greek Sophiſts, tells us, that the appellation was applied indifferently to all who excelled in any art or ſcience; whether divines, lawyers, phyſicians, poets, orators, or muſicians.— But this ſeems to be ſtretching the ſenſe of the word without all meaſure: it is poſſible a rhetor might have made verſes, &c. but that it was on account of his poetical talent, that he was denominated Sophiſt, is what we ſee no reaſon to apprehend.— However, Solon is the firſt who appears to have ever bore the appellation; which is given him by Iſocrates: afterwards, it was ſcarce ever given, but to philoſophers and declaimers.

The title ſophiſta was in great credit among the Latins in the XIIth century, and in the time of St. Bernard; but it began to loſe ground in Greece, as early as Plato's time, on account of Protagoras and Gorgias, who made a ſordid traffic thereof, by ſelling eloquence for money.—Hence Seneca calls the Sophiſts, quacks or empirics.

Cicero ſays, that the title ſophiſta was given to ſuch as profeſſed philoſophy with too much oſtentation, in order to make a trade of it, by running from town to town, to retail their deceitful ſcience. — A Sophiſt, therefore, was then, as now, a rhetor, or logician, who makes it his buſineſs to enſnare and perplex people, by frivolous diſtinctions, vain reaſonings, and captious diſcourſes.

Nothing has conduced more to the increaſing of the number of Sophiſts, than the contentious ſchool philoſophy: people are there taught to puzzle and obſcure truth, by barbarous, unintelligible terms; as antipredicaments, great and little logicals, quiddities, &c.

SO'RBUS, *the ſervice-tree*, in botany, the name of a genus of trees, the characters of which are theſe: the flower and fruit reſemble thoſe of the cratægus, but differing, in that the leaves are winged as thoſe of the aſh.

SORE, among ſportſmen, denotes a buck of the fourth year.

SO'REX, in zoology, the name of a ſpecies of wild or field mouſe, called the dormouſe, or ſleeper. There are two kinds of this creature, a larger and a ſmaller.

The larger dormouſe is nearly of the ſize of the common rat. Its colour is a browniſh grey, like that of the common mouſe, but variegated with ſomewhat of a reddiſh caſt on the ſides, and on the head. The ears are large and ſmooth; the belly is white; and the inner part of the legs, and the lower part of the tail, eſpecially towards the extremity, are of the ſame colour. The noſtrils and the feet are red; the tail is all over hairy, and is terminated by a thick tuft of white fur. The eyes are large and prominent, and of a fine jetty ſhining black. The beard is partly white, and partly black. Round about the eyes, and round the ears, there is a fine blackneſs; the upper part of the tail is alſo black. The ſmell of this creature is the ſame with that of the mouſe, and its dung is of the ſame kind. It lives in caverns under-ground, and ſleeps all the winter, as ſome affirm. It feeds on vegetables, and is particularly fond of hazel nuts, which it uſually hoards up, when ripe, for a ſcarcer ſeaſon.

The ſmaller kind is much more common than the larger one: this is of the ſize of the common mouſe, and in different countries varies much in colour. In Italy, Mr. Ray obſerved it all over of a reddiſh tawny on the upper part, except the end of the tail, and all its under part white, the tail only excepted; the tail covered with long and thick-ſet hairs, and looking ſomewhat like a ſquirrel's. The eyes are very black and prominent. Thoſe which the ſame author obſerved in England were leſs of the reddiſh hue on the back, and were not white under the belly, but only on the throat; neither had they the white tip at the end of the tail. Poſſibly the Italian and Engliſh may be really diſtinct ſpecies. This creature feeds on nuts and other ſuch fruits. It retires into caves in winter, and ſleeps much; but not through the whole winter, as has been ſuppoſed, for it lays up its winter-proviſion in its hole in autumn, and feeds on it at that time. *Ray's Syn. Quad.*

SO'RRANCE-*water*, a name given by our farmers to a ſolution of vitriol and ſome other ingredients in vinegar, a medicine much eſteemed in many of the diſeaſes of horſes: it is prepared in the following manner:

Take Roman vitriol and roach alum, of each an ounce and half, verdigreaſe an ounce, copperas two ounces; reduce all theſe to powder together, and put them into a two-quart bottle, into which pour a quart of the ſtrongeſt and beſt wine-vinegar; this is to be ſet in balneo mariæ. The ſhort way of doing which by the farrier is this: he puts a wiſp of hay into the bottom of a kettle, and then tying ſome pieces of lead or iron about the neck of the bottle, to make it heavy enough to ſink in water, it is ſet upon the hay ſo as to ſtand very upright; then three notches are cut length-wiſe in the cork to give paſſage to ſome of the vapours when the bottle is heated, that it may not burſt. When every thing is thus prepared, ſo much cold water is to be put into the kettle, that the neck of the bottle may ſtand two or three inches above it; the kettle is then to be ſet over the fire, and the water is to be made to boil, and kept boiling about half an hour, the bottle being at times taken out, and thoroughly ſhaken. When the ſalts are thus thoroughly diſſolved in the vinegar, the whole is to be kept for uſe.

The method in which they uſe it is this: take an earthen pan, which will hold about twelve quarts; let this be filled with urine that has been made by ſound, healthy, and young perſons; the ſtaler the urine is, the better it is for uſe, and indeed it ought always to ſtand, at leaſt, three weeks before it is uſed. It is proper for the farrier, therefore, always to keep a quantity of this ready, and, when the water is to be uſed, half a pint of it is to be mixed with a quart of the urine, or, if it be required ſtronger, more of the water is to be added: theſe are to be thoroughly mixed together, and the legs, or other affected part of the horſe, bathed with it with ſoft rags twice a day.

The virtues of this water are highly extolled; it is ſaid to cure the glanders in two, or three times dreſſing; it is alſo a ſovereign remedy for the mange, either dry or wet, and for the rat-tails, ſcratches, gourded or ſwelled legs and heels; and it alſo cures horſes, when the greaſe is fallen into their heels, as the farriers expreſs it. The fancy is alſo ſaid to be often cured by a long continuance in the uſe of it, purging the horſe two or three times, at different diſtances of time, during the time

of

of his being under cure by the water. They alfo find it a good cleanfer and healer of foul ulcers, and that it prevents the breeding of proud-flefh and worms in wounds, and drives away a flux of humours that were falling upon any part. They ufe it alfo in clefts and cracks of the heels, and in wind-galls, efpecially in the prevention of the laft by its repellent qualities.

The green water alone is an excellent remedy for fiftulas, cankers, and the galled backs of horfes; difpofing fuch Sorrances, as they are called, not to fefter, rot, and grow worfe, as all greafy and oily medicines do, but cleanfing them, and laying the way to a very found and ftanding cure.

SO'RREL, *acetofa*, the name of a genus of plants, the characters of which are thefe: the flower is of the ftamineous kind, being compofed of a number of ftamina arifing from a fix-leaved cup. The piftil, which is furrounded by thefe, finally becomes a triangular feed, wrapped round in a cup: this is compofed of three of the fix leaves of the cup, the other three withering away.

SORREL-*feeds*, are found to contain a vaftly larger proportion of the active principles this plant abounds with, than either the leaves or the roots. They are efteemed aftringent, and good in diarrhœas, dyfenteries, and hæmorrhages.

We much neglect this plant, becaufe it is common; yet, this plant alone has very often proved a remedy for the fcurvy. Mr. Morin of the Academy of Paris, who in the Hôtel Dieu had many hundred fcorbutic patients, cured the greater part of them only by Sorrel boiled and eaten with eggs.

Wood-SORREL, *lujula*, in medicine, is a very grateful acid; in fevers it quenches thirft, and takes off the heat of the ftomach. It is recommended in fevers of all kinds, and the fcurvy; alfo in obftructions of the liver and of the vifcera. It is fometimes given in decoction in fevers, and the expreffed juice is mixed with the juices of the other antifcorbutic plants againft the fcurvy. Externally, it is extolled againft inflammatory eruptions of all kinds in decoction, which is to be ufed by way of fomentation. There ufed to be a fyrup, but, at prefent, only a conferve of this plant is retained in the fhops.

SOUHG, *otherwife called an adit*, in minerology, is a paffage like a vault cut out under the earth, to drain the water from the mines.

SOUL (*Dict.*) — The philofophers are not at all agreed, as to the manner wherein the foul refides in the body. Some hold it equally diffufed throughout every part thereof. Others fay it influences and acts on every part of the body, though it has its principal refidence in fome particular part, called the fenfory. This principal part, Des Cartes maintains, is the pineal gland of the brain, where all the nerves terminate, &c.

Borri, a Milanefe phyfician, in a letter to Bartholine, de Ortu Cerebri & Ufu medico, afferts, that in the brain is found a certain, very fubtile, fragrant juice, which is the principal feat or refidence of the reafonable Soul; and adds, that the fubtility and finenefs of the Soul depends on the temperature of this liquor, rather than on the ftructure of the brain, to which it is ufually afcribed. This liquor, we conceive, muft be the fame with what is ufually called the nervous juice, or animal fpirits. The conftitution whereof is, doubtlefs, of great importance, with regard to the faculties of the Soul.

Mr. Locke diftinguifhes two principal faculties or powers of the rational or human Soul, viz. perception and willing.

To thefe, other philofophers add others, as fenfation, liberty memory, imagination, and habit.

The myftic divines diftinguifh two principal parts in the Soul: the fuperior part, which comprehends the underftanding and the will; and the inferior part, which comprehends imagination and fenfation. Thus, fay they, Jefus Chrift was happy on the crofs in his upper part, and fuffered in his lower part. The lower part did not communicate to the upper either its troubles, or its failings; nor the upper to the lower its peace or beatitude. From this diftinction, the Quietifts take in hand to maintain, that whatever paffes contrary to good morals, in the lower part of the Soul, is not contrary to the purity of the upper part, inafmuch as the will has no fhare therein.

As to the Soul of brutes, the Cartefians, and fome others, deny its exiftence, in the common fenfe of the word Soul; that is, they ftrip it of all the properties or faculties of the human Soul: and the Peripatetics, on the contrary, inveft it with the greateft part of them.

In man, a particular agitation of the fibres of the brain is accompanied with a fenfation of heat; and a certain flux of animal fpirits towards the heart, and vifcera, is followed by love or hatred.

Now, the Peripatetics maintain, that brutes feel the fame heat, and the fame paffions, on the fame occafions: that they have the fame averfion for what incommodes them, and, in the general, are capable of all the paffions, and all the fenfations we feel.

The Cartefians deny they have any perceptions or notices at all; that they feel any pain or pleafure; or love or hate any thing. The ground of their opinion is, that they allow of nothing in brutes, but what is material, and that they deny fenfations and paffions to be any properties of matter. Some of the Peripatetics, on the other hand, maintain matter, when fubtilifed, framed, ranged, and moved in a certain manner, to be capable of fenfation and paffion; that beafts may feel and perceive, by means of the animal fpirits, which are matter thus modified; and that the human Soul itfelf only becomes capable of fenfation and paffion, by means of the fame animal fpirits.

But we muft own it very difficult to reconcile the idea we have of matter with what we have of thought; to conceive that matter figured in any manner, whether in a fquare, a fphere, or an oval, fhould be pleafure, pain, heat, colour or fmell; or to conceive that matter, however agitated, whether in a circle, a fpiral, parabola or ellipfis, fhould be love, hatred, or joy,—furpaffes our endeavours.

The maintainers of the contrary opinion urge that appearance of fenfe, of fear, caution, love for their young, admirable fagacity, both for their own prefervation and that of their fpecies, vifible through the whole brute creation. And, it is true, all the actions of beafts plainly exprefs an underftanding; for every thing that is regular, expreffes it; even a machine or watch expreffes it: and a plant much more; the radicle of the feed turning downwards, and the ftem upwards, whatever fituation the feed is fown in: the young plant, knitting from fpace to fpace, to ftrengthen it; its putting forth prickles, &c. to defend it, &c. mark a great underftanding. All the motions of plants and brutes plainly difcover an intelligence; but the intelligence does not refide in the matter thereof: it is as diftinct from the beaft or plant, as that which ranged the wheels of the watch, is diftinct from the watch itfelf.

For, in effect, this intelligence appears infinitely great, infinitely wife, infinitely powerful; and the fame which formed us in our mother's womb, which gave us our growth, &c. Thus, in brutes, there is not either underftanding or Soul, in the fenfe we generally ufe the word: they eat without pleafure, cry without pain, grow without knowing it. They fear nothing; know nothing; and, if they act in fuch manner, as fhews underftanding, it is becaufe God, having made them, to preferve them, has formed their bodies fo as to avoid whatever might hurt them, mechanically.

Otherwife it might be faid, that there is more underftanding in the vileft infect, nay, in the fmalleft grain, than in the moft knowing of men; for it is evident, either of them contains more parts, and produces more regular motions and actions, than we are capable of underftanding. Thus does the great F. Malebranche argue againft the Souls of brutes. *Recherche de la Verite, liv.* 6.

SOUR *Land*, in agriculture, a term ufed by the farmers to exprefs a cold and fomewhat wet clayey foil.

This muft have its tilth according to its ftate and condition, when they fet about it. If it have a ftrong fwarth upon it, then they give it a fallow, by turning it up, when the fun is in Cancer; this they call a fcalding fallow, and efteem it of great ufe, becaufe it kills the grafs roots, and makes the land fine; but, if it be light, and have but a thin fwarth, they leave it for a cooler tillage, and plow it early in the year, when their clay is fallowed. Pigeon's dung and malt-duft are the moft proper manures for this foil. The malt-duft is to be fown with the winter-corn, and plowed in with it, for then it lies warm at the roots of the corn all winter. *Plot's Oxfordfhire.*

SOW, in the iron-works, the name of the block, or lump of metal, they work at once in the iron-furnace. The fize of thefe Sows of iron is very different, even from the fame workmen, and the fame furnace. Thefe furnaces having fandftone for their hearths and fides, up to the height of a yard, and the reft being made of brick, the hearth, by the force of the fire, is continually growing wider; fo that, if it at firft contains as much metal as will make a Sow of fix or feven hundred weight, at laft it will contain as much as will make a Sow of two thoufand weight.

SO'WING. One very great article, in Sowing to advantage, is to know exactly at what depth the feed may be planted, without danger of burying it. Seed is faid to be buried, when it is laid at a depth below what it is able to come up at. Different forts of feeds come up at different depths, fome fix inches, or more; and others will not bear to be buried at more than half an inch. The way to come at an accurate knowledge of the depth, at which every feed will come up beft from the Sowing, is by making gages in the following manner: faw off twelve fticks of about three inches diameter, bore a hole in the end of each ftick, and drive into each a taper peg; let the peg in the firft ftick be half an inch long, the next an inch, and fo on, every peg being half an inch longer than the other, till the laft is fix inches long: then in that fort of ground, in which you intend to plant, make a row of twenty holes with the half-inch gage, put therein twenty good feeds, cover them up, and then ftick the gage at the end of that row. Proceed in the fame manner with the eleven other gages, making the holes in the fame row all with the fame gage, and fticking it at the end of the row: when the feeds begin to appear, it will be eafy to fee at what depth they come up beft, by obferving the moft flourifhing row, and taking up the gage at the end, and feeing what is its length.

By this means we not only know what is the depth in that fort of ground, at which this fort of feed will come up beft, but alfo we are able to judge of the nature of the feed; for by obferving how many of the twenty feeds that were fown come

up

up, and how many fail, it is eafy to calculate how much bad feed there is among any given quantity, and to allow properly for it in the Sowing, that the field may be neither overftocked with plants, nor too bare of them. The farmer often fuftains great loffes by Sowing bad feed, or by burying good feed, and both might be effectually prevented, by making thefe eafy trials. One caution is to be obferved in this, that it is not proper to fow the feeds of all plants at the greateft depths at which they will come up, becaufe in wheat, and fome other grain, a moift ground will rot the roots at this depth. Experience alone, added to thefe rules, can perfectly inftruct the farmer in the certain way of fucceeding; the nature of the land, the manner how it is laid, either flat or in ridges, and the feafon of planting, muft all be confidered.

The quantity of feed is to be different alfo, according to the manner of the Sowing. The proper quantity, to be drilled into an acre, is much lefs than muft be fown in the common way; not becaufe the hoeing will not maintain as many plants as the other way, for, on the contrary, it will maintain many more; but the difference is upon many other accounts, as that it is impoffible to fow it fo evenly by hand as the drill will do. For let the hand fpread it never fo exactly, which yet is difficult enough to do with fome feeds in windy weather, yet the unevennefs of the ground will alter the fituation of the feeds, the greateft part of them rebounding in the holes, and the loweft places, or elfe the harrows, in covering, drawing them down thither; fo that thefe low places may have ten times too much feed, and the higheft may have much too little, or even none of it; and this inequality leffens in effect the quantity of the feed, becaufe fifty feeds, in the room of one, will not produce fo much as one will do; and where they are too thick, without being in thefe clufters, they cannot well be nourifhed, their roots not fpreading to near their natural extent, for want of hoeing to open the earth, and give them way. In the common way of Sowing, fome of the feeds are buried out of all hope of ever coming up again, and fome others are left naked upon the furface, where they become the food of birds, and of vermin: as fo many muft, therefore, perifh in the common way of Sowing, and fo few can be loft in the way by drilling, there is plain reafon why the feed, neceffary to fow any given quantity of ground, fhould be much lefs for the drill-way, than for the other. The farmers, in general, know nothing of the proper depth at which they fhould fow their feed, nor of the difference in quantity that is to be obferved in different circumftances; they allow the fame quantity to an acre of rough ground, as they do to an acre of fine, and forget that what is too little for one, may yet be too much for the other; it is all mere chance-work, and they put their confidence in good ground, and a large quantity of dung to cover their errors.

The farmers in Wiltfhire allow more corn for the Sowing, than in any other part of England; they ufe fometimes eight bufhels of barley to an acre, fo that, if it produce four quarters for an acre, there is but four grains for one increafe. This is fown on land plowed once, and double dunged, the feed only harrowed into the hard and ftale ground, fo that it is very probable that not fo much as two bufhels out of the eight take place, or come to any thing. Sometimes, in a very dry feafon, an acre fcarce produces four bufhels at the harveft.

Inftead of all this uncertainty and lofs in the common way, in drilling all the feed lies juft at the fame depth, not one grain of it being placed deeper or fhallower than the reft. As none of the feeds, therefore, can be loft by being buried, or by being expofed on the furface to vermin, no allowance is to be made for thefe accidents; all that is to be allowed for in the Sowing, is the mifchief that may happen from the worm, the froft, or the like unavoidable accidents, common to all feeds.

When a man has (by the ufe of the gages, and the growth of the feeds planted in the rows marked by them) proved the goodnefs of the feed, and found the depth it is to be planted at, he is to calculate what number of feeds a bufhel, or any other weight or meafure, contains; for one bufhel, or one pound of fmall feed, may contain double the number of feeds of a bufhel, or a pound of large feed of the fame fpecies. This calculation is made by weighing an ounce, and then calculating the number of feeds this ounce is compofed of; then weighing a bufhel, and multiplying the number of feeds in an ounce by the number of ounces in the bufhel, and the product will give the number of feeds in the bufhel with fufficient exactnefs. When this is known, the feeds are to be proportioned by the rule of three to the fquare feet in an acre; or elfe it may be done, by dividing the feeds of the bufhel by the fquare feet in an acre, and the quotient will give the number of feeds for every foot. Then the farmer is to confider how near he intends to plant the rows, and whether fingle, double, treble, or quadruple; for, the more numerous the rows are, the more feed will be required. The narrow fpaces between double, triple, or quadruple rows, fuppofe feven inches; the double having one, the treble two, and the quadruple three, are called partitions. The wide fpace, fuppofe of five feet, between any two of thefe double, treble, or quadruple rows, is called an interval.

Examine next what is the produce of one middle-fized plant of the annual, but the produce of the beft and largeft of the perennial fort, becaufe that, by hoeing, will be brought to its utmoft perfection; proportion the feed of both to the reafonable product, and, when it is worth while, adjuft the plants to their competent number with the hand-hoe after they are up, and plant perennials generally in fingle rows. Laftly, plant fome rows of the annual thicker than others, which will foon give experience, preferable to all the rules in the world, for the quantity of feed neceffary for the drilling.

The diftances of the rows is one extremely material point in the obtaining a good crop; but as a much larger diftance is to be allowed in thefe, than common practice has been ufed to, it is very difficult to perfuade the farmer to venture a trial at fuch diftances as he may have experience from. There is a method of planting the rows by the drill at very near diftances, and in this work one horfe may draw a drill with eleven fhares, making the rows at three inches and a half diftance from each other, and at the fame time Sowing in them three different forts of feeds, which do not mix, and thefe at different depths. Thus the barley-rows may be feven inches afunder; and the barley four inches deep; a little more than three inches above that, in the fame channels, clover-feed; and, between every two of thefe rows, a row of faintfoin feed covered half an inch deep.

Mr. Tull, who tried this method, obtained the firft year a very good crop of barley; the next year, two crops of broad clover, where that was fown; and where the hop-clover was fown, a mixture of that and faintfoin, and every year afterwards a crop of faintfoin. But the fame gentleman was afterwards fo fully convinced of the folly of thefe, or any other mixed crops, and of Sowing with thefe narrow, that he never practifed it afterwards.

Every row of vegetables, to be horfe-hoed, ought to have an empty fpace, or interval of thirty inches, on one fide of it at leaft, and of near five feet in all forts of corn: this will feem a monftrous allowance to thofe who have not experienced the good effects of it, but all who have will readily come into the practice of it ever afterwards. The line of corn is called one row, though it be double, triple, or quadruple, becaufe, when four of thefe rows grow up in the fpring, they unite, and feem to be all one row. Wide intervals are neceffary for perfect horfe-hoeing, and the largeft vegetables have generally the greateft benefit by them, though fmall plants may have confiderable benefit from much narrower intervals than thofe of five feet.

In hand-hoeing there is always lefs feed, fewer plants, and a greater crop, cæteris paribus, than in the common Sowing; yet, there the rows muft be much nearer than in horfe-hoeing, becaufe, as the hand moves many times lefs earth than the horfe, the roots will be fent out in a like fmaller proportion; and, if the fpaces, or intervals, where the broad hoe only fcratches a little of the furface, fhould be wide, they would be fo hard and ftale underneath, that the roots of the perennial plants would be a great while in running through them, and the roots of annual plants would not be able to do it at all. The advantage of the horfe-hoeing is principally owing to the depth to which it ftirs the ground, and familiar inftances have proved, that the ftirring it to a like depth, by whatever inftrument, is of the utmoft advantage to whatever plants are fet in the place.

A poor fellow in Wiltfhire was obferved to have always his cabbages much larger and finer than his neighbours, though his ground was no better, and he could afford lefs dung; but the reafon was, that, inftead of clearing away the weeds between them with a hand-hoe, he ufed to dig between them with a fpade, which goes as deep as a horfe-hoe, and comes the neareft anfwering its purpofes of any inftrument whatever. *Tull's Horfe-hoeing Hufbandry.*

SPA-*water*.—The contents of this water, by means of which it is able to do fuch great things in many chronical cafes, are underftood by the following experiments and obfervations.

Firft, when the Spa-water is carried to any diftant place, tho' ever fo well ftopped down, they always, after a time, will precipitate a fmall quantity of a yellow ochreous earth.

Secondly, if a fingle grain of galls be put into an ounce of Spa-water, it tinges the whole with a beautiful purple; but, if the water be heated before the galls are put in, there will not be the leaft change of colour produced in it.

Thirdly, mixed with milk, they do not coagulate it; but when mixed with wine, they make a great ebullition, and throw up a large quantity of air-bubbles with a peculiarly pleafing fmell.

Fourthly, the waters drank at the fpring caufe a fort of drunkennefs, but it does not laft above a quarter of an hour.

Fifthly, a fmall phial, being filled up to a certain height with Spa-water, and afterwards exactly to the fame height with pure diftilled water, and weighed, when filled with each, in a nice balance, was found, when the Spa-water was in it, to weigh three ounces, four drachms, and forty grains; and with the other three ounces four drachms and forty-one grains; fo that the Spa-water, notwithftanding its mineral particles, is fomewhat lighter than the pureft common water.

Sixthly, and finally, a pint of the Spa-water, evaporated over a very gentle fire, leaves behind only a grain and half of a white powder.

Hence, it appears, that the Spa-waters are the lighteſt and moſt ſubtile of all the mineral waters; and the ſmall quantity of earth, and large portion of ſubtile mineral ſpirit they contain, beſpeak their poſſeſſing the moſt exalted virtues of all the mineral waters.

One very remarkable virtue of this water is, that it greatly relieves in all diſorders of the kidnies, ureters, and bladder, whether occaſioned by ſtone, gravel, or ulcerations. It poſſeſſes, beſides, all the virtues of the other mineral waters, and is of the greateſt ſervice in edulcorating ſharp, and dividing viſcous humours, and removing all diſeaſes ariſing from theſe cauſes, by diſpoſing them to paſs off by the proper emunctories.

SPAR (*Dict.*)—Spars are defined to be foſſils not inflammable, nor ſoluble in water. When pure, pellucid and colourleſs, and emulating the appearance of cryſtal, but wanting its diſtinguiſhing characters; compoſed of plane and equable plates, not flexile nor elaſtic; not giving fire with ſteel, readily calcining in a ſmall fire, and fermenting violently with acids, and wholly ſoluble in them.

The obſervation, that Spar is continually formed at this time in caves and grottoes under ground, has given birth to many different conjectures, as to the origin of that ſubſtance. We have accounts from Swiſſerland, and other places, that the ſnow, by long lying on the earth, and being ſubject to repeated freezing, is at length hardened into Spar: this is much of the nature of that opinion of the ancients concerning cryſtal, that it was water frozen by ſevere colds to a ſort of ice, much harder than the common kind; both are equally erroneous and abſurd. But more rational conjectures, as to its origin, are, that it is produced either by effluvia alone, or by the joint force of effluvia iſſuing up from the depths of the earth, and mixing with water ouzing out of the rocks into their cracks and cavities, or by the ſame water or effluvia paſſing through beds of this ſparry matter contained in clay. In the firſt place we are to obſerve, that Spar is capable of being diſſolved either by water or vapour, and ſuſpended imperceptibly in either; and that, though it remains ſuſpended a long time, yet there are occaſions of its ſeparating itſelf from either of theſe vehicles; ſuch are long ſtanding ſtill and evaporation. What is called the growth and formation of Spar, therefore, is properly perhaps only the change of place in this ſubſtance, and all that theſe agents, water and vapours, do, is only to waſh it out of the ſtrata of earth or ſtone, in which it lay in ſcattered particles, and bring it together into the cracks and crevices of ſtones, where it may again ſeparate itſelf, and become more pure and perfect. The operation of nature, in this caſe, is very like that of art in the extracting of ſalts from the various bodies they are mixed with; and Spar, in its two ſtates, when blended in the ſtrata of ſtone, &c. and when pure, and in form of cryſtals in the cracks, may be compared to alum, for inſtance, in its bed and when purified. The alum in the common ſtones, from which it is made, is not perceptible to the eye, but lies in ſcattered particles; water being added to this takes up the ſalt, and, when it has been managed by evaporation and reſt, yields it again purified and alone, and it forms ſuch cryſtals on the ſides of the veſſel, as the other does on the ſides of the fiſſures of ſtone, which are the veſſels where the water, out of which it was formed, was ſet to evaporate, and to reſt a proper time. That ſome Spars grow from vapours alone, is evident from the ſtalactitæ, or ſtony icicles, hanging down from the roofs of our caverns, which, though they grow downwards, yet have many times little plants of the ſame ſubſtance growing out at their ſides, and ſtanding upwards, contrary to the growth of the other, and evidently formed of the matter ſeparated from the vapours in their aſcent, as the ſtalactitæ themſelves are from ſuch as have aſcended to the roof and there been condenſed into water, and ſent down again in drops. Nor is the ſparry matter alone thus raiſed in vapour, for even the metals, and other bodies, as little likely as thoſe to be thus raiſed, yet are found to form ſtalactitæ. The mundics, in general, though they never form regular ſtalactitæ, yet, often are found adhering to the ſides of them, and the metals, particularly iron and lead, form regular ſtalactitæ; the iron ones very common, and very perfect; the lead leſs perfect, and more rare; and Dr. Brown gives us abundant inſtances of Spars growing entirely from vapours in the baths of Buda in Hungary. *Philoſ. Tranſ.* Nº. 129.

SPA'RUS, in the Artedian ſyſtem of ichthyology, a genus of fiſhes, the characters of which are theſe: the coverings of the gills are ſcaly. The teeth are covered with lips as in quadrupeds. The teeth in the jaws reſemble the dentes canini of men. The molares, or grinders, are like thoſe of quadrupeds. The teeth are placed only in the jaws and fauces, their palate and tongue being ſmooth. There is but one back fin. The eyes are covered with a lax ſkin, and the tail in moſt of the ſpecies is forked. The inteſtines are long, and they are twiſted in ſpiral forms, and often fixed to the meſentery. The appendices to the pylorus are large, and few in number, from three to ſeven being the uſual numbers.

SPA'THA, is a word uſed by different authors in various ſenſes; ſome expreſs by it a rib; others the inſtrument called by ſurgeons a ſpatula, and uſed for ſpreading ointments and plaſters; and Celſus calls a ſort of inciſion-knife by this name. It is alſo uſed for the external covering of the fruit of the palm-tree, and by others for a ſword. This laſt is indeed its proper ſignification, and all the others are only metaphorical applications of it to different things, which bear reſemblance to a ſword.

SPATHA, among botaniſts, expreſſes that ſort of cup which conſiſts of a ſimple membrane growing from the ſtalk. This kind of cup is of various figures; often diphyllous, or divided into two parts; often ſimple; ſometimes more divided: it incloſes ſometimes a ſingle flower, ſometimes ſeveral flowers together, and theſe have often no perianthium. The Spatha is of very different texture and conſiſtence, in different plants.

SPEAR-*wort*, in botany, a ſpecies of the Ranunculus. See RANUNCLUS.

SPE'CIES (*Dict.*)—What the accurate Artedi has given, as the definition of the Species in ichthyology, is not confined to fiſhes alone, but, with proper regulations, may be made the baſis of real diſtinctions of Species in all other natural bodies. Every fiſh, which differs from all the other fiſhes of the ſame genus in ſome external part, whether that difference be in exceſs or defect, in number or in proportion, or even in colour, provided that the difference be fixed and invariable, is properly to be called a diſtinct Species.

The ſpecific differences of fiſhes are to be drawn from theſe circumſtances; but it is not to be ſuppoſed that every Species differs in all of them; ſometimes only one, ſometimes more, occaſion the variation.

If any one fiſh, in regard to all the others of the ſame genus, is found to be poſſeſſed of ſome external part which they all want; as, for example, if it have cirri, tubercles in the ſhape of horns on the head, ſpines or prickles in the head, or on any other part of the body, the fiſh is then to be eſteemed a diſtinct Species. If one fiſh differs from the others of the ſame genus in the number of any parts, as fins, ſpines, or tubercles, it is then alſo a diſtinct Species. If one fiſh differs from another in the proportion of any eſſential part, as in the having longer jaws, longer teeth, or the like, it is alſo to be eſteemed a truly different Species. If one fiſh differs from another in the figure of ſome eſſential part, as of the ſnout, the back, the teeth, or the tail, or the lineæ laterales, it is to be eſteemed a diſtinct Species. If one fiſh differs from another of the ſame genus in the exceſs of parts, having ſome part that is deficient in the other; or, if in number, proportion, or figure of ſome of the eſſential parts; the diſtinction will be the more evident as the greater number of parts differ, and the Species will eaſily be found to be truly diſtinct. *Artedi's Ichthyology.*

Change of SPECIES. — The change of Species is a term uſed in huſbandry to expreſs an expedient the farmer often has recourſe to, in order to procure good crops: this is the ſowing firſt one kind of plant, then another, and then a third, and ſo on, upon the ſame land: by this means the moſt is made of the ſoil; and it is found, when it will no longer give a good crop of the firſt corn planted on it, it will ſtill give a good one of ſome other Species; and, finally, of peaſe after all. After this laſt change of Species, it is found neceſſary, in the common method of huſbandry, to renew the land with fallowing and manure, in order to its producing any thing again. See SOIL.

This change of Species has been a practice of the farmers of all times, and is recommended, and judged neceſſary, by moſt of the writers on this ſubject; but Tull, in his New Syſtem of Horſe-hoeing Huſbandry, proves, that it is not neceſſary, and that the land only wants proper tillage, when exhauſted by one ſort of corn, to enable it to produce as good crops of the ſame corn again. The three fundamental propoſitions he lays down to prove this, are, firſt, that plants of the moſt different nature feed on the ſame ſorts of food. Secondly, that there is no plant but what muſt rob every other plant, within its reach, of a part of its nouriſhment. And, thirdly, that a ſoil, which is once proper for any kind of vegetable, will continue to be always proper for it, in reſpect to the ſort of food it gives. If only any one of theſe propoſitions were true, it would follow, that there is no need of a change of Species from year to year; and as they are all ſo, this truth is yet the more inconteſtable; and experience proves it yet more evidently, for the ſame land will produce crops of wheat every year, without any change, only by the practice of the horſe-hoeing huſbandry, inſtead of the common. *Tull's Huſbandry.*

SPI'DER, *araneus*, in zoology, the name of a well-known inſect, of which we have a great number of ſpecies.

The Spider affords to the ſagacious obſerver, as well without, as with the aſſiſtance of glaſſes, a great many extremely curious particulars. As the fly (which is the Spider's natural prey) is an animal extremely cautious and nimble, and uſually comes from above, it was neceſſary the Spider ſhould be furniſhed with a quick ſight, and an ability of looking upwards, forwards, and ſideways, at the ſame time; and the microſcope ſhews, that the number, ſtructure, and diſpoſition of its eyes, are wonderfully adapted to the ſerving all theſe purpoſes.

Moſt Spiders have eight eyes: two on the top of the head or body, for there is no diviſion between them, the Spider having no neck; theſe look directly upwards: there are two more in front, placed a little below theſe, and diſcovering all

all that passes forwards, and on each side: a couple more, one whereof points sideways forwards, and the other sideways backward; so that it can see almost quite round it. All kinds of Spiders have not, however, this exact provision; for in some we find ten, and in others only six, or four. The eyes of the Spider are not pearled; and the field-Spiders, or long-legs, have no more than two eyes.

Whatever be the number of the Spider's eyes, they are however all immoveable and transparent, and are situated in a most curious manner. The best way of viewing them with the microscope, is to cut off the legs and tail, and leave only the head for examination.

All Spiders have eight legs, which they employ in walking; and two shorter, called arms, which they use in seizing their prey. All the legs are thickly beset with hairs; each has six joints, and ends with two hooked claws, which are serrated on their inside; by means of these teeth, or jags in their claws, they seize very fast hold of any thing, and behind these there is a sort of spur, which is perfectly smooth. Besides these, nature has allotted this creature, for the seizing its prey, a pair of sharp crooked claws, or forceps, in the forepart of its head. These stand horizontally, and, when not exerted for use, are concealed in two cases contrived for their reception, in which they fold like a clasp-knife, and there lie between two rows of teeth, which are likewise employed to hold fast the prey.

Each of these claws, or pincers, has a small slit near its point, according to Lewenhoeck, like that in a viper's tooth, through which he supposes that a poisonous juice is, in like manner, thrown out. But Dr. Mead, in his essay on Poisons, dissents wholly from this opinion, having never been able, on repeated examinations, to discover any such opening, not even in the claws of the great American Spider; which, being above fifty times bigger than any of the European Spiders, would more easily have discovered this opening, if nature had allotted any to this part of the animal. Besides, repeated observations also convinced him that nothing dropped out of the claws, which were always dry, while the Spider bit any thing, but that a short white proboscis was, at the same instant, thrust out of the mouth, which instilled a liquor into the wound. And the same author observes, that the quantity of liquor, emitted by our common Spiders when they kill their prey, is visibly so great, and the wounding weapons so minute, that they contain but a very inconsiderable portion thereof, if it were to be discharged that way. *Baker's Microscope.*

Spiders frequently cast their skins, which may be found in their webs perfectly dry and transparent; and from such skins the forceps, or claws, for they are always shed with the skins, may easier be separated, and examined with much greater exactness, than in the common Spider while living.

The Spider's manner of weaving its web is very wonderful. The creature has five little teats, or nipples, near the extremity of the tail; from these there proceeds a gummy liquor, which adheres to every thing it is pressed against, and, being drawn out, hardens instantly in the air, and becomes a string, or thread, strong enough to bear five or six times the weight of the Spider's body. This thread is composed of several finer ones, which are drawn out separately, but unite together at two or three hairs breadth distance from the creature's body. These threads are finer or coarser, according to the bigness of the Spider that spins them. Mr. Lewenhoeck has computed, that a hundred of the single threads of a full-grown Spider are not equal to the diameter of the hair of his beard; and consequently, if the threads and hair be both round, ten thousand such threads are not bigger than such a hair. He calculates farther, that, when young Spiders first begin to spin, four hundred of them are not larger than one which is of full growth: allowing which, four millions of a young Spider's threads are not so big as the single hair of a man's beard.

The eggs of some Spiders are a very pleasing microscopic object; they are round at one end, and flattish at the other, with a depression in the center of the flattish end, and a yellowish circle round it. The colour of these eggs is a pearly or bluish white, and, when the young Spiders hatch, they come out in their perfect form, and run about very nimbly. The female Spider deposits her eggs, to the number of five or six hundred, in a bag composed of her own web, which she either carries under her belly, or hides in some very safe recess. *Philos. Trans.* N°. 272.

SPIEI, in glass-making, the name of an iron instrument, hooked at the end and pointed, with which the workmen take the metal out of the melting-pots for proofs or essays, to to see whether it be fit to work. *Neri's Art of Glass.*

SPIKES, *or Oil of* SPIKE, a name given by our druggists to an essential oil, much used by the varnish-makers and the painters in enamel; and of some use in medicine.

This oil, when genuine, is brought from Provence, and some other parts of France, and is there made of lavender. This plant is called in Provence aspic, and thence came the name oil of aspic, which afterwards degenerated into oil of Spike.

The manner of making the oil upon the spot is this: when the flowers are perfectly ripe, they put them into an alembic with a great quantity of water, and this they distil after several days maceration: there arises with the water a large quantity of an oil of a fine pale amber colour, and this, separated from the water, is the true and genuine oil of Spike.

The flower of this plant is the part which yields the largest quantity of oil; as is the case with all the plants with galeated flowers, of which the husk or flower-cup usually contains almost all the oil of the plant. The aromatic plants, in general, yield indeed but a small quantity of oil, but the vast abundance of this plant, in these places, makes the expence of gathering it so small, that the oil is very cheap. The quantity required on several occasions is, however, much greater than what all the lavender of the country can yield; and the price it is expected to be sold at is so small, that it is not to be wondered that there are several common adulterations of it.

The most usual ways of sophisticating it, however, are two; the one with the spirit of wine, which is esteemed the least hurtful, and the oil thus sophisticated is often called the very best of the country. The method Mr. Geoffroy took to discover the cheat was this: he procured a long and narrow phial, of an equal diameter all the way up; into this he first put an ounce of fair water, and to this he added an ounce of the oil; he marked the height of the water in the phial, then shook the two liquors together, and they became milky, and heated on the mixture, which alone would have been a sufficient proof that there was spirit of wine in the oil. After some standing the liquor became clear, and the oil floated at the top, but in a much smaller quantity than might have been expected, there being not more than a quarter of an ounce of it, the rest having been spirit of wine, which mixed with the water, and thus left all the true oil, which was only one fourth of the quantity, to float alone on the water, which was greatly increased in height in the phial. A pint of this oil of Spike, therefore, contains only four ounces of the genuine oil, and twelve ounces of plain spirit of wine.

The second method of adulterating this oil, which the same gentleman had suspected, was easily discovered next: for, on mixing this quarter of an ounce of pure oil of Spike with three quarters of an ounce of oil of turpentine, there was produced an ounce of a liquor, which appeared wholly the same with the oil of Spike commonly sold in the druggists shops. And indeed, much of what is usually sold is worse than this, being no other than oil of turpentine scented with a small quantity of the true oil of Spike.

The ready way of discovering the oil, counterfeited with oil of turpentine, is to wet a paper in it, and set it on fire; the turpentine will here be discovered by the thick smoke it yields, it being, of all vegetable oils, that which yields greatly the thickest cloud in burning: and, on the contrary, that which has been adulterated with spirit of wine, will be distinguished by the same trial, by its yielding a much finer and thinner smoke, and burning with a bright blue flame. If they be tried by firing them in a spoon, that which is adulterated with spirit of wine will burn very bright, and yield no fume at first; but, as it grows near the bottom, it will smoak a little, and finally will leave no residuum, except that it varnishes over the inside of the spoon: that adulterated with the oil of turpentine will burn more vehemently, smoak more, and leave a coarser varnish upon the spoon; and if it be of the coarsest kind, that is, if it have been adulterated with badly rectified oil of turpentine, the fume will be the more abundant, and there will be left in the spoon a fetid matter, resembling melted pitch.

Mr. Geoffroy tried whether, in the business of varnishing, the oil of turpentine alone might not do as well as the oil of Spike; he found that it dried perfectly well, but that it left a stinking smell upon the work, which never went off; whereas the mixture of this oil, with that of Spike, makes a smell like neither, and which soon goes off.

An ounce of oil of turpentine, with only twenty drops, either of our common oil of lavender, or the pure oil of Spike, makes a liquor tolerably well scented, and which serves for the purposes of oil of Spike. If two drachms of our oil of lavender be added to six drachms of spirit of wine, they immediately mix, and this, afterwards mixed in a small proportion with oil of turpentine, makes a sort of oil of Spike. The most regular method, however, that the artificer can use, if he can get the genuine oil of Spike, is to mix one ounce of it with three of oil of turpentine, which perfectly fits it for his purpose, and makes it the same with that in common use.

The method of making this perfectly pure, is to redistil it in a balneum mariæ; there will thus be procured an oil highly rectified, and pellucid as water, which will dry away, as soon as touched on any thing. *Mem. de l'Acad. Roy.*

SPINA'CHIA, *spinach, or spinage*, in botany, a genus of plants, whose characters are: it hath an apetalous flower, consisting of many stamina included in the flower-cup, which are produced in spikes upon the male plants, which are barren; but the embryoes are produced from the wings of the leaves on the female plants, which afterwards becomes a roundish or angular seed, which in some sorts has thorns adhering to it.

Winter spinage should be sown upon an open spot of ground towards the latter end of July, observing, if possible, to do it when there is an appearance of rain: for, if the season should prove dry for a long time after the seed is sown, the plants will not come up regularly; and many times there will not be half a crop. When the spinage is come up, the ground should be hoed to destroy the weeds, and also to cut up the plants where they are too close, leaving the remaining plants about three or four inches asunder; but this should always be done in dry weather, that the weeds may be destroyed soon after they are cut.

About a month or five weeks after the first hoeing, the weeds will begin to grow again; therefore the ground should be then hoed again the second time, observing, as before, to do it in dry weather. But, if the season should prove moist, it will be proper to gather the weeds up after they are cut, and carry them off the ground; for, if the spinage is not cleaned from weeds before winter, they will grow up, and stifle it so, that in wet weather the spinage will rot away.

In October, the spinage will be fit for use; when you should only crop off the largest leaves, leaving those in the center of the plants to grow bigger; and thus you may continue cropping it all the winter and spring, until the young spinage, sowed in the spring, is large enough for use, which is commonly in April; at which time the spring advancing, the winter Spinage will run up to seed; so that you will cut it up, leaving only a small parcel to produce seeds.

The two sorts with smooth seeds produce much larger and thicker round leaves than the former; but, being somewhat tenderer, are always sown in the spring.

These are either sown upon an open spot of ground, by themselves, or else mixed with radish-seed, as is the common practice of the London gardeners, who always endeavour to have as many crops from their land in a season as possible; but, where land is cheap in the country, it will be the better method to sow it alone without any other sort of seed mixed with it; and, when the plants are come up, the ground should be hoed to destroy the weeds, and cut out the plants where they are too close, leaving the remaining about three inches asunder; and, when they are grown so large as to meet, you may then cut off a part of it for use, thinning the plants that they may have room to spread; and this thinning may be twice performed, as there is occasion for the spinage; at the last of which, the roots should be left eight or ten inches asunder. If then you hoe the ground over again, to destroy the weeds, it will be of great service to the spinage; for, if the land is good upon which it was sown, the third sort, with this management, will many times produce leaves as large as the broad-leaved dock, and be extremely fine.

But, in order to have a succession of spinage through the season, it will be proper to sow the seed at three different times in the spring; the first, early in January, which must be on a dry soil; the second, the beginning of February, upon a moister soil; and the third, the beginning of March, which should be on a very moist soil: and this third sowing should be hoed out thinner at the first time of hoeing it, than either of the sowings; for there will be no necessity to leave it for cutting out thin for use, because the former sowings will be sufficient to supply the table till this third sowing is full grown; besides, by leaving it thin at first, it will not be apt to run up to seed so soon as it would if the plants were close. *Miller's Gard. Dict.*

SPINES *of echini*, in natural history. These in their fossil state make a great appearance in the cabinets of the curious, and in the works of the learned, and are of an almost infinite variety of kinds; and many of them are of the same figures and dimensions with those of the echini now living in our own and other seas, as well known to us. But besides these there are an almost infinite variety of others, which, though allowed on all hands to be truly Spines of some echini or other, yet evidently differ from those of all the known recent fish of that name, and have certainly belonged to species of it which we have not yet the least knowledge of.

SPINOZISM (*Dict.*)—Benedict Spinoza, or Espinoza, was a man well known in Holland. He was born a Jew at Amsterdam, but did not make profession of any religion, either the Jewish or Christian. — He composed several books in Latin; the most celebrated whereof is his Tractatus Theologico-Politicus, wherein he endeavours to overturn the foundation of all religion: the book, accordingly, was condemned by a public decree of the states; though it has since been sold publicly, and even reprinted, both in Latin and French, in that country, and lately in English at London.

Spinoza, here, insinuates, that all religions are only political engines, calculated for the public good; to render the people obedient to magistrates, and to make them practise virtue and morality.

He does not here lay down his notion of the Deity openly, but contents himself with suggesting it.—In his Ethics, published among his posthumous works, he is more open and express; maintaining, that God is not, as we imagine him, an infinite, intelligent, happy, and perfect being; nor any thing, but that natural virtue, or faculty, which is diffused throughout all creatures.

Spinoza, in his Tractatus above-mentioned, is very full on the subject of the authors of the scriptures; and endeavours to shew, that the Pentateuch is not the work of Moses, contrary to the common opinion, both of the Jews and Christians. He has also his particular sentiments, as to the authors of the other books.—This part of the work has been answered by M. Huet, in his Demonstratio Evangelica; and by M. Simon, in his Hist. Crit. du Vieux Test.

Spinozism is a species of naturalism, or pantheism, or hylotheism, as it is sometimes called, i. e. of the dogma which allows of no other God but nature, or the universe; and, therefore, makes matter to be God.—Accordingly, Buddeus, in a dissertation de Spinozismo ante Spinozam, proves at large, that Spinoza's doctrine of God and the world is far from being his own invention, but that it had been held by many philosophers of different sects, both among the Chaldeans and Greeks.—It is certain, the opinion of the Stoics, and those who held an anima mundi, was not far from it. Lucan introduces Cato discoursing thus:

Estne Dei sedes nisi terra, & pontus, & aër,
Et cœlum, & virtus? superos quid quærimus ultra!
Jupiter est quodcunq; vides, quocunq; moveris.
Luc. Pharf. lib. ix. v. 578.

Strato likewise, and others among the Peripatetics, maintained something very like it; and what is more, though no ancient sect seems farther removed from Spinozism than the Platonic, as they attributed the greatest freedom to God, and carefully distinguished him from matter; yet Gundlingius has proved at large, that Plato gave matter much the same origin with Spinoza.—But the sect that approached nearest to Spinozism, was that which taught that all things were one, as Xenophanes the Colophonian, Parmenides Melissus, and especially Zeno Eleates, whence it obtained the name of the Eleatic system of atheism.—To the same may also be reduced the opinion of those, who held the first matter for God, as Almaricus and David of Dinantum. Add that the sect of Foe in China and Japan, that of the Soufi in Persia, and that of the Zindikites in Turkey, are found to philosophise much after the manner of Spinoza.

The chief articles in Spinoza's system are reducible to these: —That there is but one substance in nature; and that this only substance is endued with an infinite number of attributes, among which are extension and cogitation.—That all the bodies in the universe are modifications of this substance, considered as it is extended; and that all the souls of men are modifications of the same substance, considered as cogitative. —That God is a necessary and infinitely perfect being, and is the cause of all things that exist, but is not a different being from them.—That there is but one being and one nature; and that this nature produces, within itself, by an immanent act, all those which we call creatures.—And that this being is at the same time both agent and patient, efficient cause and subject; but that he produces nothing but modifications of himself.

Thus is the Deity made the sole agent as well as patient in all evil, both physical and moral; that called malum pœnæ, as well as malum culpæ: a doctrine fraught with more impieties than all the heathen poets have published concerning their Jupiter, Venus, Bacchus, &c.—What seems to have led Spinoza to frame this system, was the difficulty of conceiving either that matter is eternal, and different from God, or that it could be produced from nothing, or that an infinite and free being could have made a world such as this is.—A matter that exists necessarily, and which nevertheless is void of activity, and subject to the power of another principle, is an object that startles our understanding; as there seems no agreement between the three conditions.—A matter created out of nothing is no less inconceivable, whatever efforts we make to form an idea of an act of the will that can change what before was nothing into real substance. Besides its being contrary to that known maxim of philosophers, Ex nihilo nihil fit.—In fine, that an infinitely good, holy, free being, who could have made his creatures good and happy, should rather chuse to have them wicked, and eternally miserable, is no less incomprehensible; and the rather, as it seems difficult to reconcile the freedom of man with the quality of a being made out of nothing.

These appear to have been the difficulties which led Spinoza to search for a new system, wherein God should not be distinct from matter, and wherein he should act necessarily, and to the extent of all his power, not out of himself (ad extra) but within himself.—But it is certain, if the new system rescue us from some difficulties, it involves us in others much greater.—For,

1. It is impossible the universe should be but one substance; since every thing that is extended must necessarily have parts; and what has parts must be compounded. And, as the parts of extension do not subsist in each other, it follows, either that extension in the general is not substance, or that every part of extension is a different substance. Now, according to Spinoza, extension in general is an attribute of substance. And he allows, with other philosophers, that the attributes of substance do not differ really from the substance itself. He must therefore allow, that extension in general is substance: whence it will follow, that every part of extension is a particular substance: which overturns the whole system.

If it be objected, that Spinoza does not consider different bodies, as different parts of extension, but as different modifications of it: the distinction between part and modification, we doubt, will hardly save him. For let him avoid the word part as much as he please, and substitute that of modality or modification for it, the doctrine will amount to much the same: the characters of diversity are not less real and evident, when matter is divided into modifications, than when it it is divided into parts. The idea of the univerſe will ſtill be that of a compound being, or an aggregate of ſeveral ſubſtances.

For proof of this, it may be obſerved, that modalities are beings which cannot exiſt without the ſubſtance which modifies them; whence it follows, that the ſubſtance muſt be found where-ever its modalities are found; and even that the ſubſtance muſt be multiplied in proportion as the number of incompatible modifications is multiplied: ſo that, where-ever there are five or ſix of theſe modifications, there muſt be five or ſix ſubſtances. It is evident, that a ſquare figure and a circular figure are incompatible in the ſame piece of wax. Whence it follows, that the ſubſtance modified by the ſquare figure cannot be the ſame ſubſtance with that modified by the round figure. So, when I ſee a round and a ſquare table in a room, I may ſafely aſſert, that the extenſion which makes the ſubject of the round table is a diſtinct ſubſtance from the extenſion which is the ſubject of the ſquare table: ſince otherwiſe it would follow, that the ſquare and round figures might be found in the ſame ſubject at the ſame time.— The ſubject, therefore, that is modified by two figures, muſt be two ſubſtances.

2. If it be abſurd to make God extended, as this robs him of his ſimplicity, and makes him be compoſed of parts; it is ſtill worſe to reduce him to the condition of matter, the loweſt of all beings, and that which moſt of the ancient philoſophers ranked immediately above nothing: matter! the theatre of all ſorts of changes, the field of battle of contrary cauſes, the ſubject of all corruptions and generations; in a word, the being moſt incompatible with the immutability of the Deity!

The Spinoziſts, indeed, maintain, that it is not ſuſceptible of any diviſion; but the argument they alledge, in proof of it, we have elſewhere ſhewn to be falſe: it is, that for matter to be divided, it is neceſſary that one of the parts be ſeparated from the other by a void ſpace, which is impoſſible: ſince there is no vacuum in nature.

3. If Spinoziſm appear extravagant, when we conſider God as the ſubject of all the mutations, corruptions, and generations in bodies; it will be found ſtill worſe, when we conſider him as the ſubject of all the modifications of thinking. It is no ſmall difficulty to unite extenſion and thinking in the ſame ſubſtance; ſince it is not an union like that of two metals, or of water and wine, that will ſerve the purpoſe: theſe laſt require only juxta-poſition; whereas to combine thinking and extenſion requires an identity; thinking and extended are two attributes identified with the ſubſtance; and conſequently are identified with each other, by the fundamental rule of all logic.

Again, when we ſay, that a man denies this, affirms that, likes that, &c. we make all thoſe attributes fall on the ſubſtance of his mind, not on his thoughts, which are only accidents or modifications of it. If therefore what Spinoza advances be true, that men are modalities of God; it would be falſe to ſay, 'Peter denies, likes, wills', &c. ſince, in reality, on this ſyſtem, it is God that denies, wills, &c. and conſequently all the denominations which ariſe from the thoughts, deſires, &c. of men, fall properly and phyſically on the ſubſtance of God. From whence it alſo follows, that God affirms and denies, loves and hates, wills and not wills the ſame thing, at the ſame time, and under the ſame conditions, contrary to the great principle of reaſoning: 'Oppoſita ſunt quæ & neq; de ſe invicem, neq; de eodem tertio ſecundum idem, ad idem, eodem modo atq; tempore verè affirmari poſſunt'; which muſt be falſe, if Spinoziſm be true: ſince it cannot be denied but ſome men love and affirm what others hate and deny, under all the conditions expreſſed in the rules.

4. But, if it be phyſically abſurd to ſay the ſame ſubject is modified at the ſame time with all the different thoughts of all men, it is horrible when we conſider it in a moral light. Since it will follow, that the infinite, the all-perfect Being is not conſtant, is not the ſame one moment, but is eternally poſſeſſed even with contrary paſſions; all the uniformity in him, in this reſpect, will be, that for one good and wiſe thought he will have twenty fooliſh and wicked ones. He will not only be the efficient cauſe of all the errors, iniquities, and impurities of men, but alſo the paſſive ſubject of them, the *ſubjectum inhæſionis*. He muſt be united with them in the cloſeſt manner that can be conceived, even by a penetrative union, or rather an identity, ſince the mode is not really diſtinct from the ſubſtance modified.

Several have undertaken to refute Spinoza's doctrine, particularly the learned Dr. Clarke; we have alſo an examination of Spinoziſm, and Mr. Bayle's objections againſt this ſyſtem, by Monſ. de Jariges, in the Mem. de l'Acad. de Berlin. Wolfius has alſo given a refutation of Spinoza, in his *Theol. Nat. Part* 2.

SPIPOLE'TTA, in zoology, the name of a ſmall bird of the lark kind, called tordino by the Venetians, and ſeeming to be the ſtopparola, as alſo the griſola and ſpipola of Aldrovandus.

SPIRÆ'A *Frutex, vulgo*, in botany, a genus of plants, whoſe characters are:

The flower is compoſed of many leaves, which are placed in a circular order, and expand in form of a roſe: out of whoſe flower-cup riſes the pointal, which afterwards becomes a fruit compoſed of ſeveral pods, in which are contained ſeveral oblong ſeeds.

Theſe ſhrubs are very common in the nurſeries near London, where it is ſold with other flowering ſhrubs at a certain price by the hundred. This ſhrub ſeldom riſes above five feet high; ſo, is proper to intermix with other ſhrubs of the ſame growth, in ſmall wilderneſs quarters, and other plantations of flowering trees.

This plant may be propagated from ſuckers, which are ſent forth in plenty from the ſtems of the old plants, or by laying down the tender branches; which, when rooted, ſhould be tranſplanted out in rows at three feet diſtance, and the plants a foot aſunder in the rows. In this nurſery they may remain two years, obſerving to keep the ground clear from weeds, and, in the ſpring, to dig up the ground between the rows, ſo that the roots may the more eaſily extend themſelves; and, if they ſhoot out many ſide-branches, they ſhould be pruned off, ſo as to reduce the ſhrubs to a regular figure; and afterwards they may be tranſplanted where they are to remain, either in ſmall wilderneſs-quarters, or in clumps of flowering ſhrubs, obſerving to place them amongſt other ſorts of equal growth. *Miller's Gard. Dict.*

Convertibility of SPI'RITS. This is a doctrine that has obtained among many of the moſt curious experimenters, and indeed the moſt intelligent of our chemiſts have always allowed, that provided proper care were taken in the getting together the materials, one Spirit may always be changed into another, as brandy into rum, malt Spirit into brandy, and brandy into malt Spirit. The principles on which this is believed are theſe: all ſimple Spirits, as they are called, conſiſt of four parts, water, oil, phlegm, and alcohol: the laſt of theſe is the eſſential part, and is what conſtitutes the whole a Spirit. In reducing Spirits, therefore, to their utmoſt degree of ſimplicity and purity, it is evident that the three ſuperfluous parts are to be got rid of, and the fourth left alone; by this means the alcohol is procured diſtinct, and is a liquor ſui generis of many peculiar qualities, not to be found in any other fluid.

Among others, it has theſe remarkable properties. 1. When abſolutely purified, it is an uniform homogene liquor, capable of no farther ſeparation, without loſs or deſtruction of ſome of its homogeneous parts. 2. It is totally inflammable, having no ſoot, nor any moiſture behind. 3. It has no peculiar taſte or flavour, any more than pure water, except what is owing to its nature, as alcohol, or perfectly pure Spirit. 4. It is an unctuous and criſpy fluid, running veiny in the diſtillation, and its drops rolling on the ſurface of any other fluid, like peaſe upon a table, before they unite. 5. It appears to be the eſſential oil of the body it is obtained from, broken very fine, and intimately and ſtrongly mixed with an aqueous fluid, which is aſſimilated or changed in its nature in the operation. 6. And, laſtly, it ſeems to be a kind of univerſal fluid, producible with the ſame properties from every vegetable ſubject; but, to produce it thus, requires ſome care in the operation.

On theſe principles, is founded the opinion, that all Spirits may be reduced to a perfect ſimilarity, or ſameneſs, from whatever ſubject they are procured, and on this depends their convertibility into one another; for, when once they are brought to this ſtandard of ſimplicity, there needs nothing more than to add the oil of ſuch of the finer Spirits as is required to convert the Spirit into that particular kind. By this means the ſame taſteleſs ſpirit, whether obtained from malt, ſugar, or grapes, may be made into either malt-ſpirit, brandy, or rum, by adding the eſſential oil of the grape, ſugar, or malt; and thus what was once malt Spirit, ſhall become brandy, or whatever elſe the operator pleaſes.

Many methods have been attempted to obtain the firſt point, that is, the reducing the Spirit to perfect and pure alcohol. The moſt practicable means ſeem to be long digeſtion, and the repeated diſtillation from water into water, where the eſſential oil will at once be left upon two ſurfaces, and the acid imbibed. The ſhorter ways are thoſe by rectifying from neutral abſorbent ſalts and earths; ſuch are ſugar, chalk, and the like. And, laſtly, the uſe of fixed alkalies may be tried, for theſe very forcibly keep down both the phlegm and oil; inſomuch that this laſt method promiſes to be the ſhorteſt of all, if the art were known of utterly aboliſhing the alkaline ſavour, which the alcohol is apt to acquire in this operation, and, which, for this purpoſe, is by no means ſuitable, as abſolutely deſtroying all vinoſity, which univerſally conſiſts in a fine volatile pungent acidity. The diſtillers are the only people, whoſe buſineſs would lead them to make the experiment. This method of converting one Spirit into another would be of immenſe profit to them, if they could perfectly ſucceed in it; but, as it would require time and ſlow proceſſes to bring it about, there is but little hope of its ever being brought to bear among them, while they are in their preſent ſcheme of doing every thing with diſpatch and hurry.

Dr. Shaw has ſaid a vaſt deal in the praiſe of a taſteleſs Spirit, which is producible from a vegetable ſubſtance, only overlooked, as he tells us, becauſe it is too common, with which all the foreign Spirits might be imitated to the utmoſt perfection

tion by means of their essential oils, all thin fine wines raised to any due degree of strength, without giving them the brandy flavour, and many other things of great use are performed; but he has not told us what the vegetable substance is from which we are to obtain this. *Shaw's Essay on Distillery.*

SPI'SSUM, in the ancient music, was used to signify those two smaller conjunct intervals of a tetrachord, which taken together were less than the third. The term for this was *πυκνα*.

SPRI'NGES, among sportsmen, a sort of horsehair nooses, made so as to run very easy, and planted in places where birds run into one particular path, to take them as they pass.

SPU'RRY, *spergula*, is sown in the Low-countries twice in a summer. The first sowing is in May; these plants flower in June and July, and the seed is ripe in August. The second time of sowing it is after the rye-harvest; they usually plow up the rye grounds, and sow them with this seed, to serve the cows in winter, when the other sorts of grass are low or dead. The cows that feed on this plant are found to yield better milk, and finer butter is made from it, than from that of cows feeding on any other pasture. Poultry also are very fond of eating this plant, and the farmers in some places have an opinion, that it makes them lay the more eggs. *Mortimer's Husbandry.*

SQUA'LUS, in the Linnæan system of zoology, the name of a distinct genus of fishes, of the general order of the chondropterygii. The characters of this are, that the body is oblong, and the apertures of the gills are five on each side.— Of this genus are the galeus, lamia, zygæna, &c. *Linnæi Syst. Nat.*

The characters of this genus, according to Artedi, are these: the foramina, or apertures of the bronchia, are five on each side, and they are placed longitudinally from the head to the pectoral fins; the head is depressed, the body oblong, and either rounded, or longish and angular; the skin is rough; the eyes are placed at the sides of the head; and the upper part of the tail is longer than the under. The mouth in most of the species is placed in the under part of the head, and opens transversely.

SQUA'TINA, the *monk-fish*, called also in Italian the pesce angelo, and thence in English angel-fish.

It is of a middle shape, between the long and flat cartilagineous fishes, being much broader than the galei, and rounder than the rays. It grows to a very large size, sometimes to four, five, or six feet long. It is covered all over with a mucous substance, but under it the skin is harsh, and rough enough to serve for the polishing wood and ivory. It is of a brownish grey on the back and sides, and white under the belly. The head is flatted and roundish, and the mouth large, and opening at the extremity of the snout, not, as in other of the fishes of this class, under the head. It has three rows of teeth, eighteen in a row. Its eyes are large, and placed near its mouth, and seem as if meant for looking sideways, rather than up or down. Its upper pair of fins very much resemble wings, from whence it has its name of the angel-fish, and at the extremities of these are a number of sharp hooked thorns. It has also a row of short prickles on its back.

It is common in the English seas, and is not unfrequently caught in Cornwall.

SQUA'TT, in minerology, a term given by the English miners to a peculiar sort of bed of ore, less valuable than a load or vein, because of its reaching but a little way.

Though the ore of the Squatts is generally very rich and good, not inferior in quality to the best vein ore, the miners are often terribly disappointed, on finding these Squatts instead of the right veins, after a long search. In the tin countries, the way of searching for mines is by looking after the shoadstones; that is, certain metalline stones which contain some ore, and which have originally made the upper part of the vein of ore, reaching up to the day, or surface of the earth.

SQU'ILLA *aquæ dulcis*, the fresh-water shrimp. Few people are aware of the vast destruction made by this little insect among the small fry of fishes. This insect is commonly very plentiful in standing waters, and particularly in breeding ponds, where they always have their prey in plenty before them; and often suffer none, or scarce any of the numerous young fry, hatched from the spawn of carp and tench, to live to grow up. They may be observed following the shoals of the young fry and seizing multitudes one after another; and at other times lurking among the weeds, to seize such as straggle by themselves. If one of these insects be put into a bason of water with a dozen or two of these young fish, though as big as himself, he will very soon destroy them all. They kill numbers that they cannot eat, but leave them to rot.

STA'BILES, in the ancient music, a name given to the extreme chords of a tetrachord; because they remained the same throughout all the genera and species of music.

STA'BLE.— Nothing conduces more to the health of a horse, than the having a good and wholsome Stable. The situation of a Stable should always be in a good air, and on a firm, dry, and hard ground, that in winter the horse may come in and go out clean. It should always be built somewhat on an ascent, that the urine, and other foulnesses, may be easily conveyed away by means of drains or sinks cut for that purpose.

As there is no animal that delights more in cleanliness than the horse, or that more abominates bad smells, care should be taken that there be no hog-sty, hen-roost, or necessary-house near the place where the Stable is to be built; for the swallowing of feathers, which is very apt to happen when hen-roosts are near, often proves mortal to horses; and the steams of a bog-house, or hog's dung, will breed many distempers; and, particularly, they will bring on the farcy and blindness in many horses. It is much better to build the walls of a Stable of brick than of stone, for the former is always dry, the other often sweats, and is very apt to be damp, and to cause rheums and catarrhs to horses that are set in the Stable in damp weather.

The walls ought therefore to be of brick, and to be made of a moderate thickness, two bricks, or a brick and half at the least, both for the sake of safety and warmth in winter, and to keep off the heat of the sun in the midst of summer, which would spoil the horse's appetite, and sink his spirits. The windows should be made on the east and north sides of the building, that the north air may be let in to cool the Stables in summer, and the rising sun all the year round, especially in winter.

The windows should either be sashed, or have large casements, for the sake of letting in air enough; and there should always be close wooden shutters, that the light may be shut out at pleasure; by which means the horse will be brought to sleep in the middle of the day, as well as in the night, when it is judged proper that he should do so.

Many pave the whole Stable with stone, but it is much better to have that part, which the horse is to lie upon, boarded with oak planks; for it will be not only easier, but more warm and comfortable to the creature.

The boards must be laid as even as possible, for this is the way to make the creature lie most at his ease, and in the most healthful posture. The dealers in horses generally indeed make the boards be laid higher towards the top, and slanting down: this shews a horse to more advantage as he lies, but it is very uncomfortable to the creature, and his hinder parts are always slipping down, and the hind legs are often made subject to swellings by it.

The planks should be laid crosswise, not lengthwise, and there are to be several holes bored through them to receive the urine, and carry it off underneath the floor into some drain, or common receptacle. The ground behind should be raised to a level with the planks, that the horse may always stand even; and the floor behind should be paved with small pebbles, and the place where the rack stands should be well wainscotted. There are to be two rings placed on each side of the stall, for the horse's halter to run through, and a logger is to be fixed to the end of this, sufficient to poise it perpendicularly, but not so heavy as to tire the horse, or to hinder him from eating. The best place for him to eat his corn in is a drawer or locker made in the wainscot partition; this need not be large, and consequently need not take up much room, so that it may be easily fixed, and taken out to clean at pleasure: by this means, the common dirtiness of a fixed manger is to be avoided.

Many people are against having a rack in their Stables; they give the horse his hay sprinkled upon his litter, and if they think he treads it too much, or too soon, they only nail up three or four boards, by way of a trough, to give it to him in. The reason of this is, that the continual lifting up the head to feed out of the rack is an unnatural posture for a horse, which was intended to take his food up from the ground, and makes him, as they express it, withy-cragged. In the way of sprinkling the hay on the litter, or laying it in a trough even with the ground, he not only takes it up as if from the earth in a natural way, but can eat as he lies, which is a piece of indulgence that a horse takes great pleasure in.

When there is Stable-room enough, partitions are to be made for several horses to stand in; these should always allow room enough for the horse to turn about, and lie down conveniently in; and they should be boarded up so high towards the head, that the horses placed in separate stalls may not be able to smell at one another, nor molest each other any way. One of these stalls ought to be covered in, and made convenient for the groom to lie in, in case of a great match, or the sickness of a valuable horse. Behind the horses there should be a row of pegs, to hang up saddles, bridles, and other necessary utensils; and some shelves for the hanging up brushes, &c. and the standing of pots of ointment and other preparations.

The Stables of the nobility are often incommoded by bins for oats placed in them, which take up a great deal of room with very little advantage. Dr. Plot has given us, in his History of Oxfordshire, a very convenient method, used by a gentleman of that county, to prevent this. It is done by making a conveniency to let the oats down from above, out of a vessel like the hopper of a mill, whence they fall into a square pipe of about four inches diameter, let into the wall, which comes down into a cupboard also let into the wall, but with its mouth so near the bottom, that there shall never be more than about a gallon in the cupboard at

a time;

a time; which being taken out, and given to the horses, another gallon immediately succeeds it from above, without any trouble to the groom or any body else. By this means there is not an inch of room lost in the lower part of the Stable where the horses stand; and there is this great conveniency besides, that the oats are always kept sweet by it; for every gallon that is taken away puts the whole quantity above in motion, by the running down of the gallon that supplies its place, and no mustiness ever comes, where there is this continual airing and motion. There may easily be contrived two of these, the one for the oats, the other for split beans; and both of these may be let into the range of presses, the oats and beans being separated above by partitions. The other requisites for a Stable are a dung-yard, a pump, and a conduit; and, if some pond or running river be near, it is greatly the better.

STA'CHYS, *base horsehound*, in botany, a genus of plants, whose characters are:

It hath a labiated flower, consisting of one leaf, whose upper lip is somewhat arched and erect, and the under lip is cut into three segments, the middle one being larger than the other two: out of the flower-cup rises the pointal, attended by four embryoes; which afterwards become so many seeds, which are roundish, and inclosed in an husk, which before was the flower-cup: to these marks may be added downy hoary leaves.

STAG-*worms*, in natural history, a name given to a species of worms produced of the eggs of a fly, and lodged in a very strange place behind, and under the palate of the stag or deer's mouth.

STA'INING, or *colouring of porcelain.*—The Chinese, for a great many ages, used only white porcelain. The first colour they employed was blue, and after that they came into the use of all the rest. Their ancient blues were prepared by themselves from a kind of a lapis lazuli; but we now supply them with the smalt so much cheaper, that it is no longer worth their while to make it themselves. They used to prepare this only by giving a gentle calcination to the stone, and then beating it to powder, and grinding it to the utmost fineness in mortars of unglazed porcelain-ware, with pestles of the same. The red, which the Chinese use, is made of our green vitriol, or common copperas. They put about a pound of this into a crucible, and lute on this another crucible inverted: this last has a hole cut in the top, which they keep covered or open at pleasure. They set this crucible in a furnace of bricks, so contrived, as to throw all the flame upon the lower vessel, in the way of our chemists reverberatory furnaces. They make a large fire of charcoal all round it, and observe the hole at the top; for, so long as there ascend thick black fumes through that, the matter is not sufficiently calcined. They watch the going off of this fume, and, when there appears in the place a fine and thin cloud, they take away the crucible, the matter being then sufficiently burnt. They try this, however, by taking a little out, and examining the colour; if it be not sufficiently red, they let it remain longer in the fire. When they find that it is of a good colour, they take away the fire, and leave the vessels to cool; this done, they find a cake of red matter at the bottom of the crucible, and a quantity of a finer powder about its sides. They keep these separate, the latter being the purest, the finest, and the brightest colour.

One pound of copperas affords about four ounces of this colour, and this is the red which they manage in different shades, and vary so much.

The Chinese have also a white colour, which they use in their figures painted on the China: the ware itself is naturally white, and the varnish, or oil of stone, is a great addition to its whiteness all over. But they have yet a way of making a much brighter and finer than these, as may be seen in most of the fine China-ware where there is any white in the figures. This white is made in the following manner: they collect on the shores of their rivers a sort of agate, which is of a whitish hue without veins, and tolerably transparent. It approaches very much to the nature of crystal, and probably crystal may be found to supply its place with us. They calcine this stone to a white powder, and to every ounce of this, when ground in their porcelain mortars to an impalpable fineness, they add two ounces of cerus in fine powder: this they mix with the varnish, and lay on in the common way of other colours.

This white mixture serves not only for the colouring white, but it is the basis of several other of those beautiful colours which we see on the China-ware, and which our manufacturers have been often perplexed what to make of. Their green colour is made of copper rusted with acid; and their fine deep violet colour is made of this green, by adding to it a due proportion of this white. It is not to be supposed that this effect is produced according to the common laws of mixing colours among our painters, for then the white and green would only make a paler green. But, copper being a metal that as well gives a fine blue, as a fine green, according to the nature of the substances it is mixed with, the white in this case alters the very nature of the green, and converts it into that fine and deep violet blue, which we may draw from copper by means of any of the volatile alkalies; such as spirit of sal armoniac, spirit of harshorn, spirit of urine, or any the like liquor. The workmen know how to bring this blue to any degree, by putting in different proportions of the two colours. There is not any admixture of them, that will not produce a blue of some kind; but always, the more of the green colour is used, the deeper the blue will be, and the less, the paler. The yellow is made by an admixture of seven drachms of this white, and three drachms of copperas, or more, if they desire the colour to be deeper.

These colours are laid on upon the vessels when they have been once baked, but they do not appear till the second baking is over in their proper shades or tinges, and sometimes scarce at all.

The black China is much esteemed in the East, and particularly when it is ornamented with gold; this colour looking better with that ornament than any other. The black is always laid on when the porcelain is first dried, and is prepared by mixing three ounces of the fine deep blue with seven ounces of that fine varnish which they call oil of stones. This admixture gives a fine deep black. When the colour is thoroughly dry, the vessels are baked, and, when this is done, the gold is laid on, and the whole is baked again in a particular furnace made for this purpose. If they would have the black degenerate into blue, they need only add less of the blue, and a little of the cerus and agate white before described.

They have two peculiar ways of applying the red, besides the common one, both which require a nice workman, and make the ware come very dear. They call the one of these oils red, and the other blown red.

There are many things practised by the Chinese in their colouring and forming the several kinds of porcelain, which may be well brought into use among us, and give a new value to our own wares, even though we should never arrive at their art of making the thing itself. One kind of colouring, easily introduced among us, would be what they call hoan ton hoan. This produces vessels of great beauty and price, and is done in this manner: the matter, of which the vessels are made, for this purpose, need not be fine; they usually take any of the common vessels baked, without having been varnished, and consequently simply white, and without lustre. When these are intended to be of one simple colour, they need only be plunged into a liquid varnish or oil, as the workmen there call it, coloured with such ingredients as will strike the most lively tinges: but, if it is to be coloured in compartments, as is usually the custom with this sort of China, it is to be done by the pencil. The usual way is to paint these in pannels, one green, another blue, and so on, and they make a very agreeable appearance. There requires no more to this, than the laying on the colours tolerably thick with a large pencil; but, if the pictures of animals and plants are to be given, they are to be done with the most permanent colours, and the vessel being again well baked, becomes very beautiful.

The Chinese, who are deceivers in every thing, find the way of cheating very much in regard to this sort of China-ware. They paint the flowers of plants, and some parts of the birds, &c. in very bright colours, after the vessel has been baked. Vermilion is a fine colour, which they often add on this occasion; but they cannot use this before the baking, because it would be destroyed by the fire. These colours which are laid on afterwards cannot last, but soon rub off in the wiping, or using the things; the others last for ever; for they are laid on with the greatest heat of all, the vessels being put into the same furnaces to lay on these, as the other things are baked in for the first time.

Salt-petre, and powder of flints, are generally the things added to the colours thus laid on, to make them penetrate, and run properly. Thus for the fine deep violet colour, which makes the greatest figure of all others on this ware, they mix together equal quantities of the fine azure, the powder of flints and salt-petre, all first powdered separately till perfectly fine; this is tempered with water, and then laid on with the pencil, and though it looks rough at first, it comes out of the furnace of as beautiful a glossy hue as any thing can be conceived. The yellow is made by mixing together three ounces of cerus, and three ounces of powdered flints, and adding three, four, or more drachms of the red copperas, till the whole is of the proper degree of colour. The white is composed only of powder of flints and cerus, with a small admixture of the salt-petre, or it will succeed tolerably well without. These are all the particulars necessary to be observed for the making a sort of porcelain of great beauty, in which the nature of the ware itself is not concerned; so that it seems easy to imitate it with any of our own wares.

In the baking of this, or any other kind of coloured China, the second time, there is, however, some caution to be used in the placing the pieces. The Chinese are very artful in their disposition of these, arranging them in the most compact manner, and putting the little ones within the great ones; but great care is also necessary, that the vessels do not touch one another in the parts where they are painted, for the consequence of that would be the spoiling of both vessels, as the colours would run together. The bottom of one vessel may generally be placed on the bottom of another, though both are painted, because the rims are not painted, and they keep the painted parts from touching one another. High and narrow vessels, such

such as chocolate-cups, and the like, are very troublesome on this occasion. The method the Chinese workmen take with them, is this: they place a range of them, so as to cover the whole bottom of the furnace, and they cover this with a thin bed of broken China-ware, over which they place another row of the cups, and so on to the top, where they lay on no covering: they never bake any thing else with these cups, when they are of this kind of twice-baked porcelain. *Observat. sur les Coutumes de l'Asie.*

STA'JOLUS, among the Romans, a measure of length used in surveying land; it was equal to five palms and three fourths of a palm.

STAKE, the name of a small anvil used by smiths; sometimes it stands on a broad iron foot, on the work-bench, to be moved up and down occasionally; and sometimes it hath a strong iron spike at the bottom, by which it is fixed to some place on the work-bench. Its use is to set small and cold work straight, by hammering it on the Stake, or to cut or punch upon with the cold chissel, or cold punch. *Moxon's Mech. Exer.*

STAKE *of a plough.* The Stake is an upright piece of wood, passing at its bottom through that link of the tow-chain which passes through the box of the plough, and at its upper end receiving the end of what is called the bridle-chain, which ties it to the crow-staff, or, if it be not long enough, a wyth, or cord, is used to tie it: it is also tied to it again, a little below the pillow of the plough, by another wyth or cord. *Tull's Husbandry.*

STALACTA'GNIA *, in natural history, the name of a genus of spars.

* The word is derived from the Greek σταλακτὸς, stillatitious, or formed by dropping, and ἁγνὸς, pure.

The bodies of this genus are formed by the dropping of water from the roofs of subterranean caverns, and are the purer sort of what are called by authors stalactitæ. They are crystalline sparry bodies, formed into oblong conical figures, composed of various crusts, and usually found in form of icicles.

STALACTOCI'BDELA *, in natural history, the name of a genus of spars.

* The word is derived from the Greek σταλακτὸς, stillatitious, and κίβδηλος, impure.

The bodies of this genus are formed by the dropping of water from the roofs of subterranean caverns, and are the coarser kinds of what authors have called stalactitæ. They are crystallino-terrene spars, formed into oblong bodies, and found hanging from the roofs of caverns and grottoes.

STALAGMODIAU'GIA *, in natural history, the name of a genus of spars, the bodies of which are the purer kinds of what authors call stalagmoscieria.

* The word is derived from the Greek, σταλαγμὸς, a drop, and διαυγὴς, pellucid.

These spars are found in form of small bells, each composed of numerous crusts, and considerably pellucid and crystalline.

STALAGMOSCIE'RIA *, in natural history, the name of a genus of spars, formed by the dropping of waters. They are composed of numerous and thin crusts, and of an opaque and coarse structure.

* The word is derived from the Greek σταλαγμὸς, a drop, and σκιερὸς, opaque.

STAMPS, in metallurgy, a kind of large pestles, lifted up by water-wheels; serving to pour the ores, and flags of metals.

STA'NCHIONS, in ship-building, those pillars which are placed perpendicularly between a ship's deck, to support the weight of the guns, &c.

STA'NDING *Rigging of a ship*, those ropes which do not run in blocks; as the throuds, stays, backstays, &c.

STAR *of the earth*, a name given by the country people to the coronopus, or buckshorn-plantane, from its leaves being always disposed on the earth, in the form of the rays of a Star.

It is famous for its virtues in curing the bite of a mad-dog. The countess of Suffolk's powder, so much celebrated in many places for that terrible disorder, is principally composed of this plant.

STAR-*fish.*—There are many species of the Star-fish, and those extremely different one from another: they have different numbers of rays, but the most common kind has five. Their upper surface, or that to which the legs are not fastened, is covered with a firm and hard skin, which is full of little eminences of a harder matter, approaching to the nature of that of the shells of the echini marini, and the like. This skin is of different colours in the different species; most usually it is red, sometimes it is green, in some blue, and in others yellow, and of all the degrees of these colours, or the mixtures that may be produced from them. This colour does not extend to the under surface, that is coloured all over with legs and with points, like the eminences of the upper side, only longer; these are all either whitish, or yellowish. In the center of the fish there may be seen a mouth or sucker, by means of which the creature draws its nourishment from the shell-fish, on which it feeds. There are five teeth placed round this sucker, or perhaps they may be more properly called five bony forceps; by means of which it seizes and holds fast the creature, while the sucker does its office in draining out the juices; and probably it is by means of these that they open the bivalve shells, when they feed on the fish in them.

The amazing property of reproducing the essential parts, when lost, is not confined to the polype, and some few others of the insect world, but it is extended to the Star-fish, and to the urticæ marinæ of various kinds, and probably to many others, in which we at present have no expectation of finding it. Mr. Reaumur, on the discovery of this property in the polype, observed these other animals, as they lay on the shores of Poictou, and other places, and often found that species of Star-fish, which is very commonly known, and which has naturally five rays or arms, with only three or four, one or two being wanting; and, on taking up and examining these mutilated ones, nature was always found reproducing the limb that was wanting; and, on cutting or breaking other Star-fish into several parts, it was but a very little while before the broken parts cicatrised, and every part remained alive; and by the appearances of things there remained no doubt, but that these living pieces will all, in time, reproduce their wanting parts.

Mr. Reaumur could not stay long enough on the spot to see this; but Mr. de Villars, on the coast of Rochelle, saw the whole process very frequently in the urticæ marinæ which he cut to pieces on purpose for the experiment, and which always reproduced the parts he had cut off; and the common fishermen of the coasts, where Mr. Reaumur was in company with Mr. Jussieu, seeing them making their experiments on the Star-fishes, appeared to be well acquainted with their nature, and told them that they might cut and tear them as much as they pleased, but they would not be able to kill them: so familiarly was this piece of natural history known among these people, though unknown to those who had employed their lives in the searches after such things.

Mr. Reaumur was very sensible of the advantages that water insects, and animals, have over others, as to the healing of their wounds, but was resolved to try the experiment on some land animals. The creature he first chose for these experiments was the earth-worm; and on cutting these creatures asunder, though many of the pieces dried, yet he had the pleasure of seeing some succeed so perfectly, that the tail part, which wanted not only the head, but also the organs of generation of both sexes (which in these animals are always both contained in the same individual) has been seen to reproduce both these organs and the head, and become as perfect a worm as the whole was. *Philos. Trans.* N°. 464.

STAR-*wort, aster*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the radiated kind. Its disk is composed of floscules, and its border of semifloscules: these all stand on the embryo seeds, and are contained in one common squammose cup. The embryoes finally ripen into seeds, which are winged with down, and fixed to the thalamus of the flower.

All the species of this plant are propagated by parting their roots early in the spring, and they will grow in almost any soil or situation; and the larger sorts increase so fast, that, if not prevented, they will, in a little time, over-run a lage space of ground. They grow best in the shade. But the lower kinds do not run so much at the root, but should be taken up and transplanted every other year, which will make them produce much fairer flowers. *Miller's Gard. Dict.*

STAR *of Bethlehem.* See ORNITHOGALUM.

STA'TICE, *thrift, or sea-pink*, in botany, a genus of plants, whose characters are: it is a plant with a flower gathered into an almost spheric head, furnished with a common scaly empalement: this head is composed of several clove-gilly-flower-flowers, consisting of several leaves in a proper empalement, shaped like a funnel: in like manner, the pointal rises out of the same empalement, and afterwards turns to an oblong seed, wrapped up in the empalement as in an husk.

STA'TUARY *Marble*, a name given by our present artists to the softer white marble, generally formed into statues; it is the same which the ancients called Parian marble.

STA'TURE (*Dict.*)—The Stature, or pitch of a man, is found admirably well adapted to the circumstances of his existence. Had man, observes Dr. Grew, been a dwarf, he could scarce have been a reasonable creature: for, to that end, he must have had a jolt-head; and then he would not have had body and blood to supply his brain with spirits: or, if he had had a small, proportional head, there would not have been brain enough for his business.—Again, had man been a giant, he could not have been so commodiously supplied with food: for there would hot have been flesh enough of the best edible beasts to supply his turn; or, if the beasts had been made proportionably bigger, there would not have been grass enough, &c.

It is a common opinion, however, and has been so ever since Homer's time, that people, in the earliest ages of the world, much surpassed the moderns in Stature; and it is true, we read of men, both in sacred and profane history, whose pitch appears surprising: but then it is as true, that they were esteemed giants.

The

The ordinary Stature of men, Mr. Derham obſerves, is, in all probability, the ſame now, as at the beginning; as may be gathered from the monuments, mummies, &c. ſtill remaining. The oldeſt monument in the world is that of Cheops, in the firſt pyramid of Egypt, which, Mr. Greaves obſerves, ſcarce exceeds the meaſure of our ordinary coffins. The cavity, he ſays, is only 6.488 feet long, 2.218 feet wide, and 2.160 deep: from which dimenſions, and thoſe of ſeveral embalmed bodies, taken by him in Egypt, that accurate writer concludes, there is no decay in nature; but that the men of this age are of the ſame Stature as thoſe three thouſand years ago.

To theſe we have other and later inſtances to add from Hakewell: the tombs at Piſa, which are ſome thouſands of years old, are no longer than ours. The ſame may be ſaid of Athelſtan's in Malmſbury church; Sheba's in Paul's, of the year 693, &c.

The like evidence we have from the ancient armour, ſhields, veſſels, &c. dug up at this day; for inſtance, the braſs helmet dug up at Metaurum, fits one of our men; yet it is allowed to have been left there at the overthrow of Aſdrubal. Add, that Auguſtus was five feet nine inches, which was the meaſure of our queen Eliſabeth; only the queen exceeded the emperor by two inches, allowance being made for the difference between the Roman and our foot.

STA'VERS (*Dict.*)—The moſt approved remedy for this diſtemper, which ſhews itſelf in horſes in a giddineſs, and reeling about, in waterineſs of the eyes, and a variety of odd motions of the head, is the following method: the creature is firſt to be blooded largely, then a glyſter is to be given him, compoſed of two quarts of emetic wine, and four ounces of the unguentum populneum. When he has repoſed an hour or two after voiding his glyſter, let another be given him, made of two ounces of the ſcoriæ of the liver of antimony finely powdered, boiled a little while in five pints of beer, and with the addition of four ounces of the ſame ointment, or of ointment of roſes. This laſt glyſter is to be frequently repeated, and his legs are to be all the while rubbed ſtrongly with wiſps of hay, wetted in warm water, to make a revulſion. His food ſhould be bran and white-bread, and he ſhould be walked from time to time in ſome temperate place. If theſe methods do not ſucceed, let an ounce of Venice treacle be diſſolved in a quart of ſome cordial waters, and given him; and, after this, let the following glyſter be given warm: take Venice treacle and ſal polychreſtum, of each two ounces; diſſolve them in two quarts of a decoction of mallows and camomile flowers; add a quarter of a pint of oil of rue. This repeated two or three times after bleeding, and the other methods, will often cure the worſt ſtages of this diſeaſe.

STEA'TITES. See SOAP-*earth*.

STEEL (*Dict.*)—The manner of making iron into Steel had remained very long a ſecret, but many authors of late date have given the proceſs, though it does not appear the ſame in all, and in many is encumbered with circumſtances, intended only to diſguiſe it. Mr. Reaumur has taken greater pains, than almoſt any man, to come at the truth; but, to be rightly informed of his reaſons, we ought to begin where he did, that is, at the origin of the iron in its pure metallic ſtate.

The ores of this metal are mixed bodies, compoſed of ſome particles truly metallic, and of others ſulphureous, ſaline, and terrene; this compound maſs is put in fuſion by the fire, and on this operation the metallic parts, being heavieſt, ſubſide to the bottom of the veſſel, or furnace, and are then eaſily ſeparated from the lighter ſubſtances which float at the top. This ſeparation, however, is not ſuppoſed to be perfect, but the metal, after this its firſt fuſion, retains many heterogene particles, which prevent it from being malleable. It is after this to be refined, that is, to be melted again, and, that ever ſo often performed, the metal becomes yet more and more pure and perfect, ſome heterogene matter being every time depoſited, or thrown off, and this is uſually much leſs after every fuſion.

The metal, when thus purified by melting, yet remains hard and brittle: theſe are two qualities which we do not want in iron, and this hardneſs and friability are no incompatible qualities, ſince their origin is this, that the iron in this ſtate is compoſed of a multitude of ſmall granules, every one of which is very firm and compact in its own texture, though they cohere but ſlightly one with another. The knife, or the file, cannot eaſily cut any one of theſe granules, but a blow of a hammer eaſily ſeparates large parcels of them from thoſe to which they were joined: this caſt iron is therefore uſed only for ſuch purpoſes as requires a ſubſtance poſſeſſed of theſe qualities; purpoſes where hardneſs is required, and where no blows are to be met with. Thus, backs of grates, iron pots, and the like, are made of it.

One of the general properties of metals is, that they are malleable; that is, their ſeveral particles cohere ſo well together, that they are ductile and extenſible under the hammer, and will ſuffer the whole maſs to bend any way without breaking, that is, without their ſeparating from one another. In the works of the artizans, ſuch ſuppleneſs and pliability is called body in a metal, and the caſt iron, which wants this, is ſaid to have no body, and is what they call no ſoft metal. It is therefore no way fit for ſuch works as require faſhioning by the hammer or the file, nor of ſuch as are to ſtand any violent blows; but, as it is eaſily fuſible, it ſerves for the caſt works where there is no great delicacy in the figuring, ſince it does not run ſo thin as to adapt itſelf to every lineament of a fine figure, nor is qualified to be repaired by inſtruments.

The ill qualities of caſt iron are, in a great degree, remedied in the forged or wrought iron, taken from the ſame quantity, and the ſame fuſion. The forging of iron is only the placing it over the fire till heated to a certain degree, and then beating it out with large hammers till it becomes ſoft. When it has been ſufficiently forged, it becomes ſoft and malleable, even when cold, and, when heated, is eaſily wrought into any figures, which it retains afterwards; and it is eaſily cut by the file when cold, and is not brittle on being ſtruck, as is the caſt iron.

While it gains theſe properties by the forging, it loſes, however, another by the ſame means, which is its fuſibility. It will no longer melt in the fire, but when the workmen give it the ſtrongeſt heat they can, it is only reduced to a ſort of ſoft paſte, and ſweats a little, as they expreſs it; that is, ſome few drops of truly melted iron fall from it.

It is very certain, that both the caſt and the forged iron are mixtures of metalline, ſaline, and ſulphureous particles, and the different arrangement of theſe, in their mere ſimple running together in the fuſion, and their being driven intimately into, and among one another, by the hammering, makes the fuſibility different in the two ſtates.

If the forged iron differ greatly from the caſt, there is however a third ſtate into which it is reducible by art, which is yet different from both; this is what we call Steel; and the quality of iron on receiving this change is not one of its leaſt valuable ones, ſince from this we have all our inſtruments for cutting, ſawing, boring, and the like purpoſes, the value of which to us is almoſt infinite. The German Steel has always been in great repute, and, though ſeveral other nations have made it, yet the Germans have kept their method a ſacred myſtery, to keep up their trade in it.

Steel is conſiderably harder than forged iron, and ſo it is neceſſary that it ſhould be, in order to many of the purpoſes it is imployed in. Shears of Steel, which are intended to cut iron, muſt be harder than iron, otherwiſe their edge will turn, and they will not cut; whereas, if the metal is too hard, then the granules will fly off, and the edge break away in ſmall fragments. This is the caſe with all edged tools; and hence it is, that good Steel is ſo nice and difficult a thing to make, ſince there is required ſuch a degree of hardneſs, and no more.

It is very well known, that Steel acquires its hardneſs from the plunging it into water; it is to be heated to a certain degree, and then immediately plunged, while the fiery particles yet remain in it, into water perfectly cold; it is then to be ſpeedily drawn out of the water, and thus the whole operation is finiſhed. It acquires its hardneſs in degrees, proportionate to its heat when plunged into the water; and this hardneſs, or temper, remains with it only till it is heated as high again; for, after that, if left to cool leiſurely, and not thrown into water, it is loſt. All the maſſes of Steel which are ſold are thus tempered; nevertheleſs, when they are wrought into tools, their temper is loſt, and is to be renewed by plunging them again into cold water, when they have been forged into the ſhape of which they are to be.

Mr. Reaumur affirms, that Steel differs in nothing from forged iron, except that it contains more ſulphurs, and more ſalts. Hence, it follows, that caſt iron ſhould be Steel, ſince it evidently differs from forged iron in the ſame manner, and by the ſame properties; and, in effect, caſt iron is Steel, ſuch as it is, eſpecially the white ſort, which is more pure, and more perfectly diveſted of its earth, than the browner ſorts; and this white kind may be accordingly brought to all the hardneſs of Steel, by repeated heating and quenching in cold water. It follows alſo, that, in order to convert iron into Steel, we are to give it new ſalts and new ſulphurs. It may be aſked, where is the neceſſity of giving again that which the mere caſt iron poſſeſſes? To which the anſwer is, that Steel is required to be malleable in ſome degree, which the mere caſt iron is not; and it is to be added to this, that it may be poſſible for us to give to forged iron ſuch ſalts and ſulphurs as are more proper for the Steel, than thoſe which the caſt iron naturally poſſeſſes.

We have great variety of ſalts and ſulphurs, out of which to chuſe for this purpoſe, and Mr. Reaumur made many trials to find which would ſucceed beſt; and the reſult of all was, that, for ſulphurs, powdered charcoal and common ſoot; and, for ſalts, ſea ſalt alone ſucceeded beſt; and that theſe were properly to be mixed with aſhes, by way of an intermediate ſubſtance. Theſe ſubſtances muſt alſo have their allotted doſe; that is, there muſt not only be a certain proportion of the ſeveral ingredients one to another, which, however, need not be very preciſe and exact, but there muſt alſo be a proportional quantity of the whole employed to the quantity of iron that is to be wrought upon; and in this alſo regard muſt be had to the ſeveral ſorts of ores from which the iron was obtained, ſince the iron of ſome ores is much ſooner convertible into Steel than that of others, and makes alſo a better Steel.

The manner of beſt introducing theſe ſalts and ſulphurs into the

the body of the iron was found by this author a matter of great difficulty to determine. He soon perceived, that fire was the only agent that could convey these bodies into the metal; and in contriving how this might be done most easily, and with least expence, he found out, after many trials, a new sort of furnace, which effected this purpose with great ease, and which was not subject to the inconveniencies of other furnaces.

As Steel is iron with an admixture of heterogene particles, it follows that it must be less metallic, that is, less malleable, or more brittle; it is also necessary that it must be, in some degree, malleable for the purpose it is required for; and it is easy to conceive that these properties cannot be given it, in a proper degree, but by means of a very accurate operation; and, even when all the parts of the process are the same, there is yet much depending on the iron itself, which can never be perfectly known but by trial. Something, however, may be judged of the iron by breaking bars of it: the several sorts of iron, when broken, shew some of them only granules, others flakes, and others fibres; some also shew all three of these moleculæ at once, and others two of them; but it is easy, in either of these cases, to see which sort is in the greatest number. The laminated and the fibrous iron are the two extremes; the first is very brittle, the latter very malleable. The laminated iron is ever the worst of all kinds for making into Steel; and of this kind such pieces are worst of all, the laminæ of which are very white and shining, and are large and irregularly disposed, and arranged in different inclinations. Mr. Reaumur began to reckon from these an arrangement of all the kinds of iron, which coming, each by degrees, to have the laminæ still smaller and smaller, and at the same time less glittering, and placed more evenly together, sunk at last into the irons of the granulated kind. It is easy to conceive how many differences there must be between these; and from these the fibrose ones may be deduced, owing their texture merely to the granulæ, which in these are disposed into long strings or streaks. Though, in this arrangement of the irons, the first are, of all others, the least proper for making Steel, it does not follow that the last are the most so; these indeed usually make a very soft and pliant sort of Steel, which has what the workmen call the greatest body of all the kinds of Steel, and is therefore most proper of all for certain purposes, as the making of watch springs, and the like; but the want of hardness makes it very unfit for cutting tools of all kinds, from the razor to the ax. The granulated iron always makes the finest and hardest Steel; and of these such succeed best, whose granules are smallest.

One thing remarkable is, that all Steel, though made of iron of the granulated or striated kind, yet is, before it has been hammered, of a flaky, or a sort of laminated structure; but this seems owing to the fire's having melted some of the granules in the operation, and run great numbers of them together into these plates. The smallness of these flakes in Steel, which has not been worked, are a proof of its being a bad kind.

A bar of iron, when converted into Steel, is not equally so converted in all its parts; the fire has always acted more strongly on its surface than on its central parts, and it is therefore more perfectly Steel there than in its inner parts; but a perfection in the operation is not necessary to the Steel's being good and useful, and the whole bar is often very good Steel, as are also many bars made at the same time, yet, all perhaps, somewhat differently affected.

If the composition, which is to convert the iron into Steel, be too strong, or if the fire be too violent, or the matter contained too long in it, in all these cases the Steel will be over made; that is, there will be an over proportion of saline and sulphureous parts added to the iron: these will therefore too far separate the particles of the metal asunder, and the consequence will be, that the Steel will be too brittle to bear hammering, and will be of great loss to the proprietor in the great quantities that will be broken, besides the loss he will have from the abundance of scales which will fly off in the working. The way to meliorate such Steel as this must be to divest it of a part of its salts and sulphurs, but particularly of the last; and Mr. Reaumur found, that by the burying the bars of such Steel in lime, or any other alkaline substance that would readily absorb the sulphurs, and placing it for a proper time in the fire, it would be in a manner decomposed again, and come out a very good and perfect Steel; and this is no trivial proof, that the account given of the manner of iron's becoming Steel is the true one.

By this management Steel may again be converted, or reduced to its primitive iron, and a body of any middle degree, between Steel and iron, may be produced, by stopping this process at different points of time, or continuing it till all the adventitious salts and sulphurs are drawn off or absorbed. Hardness and flexibility are the two great points of this operation, and what the metal gets of the one of these, it assuredly loses of the other. The greater hardness is from the greater quantity of the adventitious salts and sulphurs; and the greater flexibility, or, as the workmen call it, the greater body, is from the greater quantity of the metallic; and he who is able to calculate properly the quantities of his salt, charcoal, and soot, and to regulate exactly the degree of fire, is capable to make Steel of what degree of temper or perfection he pleases.

Iron, impregnated with new salts and new sulphurs, is not however perfectly reduced to the state of what the workmen expect in Steel; there wants yet the quenching it while hot in cold water, to compleat the operation. The Steel, penetrated every way by the particles of fire, and at that instant plunged into water, is by that quenching stopped in the very state in which it was, and is not suffered to exhale the igneous bodies, as it would otherwise have done. It was, while in the fire, rarified and dilated, and this quenching continues it in that state, and it is found, on measuring, considerably thicker and larger than it was while unheated. It might be supposed from hence, that the particles of fire, which were lodged in the Steel while red-hot, were thus detained and imprisoned in it, and so wrought the change, as they are known to remain in many calcined bodies, though they have not been so suddenly quenched; but, if this were the case, the Steel must be increased in weight as well as bigness, as many calcined bodies are; but this is not found to be so in fact.

Recourse must be had therefore to some other operation on the Steel, and this appears, in reality, to be no other than the change of its texture, or internal structure. If a body be naturally composed of a number of particles, which are in themselves hard and compact, but between which there are certain spaces; if one takes from these hard and compact particles somewhat to fill up these voids, it must appear very evidently, that, though by this the proper particles are rendered less hard, yet the whole body must be made harder than it was before. In the converting of iron into Steel, Mr. Reaumur conceives that the particles of iron, being naturally very covetous of salts and sulphurs, have imbibed great quantities of these adventitious bodies, while the spaces between them have been able to retain very few. This being then the first state of the Steel, when it is afterwards heated, in order to its being tempered by quenching, the fire drives these sulphureous and saline particles, so abundant in the iron, out of its granules, and disperses them throughout the spaces between these granules; and that it is to this equal and regular distribution of these salts and sulphurs, fixed in this state by the immediate quenching, that the hardness and other qualities of Steel are owing.

To the advantage the metal gets by this means, there is however always joined a disadvantage, which is, that its grain naturally and necessarily becomes coarser by it, and the Steel has the less body. The hardest Steel always must necessarily have the least body; but, according to the rules laid down by Mr. Reamur, one may dispose the hardness in what degree one pleases, and consequently all the other properties are in the direction of the same laws.

If the opposition of the qualities of Steel be nicely considered, we shall find, that, instead of being hurtful, they are truly what should be most wished for, and are productive of the most desireable consequences. It may appear somewhat strange, that hardness and flexibility in Steel should be such directly opposite and contradictory principles, and that the quenching, which makes Steel more powerful to resist pressure or rubbing, should, at the same time, make it more feeble in action; but this is plainly the case, and a piece of Steel wire, which, before it is tempered by quenching, will, when hung vertically, suspend a certain weight, will not sustain the same weight when tempered, but will be broken even by a less; and that if the trial be made by tempering it up to one certain part, and no farther, the wire will assuredly break at that very part where the tempered and nontempered portions meet. The increase of size in every grain of Steel, from the quenching, gives the plain solution of this phænomenon. The rupture of any body whatever, that is, the separation of its parts, by whatever means it is done, must be more difficult, the more intimately those parts touch, or the more points they touch in. The granules of Steel are those touching parts, and it is very evident that these granules, becoming larger on the quenching, must after this touch in fewer points, in the whole combination of the mass; and, on the other hand, as they are larger, they also must mutually touch each other in a larger space. Here are two contrary principles, which constitute the facility and the difficulty of the rupture by different means; and it cannot be, but that the one of these constrictions must give the greater force to resist pressure or friction, and the other to resist drawing or traction.

It has been already observed that Steel is the harder, according as it was more or less hot at the time when it was plunged into the water; and it must be added to this, that it also is the more so, the more cold the water is into which it is plunged. The degree of heat in the Steel is easily known by its colour, and the distinctions in it are familiar to the workmen. Several persons have thought there was great virtue to be communicated to the water by means of different ingredients: this Mr. Reaumur carefully tried, and the result was, that he found common cold water the best and most useful of all liquors: it is true, that vinegar and verjuice harden the Steel somewhat more, and aqua fortis greatly so; but the latter of these renders it too hard for service, and repeated ed trials have evinced, that common water alone will give Steel all the hardness it can be wished to have, provided only that it be plunged into it at a time when it is sufficiently hot. If Steel, after tempering, be found too hard, there is a very familiar way of bringing it back to what state one pleases, between that and iron, which is only the heating it in the fire; for it may be kept in the fire so long, as to be reduced wholly to iron again. It is easy to infer from hence, what was before observed, that cast iron is Steel of a peculiar kind; its properties plainly evince, that it is Steel with an over proportion of all that makes it so, and consequently of all its properties. It is not malleable, is very brittle, and too hard for the file, or any other tool, to cut. These are the qualities of Steel which is over tempered, or, as it may be called, too much Steel: it owes these qualities to its being overcharged with those sulphurs and salts, which in a due proportion make Steel of iron. The method of reducing this to the state of wrought iron is the same that we have before observed is to be used to untemper too high tempered Steel, that is, keeping it in the fire till part of its salts and sulphurs are driven off; and, if the fire alone be thought too difficult or too tedious a method, Mr. Reaumur has found that those alkaline substances, which naturally absorb sulphurs, will assist the reducing this to the state of wrought iron, as they do to the untempering of Steel; and that the very same substances of this kind, which have been found best in the untempering Steel, succeed best in the rendering this malleable; such are lime, chalk, and the like.

Cast iron may be taken for these operations in two states; the one that of simply melted iron in its first fusion, the other that of the iron which has been run into the mould. When a cast piece of iron, in a certain form, is heated again with the calx of animal bones, which is one common way, this being a substance extremely divested of salts and sulphurs, it absorbs those of the metal too greedily, and divests it of too great a quantity of them; so that, when the piece comes afterwards to be filed, the fragments fly off in large scales, and the beauty of the cast figure must be lost: to remedy this difficulty, some powdered sulphur is to be added in the heating; for this, being a sulphureous and saline body, checks and moderates the effect of the calx of bone.

Chalk in the same manner can only be employed with certain regulations; it succeeds very well, if the fire be not too violent, or too long continued; but, if it be excessive in either of these particulars, the chalk throws into the body of the iron salts and sulphurs of its own, which lay hid in its structure, and which would not have been dislodged by a smaller fire; but which being dislodged, and thrown into the iron, act upon it, and render the success of the operation quite different from what was intended, the iron becoming more hard and more brittle by it.

One great nicety, in all these operations, is the understanding the signs by which it is known at what time cast iron is sufficiently softened, or overtempered Steel is sufficiently reduced towards the state of iron again; but this is only to be acquired by nice observation, and on this depends the whole certainty of the processes, since every minute's continuance in the fire gives the operation a different turn in degree.

Mr. Reaumur, in one of his experiments in the softening a piece of cast iron of a beautiful figure, found, on taking it out, that it had lost prodigiously of its weight; and, coming to a nicer examination, he found that it was hollow, its outer crust having been sooner converted into malleable, that is, into fusible iron, than the rest, and the violence of the fire afterwards having melted away the inner part, which was not yet so changed. This accident led him to experiments, by which he found that he could, at any time, melt out the central part of a thick square bar of cast iron, the outer part changing first into the condition of malleable iron, and serving as a crucible for the fusion of the yet unaltered fusible iron within. By a proper management of this discovery, it will be easy to take off the unweildy weight of many works of cast iron, which do not require so much strength as that of the solid contained in their circumference. *Mem. de l'Acad. des Scien.* 1722.

Mr. Cramer observes, that the method of making Steel out of iron, is either by fusion, or byce mentation. That by cementation may be performed in the following manner: chuse some bars of pure iron, not too thick; prepare a cement of charcoal dust, moderately pulverised, one part, and wood ashes half a part; or of charcoal dust two parts, bones, horns, leather, or hair of animals, burnt to a blackness in a close vessel, and in a gentle fire, and afterwards reduced to a powder, one part, wood ashes half a part; mix them together. Prepare a cylindrical earthen vessel, two or three inches higher than the bars are long; put into the bottom of this vessel the cement, prepared as before directed, so that, being gently pressed down, it may cover the bottom of the vessel an inch and a half deep; place then the iron bars perpendicularly, so that they may be every-where an inch distant from the sides of the vessels, and from each other; fill the interstices with the cement, and cover the bars with it, that the vessel may be quite full; cover it with a tile, and stop the joints with a lute; put this vessel into a furnace, and keep it moderately, but equally red-hot, for six or ten hours. When this is over, take the red-hot bars out, and dip them in cold water; they will then be brittle, and turned to Steel.

The method of making Steel by fusion is this: take of iron ore, or of unmalleable iron of the first fusion; divide it into small parcels, and put them into a bed made of charcoal dust in a smith's forge; let the quantity of the iron be but small for the experiment; put to it, as a defensive menstruum, some of the vitrescent scoriæ of sand, or stones of the same nature; then put upon them a quantity of charcoal, light this, and admit only a small blast of the bellows, that the scoriæ and metal may both melt regularly: when this has been some time kept in fusion, take it out, divide it into two parts, which make red-hot, and hammer into long bars; finally, heat them red-hot, and plunge them into cold water, and they will then be found to be Steel, so very hard, as not to be filable; and so brittle, as to break asunder, when struck with a considerable force. *Cramer's Art of Assaying.*

Mr. Lemery shews a simple method of reducing Steel to a very fine powder, without rusting it: pour water on filings of Steel in an earthen vessel, till it is four inches above the filings; stir it well every day, supplying more water, as that in the vessel subsides, so that the Steel is always covered; continue this operation till the Steel falls into an impalpable black powder; then dry it for use. *Mem. de l'Acad. des Scien.* 1736.

Mr. Boyle tells us of his having opened the body of Steel, by a highly rectified spirit of urine made per se, and poured upon new filings of the Steel. This being put into a warm place, the menstruum dissolved a considerable part of the metal. *Mem. de l'Acad. des Sciences*, 1736.

Annealing of STEEL, is by some used for the softening it, in order to make it work easier; which is usually done by giving it a blood-red heat in the fire, and then taking it out, and letting it cool of itself.

Steel may indeed be made a little softer than in the common way, by covering it with a coarse powder of cow-horn, or hoofs; thus inclosing it in a loam, heating the whole in a wood fire till it be red-hot, and then leaving the fire to go out of itself, and then the Steel to cool. *Mox. Mechan. Exercises.*

STEE'LING, in cutlery, the laying on a piece of Steel upon a larger mass of iron, to make that part which is to receive the edge harder than the rest. The body of an axe may very well be of iron, as it never comes in use to cut with, and perhaps is stronger, and less liable to break than if of Steel; but it must have a quantity of Steel at that part where the edge is to be made.

STE'MPLES, in mining, cross bars of wood in the shafts which are sunk to mines. In many places the way is to sink a perpendicular hole, or shaft, the sides of which they strengthen from top to bottom with wood-work, to prevent the earth from falling in: the transverses pieces of wood, used to this purpose, they call Stemples, and by means of these the miners in some places descend, without using any rope, catching hold of these with their hands and feet. *Ray's Engl. Words.*

STE'NO's *Duct*, a name given from its discoverer to the superior salival duct.

STEP, in a ship; that piece of timber whereon the masts or capstans do stand at bottom, is called the Step of the mast or capstan.

STEREO-*statics*, is used by some for the statics or science of the equilibrium of solid bodies. *Cartel. Math. Univ.*

STERN-*posts*, in a ship, a great timber let into the keel at the stern of a ship, somewhat sloping, into which are fastened the after-planks; and on this post, by its pintle and gudgeons, hangs the rudder. See SHIP *Building*.

STIL *de grain*, in the colour trade, the name of a composition used for painting in oil or water, and is made of a decoction of the lycium or Avignon berry, in alum-water, which is mixed with whiting into a paste, and formed into twisted sticks. It ought to be chosen of a fine gold yellow, very fine, tender, and friable, and free from dirt. *Pomet's Hist. of Drugs.*

STILE, or STYLE, in a philosophical Stile, the only end of which is accurately to explain our thoughts to others; thence the particular rules to be observed by a philosopher in delivering his doctrines, naturally follow: such as,

1. Not to deviate from the received signification of terms.
2. That the same terms be always taken in the same sense.
3. To fix the meaning of such words as have only a vague sense.
4. To signify objects, essentially different, by different names.

From these rules, the use and necessity of terms of art appear, and shews with how little reason they are vulgarly condemned.

5. The philosopher ought always to make use of proper expressions, and use no more words than what are precisely necessary to establish the truth of his doctrines. *Wolf. Disc. Prælim. Logic.* See STYLE, in the Dictionary.

STILL-*bottoms*, in the distillery, a name given by the traders to what remains in the still after working the wash into low wines.

These

These bottoms are procured in the greateſt quantity from the malt waſh, and are of ſo much value to the diſtiller in the fattening of hogs, &c. that he often finds them one of the moſt valuable articles of the buſineſs.

The liquor left behind in the Still, after the rectifying the low wines into proof-ſpirit, is alſo called by ſome by the name of Still-bottoms; but this is little more than mere phlegm, or water impregnated with a few acid and oily parts, not worth ſeparating, unleſs for curioſity. The liquor left in the Still, after the rectifying the proof-ſpirit into alcohol, is alſo of the ſame kind.

The bottoms of melaſſes ſpirits ſeem calculated for many uſes. It is very probable that the vinegar-makers would find their account in the trying them; and the ſtrong and laſting yellow colour, with which they tinge the hands, may recommend them to the dyers. A ſmall proportion of them, added to the new treacle to be fermented, greatly promotes the operation, and increaſes the quantity of ſpirit.

The bottoms of the wine ſpirit, that is, the remainder, after diſtilling the ſpirituous part from damaged wines, or wine lees, may be brought to afford Mr. Boyle's acid ſpirit of wine, and that ſubſtance called by Becher the media ſubſtantia vini. A parcel of tartar may alſo be procured in very great perfection; and the laſt remainder may be converted into excellent and genuine ſalt of tartar. The liquor may otherwiſe be ſerviceable in making vinegar and white lead. *Shaw's Eſſay on Diſtillery.*

STILL *houſe.* The Dutch have much the advantage of us in the ſtructure of their Still-houſes, and have every thing in great readineſs and neatneſs. The general rules in building theſe houſes ſhould be theſe.

The firſt caution is to lay the floor aſlope, not flat, where any wet work is to be performed; it ſhould alſo be well flagged with broad ſtones, ſo that no wet be detained in the crevices, but all may run off, and be let out at the drains made at the bottom and ſides.

The Stills ſhould be placed abreaſt on that ſide of the Still-houſe to which the floor has its current. The largeſt Stills in Holland, for their greateſt works, are never of that monſtrous ſize that we ſee them of in England, but much more manageable and handy, as ſeldom containing more than ſix or eight hogſheads; and, with ſuch Stills, a ſingle hand will perform much more buſineſs than ten with one of a much larger ſize. Fronting the Stills, and adjoining to the back-wall, ſhould be a ſtage for holding the fermenting backs, and theſe, being placed at a proper height, may empty themſelves, by means of a cock and a canal, into the Stills, which are thus charged with very little trouble.

Near this ſet of fermenting backs ſhould be placed a pump or two, that may readily ſupply them with water by means of a trunk or canal, leading to each back. Under the pavement, adjoining to the Stills, ſhould be a kind of cellar, wherein to lodge the receivers, each of which ſhould be furniſhed with its pump, to raiſe the low wines into the Still for rectification; and through this cellar the refuſe waſh, or Still-bottoms, ſhould be diſcharged by means of a hoſe, or other contrivance.

Theſe are the principal things to be regarded in the erecting a Still-houſe for the original production of ſpirits, and, if theſe rules are well obſerved, malt-ſpirit will be made with little more trouble than melaſſes; for by this means the buſineſs of brewing and cooling the waſh, which, according to the method generally practiſed in England, takes up ſo much time and trouble, is entirely ſaved, fermentation is carried on to a much greater advantage, and the quantity of ſpirit increaſed. *Shaw's Eſſay on Diſtillery.* See the article MALT *Diſtillery.*

STOCCA'TO, in the Italian muſic, ſignifies that every note muſt be divided and ſeparated from the next in a very plain and diſtinct manner. *Broſſard's Muſical Dict.*

STOCKS, among ſhip-carpenters, a frame of timber and great poſts, made aſhore to build pinnaces, ketches, boats, and ſuch ſmall craft, and ſometimes ſmall frigates. Hence we ſay, a ſhip is on the Stocks, when ſhe is a building.

STŒ'CHAS, *French lavender*, in botany, a genus of plants, whoſe characters are: it hath a labiated flower, conſiſting of one leaf; whoſe upper lip is upright, and cut in two; but the under lip, or beard, is cut into three parts; but both are ſo divided, as at firſt to appear like a flower cut into five ſegments; out of whoſe flower-cup riſes the pointal, attended by four embryo's, which afterwards become ſo many roundiſh ſeeds incloſed in the flower-cup: to theſe marks muſt be added, that the flowers are ranged in a various ſeries into ſcaly heads; out of the top of which peep ſome ſmall leaves, which look very beautifully.

The flowers of the Stœchas are much uſed in medicine, in diſeaſes of the head and nerves, eſpecially ſuch as are ſuppoſed to ariſe from cold cauſes. They alſo promote the evacuation by urine, and by the menſes, and in ſome places are eſteemed one of the greateſt antidotes, and given in large doſes againſt the effect of poiſons, and the bites of venomous animals. Meſue, and the Arabians in general, ſpeak of it as a purge, and particularly as good in caſes where phlegm was to be evacuated; though they ſay it did this but ſlowly and weakly. At preſent we do not acknowledge any purging quality in it. There is a very fragrant oil drawn from the flowers and tops of this plant, in the ſame manner as that from lavender; but it is not much in uſe with us. The flowers are an ingredient in the Venice treacle, mithridate, and ſome other of the officinal compoſitions.

It is to be obſerved that there is another plant, called Stœchas, in the ſhops; and, by the writers on the Materia Medica, this has the epithet citrina, for its diſtinction from the Stœchas we have been treating of, which is either called Stœchas without any addition, or Stœchas Arabica. The citrine Stœchas has none of the virtues of this kind, nor is it of the ſame genus of plants.

Theſe plants may be cultivated by ſowing their ſeeds upon a bed of light dry ſoil in March; and, when the plants are come up, they ſhould be carefully cleared from weeds until they are two inches high; at which time they ſhould be removed; therefore there muſt be a ſpot of light dry ground prepared, and laid level, which muſt be trodden out in beds; into which the plants ſhould be planted at about five or ſix inches diſtance each way, obſerving to water and ſhade them until they have taken root; after which they will require no further care, but to keep them clear from weeds the following ſummer; but, if the winter ſhould prove very ſevere, it will be proper to cover them with mats, peaſe-haulm, or ſome other light covering, to guard them againſt the froſt, which otherwiſe would be apt to injure them while they are ſo young: but in March, or the beginning of April, the following ſpring, they muſt be removed in the places where they are to remain; obſerving, if poſſible, to tranſplant them in a warm moiſt ſeaſon, and not to let them remain long above-ground; for if their roots are dried they ſeldom grow well after. The ſoil in which theſe are planted ſhould be a dry warm ſand or gravel; and, the poorer the ſoil is in which they are planted, the better they will endure the cold of the winter, provided the ground be dry; though, indeed, the plants will thrive better in ſummer upon a rich moiſt mould; but then they will not produce ſo many flowers, nor will the plant afford near ſo ſtrong an aromatic ſcent; as is the caſe with moſt ſorts of aromatic plants.

Theſe plants may alſo be propagated by planting ſlips or cuttings of any of the kinds in the ſpring, obſerving to refreſh them with water until they have taken root; after which, they may be managed as hath been directed for the ſeedling-plants; but as thoſe plants, raiſed from ſeeds, are much better than theſe; it is hardly worth while to propagate them this way, eſpecially ſince their ſeeds ripen ſo well in this country.

STONE-*braſh*, in agriculture, is a light lean ſoil, full of larger and ſmaller maſſes of rubble-ſtones.

Theſe are to be tilled according to the condition in which they are found, for if they are graſſy they fallow them pretty late; but, if they have no graſs upon them, they fold them in winter, when the ſheep's dung, with the help of ſome hay-ſeed, will furniſh them with graſs: or elſe, early in the ſpring, they lay upon them old thatch or ſtraw, or the ſtrawy part of old dunghills, earth out of ditches, or the like, which will all, more or leſs, help forward a coat of graſs upon the land; for it is a rule, in regard to theſe lands, that they muſt have a covering of graſs before they are fallowed, elſe they will yield but a poor crop. *Plot's Oxfordſhire.*

STO'NY *land.* The farmers expreſs by this term two ſorts of land, the one full of large flints and pebbles, and the other full of fragments of free-ſtone, and other coarſe ſtones. Theſe lands in many places yield good crops, and the general rule is, that in ſtiff and cold lands the ſtones ſhould be as carefully picked out as may be, but in light and dry grounds they ſhould be left. In Oxfordſhire they have great quantities of a lean earth, and a ſmall rubble-ſtone, or a ſowre ſort of land mixed with it; this is ſometimes very full of weeds, and ſometimes very clear of them: if they are weedy, they fallow them late; but if they be ſeary, as they expreſs it, that is, if they have ſwerd upon them, they either fold them in winter, and add ſome hay-ſeed to the Sheep's dung, to bring up graſs; or elſe they lay old thatch, or ſtraw, and dung upon it; for they reckon, that, if theſe lands have no ſwerd upon them before they are fallowed, they will by no means be brought to bear a good crop, but a great deal of May-weed, and other unprofitable herbs. In September, November, and December, they fallow as the ſwerd directs them: if this is done in either of the two laſt months, they call it a winter fallowing, and never ſtir it again till they plow it, and ſow it with barley; and theſe lands are reckoned to do better than if finely tilled. They will bear wheat and meſlin in a kindly year, and large crops of barley, if they are well managed, and kept in good heart.

They always fallow theſe lands every other year, unleſs they ſow peaſe upon them; ſometimes they ſow them with lentils; and, when they are quite worn out, they lay them down for clover, or rye-graſs. *Mortimer's Huſbandry.*

STOOL, in mining, is uſed when the miners leave digging deeper, and work in the ends forward. The end before them is called the Stool. *Houghton's Compl. Miner.*

STO'PPER, in a ſhip, a piece of rope having a wale-knot at one end, with a lannier ſpliced into it; and at the other end made faſt in the place where it is to be uſed. Its uſe is to ſtop the main-halliards, or the cable.

STOVES,

STOVES, are contrivances for the preſerving ſuch tender exotic plants, which will not live in theſe northern countries, without artificial warmth in winter. Theſe are built in different methods, according to the ingenuity of the artiſt, or the different purpoſes for which they are intended; but in England they are at preſent reducible to two.

The firſt is called a dry Stove, being ſo contrived, that the flues through which the ſmoke paſſes are either carried under the pavement of the floor, or elſe are erected in the back-part of the houſe, over each other, and are returned ſix or eight times the whole length of the Stove. In theſe Stoves the plants are placed on ſhelves of boards laid on a ſcaffold above each other, for the greater advantage of their ſtanding in ſight, and enjoying an equal ſhare of light and air. In theſe Stoves are commonly placed the tender ſorts of aloes, cereus's, euphorbiums, tithymals, and other ſucculent plants, which are impatient of moiſture in winter; and therefore require, for the moſt part, to be kept in a ſeparate Stove, and not placed among trees, or herbaceous plants, which perſpire freely, and thereby often cauſe a damp air in the houſe, which is imbibed by the ſucculent plants, to their no ſmall prejudice. Theſe Stoves may be regulated by a thermometer, ſo as not to overheat them, nor to let the plants ſuffer by cold; in order to which, all ſuch plants, as require nearly the ſame degree of heat, ſhould be placed by themſelves in a ſeparate houſe; for, if in the ſame Stove there are plants placed of many different countries, which require as many different heats, by making the houſe warm enough for ſome plants; others, by having too much heat, are drawn and ſpoiled.

The other ſorts of Stoves are commonly called bark Stoves, to diſtinguiſh them from the dry Stoves already mentioned. Theſe have a large pit, nearly the length of the houſe, three feet deep, and ſix or ſeven feet wide, according to the breadth of the houſe; which pit is filled with freſh tanners bark, to make an hot-bed; and in this bed the pots of the moſt tender exotic trees, and herbaceous plants, are plunged: the heat of this bed being moderate, the roots of the plants are always kept in action; and the moiſture, detained by the bark, keeps the fibres of their roots in a ductile ſtate, which, in the dry Stove, where they are placed on ſhelves, are ſubject to dry too faſt, to the great injury of the plants. In theſe Stoves, if they are rightly contrived, may be preſerved the moſt tender exotic trees and plants, which, before the uſe of the bark was introduced, were thought impoſſible to be kept in England; but, as there is ſome ſkill required in the ſtructure of both theſe Stoves, we ſhall deſcribe them as intelligibly as poſſible, particularly the bark Stove; by which it is hoped every curious perſon will be capable of directing his workmen in their ſtructure.

The dimenſion of this Stove ſhould be proportioned to the number of plants intended to be preſerved, or the particular fancy of the owner; but their length ſhould not exceed forty feet, unleſs there are two fire-places; and, in that caſe, it will be proper to make a partition of glaſs in the middle, and to have two tan-pits, that there may be two different heats for plants from different countries, for the reaſons before given in the account of dry Stoves; and were I to erect a range of Stoves, they ſhould be all built in one, and only divided with glaſs partitions, at leaſt, the half way towards the front; which will be of great advantage to the plants, becauſe they may have the air in each diviſion ſhifted by ſliding the glaſſes of the partitions, or by opening the glaſs-door, which ſhould be made between each diviſion, for the more eaſy paſſage from one to the other.

This Stove ſhould be raiſed above the level of the ground, in proportion to the drineſs of the place; for, if it be built on a moiſt ſituation, the whole ſhould be placed upon the top of the ground; ſo that the brick-work in the front muſt be raiſed three feet above the ſurface, which is the depth of the bark-bed, whereby none of the bark will be in danger of lying in water; but, if the ſoil be dry, the brick-work in front need not be more than one foot above-ground, and the pit may be ſunk two feet below the ſurface. Upon the top of this brick-work, in front, muſt be laid the plate of timber, into which the wood-work of the frame is to be mortiſed; and the upper timber in front muſt be placed four feet aſunder, or ſomewhat more, which is the proportion of the width of the glaſs-doors or ſaſhes: theſe ſhould be about ſix feet and an half, or ſeven feet long, and placed upright; but from the top of theſe ſhould be ſloping glaſſes, which ſhould reach within three feet of the back of the Stove, where there ſhould be a ſtrong crown-piece of timber placed, in which there ſhould be a groove made for the glaſſes to ſlide into. The wall in the back-part of the Stove ſhould be at leaſt thirteen inches thick; but eighteen inches is ſtill better; becauſe, the thicker the outſide wall is built, the more the heat of the flues will be kept in the houſe; and carried up, about nine feet above the ſurface of the bark-bed; and, from the top of this wall, there ſhould be a ſloping roof to the crown-piece where the glaſſes ſlide in. This crown-piece ſhould be about ſixteen feet high from the ſurface of the bark-bed or floor, which will give a ſufficient declivity to the ſloping glaſſes to carry off the wet, and be of a reaſonable height for containing many tall plants. The back-roof may be ſlated, covered with lead, or tiled, according to the fancy of the owner: for the manner of this outſide building is often very various, and differently built.

In the front of the houſe there ſhould be a walk, about eighteen or twenty inches wide, for the conveniency of walking; next to which the bark pit muſt be placed, which ſhould be in width proportionable to the breadth of the houſe: if the houſe is twelve feet wide, which is a due proportion, the pit may be ſeven feet wide; and behind the pit ſhould be a walk eighteen inches wide, to paſs in order to water the plants, &c. then there will be twenty-two inches left next the back-wall, to erect the flues, which muſt be all raiſed above the top of the bark-bed: theſe flues ought to be one foot wide in the clear, that they may not be too ſoon ſtopped with the ſoot; and the lower flue, into which the ſmoke firſt enters from the fire, ſhould be two feet deep in the clear; and this may be covered either with caſt iron plates, or broad tiles; over this the ſecond flue muſt be returned back again; which may be eighteen inches deep, and covered on the top as before; and ſo, in like manner, the flues may be returned over each other three or four times, that the heat may be ſpent before the ſmoke paſſes off. The thickneſs of the wall in front of theſe flues need not be more than four inches; but it muſt be well jointed with mortar, and plaiſtered withinſide to prevent the ſmoke from getting into the houſe; and the outſide ſhould be faced with mortar, and covered with a coarſe cloth, to keep the mortar from cracking, as is practiſed in ſetting up coppers. If this be carefully done, there will be no danger of the ſmoke entering the houſe, which cannot be too carefully avoided; for there is nothing more injurious to plants than ſmoke, which will cauſe them to drop their leaves; and, if it continue long in the houſe, will intirely deſtroy them.

The fire-place may be made either at one end, or in the middle, according as there is moſt conveniency; for, where-ever it is placed, it ſhould have a ſhed over it, and not be expoſed to the open air; for it will be impoſſible to make the fire burn equally, where the wind has full ingreſs to it; and it will be troubleſome to attend the fire in wet weather, where it is expoſed to the rain.

The contrivance of the furnace muſt be according to the fuel which is deſigned to burn: but, as turf is the beſt firing for Stoves, where it can be had, becauſe it burns more moderately, and laſts longer, than any other ſort of fuel, and ſo requires leſs attendance, I ſhall deſcribe a proper ſort of furnace for that purpoſe.

The whole of this furnace ſhould be erected within the houſe, which will be a great addition to the heat; and the front wall on the outſide of the fire-place, next the ſhed, ſhould be three bricks thick, the better to prevent the heat from coming out that way. The door of the furnace, at which the fuel is put in, muſt be as ſmall as conveniently may be to admit of the fuel; and this door ſhould be placed near the upper part of the furnace, and made to ſhut as cloſe as poſſible; ſo that there may but little of the heat paſs off through it. This furnace ſhould be about twenty inches deep, and ſixteen inches ſquare at bottom; but may be ſloped off on every ſide, ſo as to be two feet ſquare at the top; and under this furnace ſhould be a place for the aſhes to fall into, which ſhould be about a foot deep, and as wide as the bottom of the furnace: this ſhould alſo have an iron door to ſhut as cloſe as poſſible; but juſt over the aſh-hole, above the bars which ſupport the fuel, ſhould be a ſquare hole about four inches wide, to let in air to make the fire burn: this muſt alſo have an iron frame, and a door to ſhut cloſe when the fire is perfectly lighted, which will make the fuel laſt the longer, and the heat will be more moderate.

The top of this furnace ſhould be nearly equal to the top of the bark-bed, that the loweſt flue may be above the fire; ſo that there may be a greater draught for the ſmoke; and the furnace ſhould be covered with a large iron plate, cloſely cemented to the brick-work, to prevent the ſmoke from getting out; or it may be arched over with bricks: but you ſhould be very careful, where-ever the fire is placed, that it be not too near the bark-bed; for the heat of the fire will, by its long continuance, dry the bark, ſo that it will loſe its virtue, and be in danger of taking fire; to prevent which, it will be the beſt method to continue an hollow between the brick-work of the fire and that of the pit, about eight inches wide; which will effectually prevent any damage ariſing from the heat of the fire; and there ſhould be no wood-work placed any where near the flues, or the fire-place, becauſe the continual heat of the Stove may in time dry it ſo much, as to cauſe it to take fire; which ought to be very carefully guarded againſt.

The entrance into this Stove ſhould be either from a green-houſe, the dry Stove, or elſe through the ſhed where the fire is made, becauſe, in cold weather, the front-glaſſes muſt not be opened.

The other ſort of Stove, which is commonly called the dry Stove, as was before ſaid, may be either built with upright and ſloping glaſſes at the top, in the ſame manner, and after the ſame model of the bark Stove; or elſe the front-glaſſes, which ſhould run from the floor to the cieling, may be laid ſloping floping, to an angle of forty-five degrees, the better to admit the rays of the fun in fpring and autumn: the latter method has been chiefly followed by moft perfons who have built this fort of Stoves: but, were I to have the contrivance of a Stove of this kind, I would have it built after the model of the bark Stove, with upright glaffes in front, and floping glaffes over them, becaufe this will more eafily admit the fun at all the different feafons; for, in fummer, when the fun is high, the top glaffes will admit the rays to fhine almoft all over the houfe; and, in winter, when the fun is low, the front glaffes will admit its rays; whereas, when the glaffes are laid to any declivity in one direction, the rays of the fun will not fall directly thereon above a fortnight in autumn, and about the fame time in fpring; and, during the other parts of the year, they will fall obliquely thereon; and, in fummer, when the fun is high, the rays will not reach above five or fix feet from the glaffes.

Befides, the plants placed towards the back-part of the houfe will not thrive int he fummer-feafon for want of air; whereas, when there are floping glaffes at the top, which run within four feet of the back of the houfe; thefe, by being drawn down in hot weather, will let in perpendicular air to all the plants; and, of how much fervice this is to all fort of plants, every one who has had opportunity of obferving the growth of plants in a Stove, will eafily judge: for, when plants are placed under cover of a cieling, they always turn themfelves towards the air and light, and thereby grow crooked; and if, in order to preferve them ftraight, they are turned every week, they will neverthelefs grow weak, and look pale and fickly, like a perfon fhut up in a dungeon; for which reafons, I am fure, whoever has made trial of both forts of Stoves, will readily join with me to recommend the model of the bark Stove for every purpofe. *Miller's Gard. Dict.*

STOWS, in mining, are feven pieces of wood, fet upon the furface of the earth, faftened together with pins of wood.

STRAIKS, in the military art, are ftrong plates of iron, fix in number, fixed with large nails, called Straik-nails, on the circumference of a cannon-wheel, over the joints of the fellows, both to ftrengthen the wheel, and to fave the fellows from wearing on hard ways or ftreets.

STRAKE, in the fea phrafe, a feam between two planks; as the garboard Strake is the firft feam next the keel. They fay alfo a fhip heels a Strake; that is, hangs or inclines to one fide the quantity of a whole plank's breadth.

STRA'WBERRY, *fragaria*, in botany.—The common Strawberry is frequent in the woods of England, and is thence tranfplanted into gardens. The beft feafon for this is in September, that the plants may be rooted before the frofts. They may alfo be tranfplanted in February; but then, if the fpring fhould prove dry, they will require a great deal of watering to keep them alive.

The proper foil for Strawberries is a light hazely loam, not over rich; the ground muft be well dug, and very carefully cleared of all noxious weeds; and, when it is levelled even, it fhould be marked out into beds about three feet and a half wide, leaving a path-way between each bed of two feet broad. In each of thefe beds fhould be planted four rows of plants, fo that they may ftand about a foot diftance from each other in the rows, and they fhould be planted at about eight inches plant from plant in each. This is the proper diftance for the wood Strawberry, which is of the leaft growth of any; but the fcarlet Strawberry muft be planted at a foot diftance every way, and the hautboy fixteen inches; and, finally, the large Chili Strawberry, which is the largeft grower of all, muft be fet at twenty-two inches diftance plant from plant.

In the fpring, when the Strawberries begin to flower, if the feafon is dry, they muft be very plentifully watered, and they muft be kept very carefully cleared from weeds. At Michaelmas the beds fhould be dreffed, the weeds all very carefully taken up, all the ftrings or runners muft be taken from the roots, and the weak plants, which ftand too clofe, muft be pulled up; throwing a little fine earth, at the fame time, over the plants, alfo greatly ftrengthens their roots. Thefe beds, however, well managed, will not continue good above three years; and, the beds of the firft year bearing but few fruit, it is neceffary to new-plant fome frefh ground every third year, and deftroy the old beds; but the new ones muft be firft of one year's growth.

Different palates prefer different fpecies of Strawberries, but the white-fruited one is, of all others, the beft flavoured; though it is but a very bad bearer. The great Chili Strawberry is cultivated in the fields in that country; it is a much ftronger and larger plant than any of our kinds, and its fruit is as large as a walnut, but not fo well tafted as our own Strawberries. Mr. Frezier brought them fome years ago to Paris, and, fince that, they have been fpread over the feveral parts of Europe. They grow beft in a loamy foil under the fhade of trees. *Miller's Gard. Dict.*

STREAK-*fallowing*, in hufbandry, a particular fort of tillage. The way of doing it, is to plow one furrow, and leave one, fo that but half the land is plowed, each furrow that is fo lying on that which is not: when this is ftirred, it is then clean plowed, and laid fo fmooth, that it will come, at fowing time, to be as plain as before. This is done, when lean and poor lands are not fwardy enough to bear clean tillage, nor light enough to lie to get fward. The intent of this tillage is to keep the fun from fcorching them too much; but in many places they think this wears their land too faft, and therefore are not fond of having recourfe to it. *Plot's Oxfordfhire.*

STRI'KING-*wheel*, in a clock, the fame with that which by fome is called the pin-wheel, becaufe of the pins which are placed on the round or rim, which in number are the quotient of the pinion divided by the pinion of the detent-wheel. In fixteen-days clocks, the firft, or great wheel, is ufually the pin-wheel: but, in fuch as go eight days, the fecond wheel is the pin-wheel, or ftriking-wheel.

STRINGS *of metal*, a term ufed by our miners to exprefs thofe thin and fmall veins of ore, into which the beds or veins degenerate towards their terminations.

STRO'BILUS, among botanifts, a kind of pericarpium, formed of a number of vaginæ with contorted points applied clofe to one another.

STRO'CAL, in glafs-making, a long iron inftrument like a fire-fhovel, ufed to empty the metals out of a broken pot into a whole one. *Neri's Art of Glafs.*

STROMA'TEUS, in ichthyology, a genus of fifhes of the malacopterygious, or foft-finned kind, the characters of which are thefe: the body is very much compreffed, and very broad and thin; it has no belly-fins, and has only one back-fin, which is extended over the whole back. The only known fpecies of this genus is the callichthys of authors, a fifh called the fiatola at Rome. The tail is very forked; the mouth is very fmall; the teeth are placed in the jaws and palate; and the tongue is fmooth and broad. The body is ftriped crofsways.

STRO'MBUS, in conchyliology, the name of a genus of fhells, nearly allied to the buccinums, and called by the generality of authors turbo.

STRUT, a term ufed by fome builders for that brace which is framed into the king-piece and the principal rafters.

STU'DDING-*fail*, in a fhip, the fame with what is called a goofe-wing.

STUM, in the wine-trade, a term for the unfermented juice of the grape, when it has been feveral times racked off, and feparated from its fediment. The cafks are for this purpofe well matched, or fumigated with brimftone every time, to prevent the liquor from fermenting, as it would otherwife readily do, and become wine.

It is this fume of the fulphur from the match that prevents, in this cafe, all tendency to fermentation, and continues the natural juice of the grape in a fweet tafte, fit to be readily mixed with wines inftead of fugar; for which purpofe it is very much ufed in Holland, and fome other countries, as alfo for giving a new fret or brifknefs to decayed wines. So that very large quantities of this Stum are annually imported to all parts along with the foreign wines; and after the fame manner a Stum is prepared in England from the juice of apples, which ferves the ordinary purpofes of the wine-cooper. In the preferving this liquor in this ftate, we fee the vaft ufe of brimftone, for it could never be done otherwife than by the matching the cafks. *Shaw's Lectures.*

Artificial STUM.— An artificial muft, or Stum, as good as the natural, and as fit for the refermenting, fretting, improving, or making of wines, vinegars, or fpirits, may be prepared in the following manner:

Take three pounds of fine lump fugar, or fuch as has been well refined from its treacle; melt it in three quarts of water, and add in the boiling of Rhenifh tartar, finely powdered, half an ounce; this diffolves with a remarkable ebullition, and gives a grateful acidity to the liquor; take the veffel from the fire, and fuffer it to cool, and you have an artificial muft, which, in all refpects, refembles the natural tafte and fweet juice of a white flavourlefs grape, when well purified, and racked off from its fediment, in order to make Stum. If this artificial muft be ftummed, that is, well fumigated, with burning brimftone, it becomes a perfect Stum, and may be made of any flavour, at the difcretion of the artift. *Shaw's Lectures.*

STU'RIO, *the fturgeon*, a very well known large and fine-tafted fifh, caught in many places, and fometimes in the river Thames, being one of thefe fifhes called anadromi by authors, which fpend a part of their time in the fea, and a part in rivers.

It never goes into the fea to any great diftance, and never is caught there of any very great fize. The fea ferves for its production, but it is only in large rivers that it grows to its ufual fize. *Ray's Ichthyogr.*

STYE, or STITHE, the Englifh name for a diforder on the eye-lids, called by the phyficians hordeolum, and by fome crithe, chalazium, or grando.

It is a fmall encyfted tumor, ufually about the bignefs of a barley-corn, which fometimes degenerates into matter, and occafions great pain and uneafinefs.

When they are fmall, it is beft to let them take their own courfe; but if fo large as to occafion deformity, or danger of hurting the fight, the way to extirpate them is to make a longitudinal incifion on the part, and carefully take them out whole; or, if it cannot be thus got out clean, it muſt be cut out, as far as may be, with ſciſſors, and dreſſed with Ægyptian ointment, and a little red precipitate; or touched at times with the common cauſtic, till eaten thoroughly away, and then the wound dreſſed and healed in the common manner.

STYLO'BATON, or STYLOBATA, in architecture, the ſame with the pedeſtal of a column. It is ſometimes taken for the trunk of the pedeſtal, between the cornice and the baſe, and then called truncus. It is alſo called by the name of abacus.

SUBDU'PLICATE ratio of any two qualities, is the ratio of their ſquare roots.

SU'BITO, in the Italian muſic, is uſed to ſignify that a thing is to be performed quickly and haſtily; thus we meet with volti Subito, turn over the leaf quickly.

Blue SUB'LIMATE, a preparation of mercury with ſome other ingredients, yielding a fine blue for painting. The method of making it is this: take quickſilver two parts, flower of brimſtone three parts, ſal ammoniac eight parts; grind theſe upon a porphyry, and with the quickſilver put them into a long-necked glaſs veſſel luted at bottom; place it in a ſand-heat, and when the moiſture is aſcended, you will have a fine blue Sublimate for painting. *Neri's Art of Glaſs.*

SUBSI'STENCE, in the military art, is the money paid to the ſoldiers weekly, not amounting to their full pay, becauſe their cloaths, accoutrements, tents, bread, &c. are to be paid; it is likewiſe the money paid the officers upon accompt, till their accompts be made up, which is generally once a year, and then they are paid their arrears.

SU'BSTANCE (*Dict.*)—Spinoſa maintains, that there is but one only Subſtance in nature, whereof all created things are ſo many different modifications; and thus he makes the ſoul of the ſame Subſtance with the body. The whole univerſe, according to him, is but one Subſtance; which Subſtance he holds endowed with an infinity of attributes, in the number of which are thinking and extenſion. All bodies are modifications of this Subſtance, conſidered as extended; and all ſpirits modifications of the ſame Subſtance, conſidered as thinking.

Mr. Locke's philoſophy of Subſtances is more orthodox: our ideas of Subſtance, that great author obſerves, are only ſuch combinations of ſimple ideas, as are taken to repreſent diſtinct things, ſubſiſting by themſelves; in which the confuſed idea of Subſtance is always the chief. Thus the combination of the ideas of a certain figure, with the powers of motion, thought, and reaſoning, joined to Subſtance, make the ordinary idea of man; and thus the mind obſerving ſeveral ſimple ideas to go conſtantly together, which being preſumed to belong to one thing, or to be united in one ſubject, are called by one name; which we are apt, afterwards, to talk of and conſider as one ſimple idea.

We imagine the ſimple ideas do not ſubſiſt by themſelves; but ſuppoſe ſome ſubſtratum, wherein we ſubſiſt, which we call Subſtance.

The idea of pure Subſtance is nothing but the ſuppoſed, yet unknown ſupport of thoſe qualities which are capable of producing ſimple ideas in us.

The ideas of particular Subſtances are compoſed out of this obſcure and general idea of Subſtance, together with ſuch combinations of ſimple ideas, as are obſerved to exiſt together, and ſuppoſed to flow from the internal conſtitution, and unknown eſſence of that Subſtance.

Thus we come by the ideas of man, horſe, gold, &c. Thus the ſenſible qualities of iron, or a diamond, make the complex idea of thoſe Subſtances, which a ſmith, or a jeweller, commonly knows better than a philoſopher.

The ſame happens concerning the operations of the mind, viz. thinking, reaſoning, &c. which we concluding not to ſubſiſt by themſelves, nor apprehending how they can belong to body, or be produced by it, we think them the actions of ſome other Subſtance, which we call ſpirit; of whoſe Subſtance or nature we have as clear a notion, as of that of body; the one being but the ſuppoſed ſubſtratum of the ſimple ideas we have from without; as the other of thoſe operations, which we experiment in ourſelves within: ſo that the idea of corporeal Subſtance in matter is as remote from our conceptions, as that of ſpiritual Subſtance.

Hence we may conclude, that he has the perfect idea of any particular Subſtance, who has collected moſt of thoſe ſimple ideas which exiſt in it; among which, we are to reckon its active powers and paſſive capacities, though not ſtrictly ſimple ideas.

Subſtances are generally diſtinguiſhed by ſecondary qualities; for our ſenſes fail us in the diſcovery of primary ones, as the bulk, figure, texture, &c. of the minute parts of bodies, on which their real conſtitutions and differences depend.—And ſecondary qualities are nothing but powers, with relation to our ſenſes.

The ideas that make our complex ones of corporeal Subſtances, are of three ſorts: firſt, the ideas of primary qualities of things, which are diſcovered by our ſenſes; ſuch as bulk, figure, motion, &c. Secondly, the ſenſible ſecondary qualities, which are nothing but powers to produce ſeveral ideas in us, by our ſenſes. Thirdly, the aptneſs we conſider in any Subſtance, to cauſe or receive ſuch alterations in its primary qualities, as that the Subſtance ſo altered ſhould produce in us different ideas from what it did before.

Beſides the complex ideas we have of material Subſtances, by the ſimple ideas taken from the operations of our own minds, which we experiment in ourſelves, as thinking, underſtanding, willing, knowing, &c. co-exiſting in the ſame Subſtance; we are able to frame the complex idea of a ſpirit: and this idea of an immaterial Subſtance is as clear, as that we have of a material.

By joining theſe with Subſtance, of which we have no diſtinct idea, we have the idea of ſpirit: and by putting together the ideas of coherent ſolid parts, and a power of being moved, joined with Subſtance, of which likewiſe we have no poſitive idea; we have the idea of matter.

Further, there are other ideas of Subſtances, which may be called collective, which are made up of any particular Subſtance, conſidered as united into one idea; as a troop, army, &c. which the mind does by its power of compoſition. Theſe collective ideas are but the artificial draughts of the mind, bringing things remote, and independent, into one view, the better to contemplate and diſcourſe of them united into one conception, and ſignified by one name. For there are no things ſo remote, which the mind cannot, by this art of compoſition, bring into one idea; as is viſible in that ſignified by the name univerſe.

Such is the generally received doctrine of Subſtance: but Bp. Berkeley, in his Principles of Human Knowledge, and Mr. Collier, in his Clavis Univerſalis, have made great refinements thereon.

SUBSTAN'TIAL, or SUBSTANCIAL, in the ſchools, ſomething belonging to the nature of Subſtance.

It is generally diſputed, whether or no there be ſuch things as Subſtantial forms? i. e. forms independent of all matter; or forms that are ſubſtances themſelves.

SUBSTANTIAL is alſo uſed in the ſame ſenſe with eſſential, in oppoſition to accidental: in which relation it gives room for abundance of diſtinguo's

SU'BSTANTIVE (*Dict.*)—All nouns either ſignify an individual, as Socrates, Alexander, &c. or a ſpecies, as man, horſe, &c. or an eſſential quality, as rational, material, &c. or an accidental one, as black, white, good, fair, &c. or a dignity, office, art, &c. as king, preſident, philoſopher, &c.

Thus have we four kinds of nouns; whereof the firſt is very rarely taken adjectively; for, as they ſignify individuals or particular beings, they can ſcarce be applied to any thing but the thing they properly ſignify: yet we have ſometimes known the name of Cato taken adjectively; as, 'This is to be Cato, indeed.' Nor does Malherbe ſcruple to ſay in French, 'Plus Mars que le Mars de la Thrace.' Add that proper names are ſometimes converted into the name of dignities, &c. as Cæſar, Auguſtus, &c. In which caſe, they may be conſidered, in the ſame light, as nouns of the fourth kind.—Nouns of the ſecond kind are alſo ſometimes taken adjectively, as, 'He is much a man,' &c. The third kind are adjectives of themſelves. For the fourth kind, all grammarians rank them among Subſtantives, excepting F. Buffier who will have them to be adjectives; or, to uſe his own term, modificatives. Be that as it will, they are frequently uſed adjectively: 'He is more a king, and more a philoſopher, than any of his predeceſſors.'

Now for adjectives taken ſubſtantively, 1°, Particles paſſive are very rarely thus taken; though we ſometimes ſay, 'The loved are leſs happy than the lovers; the taught have the advantage of the untaught: the beſieged made a ſalley,' &c. And, 2°, Participles active are taken ſtill more rarely for Subſtantives. We ſcarce ever, e. gr. ſay 'the loving, the reading;' but 'the lover, the reader:' yet we ſay, 'the ſtudent, the proteſtant, the tenant, the appellant, the opponent,' &c. — 3°, For nouns adjectives, thoſe applied to men are not only uſed ſubſtantively, but are even become Subſtantives by uſe; whether they be ſuch as regard religion; as 'Chriſtian, Pagan, Mahometan,' &c. or opinion; as 'Stoic, Peripatetic, Carteſian,' &c. or country; as 'the Engliſh, French, Italians;' or temperament; as 'the melancholic, phlegmatic, choleric,' &c. Under the ſame rule, are likewiſe comprehended abundance of adjectives, ſignifying a number of people agreeing in ſome common attribute; as, 'the learned, the great, the devout, the brave, the diſſolute,' &c. But uſe is here to be regarded; for we do not ſay 'the elegant,' as we ſay 'the learned;' but 'elegant writers,' &c. It is cuſtom, and the ear alone, that are to decide about theſe differences.

Again, adjectives taken Subſtantively, for other things beſides men, are either ſo uſed, to ſignify a number or ſet of things that have ſome common quality; or to expreſs an abſtract quality. In both which, as in thoſe of men, there are ſome authoriſed by cuſtom, and others formed every day on their model.

SVEGLIA'TO, in the Italian muſic, is uſed for a briſk, lively, gay manner of ſinging or playing. Thus they ſay maniera Svegliata.

SU'FFOCATIVE *catarrh*, in medicine, the name of a diſeaſe, which conſiſts in a copious eruption of a ſerous and mucous humour

humour into the vesicles of the lungs, which takes its origin from a sudden congestion of humours about the breast, and a flaccid and weak state of the breast and lungs.

Method of cure. In the time of the fit a stimulating clyster must be given, made of a decoction of marjoram and other warm herbs, with colocynth, and a few grains of euphorbium, in order to abate the infarction of the breast, and give a new course to the matter that might add to it; and, when there appears to be a plethora besides, a vein must be immediately opened after the clyster. After this, if the stomach be nauseating and uneasy, let a scruple of salt of vitriol be given as a vomit, with a large quantity of warm water; and, if the patient is of a very phlegmatic habit, a few grains of gamboge may be added to this, to carry the humour off downwards; or, if the case be very pressing, a draught of a decoction of asarum, or of tobacco, may be taken, the bad effects of which last are taken off by a draught of wine with the spices; and all this time there may be frictions and sinapisms applied to the lower extremities: and, finally, to attenuate and discuss the mucous stasis, gentle alexipharmics and sudorifics may be given, such as the essence of amber, tincture of salt of tartar, and tartarised tincture of antimony; and all nitrous medicines are also of the greatest use, as they partly mitigate the causes, and partly prepare the humours for evacuation; and, after all these, the cortex eleutheriæ is of great use in discussing and mitigating the pain. As soon as the fit is over, the corroborating medicines are to be given, and all things that can restore the parts to their due tone; of this number are the milder chalybeates, and the like; and with these analeptics are to be given, to recruit the flesh and strength, such as emulsions, and a proper diet; and, in such as are used to wine, the richest wines, in moderate quantities, and the highest foods will be of service. If there be perceived a fever after the other symptoms are gone off, this must be cured by the gentle alexipharmics, and by powders of nitre, and the absorbents; and, if a chronic indisposition seems left behind, then the gums, which act as discutients, are to be given for some time, such as the ammoniacum and sagapenum, and a warm regimen is to be recommended. And, finally, to prevent a return of the disease, bleeding is very proper in the spring and autumn, and purging medicines taken in the intermediate time; the patient must also avoid all violent passions of the mind, and must never sleep in a damp air. We are not to fear bleeding in the time of the fit, because of the patient's complaining of want of strength; for, as the danger of suffocation is sudden and imminent, it must be suddenly removed, and, when that is done, the patient's strength will return in good time: the same is also to be alledged in favour of the violent vomits. In people of very phlegmatic constitutions, bleeding is not necessary nor proper; but in these cases a vomit is safe and right, and usually gives great relief, especially if the patient have eaten heartily some little time before. *Junker's Consp. Med.*

SU'FFOLK-*powder*, the name of a medicinal powder, good for the bite of a mad dog. It had its name from a countess of Suffolk, who used to give it with great success. It is still kept as a secret in some private families, but seems to be only the star of the earth, or the common buck-thorn plantain dried and powdered, or this powder with some very trifling addition. This plant has been famous for its virtues in this case a great while among us, and De Grey, in his Complete Farrier, gives the method by which he had cured dogs by it with great success. See *Phil. Transf.* N°. 450.

SU'GAR-*candy*, *saccharum candum*, or *crystallinum*, — is Sugar depurated and and crystallised.

This is better made of earthed Sugar, than refined Sugar, in regard the former is sweeter.

The Sugar to be used herein is first dissolved in a weak limewater, then clarified, scummed, strained through a cloth, and boiled, and put in forms or moulds that are traversed with little rods, to retain the Sugar, as it crystallises. These forms are suspended in a hot stove, with a pot underneath, to receive the syrup that drops out at the hole in the bottom, which is half stopped, that the filtration may be the gentler. When the forms are full, the stove is shut up, and the fire made very vehement.

Upon this the Sugar fastens to the sticks that cross the forms, and there hangs in little splinters of crystal. When the Sugar is quite dry, the forms are broke and the Sugar taken out, candied. Red Sugar-candy they make, by casting into the vessel, where the Sugar is boiling, a little juice of the Indian fig; and, if it is desired to have it perfumed, they cast a drop of some essence in, when the Sugar is putting into the forms.

This method of making Sugar-candy is that of F. Labat, practised in the Caribbees: the method in Europe, described by Pomet, is somewhat different.

White SUGAR-*candy* they make of white refined Sugar, boiled with water into a thick syrup, in a large pan. It is candied in a stove, whither it is carried, inclosed in brass peels, crossed with little rods, about which the crystals fasten, as they are formed.

The fire of the stove is kept equable for fifteen days; after which the Sugar is taken out of the peels to be dried. Red or brown Sugar-candy is made like the white, except that they only use brown Sugars and earthen pots.

Barley SUGAR, *saccharum hordeatum*, is a Sugar boiled till it be brittle, and then cast on a stone anointed with oil of sweet almonds, and formed into twisted sticks, about the length of the hand, and the thickness of a finger.

It should be boiled up with a decoction of barley, whence it takes its name; but in lieu thereof they now generally use common water, to make the Sugar the finer.—To give it the brighter amber colour, they sometimes cast saffron into it.—It is found very good for the cure of colds and rheums.

SUGAR-*spirit*, a name given by our distillers to a spirit made in England, Holland, and other places, from the washings, scummings, dross, and waste of a Sugar-baker's refining-house. The manner of preparing it is the same with that used for the malt and melasses spirits. The refuse of the Sugar is fermented with water in the usual manner, then distilled into what is called low wines, and afterwards rectified, without an addition, into proof spirit.

When the operation is well performed, and no foul, fœtid, or foreign matter, has got in among the wash, this is a tolerably clean spirit. We usually make it such, but in Holland it is usually made very nauseous and disagreeable; though capable, by an easy rectification familiar with us, though not much known abroad, of being brought to a fine and clean spirit. With us this Sugar spirit is used to mix with and adulterate brandy, rum, and arrac, which will receive a large dose of it without its being at all discoverable; but the Dutch who have it very coarse, can only adulterate rum with it, and even that will bear but a small proportion, without being trayed by its nauseousness.

This Sugar spirit reduced to alcohol makes one of the purest spirits we are acquainted with, much superior to that of melasses, and much more to that of malt. *Shaw's Essay on Dist.*

Fixed SULPHUR is used by the enamellers, and is prepared in the following manner: boil flower of brimstone in common oil for an hour, take the matter off the fire, and pour on it a quantity of very strong vinegar, the flower of brimstone will on this sink to the bottom; pour off the liquors, and repeat the operation to the third time, and the powder then separated is the fixed sulphur. *Neri's Art of Glass.*

SUMP, in metallurgy, a round pit of stone lined with clay within, for the receiving the metal on its first fusion from the ore. *Ray's Words.*

SUMP, in the English salt works, where sea water is boiled into salt, is used as the name of a sort of pond which they make at some small distance from the saltern on the sea shore, between full sea and low water mark. From this pond they lay a pipe, through which, when the sea is in, the water runs into a well adjoining to the saltern; and from this well they pump it into troughs, through which it is carried to their cisterns, in order to be ready to supply the pans.

SUN-*fish*, mola, in ichthyology. See the article MOLA.

SUN-*flower*, corona solis, in botany, the name of a genus of plants, the characters of which are these: the flower is of the radiated kind; its disk is made up of floscules, and its outer edge of semifloscules; these stand upon the embryo seeds, and are separated from one another by little leaves of an imbricated figure, and contained in a scaly husk, or cup; the embryo's finally ripen into seeds furnished with two little leaves.

There are several different species of this flower, all which are very beautiful in large gardens. They are most of them annual plants, and are to be sown every spring in a bed of good light earth. When the shoots are about three inches high, they must be transplanted into nursery beds, and set at eight inches distant every way; they should remain there till they are a foot high, and then be carefully taken up with a ball of earth at their roots, and planted in large borders, or intermixed in the bosquets of large growing plants; they must be frequently watered till they have taken root, and after that will require no farther care. In July the flowers appear, and stand a considerable time: the largest of these should be left to stand for seed. The birds are very apt to devour this seed, but it should be carefully guarded from them, and the head left on the plant till October, at which time it should be cut off, and hung up to dry in an airy place, and in a month more the seeds will be perfectly hardened.

Several species of this plant also are perennial, and increase greatly by the root. Among these the common smaller flowered one is a very valuable plant in gardens, as it requires no culture, will grow in all soils and situations, and is a very ornamental flower, continuing in bloom from June to October. *Miller's Gard. Dict.*

SUN-*scorched*, a term used by our gardeners in some parts of England to express a distemperature of fruit-trees, owing to the sun's affecting them too forcibly and too suddenly; the consequence of which is the loss and withering of the fruit. Such trees only are subject to this, as are planted in places sheltered from the spring sun, and only open to the summer's; and it may be always cured by proper waterings.

SUPE'RFLUOUS *Interval*, in music, is one that exceeds a true diatonic interval by a semitone minor. Thus the

SUPERFLUOUS *Second*, or *tone*, contains a femitone minor more than a tone, or greater fecond; and will therefore be expreffed by $\frac{125}{108}$, or by $\frac{75}{64}$. The firft of thefe expreffions is a tone minor, and a femitone minor; fince $\frac{10}{9}\times\frac{25}{24}=\frac{125}{108}$: and the other is a tone major, and a femitone minor; for $\frac{9}{8}\times\frac{25}{24}=\frac{75}{64}$. This laft occurs in practice, and is one of the intervals of the chromaticum toniæum.

In temperate fcales thefe two Superfluous tones coincide. Thus from B ♭ to C fharp, or from F to G fharp, are Superfluous tones.

SUPERFLUOUS *Third*, is greater than the third major by a femitone minor, and will therefore be expreffed by $\frac{125}{96}=\frac{5}{4}\times\frac{25}{24}$. It is not in ufe. It feems a fourth on our harpfichords. Thus from B ♭ to D fharp is, properly fpeaking, a Superfluous third; but, D fharp and E ♭ being confounded, it paffes for a fourth.

SUPERFLUOUS *Fourth*. This interval is expreffed by $\frac{25}{16}=\frac{4}{3}\times\frac{25}{24}$. It is by practitioners, and in temperate fcales, confounded with the tritonus.

SUPERFLUOUS *Fifth*, is expreffed by $\frac{25}{16}=\frac{3}{2}\times\frac{25}{24}$. This is equal to two thirds major, for $\frac{5}{4}\times\frac{5}{4}=\frac{25}{16}$. The Superfluous fifth occurs in practice as from C to G fharp.

SUPERFLUOUS *Sixth*. This interval is of two kinds, being the refpective complements of the two diminifhed thirds to the octave. One only, ftrictly fpeaking, anfwers to the general definition of a Superfluous interval, which is that interval which exceeds the fixth major by a femitone minor, and is therefore expreffed by $\frac{125}{72}=\frac{5}{3}\times\frac{25}{24}$. But the other interval, which is a comma more than the former, and is two femitones major lefs than the octave, is chiefly ufed in harmony, as between B ♭ and A fharp, where it has a fine effect. It is expreffed by $\frac{225}{128}=\frac{2}{1}:\frac{16}{15}:\frac{16}{15}=\frac{2}{1}:\frac{256}{225}$.

See the article INTERVAL.

SUPERFLUOUS *Seventh*, is expreffed by $\frac{15}{8}\times\frac{25}{24}=\frac{125}{64}$. This is a diefis lefs than the octave.

SUPERFLUOUS *Octave*, is a femitone minor more than the octave, as from C to C fharp. It fometimes occurs in the baffes of inftrumental pieces.

SU'SSEX *Marble*, a name given by many to a peculiar fpecies of marble found in the county, the name of which it bears, and formerly much ufed in the pillars of churches, and other buildings, but now lefs in efteem. The ground of this marble is grey, with a faint caft of green, and it is very thick fet in all parts with fhells: thefe are chiefly of the turbinated kind, and they are generally filled with a white fpar, which adds very greatly to the beauty of the ftone.

It is plain, from confidering the whole mafs of this marble, that this fpar was received into the fhells before they were depofited in the marble. This is about the hardnefs of the common white Genoefe marble, if any thing, fomewhat more hard. The flender round fcapi of the pillars in Weftminfter-Abbey, and in many other of our Gothic buildings, are made of this kind of marble. Some people have thought that the fcapi of pillars of this kind, which occur in moft of our Gothic buildings, are artificial, and that they are a kind of fufile marble caft in cylindric moulds. But any one who will compare the marble, of which thofe pillars are made, with its fhells, and the fpar they are filled with, with the marble of Suffex quarries, will find both to be the fame in every particular. *Woodward's Cat. of Foff.*

SU'TURE, in chirurgery, denotes a feam made to clofe the lips of a wound, in order to its healing.

The ancients invented a great variety of Sutures, which they reduced to three kinds; incarnatives, reftrictives, and confervatives.

Incarnative SUTURE, is thus called, becaufe, by rejoining the edges of a wound, and keeping them together by means of a thread run acrofs them with a needle, they grow together, and incarnate as before.

This they fubdivided into five kinds, viz. the 'interrupted, intertwifted, penned, or feathered, with clafps, and the dry Suture.'

Of thefe five, two are perfectly difufed, viz. the feathered Suture, and the Suture with clafps, as being too barbarous, and at the fame time unneceffary. The firft was called pinned, when little pins were made u e of; and feathered, when the barrels of feathers or quills were ufed.

To perform it, two or three needles, threaded with a double thread, were paffed through the lips of the wound, at a finger's breadth from each other, and a pin or feather put in the ftitch; and another pin or feather bound with the ends of the fame thread, and the feathers might keep the lips of the wound clofe together.

To perform the fecond, they had large, crooked clafps, pointed at each end; one of which they thruft into the upper part of the wound, the other into the lower, to bring the lips together.

Thefe Sutures, cruel as they were, are yet known to be ufelefs; for in the only cafes where they fhould feem ferviceable, viz. in deep wounds, where the contraction of the flefhy parts keeps the lips far afunder, and in wounds of tendons; they expofe the patient to terrible convulfions and fhudderings, which are avoided, by diminifhing the dilatation of the wounds, by moderate compreffions, and waiting till the fibres relax.

Reftrictive SUTURES, were thofe wherewith they endeavoured to ftop the flux of blood from large wounds, where any confiderable veffels were cut.

To this end, they invented feveral kinds, in the number whereof, were the fhoe-makers, taylors, fkinners, and other feams, each more impertinent than other. It is evident, the very defign of fuch a Suture is blameable: for fuppofing the wound fo exactly fewed up, that no blood could efcape thro' the lips thereof; yet will it ftill flow out of the veffels, and will thus be forced to make its way between the laminæ of the mufcles, by which means the part will fwell, rot, and gangrene. Yet, the fkinners Suture, futura pellionum, is ftill in ufe for wounds of the inteftines: it is thus called, becaufe the fkinners ufe the like, in fewing up the holes made by the butchers, in fleaing off the fkin.

Confervative SUTURE, is that kind of ancient Suture, whereby the lips of large wounds, wherein there was a lofs of fubftance, were prevented from receding too far. But a bandage, now, fuffices.

Intertwifted SUTURE, is thus called, becaufe, the needles being left fticking in the wound, the thread is wound around them; much after the fame manner as the taylors do the threaded needles they keep in their fleeves, &c. This Suture is performed two ways; for either the needles are paffed a-crofs the wound, or they are ftuck on the fides thereof.

All the Sutures, hitherto mentioned, are made with needle and thread: befides which, there is another kind called dry Sutures, which are performed with glue or fize, or other proper vifcous matter.

The dry SUTURE, is ordinarily made with fmall pieces of leather, on linen cloth, indented like a faw, fo that the teeth may fall between each other, and the whole row may be clofed. The cloth, before it is cut into this form, is fpread with fome proper plaifter, in order to its firm adhefion.

The plaifters thus prepared, being cut into the form, are applied on the firm flefh, according to the length of the wound, reaching from it to the diftance of fome inches; and after they are dried, or well faftened to the part, the lips of the wound being approached, they may conveniently be held together by the Suture in that pofture.

This kind of Suture is principally ufed for wounds in the face, to prevent unfightly fcars: it is likewife convenient when the fibres of the mufcles are cut a-crofs, and where it is difficult or impoffible to apply a bandage.

In the other kinds of Sutures, the ftitches ought always to be taken of a depth proportionable to that of the wound; care being had to avoid the nerves as much as poffible. In long wounds they are beft begun at the ends, but in fhort ones at the middle.

SWA'LLOW, *hirundo*, in the Linnæan fyftem of zoology, makes a diftinct genus of birds of the order of the pafferes.

The characters of this are, that the beak is extremely fmall, pointed, and depreffed at the bafe, and the opening of the mouth larger than the very head of the bird. *Linnæi Syft. Nat.*

The characters of this genus, according to Ray, are thefe: they have very large heads, and very fhort beaks, but very wide mouths, adapted to the fwallowing large infects, which are their food. Their tails are long and forked, their eggs are white, they are birds of paffage, and with us are the foretellers of fummer.

The common houfe Swallow is well known every-where with us, and is fometimes feen all over of a fine white.

The martin, or martlet, has a very broad and flat head, and a very broad beak pointed at the end; its legs are very fhort, and its claws white; its toes are all covered, to the very claws, with a white downy plumage, by which it is diftinguifhed from all the other Swallows.

The fand martin, or fhore bird, is the fmalleft of all the Swallow kind. Its head, neck, and back, are of a moufe colour; its breaft and belly white; it has a ring of brown round the lower part of its throat. It builds in the banks of the rivers, and makes its neft of ftraw, the ftalks of plants, &c. and covers it with feathers. It is not uncommon with us, but is extremely plentiful in Spain, in the fummer months, where it is eaten, and is called by the common people papilion or montana. *Ray's Ornithology.*

The black martin or fwift, by fome called the diveling, is the largeft of all the Swallow kind: its head is remarkably broad and flat; its beak is very fmall, fhort and weak; but its mouth opens to an immenfe width, like that of the goat-fucker, or churn owl. It is all over of a brown colour, with a ſlight admixture of green, and has no other variegation but a greyiſh white ſpot at the top of its throat. Its legs are extremely ſhort, and its feet remarkably ſmall. It feeds on beetles, and other inſects, and ſeldom alights on the ground, the ſhortneſs of its legs making it not eaſy for it to riſe again. *Ray's Ornithol.*

SWARM. — The ſignal of the going out of a Swarm from a hive is ſometimes only by a humming noiſe made by one ſingle bee, but that a very particularly acute and clear ſound: this ſeems to be the voice of the new queen or female bee, calling together the Swarm that is to follow her out, and animating them with a ſort of martial muſic for the great adventure they are going to engage in.

Some who have pretended to be extremely well verſed in the language of the bees, as Butler, and others, ſay, that this is a voice of intreaty, by which the young queen begs permiſſion of the old queen, or parent of the hive, to take out a Swarm with her to ſome other place: they ſay this noiſe of intreaty uſually laſts about two days, and that, at the end of that time, if the parent grants the requeſt, ſhe is heard to anſwer with a louder and clearer voice of the ſame kind. Theſe noiſes are not to be heard, unleſs the ear be applied cloſe to the place; and they ſay, that when this laſt ſound is made, the new Swarm may be expected certainly to go out the next day, if the weather be proper.

But he ſeems to have taken great pains to diſtinguiſh theſe ſounds; he gives all the modulations of the voice of the young female, and every note that ſhe runs into; and obſerves, that all theſe are notes of ſupplication, and that the ſounds iſſued by the parent, or reigning queen of the hive, have an air of majeſty, and are greatly different; and adds, that, if the young female attempts to make the ſounds of the reigning bee, it is looked upon as a rebellion in the hive: and he pretends to be acquainted with the proceedings againſt her in theſe caſes; he ſays ſhe loſes her head, and that ſeveral of the bees that followed her are treated in the ſame manner for having been ſeduced to a rebellion. *Reaumur's Hiſt. Inſect.*

If a hive has been very well peopled during the winter, the young progeny go out early in the ſpring; and, if it have been very thinly peopled, it is ſometimes as late as the middle of June before they go out, even without any accidental delay from the want of a queen.

The people who manage bees, are informed of the time when they are going to ſend out new Swarms by ſeveral ſigns. One is, when the hive is ſo peopled, that many of the bees cannot find room within, but ſtand in cluſters on the outſide of the hive; another, is the appearance of a large number of drones, or male bees; theſe, however, are not certain ſigns, nor do they point out the very day of the ſwarming; but there is one which declares it very punctually, which is the obſerving, that though the hive be very full, and the day very fine, yet very few bees go out in ſearch of honey; in this caſe it is a certainty that they are aſſembling themſelves in the hive, and preparing to be gone in a very little time. If a perſon go near the hives that are ready to ſend out Swarms, in the evening, or even in the night, he will hear a ſort of a humming noiſe in them, which is not to be heard at ſuch times on any other occaſion: in ſhort, the whole is in agitation on the occaſion, and the tumult never ceaſes till the new colony goes out.

SWEA'TING-*houſe*.— The natives of North-America, when we firſt ſettled among them, had a great many houſes to Sweat in, it being their general remedy for diſeaſes of whatever kind; but at preſent they are leſs uſed among them.

The cave, or Sweating-houſe, was uſually eight feet in diameter, and four feet high, the roof being ſupported by ſticks or boards. They uſually dug theſe caves in the ſide of a hill, and as near as could be to ſome river, or pond. The entrance into the cave was ſmall, and, when any perſon was Sweating in it, the door was covered with a blanket, or ſkin. Near the cave they uſed to make a large fire, and heat in this a quantity of ſtones, perhaps, five hundred weight; theſe they rolled into the cave, and piled up in a heap in the middle. When this is done, the Indians go in naked, as many as pleaſe, and ſit round the heap of ſtones; and as ſoon as they begin to grow faint, which is uſually in a quarter of an hour, they come out, and plunge themſelves all over in the water, remaining in it a minute or two; and, repeating this a ſecond time, they dreſs themſelves, and go about their buſineſs.

This has been uſed for many ages among them with ſucceſs, in caſe of colds, ſurfeits, ſciaticas, and pains fixed in their limbs; and the Engliſh have often uſed the ſame means, and found relief by it. It is practiſed equally at all times of the year, and the Indians do it not only in ſickneſſes, but by way of refreſhment after long journies, and other fatigues, and ſo ſtrengthen themſelves for any expeditions. *Philoſ. Tranſ.* N°. 384.

SWEET *Corn*, a term uſed by the Indians to expreſs a ſort of corn they are very fond of, and generally keep it in their houſes.

While the ear of the maiz, or Indian corn, is yet green, but full, they gather it, and firſt boil, and afterwards dry it, and lay it up for uſe in bags, or baſkets. When they eat it, they boil it again, either whole, or groſly beaten in a mortar; they then mix it with fiſh, or with veniſon, or beaver fleſh, and account it a very fine diſh. The green ears, or freſh Sweet corn, they alſo ſometimes eat as ſoon as it is gathered, roaſting it before the fire, and then picking out the grains. This is a new ſupply of food for them many times, when their winter or laſt harveſt-ſtore is exhauſted. Their ſoldiers alſo commonly go out to war againſt their enemies about this time of the year, and find this ſupply in their enemies fields.

SWEET-*williams*, the Engliſh name of ſeveral ſpecies of cariophyllus, or carnation.

There is a great variety of ſpecies, and very elegant diverſities of colouring in theſe flowers; the principal difference, however, is between the ſingle and double kinds.

The ſingle kinds are to be propagated by ſowing their ſeeds in March, on a bed of light earth; in May, they will be ready to plant out, and muſt then be ſet at ſix inches diſtance in beds of the ſame kind of earth. In theſe beds they ſhould remain till Michaelmas, and then be tranſplanted to the places where they are to remain. They will flower the next year in May, and ripen their ſeeds in Auguſt, when that of the beſt flowers ſhould be ſaved.

The double kinds are propagated by layers in the ſame manner with the carnations; they love a middling ſoil, neither too light, nor too ſtiff; they continue flowering a long time, and are very beautiful, eſpecially the male kind, which produces yearly too full blooms of flowers, the one in May, the other in July. *Miller's Gard. Dict.*

SWINE, *ſus*.—Swine are very profitable creatures to the owner, being kept at ſmall expence, feeding on things that would be otherwiſe thrown away, and producing a very large increaſe. They are apt to dig up the ground, and to break fences; but this may be prevented, by putting rings in their noſes, and yokes about their necks. Leiceſterſhire, Northamptonſhire, and Hampſhire, are famous for theſe animals, which ſeems owing to their being clayey countries, and that more beans and peaſe are ſown there, than in other places. The wild kind never grow ſo large as the tame, but they are much better taſted. The keepers of hogs ſhould always chuſe ſuch boars to breed out of as are long-bodied, and have deep bellies and ſides, ſhort noſes, thick thighs, ſhort legs, high claws, a thick neck, and a thick chine, well ſet with large briſtles. It is not proper to keep too many breeding ſows; for they will produce ſo many young at a time, and this three times a year, that they will not find food enough. They uſually bring thirteen or fourteen young ones in a litter, ſometimes more; but they can bring up no more than they have teats to ſuckle, and they bring forth three times in a year. Young ſhoots, as they are called, that is, Swine of three quarters of a year old, are beſt for pork, and thoſe of a year and half, for bacon. Moiſt and ſedgy grounds are good for Swine, for they eat the roots of many of the plants that grow there; and the fruit of the beech, cheſnut, and hedge buſhes, fatten them well, and make their fleſh much better taſted, than when bred intirely in the ſtye. *Mortimer's Huſbandry.*

SWING-*wheel*, in a royal pendulum, the wheel which drives the pendulum. In a watch or balance clock, it is called the crown-wheel.

SWINGLE, in the wire works in England, the wooden ſpoke which is fixed to the barrel that draws the wire, and which, by its being forced back by the cogs of the wheel, is the occaſion of the force with which the barrel is pulled. *Ray's Engliſh Words.*

SYMBOLO'GICE, is uſed by ſome for that part of the ſcience of medicine which treats of the ſymptoms of diſeaſes.

SYMPLE'XIUM *, in natural hiſtory, the name of a genus of foſſils, of the claſs of the ſelenitæ, but not of the determinate and regular figure of moſt of the genera of thoſe bodies; but compoſed of various irregular connections of differently ſhaped, and uſually imperfect bodies.

* The word is derived from the Greek συμπλέκω, to connect or compound a mixed maſs of different things.

SYMPO'SIARCH, in antiquity, the director or manager of an entertainment.

SY'MPTOSIS, a word uſed by the ancients to expreſs a contraction, or ſubſidence of the veſſels, ſuch as happens under evacuations. It alſo is ſometimes uſed to expreſs a remiſſion in a diſeaſe, and the falling away in fleſh of people in ſickneſs.

SYNAGELA'STIC, an epithet uſed to expreſs the fiſhes of the gregarious kind, or which ſwim together in large ſhoals, in oppoſition to the ſolitary kinds.

SY'NCAUSIS, a word uſed by ſome medical writers to expreſs the drying, and, as it were, burning up of the excrements within the body, by a febrile heat.

SY'NCHISIS, a word uſed by the old medical writers to expreſs a confuſion and perturbation of all the humours in concoction, from the imbecillity of the ſtomach. It is alſo uſed to expreſs a diſeaſe of the eye, which conſiſts in a confuſion of the humours: this generally proceeds from a violent blow; ſometimes from an inflammation of the uvea, occaſioning a rupture of the veſſels, and an effuſion of the humours.

SY'NCHYSIS, in rhetoric, a confused manner of expression, where the natural order of the words is perverted. Horace affects it much: thus *lib.* i. *sat.* 5.

Pœne macros arsit dum turdos versat in igne.

SY'NCRISIS, a word used by the chemical writers to express a concretion or coagulation of any thing, effected by a spontaneous, or violent reduction of a liquid substance to a solid one, by a privation of the humid.

SYNGENE'SIA *, in botany, a class of plants with hermaphrodite flowers, whose stamina are naturally formed into a single regular congeries.

* The word is derived from the Greek συν, together, and γένεσις, formation. The plants comprehended under it are those whose stamina, by the junction of their apices, are formed into a single regular cylindric body; and among these are the lettuce, succory, hawkweed, &c.

The Syngenesia expresses the same class of plants with the compound flowered plants of Ray, and others. The general characters of the class are these:

The cup is the crown of the seed, and stands on the summit of the germen. The flower consists of one petal, and has a very narrow and long tube placed upon the germen: this is either tubular, ligulated, or naked.

The tubular flower of the Syngenesia has, at the summit of the tube, a wide campanulated mouth, divided into five segments, which are expanded, and somewhat bent backward. The ligulated flower is that which has a plain and straight edge turning outwards, with a truncated apex undivided, but furnished with three or four teeth. The naked flowers are those which have no mouth at all; and often, in these, even the tube is also wanting. The stamina are five very short and slender filaments, inserted into the tube of the flower. The antheræ are of the same number with the stamina: they are slender, erect, and grow together at their sides, so as to form a tubular cylindric body of the length of the mouth of the flower, and divided into five segments at the edge. The germen of the pistil is oblong, and placed under the receptacle of the flower. The style is capillary, erect, and of the length of the stamina, and goes through the cylinder formed by the antheræ. The stigma is divided into two parts, which stand open, and bend backwards. These plants have properly no pericarpium, tho' in some few species there is a coriaceous crust placed about the seed. The seed is single and oblong, often of a quadrangular figure, and sometimes narrower at the base than in any other part. *Linnæi Gen. Plant.*

SYNGNA'THUS, in ichthyology, the name of a genus of fishes, the characters of which are these: the coverings of the gills are on each side composed of a thin and single bony lamella; the head is oblong and compressed; the jaws are closed up at the sides; and the mouth is only capable of opening at the extremity of the snout. The body is long and very slender; the shape is sometimes roundish, but more usually angular. The fins are in most species four in number, but in some only one.

SYNO'NYMISTS, among the botanical writers, such as have employed their care in the collecting the different names or synonyma, used by different authors, and reducing them to one another.

SYNTE'NOSIS, a word used by anatomists to express an articulation of the bones when they are connected, as the ossa sesamoidea of the toes only by a tendon.

SY'RINGA, *the pipe-tree*, in botany, the name of a genus of trees, the characters of which are these: the flower is of the rosaceous kind, being composed of several petals arranged in a circular form. The pistil arises from the cup, and finally becomes a fruit adhering to the cup, of a turbinated form, and divided into four cells, which contain small seeds.

The several species of this beautiful and sweet flowering shrub are easily propagated, by taking off their suckers in autumn, of which they always produce great plenty. These should be transplanted into the nursery, where after they have remained two years, they will be fit to be removed to the places where they are to remain. They are very hardy, and may be planted in almost any soil or situation; and require no farther culture, but to take away the suckers, and cut out the dead wood every year, and now and then to dig up the earth about their roots. They flower in May and June. *Miller's Gard. Dict.*

SYRINGOI'DES *Lapis*, the pipe-stone, in natural history, the name of a very beautiful fossil substance of which there are several different kinds. The tubuli marini, or cases of sea worms, lodged in any solid substance of the fossil kind, constitute what is called the lapis Syringoides.

The most frequent kind is made of the common matter of the ludus Helmontii, or septaria, with tubuli of different kinds and dimensions in it; but the most beautiful sort is that made of the bottoms of ships, old boards, or piles of wood; which, having been long in the sea, have been pierced by the sea worms, which have made their several burrows, and left their shells behind in them: the whole of these substances, becoming afterwards petrified, is found in a form of wood, with all the knots, veins, and other characters, but wholly of the hardness of stone. This is usually of a blackish colour, and, the pipes being of a pale yellow, the whole makes a very elegant appearance.

Our clay-pits about London afford also a Syringoides of this kind, but, the earth there abounding with the matter of the common vitriolic pyrites, that substance by degrees gets into the pores of the wood, and the whole seems a mass of pyrites with these pipes lodged in it in different directions. This has been called by authors pyrites Syringoides. *Hill's Hist. of Foss.*

SYSTEMA'TICAL *Qualities*, a term used by Mr. Boyle to express such qualities as are also called cosmical, and do not depend on the nature and constitution of the body itself, but on its being a member of this general system of the universe, in which capacity it is acted upon by agents unperceived by us, which occasions great changes in it.

SYSTEMA'TISTS, in botany, those authors, whose works in this science are principally employed about the arranging plants into certain orders, classes, or genera. *Linnæi Fund. Bot.*

T.

TA'BLES (*Dict.*)—*Astronomical* TABLES.—The oldest astronomical Tables are the Ptolemaic, found in Ptolemy's Almagest; but these no longer agree with the heavens.

In 1252, Alphonso XI, king of Castile, undertook the correcting them, chiefly by the assistance of Isaac Hazan, a Jew; and spent 400 thousand crowns therein. Thus arose the Alphonsine Tables, to which that prince himself prefixed a preface. But the deficiency of these was soon perceived by Purbachius and Regiomontanus; upon which Regiomontanus, and after him Waltherus and Warnerus, applied themselves to cœlestial observation, for the further amending them: but death prevented any progress therein.

Copernicus, in his books of the cœlestial revolutions, instead of the Alphonsine Tables, gives others of his own calculation, from the latter, and partly from his own observations.

From Copernicus's observations and theories, Eras. Reinholdus afterwards compiled the Prutenic Tables, which have been printed several times, and in several places.

Tycho de Brahe, even in his youth, became sensible of the deficiency of the Prutenic Tables; which was what determined him to apply himself with so much vigour to cœlestial observation. Yet all he did thereby, was to adjust the motions of the sun and moon; though Longomontanus, from the same, to the theories of the several planets published in his Astronomia Danica, added Tables of their motions, now called the Danish Tables; and Kepler likewise, from the same, in 1627, published the Rudolphine Tables, which are now much esteemed. These were afterwards, anno 1650, turned into another form, by Maria Cunitia, whose astronomical Tables, comprehending the effect of Kepler's physical hypothesis, are exceedingly easy, and satisfy all the phænomena, without any trouble of calculation, or any mention of logarithms; so that the Rudolphine calculus is here greatly improved.

Mercator made a like attempt in his Astronomical Institutions, published in 1676; and the like did J. Bap. Morini, whose abridgment of the Rudolphine Tables was prefixed to a Latin version of Street's Astronomia Carolina, published in 1705.

Lansbergius, indeed, endeavoured to discredit the Rudolphine Tables, and framed perpetual Tables, as he calls them, of the heavenly motions; but his attempt was never much regarded by the astronomers; and our countryman Horrox gave an abundant check to his arrogance, in his defence of the Keplerian astronomy.

Nor was the authority of the Rudolphine Tables impaired by the Philolaic Tables of Bullialdus, the Britannic Tables of Vincent Wing, calculated on Bullialdus's hypothesis; or the Britannic Tables of Newton; or the French ones of the count de Pagan, or the Caroline Tables of Street, all calculated on Dr. Ward's hypothesis, or the Novalmagestic Tables of Ricciolus. Among these, however, the Philolaic and Caroline Tables are esteemed the best; insomuch that Mr. Whiston, by the advice of Mr. Flamsteed (a person of undoubted authority in such cases) thought fit to subjoin the Caroline Tables to his astronomical lectures.

The Ludovician Tables were published in 1702, by M. de la Hire, wholly from his own observations, and without the assistance of any hypothesis; which, before the invention of the micrometer, telescope, and the pendulum-clock, was held impossible.

But the latest, and much the best, are those of the celebrated Dr. Halley.

TACO'MAR-*tree*, a name by which some authors call the sugar-cane.

TA'DPOLE.—The animal called by this name is no other than the frog in its first state from the spawn; and this creature furnishes the curious in microscopic observations with a beautiful view of the circulation of the blood, especially when the animal is young.

The method of procuring them for this purpose in the greatest perfection is this: let a small quantity of frog's spawn be kept some days in water, and from this will be produced a vast number of young Tadpoles; these, while very young, are perfectly transparent, and, when placed before the double microscope, the heart may be easily seen, and its pulsation regularly observed; and the blood protruded thence may be beautifully seen circulating through the whole body; but particularly in the tail, where, though so very minute, more than fifty vessels may be seen at one view. The young brood grow more and more opake every hour, and in a day or two the circulation of the blood can only be seen in their tail, or in the fins near the head. *Baker's Microscope.*

TA'FFETAS noir lustré is our Alamode. — Non lustré is our lustring.

There are Taffaties of all colours, some plain, others striped with gold, silver, silk, &c. others chequered, others flowered, others in the Chinese point, others the Hungarian; with various others, to which the mode, or the caprice of the workmen, give such whimsical names, that it would be as difficult, as it is useless, to rehearse them; besides that, they seldom hold beyond the year wherein they first rose. The old names of Taffeties, and which still subsist, are Taffeties of Lyons, of Spain, of England, of Florence, of Avignon, &c. The chief consumption of Taffeties is in summer-dresses for women, in linings, scarves, window-curtains, &c.

There are three things which contribute chiefly to the perfection of Taffeties, viz. the silk, the water, and the fire. The silk is not only to be of the finest kind, but it must be worked a long time, and very much, before it be used. The watering, besides that it is only to be given very lightly, seems only intended to give that fine lustre, by a peculiar property not found in all waters. Lastly, the fire, which is passed under it to dry the water, has its particular manner of application, whereon the perfection of the stuff depends very much.

Octavio May, of Lyons, is held the first author of the manufacture of glossy Taffeties; and tradition tells us the occasion of it.—Octavio, it seems, going backwards in the world, and not able to retrieve himself by the manufacture of Taffeties, such as were then made, was one day musing on his misfortunes, and, in musing, chanced to chew a few hairs of silk which he had in his mouth. His reverie being over, the silk he spit out seemed to shine, and on that account engaged his attention. He was soon led to reflect on the reason; and, after a good deal of thought, concluded, that the lustre of that silk must come, first, from his having pressed it between his teeth. Secondly, from his having wet it with his saliva, which had something glutinous in it: and, thirdly, from its having been heated by the natural warmth of his mouth. All this he executed upon the next Taffeties he made; and immediately acquired immense riches to himself, and to the city of Lyons the reputation it still maintains, of giving the gloss to Taffeties, better than any other city in the world.

It will not, we conceive, be less useful than curious, to give here the description of the engine contrived by Octavio to give the gloss to Taffety; to add the manner of applying it, and the composition of the water used therein.

The machine is much like a silk loom, except that, instead of iron points, here are used a kind of crooked needles, to prevent the Taffety from slipping: at the two extremities, are two beams; on one of which is rolled the Taffety, to take the gloss; and, on the other, the same Taffety as fast as it has received it. The first beam is kept firm by a weight of about 200 pounds; and the other turned by means of a little lever passing through mortises at each end. The more the Taffety is stretched, the greater lustre it takes; care, however, is to be used it be not over-stretched.

Besides this instrument for keeping the stuff stretched, there is another to give it the fire: this is a kind of carriage, in form of a long square, and the breadth of the Taffeties. It moves on trundles, and carries a charcoal fire under the Taffety, at the distance of about half a foot.

The two machines prepared, and the Taffety mounted, the lustre is given it by rubbing it gently with a ball, or handful of lists of fine cloth, as it rolls from one beam to the other; the fire, at the same time, being carried underneath it to dry it. As soon as the piece has its lustre, it is put on new beams to be stretched, a day or two; and, the oftener this last preparation is repeated, the more it increases the gloss.

For black Taffeties, the gloss is given with double beer, and orange or lemon juice; but this last is the least proper, as being

ing apt to whiten. The proportion of the two liquors is a gallon of orange juice to be boiled together to the consistence of a rich broth. For coloured Taffeties they use gourd-water, distilled in an alembic.

TA'GETES, *African marygold*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the radiated kind: its disk is composed of floscules divided into several segments, and its outer edge of semi-floscules; all standing on embryo seeds, and contained in a one-leaved cup of a tabulated form. The embryo's finally become seeds of an angular form, furnished with a foliaceous head, and affixed to the thalamus of the flower. There are also some species in which the flower is wholly composed of semi-floscules.

We have a great many species of this plant annually raised in our gardens, for the beauty of their flowers. They are propagated by sowing the seeds in spring, on a moderately hot bed; when the young plants come up, they must have air allowed them; and, when three inches high, they should be removed to another hot-bed, which should be arched over with hoops that it may be sheltered with mats. They are to be planted here at about eight inches distance, and, when they are grown stronger, as about the beginning of May, they are to be taken up with a ball of earth about their roots, and placed where they are to remain; or else at eighteen inches distance in a nursery, where, when they flower, the finest sorts may be marked and removed, with a large ball of earth to their roots, either into pots, or into the borders of the flower-garden. They are very beautiful; but their smell is very offensive. *Miller's Gard. Dict.*

TAILS *of comets*.— We have an enquiry into the cause of the Tails of comets by Mr. Euler in the Mem. de l'Acad. de Berlin. He thinks there is a great affinity between these tails, the zodiacal light, and the aurora borealis; and that the common cause of them all is the action of the sun's light on the atmospheres of the comets, of the sun, and of the earth. He supposes that the impulse of the rays of light on the atmosphere of comets may drive some of the finer particles of that atmosphere far beyond its limits; and that this force of impulse, combined with that of gravity towards the comet, would produce a Tail, which would otherwise always be in opposition to the sun, if the comet did not move. But the motion of the comet in its orbit, and about an axis, must vary the position and figure of the Tail, giving it a curvature, and deviation from a line drawn from the center of the sun to that of the comet; and that this deviation will be greater, as the orbit of the comet has the greater curvature, and the motion of the comet is more rapid. It may even happen, that the velocity of the comet, in its perihelion, may be so great, that the force of the sun's rays may produce a new Tail before the old one can follow; in which case the comet might have two or more tails. The possibility of this is confirmed by the comet of 1744, which was observed to have several Tails, while it was in its perihelion. See the article ZODIACAL *Light*.

TA'LED, in the Jewish antiquities, a sort of habit that the Jews wore, chiefly when they repeated their prayers in the synagogue.

TA'LPA, *the mole*, in the Linnæan system of zoology, makes a distinct genus of animals, the characters of which are: that they have feet with five claws on each, as well on those behind as on those before; and have their fore-feet made like hands, and fitted for digging. *Linnie Syst. Nat.*

It hath been supposed by many, that the mole had no eyes; and others have affirmed, that it had eyes, but that they were covered with a membrane; but neither of these assertions are true. The eyes are small, and have apertures in the skin, through which they may easily be discerned by a curious observer; and are very black, about the size of a millet seed, and fastened to a nerve.

The reason they have not been observed by the common people, is, that they are hid by the fur, but, only blowing them away, they always shew themselves. It has no ears.

Its skin is extremely firm and tough, so that it requires a sharp knife to pierce it. *Ray's Syn. Quad.*

TA'MARINDS (*Dict.*)— *Plate* XL. *fig.* 8, represents the Tamarind tree, where *a* is the flower, *b* the fruit, *c* the seed. For a description of both the tree and fruit, consult this article in the Dictionary.

TAMARI'SCUS, *the tamarisk-tree*, in botany, the name of a genus of trees, the characters of which are these: the flower is of the rosaceous kind, being composed of a number of petals, arranged in a circular form; the pistil arises from the cup, and, finally, becomes a capsule, resembling that of the willow, of a long figure and membranaceous structure, and containing seeds winged with down. *Tourn. Inst.*

TA'MBOS, in Peruvian antiquity, buildings placed at certain distances for the lodgings of the princes of that country, in their travels through their dominions.

TAN (*Dict.*)— Tan is of great use in gardening: first, by its fermentation, when laid in a body, which is always moderate, and of a long duration, which renders it of great service to hot-beds: and, secondly, after it is well rotted, it becomes excellent manure for all sorts of cold stiff land; upon which one load of Tan is better than two of rotten dung, and will continue longer in the ground.

The use of Tan for hot-beds has not been many years known in England; the first Hot-beds of this sort, which were made in England, were at Blackheath, in Kent, about fifty-five years ago: these were designed for raising of orange-trees; but, the use of these hot-beds being but little known at that time, they were made but by two or three persons, who had learned the use of them in Holland and Flanders, where the gardeners seldom made any other hot-beds: but in England there were very few hot-beds made of tanner's bark, before the ananas were introduced into this country, which was in 1719. Since which time the use of these hot-beds have been more general; and are now made in all those gardens, where the ananas plants are cultivated, or where there are collections of tender exotic plants preserved: and the gardeners here are now better skilled in making and managing of these hot-beds, than in most other countries; which might render it less necessary to give a full description of them here: but, yet, as there may be some persons in the remote parts of England, who have not had an opportunity of informing themselves of the use of tanners bark for this purpose, I shall insert the shortest and plainest method of making and managing these hot-beds, as they are practised by the most knowing persons, who have long made use of these hot-beds: and, first, I shall begin with the choice of the Tan.

The tanners in some parts of England do not grind the bark, to reduce it into small pieces, as is commonly practised by the tanners near London; where there is great difference in the size of the bark, some being ground much smaller than the other, according to the different purposes for which it is intended; but in many places the bark is only chopped into large pieces, which renders it very different for the use of hot-beds; for, if the Tan is very coarse, it will require a longer time to ferment, than the small Tan; but, when it begins to heat, it will require a much greater degree, and will retain the heat a much longer time than the small; therefore, where there is choice, the middling-size Tan should be preferred; for it is very difficult to manage an hot-bed when made of the largest Tan: the heat of which is often so great, as to scald the roots of plants, if the pots are fully plunged into the bed; and I have known this violent heat continue upwards of two months; so that it has been unsafe to plunge the pots more than half their depth into the Tan, till near three months after the beds have been made: therefore, where the persons, who have the care of these beds, do not diligently observe their working, they may in a short time destroy the plants which are placed in the beds: on the other hand, if the Tan is very small, it will not retain the heat above a month, or five weeks; and will be rotten and unfit for an hot-bed in a short time; so that, where the middle-sized Tan can be procured, it should always be preferred to any other.

The Tan should be always such as has been newly taken out of the pits; for if it lies long in the tanner's yard, before it is used, the beds seldom acquire a proper degree of heat; nor do they continue their heat long; so that when it has been more than a fortnight or three weeks out of the pit, it is not so good for use as that which is new. If the Tan is very wet it will be proper to spread it abroad for two or three days to drain out the moisture, especially if it is in the autumn or winter season; because, then, as there will be little sun to draw a warmth into the Tan, the moisture will prevent the fermentation, and the beds will remain cold: but, in the summer-season, there is no great danger from the moisture of the Tan; the heat of the sun through the glasses will be then so great, as soon to cause a fermentation in the Tan.

These Tan-beds should always be made in pits, having brick walls round them, and a brick pavement at the bottom, to prevent the earth from mixing with the Tan; which will prevent the Tan from heating: these pits must not be less than three feet deep, and six feet in width: the length must be in proportion to the number of plants they are to contain: but, if they are not ten feet in length, they will not retain their heat long: for, where there is not a good body of Tan, the outside of the bed will soon lose its heat; so that the plants which are there plunged, will have no benefit of the heat; nor will the middle of these beds retain their heat long; so that they will not answer the purpose for which they are intended.

When the Tan is put into the bed, it must not be beaten or trodden down too close; for that will cause it to adhere, and form one solid lump; so that it will not acquire an heat; nor should it be trodden down at the time when the pots are plunged into the beds; to avoid which there should be a board laid cross the bed, which should be supported at each end to prevent its resting on the Tan; upon which the person should stand, who plunges the pots; so that the Tan will not be pressed down too close. When the Tan is quite fresh, and has not been out of the pits long enough to acquire an heat, then the beds will require a fortnight or three weeks time, or sometimes a month, before they will be of a proper temperature of warmth to receive the plants: but, in order to judge of this, there should be three or four sticks thrust down into the Tan,

Tan, about eighteen inches deep, in different parts of the bed; ſo that by drawing out the ſticks, and feeling them at different depths, it will be eaſy to judge of the temper of the beds; and it will be proper to let a few of theſe ſticks remain in the bed, after the plants are plunged, in order to know the warmth of the Tan; which may be better judged of by feeling theſe ſticks, than by drawing out the pots, or plunging the hand in the Tan.

When the Tan is good, one of theſe beds will retain a proper degree of heat for near three months; and, when the heat declines, if the Tan is forked up, and turned over, and ſome new Tan added to it, the heat will renew again, and will continue two months longer; ſo that by turning over the Tan, and adding ſome new Tan every two months, or thereabout, as the bed is found to decline of its heat, they may be continued one year: but every autumn it will be proper to take out a good quantity of the old Tan, and to add as much new to the bed, that the heat of the bed may be kept up in winter; for, if the heat is ſuffered to decline too much during the cold ſeaſon, the plants will ſuffer greatly: to prevent this, there ſhould always be ſome new Tan added to the bed in winter, when the heat is found to decline; but the Tan ſhould be laid in a dry place a week or ten days, to dry, before it is put into the bed; otherwiſe the moiſture will chill the old Tan in the bed, and prevent the fermentation: ſo that unleſs the Tan is turned over again, there will be little or no heat in the beds; which often proves fatal to the plants which are plunged into them: therefore, whoever has the management of theſe beds, ſhould be very careful to obſerve conſtantly the warmth of the Tan; ſince, upon keeping the beds in a due temperature of warmth, the whole ſucceſs depends; and, where this caution is not taken, it frequently happens, that the ananas plants run into fruit very ſmall, or the plants are infeſted by inſects; both which are occaſioned by the growth of the plants being ſtopped by the decline of the heat of the Tan; therefore great regard muſt be had to that, eſpecially in winter.

The great advantages which theſe Tan-beds have of thoſe which are made of horſe-dung, are the moderate heat which they acquire; for their heat is never ſo violent, as thoſe of horſe-dung; and they continue this heat much longer; and, when the heat declines, it may be renewed, by turning the beds over, and mixing ſome new Tan with the old; which cannot be ſo well done with horſe-dung; and, likewiſe, the beds will not produce ſo great ſteams, which are often injurious to tender plants; ſo that theſe Tan-beds are much preferable to thoſe of horſe-dung for moſt purpoſes.

Tan, when it is well rotted, is alſo an excellent manure for all cold and ſtiff lands; and if it is laid upon graſs-ground in autumn, that the rains in winter may waſh it into the ground, it will greatly improve the graſs; but, when it is uſed new, or in the ſpring of the year, when dry weather comes, it is apt to cauſe the graſs to burn; which has occaſioned the diſuſe of Tan in many places; but, if properly uſed, it will be found an excellent dreſſing for all ſtiff lands.

Flowers of TAN.— Flower of Tan is a name given by the people employed in the tanning-trade to a yellow ſubſtance, often found upon old Tan, or oak bark broken to pieces, which has been uſed as Tan, and is of no farther ſervice.

The name, however, is very improper; and, though every body converſant in Tan-yards muſt have ſeen the thing, yet it has always paſſed as an effloreſcence of the bark, till the curious Mr. Marchand enquired more accurately into its nature, and found it to be a plant of itſelf, wholly different from the matter of the Tan; and to which the bark which had been often wetted and dried again, ſerved as a proper matrix. He found it to be more nearly allied to the ſpunge than to any other genus of plants, and therefore named it ſpongia fugax, mollis, flava, et amœna in pulvere coriario naſcens, ſoft, beautiful, yellow, fading ſpunge, growing on tanners bark.

It makes its appearance moſt frequently in the ſummer months, and is then ſeen in ſmall tufts of a beautiful yellow colour, on different parts of the old heaps of bark. It appears at firſt in form of a thin yellow ſcum, and is of a ſort of jelly-like ſtructure; but it every day grows larger and thicker, till it ſtands above half an inch out from the ſurface of the bark. As it grows, its ſurface becomes more and more cavernous and ſpungy, the pores or holes being of different diameters, and the interſticial matter forming a ſort of net-work more or leſs regular, and often interrupted by irregular prominences in ſeveral parts; and, in fine, when the growth is complete, the whole more reſembles a ſpunge, than any other vegetable ſubſtance, and is of a deep yellow colour, and conſiderably thick and tough conſiſtence; there are no roots to be diſcovered iſſuing from it; its ſmell is like to that of rotten wood, and its taſte is ſomewhat ſtyptic. It always appears in the warm months, and always upon ſuch old Tan as has begun to ferment, and is in the ſtate in which our gardeners uſe it for hot-beds. If it happens to ſtand expoſed to the ſouth ſun, it is but of ſhort duration; but, if it be in a ſheltered place, it will laſt a conſiderable time, and often ſpread itſelf to a great extent, and make a very beautiful figure for many weeks. *Mem. Acad. Par.* 1727.

TA'NNING (*Dict.*)— The operation of Tanning is performed, on leather, better in the Weſt-Indies than in England. They uſe three ſorts of bark, the mangrave-bark, the olive-bark, and another; and the whole buſineſs is ſo ſoon done, that a hide delivered to them is in ſix weeks ready to be worked into ſhoes, though they beſtow leſs labour than we do. *Phil. Tranſ.* N°. 36.

Every part of the oak-tree, of what age or growth ſoever, is fit for the tanners uſe, and all oaken coppice-wood, of any age or ſize, being cut and procured in barking-time, will tan all ſort of leather, at leaſt as well as the bark alone. When this material is got at the proper ſeaſon, it muſt be very well dried in the ſun more than the bark alone; thence it is to be cut up, and preſerved in a covered place for uſe.

When it is to be uſed, the greater wood muſt be firſt cleft ſmall, to fit it for the beating and cutting engine; and the ſmaller muſt be put into the engine as it is. Which done, it muſt be again dried on a kiln, and after that ground in the ſame manner that the tanners grind their bark. Such wood as is to be uſed preſently after it is gotten, will require the better and the more drying upon the kiln; and, if this is omitted, it will blacken and ſpoil all the leather it is to be uſed about. Where oak is ſcarce, black-thorn will tolerably well ſupply its place, and, where that is not to be had in ſufficient plenty, the white-thorn will do. *Philoſ. Tranſact.* N°. 108.

Birch alſo, being ordered in the ſame manner with oak, is fit for ſome uſes in Tanning, particularly it does very well for Tanning of ſhoe-ſoal leather. All theſe ingredients will tan much better than bark alone, and that with much leſs charge; ſo that this diſcovery may very well ſave the felling of trees when the bark is wanted, at a ſeaſon when the ſap is up, which, when it is done, cauſes the outſides of the trees to rot and grow worm-eaten; whereas, if the trees had been felled in winter, when the ſap is down, they would have been almoſt all heart, as the people expreſs it, and not ſubject to worms. This manner of uſing the wood with the bark, in Tanning, will alſo increaſe the value of underwoods very conſiderably. *Phil. Tranſ.* N°. 105.

The engine neceſſary for cutting the wood conſiſts of a long ſquare wooden block, and ſome pieces of iron to be faſtened on, and uſed about it, viz. a hammer, an anvil, and iron holding the wood to be bruiſed and cut, and a knife to cut it. The whole is a very ſimple and cheap machine, and is deſcribed at large, and figured in the above-mentioned number in the Philoſophical Tranſactions.

By Mr. de Buffon's experiments upon different ſkins, it was found that a decoction of young oak wood ſucceeded perfectly well in Tanning ſheep and calves ſkins, but did not do equally well for ox, and the other harder ſkins. This, however, he imagines might be only for want of knowing the beſt method of uſing the wood. And, certainly, theſe trials deſerve to be farther proſecuted; ſince the ſmall branches of the oak, which are of little value, might be thus made to ſupply the place of a much dearer commodity, the bark; and as, in many trees, the bark of the young branches is found to be of greatly more virtue than that of the larger branches, or the trunk, the uſe of theſe ſmall bows, bark and all, might very probably be found to anſwer to all the effects of the bark, of the larger kind alone. *Memoires Acad. Scien. Par.* 1736.

TAP-*root*, in trees, that part of the root that deſcends ſtraight down.

In removing or tranſplanting young oaks, great care ſhould be taken not to wound this root, much leſs to cut it off; but it muſt be dug up to the bottom, and the hole prepared deep enough to ſet it; otherwiſe the tree either dies, or, if not, yet it is always greatly ſtinted and impeded in its growth. *Ray's Engliſh Words.*

TAPE-*worm*, a ſpecies of worm breeding in the human bowels, and called by authors tænia, and lumbricus latus, or the broad worm.

The true hiſtory of this animal is, that it is ſhort and broad. What is called a link of the long worm is really a diſtinct worm; and, when one of theſe multiplies in the bowels, its young adhere to it, and to each other endwiſe, ſo as to form a ſort of chain, which lengthens as they continue to increaſe, and, in fine, becomes immoderately long. Hence it is, that the breaking, as it is called, of this worm, does not deſtroy it, and that the voiding large pieces of it is no cure, ſince it ſtill recovers that length again by new young ones. Every ſeparate link of ſuch a chain, if examined, is found to be intire, lively and briſk, and not at all injured by the ſeparation.

Authors who have treated of theſe worms as a diſeaſe, have given a canine appetite, or unnatural appetite to food, as one of the ſymptoms; but this is wrong, for it has never been found, in reality, that theſe worms, even where moſt numerous, have at all increaſed the natural appetite; and, indeed, it is very difficult to judge of their being in the body by ſymptoms, ſince they occaſion none which are not alſo common in many other diſeaſes. Many people have had them a long courſe of time, without being ſenſibly hurt by them; and there has never been a known inſtance of their occaſioning any one's death, or indeed any conſiderable diſorder. See the article WORMS.

TAPHNEUS, a word uſed by ſome writers to expreſs any

thing

thing when depurated or purified to the greateſt degree, as the ſalts by repeated ſolutions and cryſtalliſations, and the like. Paracelſus uſes it for a ſpecies of earth, and things produced from which, he ſays, never alter their nature by calcination or reverberation, or the like operations.

TAPI'NOSIS, in rhetoric, the ſame with diminution.

TA'PLINGS, in the Engliſh ſalt-works, the name given to certain bars of iron which ſupport the bottom of the pan in which the brine is boiled.

Theſe pans are very large, and cover a wide furnace; but as their width would make them apt to bend in the middle, which would ſpoil the working of the ſalt, there is a ſort of wall of brick carried along the middle of the furnace; and on the top of this are placed theſe Taplings: they are about eight inches high, and from four to ſix in thickneſs, being ſmalleſt at the top. Theſe are placed at about three feet diſtance one from another, and the wall which ſupports them, and which is called the mid-feather, is broad at the baſe, and ſo narrow at the top, as barely to give room for the baſes of the Taplings.

TAR-*water*.—In ſome parts of America, Tar-water is made by putting a quart of cold water to a quart of Tar, and ſtirring them well together in a veſſel, which is left ſtanding till the Tar ſinks to the bottom. A glaſs of clear water, being poured off for a draught, is replaced by the ſame quantity of freſh water, the veſſel being ſhaken, and left to ſtand as before. And this is repeated for every glaſs, ſo long as the Tar continues to impregnate the water ſufficiently, which will appear by the ſmell and taſte.

But, as this method produces Tar-water of different degrees of ſtrength, Biſhop Berkley ſays, he chuſes to make it in the following manner: pour a gallon of cold water on a quart of Tar, and ſtir and mix them thoroughly with a ladle or flat ſtick, for the ſpace of three or four minutes; after which the veſſel muſt ſtand eight and forty hours, that the Tar may have time to ſubſide; when the clear water is to be poured off, and kept for uſe, no more being made from the ſame Tar, which may ſtill ſerve for common purpoſes.

It has been found, that ſeveral perſons infected with cutaneous eruptions and ulcers were immediately relieved, and ſoon after cured, by the uſe of this medicine. It is ſaid, that, even in the fouleſt diſtempers, it proved much more ſucceſsful than ſalivations and wood-drinks had done. It alſo ſucceeded, beyond expectation, in a tedious and painful ulceration of the bowels, in a conſumptive cough, and, as appeared by expectorated pus, an ulcer in the lungs, in a pleuriſy and peripneumony. And, when a perſon who had been for ſome years ſubject to eryſipetalous fevers, perceived the uſual forerunning ſymptoms to come on, the drinking of Tar-water prevented the eryſipelas.

Tar-water cures indigeſtion, and gives a good appetite. It is an excellent medicine in an aſthma; it imparts a kindly warmth and quick circulation to the juices, without heating, and is therefore uſeful, not only as a pectoral and balſamic, but alſo as a powerful and ſafe deobſtruent in cachectic and hyſteric caſes. As it is both healing and diuretic, it is very good for the gravel. The biſhop ſays, he believes it to be of great uſe in a dropſy, having known it cure a very bad anaſarca in a perſon whoſe thirſt, though very extraordinary, was in a ſhort time removed by the drinking of Tar-water. It may likewiſe be ſafely uſed in inflammatory caſes; and, in fact, hath been found an admirable febrifuge, at once the ſafeſt cooler and cordial.

To ſailors, and all ſea-faring perſons, who are ſubject to ſcorbutic diſorders, and putrid fevers, eſpecially in long ſouthern voyages, he is perſuaded this Tar-water would be very beneficial.

It is to be obſerved, that Tar-water ſhould not be made in unglazed earthen veſſels, theſe being apt to communicate a nauſeous ſweetneſs to the water.

The ſame ingenious author recommends Tar-water in the plague, and for the diſtemper among the horned cattle now raging; with what ſucceſs muſt be left to experience.

TA'RSO, in the glaſs-trade, a ſort of white ſtone found in many rivers of Italy, and other places; and uſed inſtead of ſand for the fineſt cryſtal-glaſs, being firſt burnt, and calcined with the ſalt of the polverine into frit. *Neri's Art of Glaſs.*

The Tarſo of this and other authors is truly a cryſtalline matter debaſed by an admixture of white earth, and found in form of ſmall pebbles, of a whitiſh, yellowiſh, or pale reddiſh colour; and this is common in all the gravel-pits of England, and in the beds of ſome of our rivers; and might be uſed with great advantage by our glaſs-makers, if they knew it was ſo eaſily to be had.

On comparing theſe ſtones of ours with the cuogolo or Tarſo of the foreign glaſs-makers, there is no difference diſtinguiſhable to the eye, nor will the niceſt experiments by the fire, acid menſtrua, &c. ſhew the leaſt diſtinction between them. We are not to wonder, however, that the glaſs-makers did not hitherto diſtinguiſh this to be the true cuogolo or Tarſo, ſince the characters of foſſils have been hitherto ſo little aſcertained, that the beſt and lateſt author on theſe ſubjects, Dr. Woodward, ſo far miſtook the ſtructure of this ſtone, as to call it a ſparry pebble. It is certain that ſpar could never have any thing to do with glaſs-making; but this ſtone has no ſpar in its compoſition.

Soluble TARTAR. The proceſs for making ſoluble Tartar is this: take of an alkaline fixed ſalt a pound, of water a gallon; and, having diſſolved the ſalt in this water boiling, throw in cryſtals of Tartar in powder as long as any fermentation is raiſed, which uſually ceaſes before thrice the weight of the alkali is thrown in. Then ſtrain the liquor through paper; and after due evaporation ſet it by for the ſalt to cryſtalliſe, or elſe evaporate the liquor wholly away, that the ſalt may be left dry.

This ſalt, by the action of the alkali on the acid of Tartar, being freed from thoſe groſs terreſtrious parts, with which the cryſtals of Tartar, how pure ſoever, remain ſtill charged; it diſſolves readily, and keeps ſuſpended in cold water. *Pemberton's Lond. Diſp.*

TA'WING (*Dict.*)—*Method of* TAWING, *or drawing ſkins in white.*—The wool or hair being well got off the ſkins, by means of lime, &c. as deſcribed under the article SHAMMY, they are laid in a large vat of wood or ſtone ſet in the ground, full of water, wherein quick-lime has been ſlacked; wherein they continue a month or ſix weeks, as the weather is more or leſs hot, or as the ſkins are required to be more or leſs ſoft and pliant.

While in the vat, the water and lime is changed twice, and they are taken out and put in again every day. When taken out for the laſt time, they are laid all night to ſoak in a running-water, to get out the greateſt part of the lime; and, in the morning, are laid, ſix together, on the wooden leg, to get off the fleſh, by ſcraping them ſtoutly, one after another, on the fleſh ſide, with a cutting two-handed inſtrument, called a knife; and, while this is in hand, they cut off the legs, and other ſuperfluous parts about the extremes.

This done, they are laid in a vat or pit with a little water; where being well fulled with wooden peſtles for a quarter of an hour, the vat is filled up with water, and the ſkins rinſed therein. They are next thrown on a clean pavement to drain; which done, they are caſt into a freſh pit of water, where being well rinſed, they are taken out, and laid on the wooden leg, ſix at once, with the hair ſide outermoſt, over which they rub a kind of whetſtone very briſkly, to ſoften, and fit them to receive four or five more preparations given them on the leg, both on the fleſh ſide and the hair ſide, with the knife, after the manner above-mentioned.

Theſe over, they are put in a pit with water and wheat-bran, and ſtirred about therein, with wooden poles, till the bran is perceived to ſtick to them; and then they are left; as they riſe of themſelves to the top of the water by a kind of fermentation, they are plunged down again to the bottom; and, at the ſame time, fire is ſet to the liquor, which takes as eaſily as if it were brandy, but goes out the moment the ſkins are all covered.

This operation is repeated as often as the ſkins riſe above water; and, when they riſe no more, they are taken out, laid on the wooden leg, the fleſh ſide outermoſt, and the knife paſſed over it to ſcrape off the bran. The bran thus cleared, the ſkins are laid in a large baſket, where they are loaden with huge ſtones to promote their draining; and, when ſufficiently drained, their feeding is given them, which is performed after the following manner:

For a hundred large ſheep-ſkins, and for ſmaller in proportion, they take eight pounds of alum, and three of ſea-ſalt, and melt the whole with water in a veſſel over the fire; pouring the diſſolution out while yet lukewarm into a kind of trough, wherein are twenty pounds of the fineſt wheat flower, with eight dozen yolks of eggs; of all which is formed a kind of paſte, a little thicker than children's pap; which, when done, is put into another veſſel, to be uſed in manner following: a quantity of hot water being poured into the trough wherein the paſte was prepared, two ſpoonfuls of the paſte are mixed therewith; in order to which, they uſe a wooden ſpoon, which contains juſt what is required for a dozen ſkins: and, when the whole is well diluted, two dozen of the ſkins are plunged therein: care being taken, by the way, that the water be not too hot, which would ſpoil the paſte, and burn the ſkins.

Having ſtaid ſome time in the trough, they are taken out, one after another, with the hand, and ſtretched out; which is repeated twice: when they have all had their paſte, they are put in tubs, where they are fulled afreſh with wooden peſtles. Then they are put in a vat, where they remain five or ſix days, or more; and are at laſt taken out in fair weather, and hung out to dry on cords or racks; the quicker they dry, the better; for, if they be too long a drying, the ſalt and alum within them are apt to make them riſe in a grain, which is an eſſential fault in this kind of dreſſing.

When the ſkins are dry, they are put up in bundles, and juſt dipped in fair water; from which being taken out and drained, they are thrown into an empty tub; and, after ſome time, are taken out, and trampled under foot.

They are then drawn over a flat iron inſtrument, the top whereof is round like a battledore, and the bottom fixed into a wooden block, to ſtretch and open them: when opened, they are hung in the air upon cords to dry; and, when dry, are

are opened a second time by repassing them over the same instrument.

Lastly, they are laid on a table, pulled out, and laid smooth; and are thus in a condition for sale and use.

After the same manner are dressed horses, cows, calves skins, &c. for the sadlers, harness-makers, &c. as also dogs, wolves, bears-skins, &c. excepting that in these the use of the paste is omitted, salt and alum-water being sufficient.

TEETH (*Dict.*)—When the Teeth are subject to be overspread with a black or yellow crust, it is a very good method to rub them well every day with a mixture of tincture of gum lac, honey of roses, and spirit of vitriol, which will not only whiten the Teeth, but render the gums more firm.

The world is fond of tooth powders, and a moderate use of them may do service; but the daily rubbing with them does more harm to the teeth than wholly neglecting them. Powders of this kind may be prudently used once in six or seven days, and will render the Teeth white and splendid. The common powders, prepared for this purpose, are too hard, and wear away the gums; softer substances should be employed, and, when the gums are furred, a few drops of some acid spirit may be added to the powder. The following is a very efficacious and safe powder: take chalk in powder, myrrh, burnt hartshorn levigated, and Florentine rice-root, of each two drachms. Spirit of salt, six drops; mix all into a powder.

The common trick of mountebanks, and other such practisers, is to use various washes for the Teeth, the sudden effects of which, as cleaning and whitening the Teeth, surprise and please people; but the effects are very pernicious. All the strong acid spirits will do this. As good a mixture as any thing can be, on this occasion, is the following: take plantane-water, an ounce; honey of roses, two drachms; spirit of salt, ten drops: mix the whole together, and rub the Teeth with a piece of linen rag dipped in this, every day, till they are whitened. The mouth ought to be well washed with cold water, after the use of this or any other acid liquor; and indeed the best of all Teeth-washes is cold water, with, or without a little salt; the constant use of this will keep them clean and white, and prevent them from aching. *Heister's Surg.*

TEGS, a term used in some parts of the kingdom by the farmers, to express lambs of a year old.

TELEO'LOGY, the science of the final causes of things. This is an ample and curious field of enquiry, though pretty much neglected by philosophers. *Wolf. Disc. Prælim. Logic.*

TELE'PHIUM, *orpine*, in botany, the name of a genus of plants; the characters of which are these: the flower is of the rosaceous kind, consisting of several petals, arranged in a circular form, and contained in a cup, consisting also of many leaves. The pistil arises from the cup, and is finally converted into a triangular shaped unicapsular fruit, containing a number of small and roundish seeds. To these marks it may be added, that the leaves stand alternately on the stalks.

TE'MACHIS, in natural history, the name of a genus of fossils, of the class of the gypsums, the characters of which are these: it is of a softer substance than many of the other genera, and of a very bright and glittering hue.

The name is derived from the Greek τεμαχιον, frustulum, a small irregular fragment; the bodies of this genus being composed of an assemblage of multitudes of irregular flaky fragments, as are all gypsums; but no genus of them so visibly as these.

TE'MPERATURE, or *climate for plants.*—The difference of climate or Temperature of the air has a very great effect on plants. The different degree of heat is the great cause of these changes, and the different degree of moisture somewhat assists in it. The American and Asian plants, famous in medicine, when of the growth of their native soils, yet when removed into our climate, though they grow and even produce their flowers and ripen their seeds, which seems the last perfection of a plant, when put to the trial, have been always found to want their proper medicinal virtues.

Many of those plants and trees, which, though natives of another climate, will endure the open air with us, and grow in our gardens; yet lose much of their strength, and become dwarfs, in proportion to what they were when in their proper climate. But much less violent changes than these are able to produce the like effects, at least in some degree. The several parts of Europe are able to alter the quality of the same plant, even while it grows naturally in them. Thus, the blue aconite or napellus, the root of which is a terrible poison in the south of France; yet, in Brittany, a northern province of the same kingdom, the root of the same plant, though it seems to grow with equal vigour there, is equally large and succulent, has no bad effects; but has been eaten by old people and children without any injury.

In general, the farther north we go the less and less hurtful this plant becomes. It is common to almost all Europe, and we find the inhabitants of some places dreading it, and that, with great justice, as a fatal poison; while those of others eat the leaves in their sallads, and even esteem them good to restore the appetite.

The common woad which succeeds well in many parts of England, is not so certain in France; but the different climates, in different parts of that great kingdom, make strange alterations in its juices. In upper Languedoc they raise great quantities of it, and it makes an extremely fine blue dye for stuffs of all kinds; but, in Brittany, though the plant grows as high, and seems to flourish as well, yet the leaves never are so succulent, and the colour obtained from them is not of so fine a blue, but is dusky and brownish.

This effect of the different climates, in changing the nature of things produced in them, is not confined to plants; but the animal kingdom shares in it. The whole serpent kind are in general larger and more venomous, as we approach the hotter climates. The tarantula, so poisonous in the hot countries, is found greatly less so, as it is found in more cold regions; and the scorpion, whose sting is fatal in some parts of Africa, is little more mischievous than the wasp or hornet, in some of the coldest places where it lives. Nay, the Philosophical Transactions inform us, that the bite of the tarantula, even in those very places where most mischievous, does not exert its power in cold weather; but that the person bitten at such a time feels not the effect of the bite till the next sultry hot day, though that may not happen till after two or three weeks.

The differences, made by variety of climates upon plants, are not limited to distance of place, but even in the same province the climate differs greatly in different years, by means of accidents, and more or less heat; and more or less moisture will do as much violence to plants sometimes, as change of place, which only operates by means of the same agents. Our farmers complain of great mischiefs, from long droughts; and the French husbandmen, in many of the provinces, always find, that when there has fallen very much rain, or thick fogs have been very frequent, all the bread-corn of every kind degenerates; the wheat and barley are poor and thin in the ear, and the grain small; but the rye becomes so altered, that it is pernicious to use it in making of bread; and the poor, who are obliged to eat the bread made with it, are subjected to many diseases by it. They call the rye thus vitiated ergot, and blé cornu. *Dressand's Trait. Phys.*

TENCH, the English name of the tinca of the modern authors, the fullo and gnapheus of the ancients.

It is, according to the Artedian system, a species of the cyprinus, and distinguished by that author by the name of the blackish, mucous, or slimy cyprinus, with the end of the tail even.

This is a delicately tasted fish, though it lives in foul water, and seems to feed very coarsely. It is always found in the muddiest parts of ponds, and where there are most weeds.

The slime of the skin of this fish is said to be of a healing nature, and to cure all fresh wounds; and it is pretended that the other fish know this property in it, and always apply to the Tench when wounded. Whether their opinion be true or false, the Tench has obtained by it the name of the fishes physician. The pike is said to pay such respect to this fish, on this account, that he never seizes him. But these are things easier to be fancied and said than proved; and, if it should prove that the pike does not eat the Tench, it may be resolved into a much more natural cause, by supposing the slime of the Tench too disagreeable in his stomach to suffer it.

The season for angling for Tench is in June, July, and August. The time of their biting is early in the morning, or late in the evening, and, in hot weather, all night long. The favourite bait for the Tench is a large red worm, and they will take this much more greedily, if it be dipped in tar, after it is put on the hook. There are several sorts of paste also that he bites very well at, particularly one made of brown bread and honey, with an admixture of tar. All pastes that have any of the strong-scented oil in them, are also good baits. Other baits are the cad-worm, lob-worm, flag-worm, green-gentle, marsh-worm, or soft-boiled bread-corn. All these will do very well at a proper season.

When a number of Tench are to be taken out of a muddy pond, where they will not bite freely at the hook, the method is to take a very good and large casting-net, well leaded, and with the meshes from the crown to a full yard and an half, not too small; for then, if the pond be deep, the fish will strike away before the net gets to the bottom. The place where the net is intended to be thrown, must be made clean from bushes and large weeds, with a rake. When the place is thus cleared of any obstacles to the even descent of the net, a bait is to be prepared to draw the fish together, where the net is to be thrown. This bait is to be thus made: put a quarter of a peck of wheat into three quarts of water, send it to an oven, and let it be well soaked; then add to it five pints of blood, and as much bran as is necessary to give it the consistence of a paste. Mix some clay with it, that it may the better hold together; and, finally, add a quart of lob-worms chopped to pieces. Let the whole be wrought up into a stiff paste, and rolled into balls of the size of a hen's egg; and let these be thrown into the pond, in the place where the net is to be thrown. At times these, and at times some grains, are to be thrown in; and the place in this manner thoroughly baited for several days. When the fish may be supposed to

be

be very well acquainted with the spot, let a very good baiting be given in the morning, and in the close of the evening let the casting-net be carefully thrown in. When the net is sunk, the mud all about is to be stirred up with a long pole, with a fork at the end; the net is to lie half an hour, and the mud to be thus stirred all the time; by this means the Tench will be raised, and will be taken in the pulling out the net; but, if the net were to be thrown in and taken out in the common way, there would hardly be one fish taken; for the custom of both Tench and carp, when they are frighted, is to plunge their heads up to eyes in the mud, and thus placed, with their tails erect, any net in the world must draw over them, without a possibility of its entangling them.

TE'NTER (*Dict.*)—It is usually about four feet and a half high, and for length exceeds that of the longest piece of cloth.—It consists of several long square pieces of wood, placed like those which form the barriers of a manege, so, however, as that the lower cross piece of wood may be raised or lowered, as is found requisite, to be fixed at any height, by means of pins.—Along the cross-pieces, both the upper and under one, are hooked nails, called Tenter-hooks, driven in from space to space.

To put a piece of cloth on the TENTER; while the piece is yet quite wet, one end is fastened to one of the ends of the Tenter; then it is pulled by force of arms towards the other end, to bring it to the length required: that other end being fastened, the upper list is hooked on to the upper cross-piece, and the lowest list to the lower cross-piece, which is afterwards lowered by force, till the piece have its desired breadth.—Being thus well stretched, both as to length and breadth, they brush it with a stiff hair-brush, and thus let it dry.—Then they take it off; and, till they wet it again, it will still retain the width and breadth the Tenter gave it.

TE'PID, in natural history, a term used by writers on mineral waters, to express such of them as have a less sensible cold than common water.

They distinguish all the medicinal springs into three kinds; the hot, the tepid, and the cold; but the middle term might easily be understood to mean a great deal more than they express by it; all that have what can be called the least sensible warmth, are called hot; and the tepid are distinguished from the absolutely cold, only by their being less cold.

Some of this class of mineral waters, and some few also of the cold ones, have a sharpish vinous taste, which is never observed in any of the hot ones. This taste is lost on the giving the waters the slightest heat, and is therefore very difficult to be guessed at as to its origin. It is not only found in the aluminous and vitriolate waters, but also in those which are manifestly nitrous, and which abound in sulphureous salts, quite different in their nature from acids. It is therefore an additional somewhat, quite distinct from the saline properties of the fluid, and as easily connected with one kind of that as with the others.

The causes of heat in the mineral waters remain yet wholly unknown, notwithstanding all that has been written concerning them. It is hard to believe, that there are continual subterranean fires near enough the surface, to give a heat that preserves itself in so great a degree to the very place of their eruptions; and it is equally hard to conceive, that there can be beds of fermenting mineral matters, sufficient in quantity and force to have given the same degree of heat to waters for so many ages, as some of our hot springs are known to have subsisted. *Duclos's Exam. des Eaux Miner.*

TEREBI'NTHUS, *the turpentine-tree*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the apetalous kind, being composed of several stamina, furnished with their apices; these are however barren, and the embryo-fruits are produced on other plants of the same species, which produce no flowers. These finally become a capsule, composed of one or two cells, and containing oblong seeds.

TERE'DO, a name given by naturalists to a species of sea-worm, which eats its way into the bottoms of ships, lining the hole it makes with a kind of shelly matter.

The head of this creature is well prepared by nature for the hard offices it is to undergo, being coated with a strong armour, and furnished with a mouth like that of the leech; by which it pierces wood, as that animal does the skin. A little above this it has two horns which seem a kind of continuation of the shell. The neck is as strongly provided for the service of the creature as the head, being furnished with several strong muscles. The rest of the body is only covered by a very thin and transparent skin, through which the motion of the intestines is plainly seen by the naked eye; and, by means of the microscope, several other very remarkable particulars become visible there.

At that part where the intestines end, the tail begins; this is longer than all the rest of the body; it is depressed in the middle, and puffed out on each side, and is joined to the callous part of the lower end of the body in an irregular manner, so that there is an intermediate void space left between: this occupies the middle part between what the natural historians call two soleæ-form fins. This creature is wonderfully minute, when newly excluded from the egg, and at its utmost bigness is a foot long; three or four inches is however its more frequent length.

The skin of this little animal being stripped off, the heart, stomach, and intestines come plainly in view, as also the callous muscles of the neck, and two white ovaries; the heart is composed of two pyramidal vessels.

TERRE *verte*, in the colour trade, the name of a green earth much used by painters, both singly for a good standing green, and in mixture with other colours.

The name is French, and signifies green earth.

It is an indurated clay, of a deep bluish green colour, and is found in the earth, not in continued strata or beds as most of the other earths are, but in large flat masses of four or five feet in diameter; these break irregularly in the cutting, and the earth is generally brought out of the pit in lumps of different sizes. It is of a fine regular and even structure, and very hard. It is of an even and glossy surface, very smooth to the touch, and in some degree resembling the morochthus, or French chalk, but adhering firmly to the tongue. It does not stain the hands in touching it; but, being drawn along a rough surface, it leaves an even white line, with a greenish cast. It does not ferment with acids, and it burns to a dusky brown colour.

It is dug in the island of Cyprus, and in many other parts of France and Italy. That from the neighbourhood of Verona has been used to be esteemed the best in the world; but, of late, there has been some dug in France that equals it. There is also an earth dug on Mendip Hills, in the sinking for coal, which, though wholly unobserved, is nearly, if not wholly, of equal value. *Hill's Hist. of Fossils.*

TERRES'TRIAL *Line*, in perspective, is the line an object is placed or stands upon, of which each object has its particular one, and the whole draught a general one.

The Terrestrial line is always parallel to the horizon. Thus A B (*Plate* XLIV, *fig.* 25. in the Dictionary) is the Terrestrial line, being parallel to D C, the horizontal line. Its use is to determine the lengths and breadths. Thus the visual lines A E, B E, meeting in the point E, determine the dimensions of a figure equal in length or breadth to A B, when it is removed to any distance from A B towards the point E.

TER'TIUM *Sal*, a third salt, a term used in chemistry to express a salt resulting from the mixture of an acid and an alcali, which partakes so of the nature of both, as to be itself neither acid, nor alcali, but neutral.

TEST *Liquor*, a term used by our dealers in brandies, &c. for a liquor which they use as the Test of brandy, &c. to prove whether they be genuine, or mixed with home spirit.

The people who use this, place great confidence in it, but it is really a very vague and uncertain thing. They pretend, that this liquor will shew by the colour which it makes, on being poured into brandy, whether it be genuine and unadulterated; or, if not, in what proportion the adulterating spirit is mixed with it.

The whole fact is this: if a little common green or white vitriol be dissolved in some fair water, it makes a Test liquor; a few drops of which, being let fall into a glass of old French brandy, will turn the whole to a purple, or fine violet colour; and, by the strength or paleness of this colour, the dealer judge the brandy genuine or mixed, in different proportions, with home spirits.

Old French brandy, having long lain in the cask, takes a dilute tincture of the wood of the cask, that is, of oak; and this, being of the same nature with a solution or tincture of galls, naturally turns bluish or blackish with vitriol. A new distilled brandy, though wholly foreign, would not give this Test; and a common malt-spirit, with oak chips infused in it, will turn as dark as the finest brandy. While our distillers indeed had nothing in use for the colouring their spirits but burnt sugar, it was possible to make some guess at an adulteration with them, because the brandy, in this case, would not become blackish in proportion to its former colour, the sugar-colour not turning to ink with the vitriol like the other: but our distillers have of late found a way of using an extract of oak for the colouring of their spirits, and, since that, this Test liquor is of very little use, our common spirits, of any kind, turning as deep with it as the foreign brandies.

The very best way of making this Test liquor is with a calcined vitriol of iron, dissolved in a dilute or aqueous mineral acid. The liquor, when well made in this manner, is of a fine yellow colour, and will give, for a time, the finest blue to any spirituous tincture of oak.

The English were, at one time, very fond of high-coloured brandies, and it was then that the use of this Test-liquor was most esteemed; afterwards we, as well as other nations, finding that this colour was only owing to the cask, began to dislike it, and to favour the pale brandies; at length we fell into the use of such as were wholly limpid and colourless, and the redistilling of all the old brandies people were possessed of took place; on this, the Test liquor was found to be of no use at all, and accordingly rejected; but as we are of late again come into the esteem of coloured brandies, and that with great justice, as the colour, when genuine, is a certain mark of the age of the liquor, this Test liquor is again got into more credit than it deserves.

The famous Helvetian styptic depended wholly on this accident for its colour; and it was no small mortification to our chemists, when, some years ago, it was introduced into use among us, that they could not make it with our own spirits, but must be at the expence of true French brandy for it; our own spirits, though equally coloured, would never make that violet tincture, because their colour was owing to burnt sugar, not a tincture of oak. At length this mystery was explained, and a little scrapings of galls made all those quantities of this styptic, which had been set by as good for nothing, perfectly fine, and well coloured. *Shaw's Essay on Distillery.*

TETRADECARHO'MBIS, in natural history, the name of a genus of fossils, of the class of the selenitæ.

The word is derived from the Greek, τετρας four, δεκα, ten, and ῥομβος, a rhomboidal figure, and expresses a rhomboidal body consisting of fourteen planes.

The characters of this genus are, that the bodies of it are exactly of the same form with the common selenitæ; but that in these each of the end planes is divided into two, and there are by this means eight of these planes, instead of four. *Hill's Hist. of Foss.*

TETRADYNA'MIA *, in botany, a class of plants, whose flowers have four of their stamina of more efficacy than the rest: these are always known by leaving the four efficacious stamina longer than the rest. See *Plate* XLIII. *fig.* 5.

* The word is formed of the Greek τετρας, four, and δυναμις, power. Of this class of plants are scurvy-grass, mustard, radish, &c.

TETRA'NDIA *, in botany, a class of plants which have hermaphrodite flowers, with four stamina or male parts in each. See *Plate* XL. *fig.* 4.

* The word is formed of the Greek τετρακις, four times, and ανηρ, male. Of this class of plants are the teasel, madder, plantane, &c.

TETRAPYRAMI'DIA *, in natural history, the name of a genus of spars.

* The word is derived from the Greek τετρας, four, and πυραμις, a pyramid.

The bodies of this genus are spars influenced in their shape by an admixture of particles of tin; and are found in form of broad-bottomed pyramids of four sides.

Of this genus there is only one known species, which is usually of a brownish colour, and is found in Saxony; as also in Devonshire, Cornwall, and other counties of England, where there is tin. *Hill's Hist. of Foss.*

TEU'CRIUM, *tree-germander* in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, and is of the labiated kind; the stamina supplying the place of the upper lip; the lower lip is divided into five segments, the middle one being largest and hollowed like a spoon; the others standing overagainst one another in the neck of the flower. The cup is bell-fashioned, and from it arises a pistil which is fixed in the manner of a nail to the hinder part of the flower, and is surrounded by four embryoes, which afterwards become four roundish seeds, and ripen in the bell-shaped cup of the flower.

TFU'OI, in the Chinese manufactory of porcelaine, a word used to express a particular sort of varnish for that ware with violet colour and gold. The usual method of doing this, at first, was by mixing gold with the common varnish, breaking the leaves very small, and then adding the common blue and the powder of calcined agate of a coarse kind, found in great plenty on the shores of their rivers. But they have since found, that the brown varnish called tsekin succeeds greatly better; for, when the blue is mixed with this, its brown colour is lost, and the gold lies on much better than it would any other way.

They had once a method of a varied varnish, which was very beautiful, but is much neglected now; this was the giving a vessel the brown varnish on the outside with a large portion of gold, and the common white varnish within. They also varied the degree of colour on the outside, by laying on more or less of the varnish; and gave this way a variety, even in the same colour. *Observ. sur les Coutumes de l'Asie.*

THA'LAMUS, in botany, a term used to express that part of the flower in the capitated, or flosculous flowered plants, where the embryo fruits of every separate floscule are lodged, and where afterwards the seeds are contained. This is the bottom of the cup, in the central part of which it adheres to the stalk.

THALI'CTRUM, *meadow rue*, in botany the name of a genus of plants. The characters of which are these: the flower is of the rosaceous kind, being composed of several petals arranged in a circular form. The pistil arises from the center of the flower, and is surrounded by a vast congeries of stamina. This finally becomes a fruit composed of several capsules gathered into a sort of head; these are sometimes alated, and sometimes plain, and each of them contains one oblong seed.

THALLO'PHORI, Θαλλοφοροι, in antiquity, the old men and women, who, in the procession of the festival Panathenæa, carried olive boughs in their hands. *Potter, Archæol. Græc.*

THALY'SIA, Θαλυσια, in antiquity, a sacrifice offered by the husbandmen after harvest. *Potter, Archæol. Græc.*

THA'PSIA, in botany, the name of a genus of plants, the characters of which are these: the flowers are disposed in umbels, and are of the rosaceous kind, being composed of several petals, disposed in a circular order on a cup, which afterwards becomes a fruit composed of two long striated seeds, surrounded with a foliaceous edge, and from both sides emarginated inwards.

THARGE'LIA, Θαργηλια, in antiquity, an Athenian festival, in honour of the sun, and his attendants the hours; or, as others think, of the Delian Apollo and Diana. *Pot. Arch. Græc.*

THARGE'LION, Θαργηλιων, in chronology, the eleventh month of the Athenian year. It continued thirty days, and answered to the latter part of our April, and the beginning of May.

THE'ATINES, an order of nuns, under the direction of the Theatins.

There are two kinds of Theatines, under the title of sisters of the immaculate conception, who form two different congregations, the one engaged by solemn vows, and the other only by simple vows. — Their common foundress was Ursula Benincasa. Those who make the simple vows are the most ancient, and are called absolutely Theatines of the congregation: they had their rise at Naples, in 1583.

The others are called Theatines of the hermitage: the whole business of these is praying in retirement, and an austere solitude, to which they engage themselves by solemn vows.

The Theatines of the first congregation take care of the temporal concerns of these last. Their houses stand together, and communicate by a large hall. Their foundress drew up their constitutions, and laid the foundation of their house at Naples, but died before it was finished.

Gregory the XVth, who confirmed the new institute under the rule of St. Augustin, appointed that they should be under the direction of the Theatins. Urban VIII. revoked this article by a brief in 1624, and subjected them to the nuncio of Naples; but Clement IX. annulled this brief, and submitted them anew to the Theatins by a brief in 1668.

THE'ATINS, a religious order of regular priests, thus called from their first superior Don John Pietro Caraffa, archbishop of Chiesi, in the kingdom of Naples, which was anciently called Theate.

The same archbishop was afterwards pope, by the name of Paul IV, after having been a companion of Gaëtan, a Venetian gentleman, the first founder of this order, at Rome, in 1524.

The Theatins were the first who assumed the title of regular clerks. They have not only no lands, or fixed revenues, either in common or in propriety; but they do not even ask or beg any thing; but wait for what providence shall send them for their subsistance.

They employed themselves much in foreign missions; and in 1627 entered upon Mingrelia, where they have an establishment: they have had the like in Tartary, Circassia, and Georgia, which they have since abandoned, by reason of the little fruit they perceived thereof.

Their first congregation appeared at Rome in 1524, and was confirmed the same year by Clement VII.—Their constitutions were drawn up at a general chapter in 1604. and approved by Clement VIII.—They wear the priests habit.

THE'MIS, in astronomy, a name given by some to the third satellite of Jupiter.

THEO'DOLITE, *(Dict.)*— This instrument is now commonly made use of by surveyors. One of the best of the kind seems to be Mr. Sisson's latest improved Theodolite.

In this instrument the three staves, by brass ferrils at top, screw into bell-metal joints, moveable between brass pillars, fixed in a strong brass plate, in which round the center is fixed a socket with a ball moveable in it, and upon which the four screws press that set the limb horizontal. Next above is such another plate, through which the said screws pass, and on which round the center is fixed a frustum of a cone of bell-metal, whose axis, being connected with the center of the ball, is always perpendicular to the limb by means of a conical brass ferril fitted to it, whereon is fixed the compass box, and on it the limb, which is a strong bell-metal ring, whereon are moveable three brass indexes, in whose plate are fixed four brass pillars, that joining at top hold the center-pin of the bell-metal double sextant, whose double index is fixed in the center of the same plate. Within the double sextant is fixed the spirit level, and over it the telescope.

The compass-box is graved with two diamonds for north and south, and with twenty degrees on both sides of each, that the needle may be set to the variation, and its error also known.

The limb has two flour-de-luces against the diamonds in the box, and is curiously divided into whole degrees, and numbered to the left hand at every 10°. to twice 180°, having three indexes (with Nonius's divisions on each for the decimals of a degree) that are moved by a pinion fixed below one of them without moving the limb, and in another is a screw and spring under, to fix it to any part of the limb: it has also divisions numbered for taking the quarter girt in round timber; to which a shorter index is used, having Nonius's divisions for the decimals of an inch; but an abatement must be made for the bark, if not taken off.

The double ſextant is divided on one ſide from under its center (when the ſpirit-tube and teleſcope are level) to above 60 degrees each way, and numbered at 10, 20, &c. And the double index (through which it is moveable) ſhews on the ſame ſide the degree and decimal of any altitude or depreſſion to that extent, by Nonius's diviſions; on the other ſide are diviſions numbered for taking the upright height of timber, &c. in feet, when diſtant ten feet, which at twenty muſt be doubled, and at thirty trebled; and alſo the quantities for reducing hypothenuſal lines to horizontal: it is moveable by a pinion fixed in the double index.

The teleſcope is a little ſhorter than the diameter of the limb, that a fall may not hurt it; yet it will magnify as much and ſhew a diſtinct object as perfect, as moſt of treble its length; in its focus are very fine croſs wires, whoſe interſection is in the plane of the double ſextant, and this is a whole circle, and turned in a lathe to a true plane, and is fixed at right angles to the limb; ſo that whenever the limb is ſet horizontal (which is readily done by making the ſpirit-tube level over two ſcrews, and the like over the other two) the double ſextant and teleſcope are moveable in a vertical plane, and then every angle taken on the limb (though the teleſcope be never ſo much elevated or depreſſed) will be an angle in the plane of the horizon; and this is abſolutely neceſſary in plotting an horizontal plane.

THE'RAPHIM or *Teraphim* (*Dict.*) — We meet with this word thirteen or fourteen times in ſcripture, where it is commonly interpreted idols: but the rabbins are not contented to have it ſimply ſignify idols, but will have it denote a peculiar ſort of idols or images for the knowledge of futurity, i. e. oracles.

R. David de Pomis obſerves, that they were called Theraphim, from רפה, raphah, to leave, becauſe people quitted every thing to conſult them.—He adds, that the Theraphim were in human ſhape; and that, when raiſed upright, they ſpoke at certain hours, and under certain conſtellations, by the influence of the celeſtial bodies. This is a rabbinical fable, which he has learned from Abenezra.

Others hold, that the Theraphim were brazen inſtruments which pointed out the hours and minutes of future events, as directed by the ſtars.—De Pomis corrects Abenezra, ſaying, that, the Theraphim being made under a certain conſtellation, the devil made them ſpeak under the ſame.

R. Eliezer tells us the reaſon why the rabbins will have the Theraphim to ſpeak, and render oracles: it is, ſays he, becauſe it is written, in the prophet Zachary, x. 2. The Theraphim have ſpoken vain things.

The ſame rabbin adds, that, to make the Theraphim, they killed a firſt-born child, clove his head, and ſeaſoned it with ſalt and oil; that they wrote on a plate of gold the name of ſome impure ſpirit, laid it under the tongue of the dead, placed the head againſt the wall, lighted lamps before it, prayed to it, and it talked with them.

Be this as it will, Vorſtius obſerves, that, beſides the paſſage of Zachary juſt quoted, it appears likewiſe from Ezekiel xxi. 22, that the Theraphim were conſulted as oracles.

De Pomis endeavours to ſhew, that the Theraphim, which Michol put in David's bed, were not of this kind, becauſe they were not in the figure of men; but R. Eliezer is of another ſentiment.

As to the manner of making the Theraphim, Vorſtius takes it to be a vain tradition of the rabbins, though R. Tanichuma and Jonathan, in his Targum, Gen. xxxi. 19, relate it after R. Eliezer.—The chief reaſon of his diſbelief is, that Laban who had not quite loſt all notion of the true God, as appears from Gen. xxxi. 53, could not be guilty of ſo great a cruelty: but Vorſtius does not conſider, that the cuſtom might not be leſs real, for its not having been eſtabliſhed ſo early as Laban: and that the Hebrews ſometimes burnt their children to Moloch.

F. Kircher directs us to ſeek the origin of the Theraphim in Egypt; adding, that the word is Egyptian.—Spencer, in his diſſertation on the Urim and Thummim, maintains the word to be Chaldee, and to ſignify the ſame with ſeraphim, the Chaldeans being frequently known to change the ש into ת, that is, *ſ* into *t*. He adds, that thoſe images were borrowed from the Amorites, Chaldeans, or Syrians; and that the Serapis of the Egyptians is the ſame thing with the Theraphim of the Chaldeans. See *Selden de Diis Syriis*, *ſynt.* 1. c. 2.

THESMOPHO'RIA, Θεσμοφόρια, in antiquity, a feſtival in honour of Ceres, which was celebrated by many cities of Greece; but eſpecially the Athenians obſerved it with great devotion and pomp.

THESMOTHE'TÆ, Θεσμοθέται, in antiquity, an appellation given to ſix of the nine Athenian archons; the firſt and chief of the nine was called, by way of eminence, archon; the ſecond in dignity was called baſileus, the third polemarchus, and the other ſix Theſmothetæ.

THE'TA, Θ, among the antients, one of the Greek letters. It was uſed as a mark on the ballots of judges, by which they condemned the perſon to death, it being the firſt letter of the word θάνατος, death. Whence it had the epithet of niger and infelix, thus: O multum ante alias infelix litera Theta.

THE'TES, Θῆτες, in antiquity, the loweſt claſs of people at Athens. Ariſtides repealed Solon's law, by which the Thetes were made incapable of bearing any office in the government. *Potter, Archæol.*

THE'VET, a name of one of the Hebrew months, anſwering to our December moon.

THIRD *Major*. The logarithm or meaſure *a* of the octave $\frac{1}{2}$ being 1.000000, the meaſure of the greater Third $\frac{4}{5}$ will be 0.321928.

The Third major is by practitioners often taken for the Third part of an octave; but this is a great error, ſince three greater Thirds fall ſhort of the octave by a dieſis: For $\frac{4}{5} \times \frac{4}{5} \times \frac{4}{5} \times \frac{125}{128} = \frac{1}{2}$; or by logarithms $3 \times 0.321928 + \log.$ dieſis $= 0.965784 + 0.034215 = 0.999999$ or 1.000000 the logarithm of the octave.

THIRD *Minor*. The logarithm or meaſure of the octave $\frac{1}{2}$ being 1.000000, the meaſure of the Third minor $\frac{5}{6}$ will be 0.263034. Hence, it appears, that four leſſer Thirds exceed the octave. But practical muſicians are apt to ſuppoſe them equal to the octave, as they are apt to confound three greater Thirds with that interval. Three leſſer Thirds exceed the octave by a dieſis and a comma, as it is eaſily proved by logarithms. *Euler. Tent. Nov. Theor. Muſ.* See the article INTERVAL.

THI'STLE, *carduus*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the floſculous kind, being compoſed of ſeveral floſcules, which, at the upper end, are divided into ſegments, and ſtand upon the embryo ſeed. The general cup which contains theſe floſcules is of a prickly ſtructure, and the embryoes finally become ſeeds winged with down.

THISTLE *Fly*, in natural hiſtory, a ſmall fly produced from a fly-worm, hatching in the protuberances of the carduus hæmorrhoidalis. In the protuberances of this Thiſtle, while they are cloſed in all parts, the worm of this fly, from whoſe injuring it, at the time of depoſiting the egg from which it was hatched, the protuberances aroſe, undergoes its laſt transformation. It here makes of its own ſkin a ſhell, in form of an egg, within which it puts on the nymph ſtate. When this nymph becomes a living fly, the leaſt part of its difficulty is the finding its way out of this ſhell; it has a much ſtronger priſon than that, and before it can obtain its liberty, muſt force its way through the much more cloſely compacted fibres of the protuberance of the vegetable. It has, however, no other means of doing this difficult and laborious work, but that of inflating its head, and throwing out the bladder or muzzle with which all theſe creatures are, by bountiful nature provided in this ſtate.

This is a difficult operation, and many of the creatures periſh in the attempt; but, what much forwards the ſucceſs of it, in many caſes, is, that the ſtalk of the Thiſtle often becomes naturally half rotten before the time of the fly's egreſs. *Reaumur, Hiſt. Inſ.*

Order of the THISTLE (*Dict.*)—The legend is, that, a croſs of St. Andrew (the patron of that kingdom) appearing to him at the time of the engagement, he bleſſed the happy augury, took the figure thereof into his ſtandard in honour of his protector, and inſtituted an order of knights whoſe collar is of gold interwoven with Thiſtle flowers, and ſprigs of rue.

From the collar hangs a medal, on which is the image of St. Andrew with his croſs on his breaſt; with this motto, Nemo me impune laceſſet, Nobody ſhall provoke me unpuniſhed.

Others give a different account of its origin, and aſſure us, it was inſtituted after the concluſion of a peace between Charles VII. of France and the king of Scotland.

The abbot Juſtiniani goes up higher, and will have it to have been inſtituted by Achaius I, king of Scotland, in 809; who, after an alliance made with Charlemaign, took for his device the Thiſtle, with the words Nemo me impune laceſſet, which, in effect, is that of the order: he adds, that king James IV. renewed the order, and took St. Andrew for his protector.

The order only conſiſts of twelve knights, beſides the king, who is the chief, or ſovereign. Their ordinary badge is a green ribbon, to which hangs a Thiſtle of gold, crowned within a circle of gold, in which is the foreſaid motto.

Our Lady of the THISTLE, was alſo a military order inſtituted, in 1370, by Louis II, duke of Bourbon. — It conſiſted of 26 knights, whereof that prince and his ſucceſſors were the chiefs: their badge was a ſky-blue girdle; and, on ſolemn occaſions, a mantle of the ſame colour, with a gold collar, interwoven with flower-de-luces, among which was the word eſperance, hope, in capitals.

THI'MBLE-*making*. This art was brought from Holland, by Mr. John Lofting, a Dutchman, in 1695, who ſet up a work at Iſlington, and practiſed it with ſucceſs.

Thimbles are made of ſhruff, or old hammered braſs, the beſt being too dear, and the ordinary too brittle.

This they melt and caſt in a ſort of ſand, gotten only at Highgate, with which and red okre are made mould and cores, and in them they uſually caſt ſix groſs at a caſt, and about ſix or ſeven of theſe caſts in a day. They are caſt in double rows, and, when cold, taken out and cut off with greaſy ſhears.

Then boys take out the cores from the inſide with a pointed

piece

piece of iron, which cores were made by them, every core having a nail with a broad head in it, which head keeps it from the mould, and makes the hollow to caſt it in.

This done, they are put into a barrel as they do ſhot, and turned round with a horſe, till they rub the ſand one from another.

Thus far the foundery, in which are employed ſix perſons: firſt, the founder and two men make the moulds ready. Secondly, two boys make cores, for each Thimble one. Thirdly, one that blows the bellows. From hence they are carried to the mill to be turned.

Firſt, the inſide, which works with an inſtrument to the bottom, while its hold laſts, and flies back, when let looſe. Secondly, the outſide, which with a coarſer engine called a rough turning is made pretty ſmooth at one ſtroke; and afterwards with a finer engine both the ſide and bottom are at one ſtroke made very ſmooth.

Then ſome ſaw-duſt or filings of horn-combs are put half way into each Thimble, and upon it an iron punch, and then, with one blow againſt a ſtudded ſteed, the hollow of the bottom is made.

After this with an engine the ſides have the hollow made, and in this engine is their chief ſecret, and they can work off with it thirty or forty groſs in a day.

This done, they are again poliſhed on the inſide.

Then the rim, whether a ſingle or double one are turned at one ſtroke, and all theſe turnings are performed with five men and three boys.

After this, they are again turned in the barrel with ſaw-duſt or bran to ſcour them very bright, and ſo they are complete Thimbles.

Thus finiſhed, they are ſorted, and put ſix together one in another; and ſix of theſe ſixes are wrapped up in a blue paper, and four of theſe papers, making a groſs, are wrapped up in another blue or brown paper, and tied with a packthread, which makes them almoſt a ſquare, and are ſold by the firſt maker at four or five ſhillings the groſs.

The charge of this work per annum is much about 700 l. and there has been made, one week with another, about 140 groſs, which makes 7280 groſs, or 1048320 Thimbles, which at four ſhillings the groſs amounts to 1456 l. Out of this a great deal goes for the ſhruff they are made of, a groſs of Thimbles weighing about twenty-four or twenty-eight ounces.

THLA'SPI, *treacle muſtard*, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts of four leaves, and is of the cruciform kind. The piſtil ariſes from the cup, and finally becomes a roundiſh fruit, of a flatted ſhape, and uſually terminated all round with a foliaceous edge ſplit at the extremity, and divided by an intermediate membrane into two cells, which uſually contain a number of flat ſeeds. To theſe marks it is to be added, that all the Thlaſpi's have whole, not divided leaves, in which they evidently differ from the naſturtium, or creſs kind.

THLASPI'DIUM, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts of four leaves, and is of the cruciform kind. The piſtil ariſes from the cup, and finally becomes a ſort of double fruit, flat, and compoſed of two parts ſeparated one from the other by an intermediate membrane, and each containing uſually one long-ſhaped flatted ſeed.

THOUGHTS, in a boat, a name given by ſeamen to the benches on which the men ſit down to row.

THOWLES, in a boat, are thoſe pins in its gunnel, between which the men put their oars, when they row.

THRA'NITÆ, in the Roman trireme gallies, or thoſe which had three rows of rowers; thoſe of the upper row were called by this name, the ſecond the zygitæ, and the loweſt thalamitæ.

THRAUSTO'MICTHES *, in natural hiſtory, the name of a genus of compound earths.

* The word is derived from the Greek θραυστός, brittle, and μικτός, mixed.

The bodies of this genus are loams compoſed of ſand and a leſs viſcid clay, and are therefore of a friable or crumbly texture.

THREAD.—The Thread of the Laplanders is very fine, white, and ſtrong, but it is of a very different nature from ours; they know nothing of flax or hemp, nor of any other plant whoſe ſtalks might ſupply the place of theſe in making Thread, but theirs is made of the ſinews of the rain-deer. They kill of theſe animals a very great number continually, partly for food, partly for the ſkins which they uſe in cloathing themſelves, covering their huts, and on many other occaſions; the ſinews of all that they kill are carefully preſerved, and delivered to the women, whoſe province it is to prepare this neceſſary matter. They beat the ſinews very well, and after having ſteeped them a long time in water, and then they ſpin them out.

The Thread they thus make is of any degree of fineneſs they pleaſe; but it never is any longer than the ſinew from which it is made. They uſe this in ſewing their cloaths, ſhoes, gloves, &c. and the trappings of their rain-deer. The Threads of the ſame ſinew are laid up together, and are all of a length; and, as the different ſinews afford them of very different lengths, they accordingly pick out ſuch as the preſent uſe requires, both in regard to length and fineneſs. This ſort of Thread is made with much more labour than ours; but it is greatly ſuperior to it on many occaſions, where ſtrength is rather required than beauty.

Theſe people have, beſides this, a way of making a ſort of yarn of ſheep's wool, which they weave into garters, and a ſort of ribbons, uſed by way of ornament; but they place no value on it, becauſe of its want of ſtrength. *Scheffer's Hiſt. of Lapland.*

THU'YA, *tree of life*, in botany, the name of genus of trees, the characters of which are theſe: the embryo fruits are of a ſquammoſe ſtructure, and finally become a ſort of oblong fruit, between the ſcales of which there lie a ſort of marginated ſeed. To this it is to be added, that the leaves are ſcaly.

THY'IA, Θυΐα, in antiquity, a feſtival in honour of Bacchus, celebrated by the Eleans. *Potter, Archæol. Græc.*

THY'MALLUS, in ichthyology, the name of a fiſh of the truttaceous kind, called in Engliſh the greyling or umber.

It is of a long and flatted body, the belly is ſomewhat broad, and the back rigid and thin. It ſeldom exceeds a pound, or at the utmoſt a pound and half weight. Its back is of a duſky browniſh green, with a ſomewhat bluiſh caſt intermixed, and its ſides of a more ſhining gloſs with an admixture of gold colour. The ſcales are of a ſort of rhomboidal form, and the ſide-lines are much nearer the back than the belly. The ſides are variegated with black ſpots placed irregularly, but there are none of theſe near the tail. The back has two fins, and the tail is forked. The head is ſmall, the eyes large and protuberant; the mouth is moderately large, and the upper jaw larger than the under; it has no teeth, but the whole jaws are rough like a file.

It is caught in the freſh rivers in the mountainous counties of England, and in the like ſituations in Germany and other kingdoms, and is one of the fineſt-taſted of all the freſh-water-fiſh. It feeds on worms, and ſpawns in May.

THY'MBRA, in botany, the name of a genus of plants, the characters of which are theſe: the flowers and ſeeds are in all reſpects like thoſe of thyme, but that they are placed verticillately round the ſtalks.

THY'NNIA *, Θύννια, in antiquity, a ſacrifice offered to Neptune by the fiſhermen, after a plentiful draught.

* The word is derived from θύννος, a tunny, that being the ſacrifice offered.

THY'NNUS, in ichthyography, the name of a fiſh, called in Engliſh the tunny, or Spaniſh mackarel, common in the Mediterranean, and other ſeas, and ſometimes, though not frequently, caught on the Engliſh coaſts.

It is a very large fiſh, growing ſometimes to ſeven or eight feet long, and more than an hundred weight. It is of a rounded and thick body, growing gradually ſmaller towards the tail, until it is at length extremely ſlender. It very much reſembles the pelamis in its whole figure, but that it wants the oblong black ſtreaks which that fiſh has on its ſides, and is much larger. The back is black, or, if held in ſome lights, is of a ſhining bluiſh or greeniſh hue. Its belly and half its ſides are of a ſilvery whiteneſs. Its ſcales are very ſmall, its ſnout pointed. Its jaws both of equal length, and armed each with one row of teeth. The mouth is large and black within, except that part of the palate is red. The eyes are large. The larger black fins are two in number; the foremoſt placed near the head, and riſing out of a cavity in the back, and the other at a ſmall diſtance behind that; and, in ſome fiſh of this ſpecies, of a reddiſh or yellowiſh colour; and, behind this laſt, there are eight, nine, or ten ſmall fins running down the ridge of the back, at equal diſtances to the tail. The tail is very forked. The fins at the gills are black, ſmall, and terminate in a point. The belly fins are placed but at a ſmall diſtance behind theſe, and are alſo ſmall; and both theſe, and the gill-fins, have ſinuſes in the body of the fiſh, into which they may be depreſſed. Behind the anus is a fin like that on the back, and behind it eight more ſmall ones, anſwering to thoſe on the back alſo; and the ſkin of the ſides, near the tail, is extended into two fins; ſo that this part of the fiſh looks in ſome ſort ſquare. It is a good fiſh for the table, and is ſalted in vaſt quantities in Spain and Italy.

THY'OS, Θύος, in antiquity, an offering of fruits, leaves, or acorns, which were the only ſacrifices at firſt in uſe. *Potter, Archæol. Græc.*

TIBERIA'DES *Water*, the water of a hot ſpring near Tiberiades in Egypt. Dr. Perry, when on the ſpot, tried ſome experiments on this water, which give us a much better idea of its nature, than we have from any other accounts of it. Half a drachm of oil of tartar being mixed with an ounce and half of the water, it becomes turbid and muddy; and, after twelve hours, three parts of the whole appear like white wool, only leaving a ſmall portion of clear water at the top. This white woolly matter, dried, produced only a ſmall quantity of yellow ochre.

Spirit of vitriol added to the water in the ſame quantity, affords a large unctuous ſediment of a white colour. A ſolution of ſublimate being mixed in the ſame quantity, it became turbid and yellowiſh, and yielded an earthy ſediment in a ſmall quantity; whence it ſeems evident, that it contains a ſal murale.

Saccharum faturni being added in the fame quantity, the water depofited a lateritious fediment in a fmall quantity. Mixed with fpirit of fal armoniac, it turns to a bluifh green turbid liquor, and finally yields a woolly fediment. Sugar of violets, mixed with it, turned it to a yellowifh colour; and the fcrapings of galls, mixed with it, turned it to a deep purple; and on fhaking this became as black as ink.

It appears from thefe experiments, that the water contains a good deal of a grofs fixed vitriolic falt, fome alum, and a fal murale. It is too falt and naufeous for internal ufe; but it muft be of ufe as a bath in all cutaneous foulneffes, efpecially in fcorbutic and leprous cafes; for it will powerfully deterge, fcour, and cleanfe the excretory pores, and it may, by its weight and ftimulus, reftore them to their natural ftate and tone, and reftore the true ftate of the vitiated folids in general. *Philof. Tranf.* N°. 462.

TI'BICEN, in zoology, a fifh of the cuculous kind, called by many authors lyra, or the harp-fifh; and, in fome parts of England, the piper.

TIES, aboard a fhip, are thofe ropes by which the yards do hang; and, when the halliards are ftrained to hoife the yard, thefe Ties carry them up.

TI'FFE *de mer*, in natural hiftory, a name given by Count Marfigli to a fpecies of fea plant, commonly but erroneoufly reckoned among the fpunges, and called by authors a branched fpunge. This author has called it by this name from its refemblance to the heads of the typha paluftris, or cat's tail, when ripe in the month of September.

TI'GRIS, *the tyger or tiger*, in the Linnæan fyftem of zoology, makes a diftinct genus of the quadruped clafs; the characters of which are, that it has four paps placed near the navel, and feet adapted to climbing. The author takes in the panther to this genus, and diftinguifhes the tyger by the name of Tigris maculis oblongis, and the panther by that of Tigris maculis orbiculatis. *Linnæi Syftem. Naturæ.*

The tyger has its name from its fuppofed fwiftnefs, and has been defcribed by almoft all authors as one of the fwifteft of all the wild carnivorous animals; but this has been wholly contradicted by fuch authors as have feen the creature, who all declare that it is a flow and fluggifh animal, and is unable to overtake a man, or almoft any animal that has an opportunity of running away from it. It will give two or three large leaps; but, if it do not feize its prey in thefe, is but ill qualified to catch it afterwards. *Ray. Syn. Quad.*

It exceeds the lion in fize, and is of an unconquerable fiercenefs. It agrees with the panther in the variegation of its colours, but differs in the difpofition of them; for in the panther the colours are difpofed in round fpots or eyes, and in the tyger they are difpofed in long ftreaks.

The Tyger is found in the Eaft-Indies, in many parts of Afia, and in America: but there feems fome difference in fpecies between the Afiatic and American tygers, and poffibly fuller obfervation may prove, that the Afiatic are fwift as the ancients have defcribed them, and the American ones, of the flownefs of which we have accounts, may be a different fpecies.

The manner of carrying off the young brood of this animal is defcribed by Pliny as follows: The Hircanians and Indians bring up the Tyger, fays he, an animal of a dreadful fwiftnefs, which is moft put to the proof, when going to be taken. The whole brood, which is always very numerous, is carried off upon a horfe, as fwift as poffible, and often removed to a frefh one. When the mother tyger finds the neft empty, and the brood gone, for the males take no care of them, fhe traces the fcent with furious fpeed; and when fhe is arrived within hearing of the perfon who is carrying off her young, he throws down one of them; this fhe takes up in her mouth, and, as if made more fwift by the load, carries it back, and then, returning, is treated in the fame manner till the perfon gets on board a fhip, and leaves her to vent her rage on the fhore.

TI'LIA, *the lime-tree*, in botany, the name of a genus of trees, the characters of which are thefe: the flower is of the rofaceous kind, and is compofed of feveral petals, arranged in a circular form. The piftil arifes from the cup, and finally becomes an unicapfular hufk, containing oblong feeds.

TILLS, a name given by our farmers to the lentil, a kind of pulfe propagated in fome parts of the kingdom; they are the fmalleft of all pulfe. They require but an ordinary ground, but they produce a vaft quantity, though they lie in a fmall compafs. They make a fine fweet fodder, and are the beft of all things of this kind, for calves, or any other young cattle. They are alfo the beft of all forts of food for pigeons. *Mortimer's Hufbandry.*

TI'LLAGE. The term Tillage, in its proper fenfe, fignifies the opening, breaking, and dividing the ground by the fpade, the plough, the hoe, or other inftruments which divide it by attrition, as the addition of dung does by fermentation. See AGRICULTURE.

TIMBER (*Dict.*) — The ufes of Timber are fo many and fo great, that the procuring a fufficient fupply of it extremely well deferves the care of every ftate, as it muft be a great difadvantage to it to be obliged to have recourfe to its neighbours, and purchafe, at a very confiderable and continually renewed expence, what might, by an eafy œconomy, be fufficiently fupplied at home.

This œconomy, however, muft be applied in time; for natural indolence, our love to reap the advantages of every thing ourfelves, and our little care for pofterity, give great room to fear fucceeding ages will want wood, both for private and public exigencies. All our art fhould be employed on this fubject with two views: the one, to preferve and cherifh our growing wood; the other, to renew the trees which have been and are continually cut down.

The quantity of acorns, that the oak bears, has made many people fuppofe, that nature has taken care for a renewal for us, and that, of this vaft quantity of feeds which annually fall, there will be always an over-fufficient fupply of young trees, which will grow up in the place of the old ones: but experience proves, that this is by no means the cafe. The greater number of thefe fallen acorns are devoured by a number of different animals, for whofe nourifhent nature has provided that abundance of them: and, of thofe which efcape this fate, we are to confider how few can come to good, from the natural accidents they are unavoidably expofed to; they fall on a covered ground, where dead leaves, and decayed parts of branches of trees, ufually prevent their touching the earth, into which they are to fhoot; or, if they can fhoot here, it is merely from the furface, where they are, in their flow growth, liable, while very tender, to all the inclemencies of frofts; add to this, that it is very difficult for fuch tender plants, as the young feedlings of thefe, to find room for growth or nourifhment among the every-way-fpreading roots of other trees; and the continual fhade, and the want of free air, muft render them very weakly and irregular in their growth, even fuppofing them to get over all the other difficulties.

It is very certain, that Timber-trees of oak are frequently met with among the underwood of forefts; but we fhall always find this to be the cafe, not in the clofe places but on certain fpots where there has been a vacancy or opening; and that, ufually, where there are not, nor have at any time been, oaks in the neighbourhood of the fpot. The acorns that fall from the oaks ufually come to nothing, from the beforementioned accidents; and thefe trees, which grow at diftances, are owing to the acorns brought thither by birds, and accidentally dropped there. This is an inftance familiarly verified by obferving, that there are frequently little bufhes near woods, which, tho' of white-thorn, or other trees, are ufually furrounded and ornamented with young oaks; the jays and the like granivorous birds are the authors of this crop; for, bringing the acorns from the adjoining woods, to eat under thefe bufhes, they drop many by the way, which they do not trouble themfelves to look for on the ground, and which, having here a freer ground to take root, and an open air to grow in, feldom fail of coming to good, unlefs deftroyed, while young.

In order to the preferving our growing Timber-trees, it would be a very ufeful law, that all, who cut down any number of oaks, fhould alfo leave a given number in good condition for after-cutting; and that no Timber fhould be cut down, but at a proper age, in regard to the nature of the foil; fince it is certain, that trees grow to their perfection at very different periods of time, in proportion to the depth of foil they have to grow in; and that, as it is, on the one hand, not for the intereft of the ftate to fuffer trees to be cut, till at their perfection for fize and foundnefs, fo, after they are arrived at that perfection, it is equally certain, that they gradually decay.

The quality of the foil the tree ftands in may be neceffary to be obferved to this purpofe; but the quantity or depth of it is the great fubject of inquiry; and a great number of obfervations have proved, that the proper feafon for cutting oaks, in a foil of two feet and an half deep, is at fifty years old; thofe, which ftand in a foil of three feet and an half deep, fhould not be cut down before feventy years; and thofe, which ftand in a foil of four feet and an half deep, or more than that, will increafe in goodnefs, and in fize, till they are an hundred years old: and obfervation has proved, that, after thefe feveral periods, the trees begin to decay.

This feems the beft rule to eftablifh, in regard to the common foils; but thofe, which grow in a lighter or more fandy foil, may have their periods changed from thefe to forty, to fixty, and to eighty years at the greateft depth; and after thefe times it is always beft to fell the wood meant for public fervice, whether then wanted, or not; fince it is much better to keep it in public magazines, than to leave it to be daily decaying.

Heaths, and other uncultivated places, where there is no regular growth of wood, but where fern and ufelefs plants alone feem to flourifh, ufually afford alfo fome ftraggling trees of the oak. Thefe, probably, have had their origin from acorns dropped by birds; but thefe feldom grow tall or regular, fince, not having been defended from the injuries of cattle, they are ufually browfed on and ftunted, while young, and fo become crooked and fhort-trunked, or pollard trees. Thefe, though not of fuch value as the regular oaks, yet deferve care, both with regard to their prefervation and felling, fince they afford a number of trees naturally bent and formed for many parts of fhip-building.

The little care ufually taken of thefe trees, though on this occafion of great value, feems to threaten a general lofs of them; but, as trees, thus naturally crooked and bent, are of value, it is a laudable attempt to try at the finding a regular method of pro-

I

producing such; and this is easily practicable, by following the same method by which these wild ones become so. They wholly owe their figure to the cattle's biting off their tops, while young, and afterwards biting off again the tops of the shoots from the first wound. In this manner, if a number of young trees, set apart for the experiment, have their tops cut off at two, four, six, eight, ten, and twelve feet from the ground, and, four years afterwards, the shoots from these stunted tops are again cut in the same manner, the trees will be found afterwards to grow up in all the irregularly crooked figures that can be conceived; and, by this means, a supply of naturally crooked wood may be raised for all the occasions of ship-building, with infinitely greater ease, and more certainty, than by the method, proposed by some, of bending them down with weights tied to their tops, while young.

As to the supply of young wood in the place of what is cut down, there are some circumstances, which have not had the attention paid to them which they deserve. The spring frosts, which come on at a time when the shoots, by which nature is to raise the supply for what is cut down, are just preparing to grow, are of prodigious injury, and do not less mischief to these, than to the young shoots of garden-plants, though the distant hope of the succession to the proprietor, and usually also the distance of the place, and want of repeated observations, occasions its not being perceived. This, however, may in a great measure be guarded against. Frequent experiments, and repeated observations, prove, that the mischief done by these frosts affects, in a much greater degree, those shoots which are exposed to the north, than those which face the south; and that it is greatly more powerful against such as are wholly exposed to the wind, than against such as are sheltered. These known circumstances may give the hint to a method of saving, at least, a great part of a wood to be felled, from this destruction, to its renewal, by the making it a rule to begin cutting down on the south side; and, as the whole felling is a work of some years, the standing wood of every season will defend the young shoots of the newly-cut stumps, the following spring, not only from the north exposure, but will shelter them also from the wind.

Many prudent managers have made fine estates of their coppice-woods, by regularly felling a certain portion every year, and providing for a renewal of the first cutting against the felling of the last portion, by proportioning the time of growth to the quantity to be cut every year; and there is great interest to be made of a true knowledge of the growth of wood in this manner. Whosoever observes the growth of young trees will find, that the second year's growth is much more considerable than that of the first; the third year's growth is much more considerable than that of the second, and so on for many years, the yearly growth of young wood greatly increasing every season, up to a certain time or age of the tree; after which, the increase in bulk, by growth, becomes gradually less. The great advantage to be made of coppice-wood would be by knowing this interesting period, and seizing on it, always to cut down the trees just at that time when they have arrived at the end of their quick growth, and so, setting nature to work with new shoots, to employ the same speed on inriching again the owner. Regular observation and experiment alone can ascertain this happy period; but any man, who has much coppice-wood upon his estate, may assure himself of it, by cutting a given quantity every year, for ten years successively, and then carefully reviewing the differences of the yearly produce.

Preserving of TIMBER.—When boards, &c. are dried, seasoned, and fixed in their places, care is to be taken to defend and preserve them; to which the smearing them with linseed-oil, tar, or the like oleaginous matter, contributes much.

The Dutch preserve their gates, port-cullices, draw-bridges, sluices, &c. by coating them over with a mixture of pitch and tar, whereon they strew small pieces of cockle and other shells, beaten almost to powder, and mixed with sea-sand, which incrusts and arms it wonderfully against all assaults of wind and weather.

Timber, felled before the sap is perfectly at rest, is very subject to the worms; to prevent or cure which, Mr. Evelyn gives us the following secret, as most approved: put common sulphur in a cucurbit, with as much aqua-fortis, as will cover it three fingers deep; distil it to a dryness, which is performed by two or three rectifications.

Lay the sulphur remaining at bottom on a marble, or in a glass, and, with the oil it dissolves into, anoint the Timber. This, he adds, not only infallibly prevents or cures the worminess, but preserves all kinds of woods, and even many other things, as ropes, nets, and masts, from putrefaction, either in air, water, snow, &c.

For such as would go a shorter way to work, two or three anointings with linseed oil may do very well. As to posts, &c. that are to stand in the ground, the burning the outsides to a coal is a great preservative.

As to the chops or clefts green Timber is liable to after working, a very great eye-sore in many fine buildings, they are closed by anointing, suppling, and soaking it with the fat of powdered beef broth, twice or thrice repeated.—Some carpenters use grease and saw-dust mingled for the same purpose.—

But the former method is excellent, only it is not to be used, while the Timber is green.

Seasoning of TIMBER, a term used by our husbandmen to express the preparing Timber after it is felled, for cutting and working up for use.

As soon as felled, it should be laid up in some dry airy place, but out of the reach of too much wind or sun, which, when in excess, will subject it to crack and fly. It is not to be set upright but laid along, one tree upon another, only with some short blocks between to give it the better airing, and prevent its becoming mouldy, which will rot the surface and produce mushrooms on it. Some persons daub the trees all over with cow-dung, which occasions their drying equally, and prevents their cracking, as they are otherwise very apt to do.

Some recommend the burying Timber in the earth, as the best of all ways of seasoning it; and others have found it a fine preservative to bury their Timber under the wheat in their grainaries; but this cannot be made a general practice. In Norway, they season their deal planks, by laying them in salt water for three or four days, when new sawed, and then drying them in the sun; this is found a great advantage to them; but neither this, nor any thing else, can prevent their shrinking.

The seasoning Timber by fire is the best way of all, for piles, and other pieces that are to stand under the earth, or water. The Venetians first found out this method, and the way they do it is this: they put the piece to be seasoned in a strong and violent flame, in this they continually turn it round by means of an engine, and take it out when it is every-where covered with a black coaly crust; by this means the internal part of the wood is so hardened, that neither earth nor water can damage it for a long time afterwards. This method is practised in many places for seasoning the posts for paling of parks, &c. and has this to recommend it, that in the very oldest ruins we have ever been acquainted with, there have been found many times pieces of charcoal, all of which has been found uninjured, though buried in the earth for ever so many ages. *Mortimer's Husbandry.*

TIN-*floors*, a contrivance used by our husbandmen who propagate hops to dry them after the gathering. The common way of doing this is either on a hair-cloth on a malt-kiln, or else by the oost.

In both these ways, however, the hops suffer very much; the best way is by the Tin-floor. It is thus done: let a square brick room be built, with a door on one side, and a long fire-place of a foot wide in the middle, reaching almost across it; let holes be made at the sides of this fire-place, to let out the heat into the room; and, at the height of five-feet above this, let a floor be made of laths of an inch thick, laid lattice-wise. Let this be covered with great plates of double Tin, taking care that the joinings of the Tin be well soldered, and lie upon the laths, not over the interstices, which may be about four inches wide. Let a row of boards be fitted round the edge of this floor, to keep the hops from falling off; then lay on a covering of hops of a foot thick; then make a small fire of charcoal in the mouth of the fire-place, and the hops will dry very quick and very regularly. They may be continually stirred about while drying, and, when enough, a part of the boarded edge of the kiln may be taken down, and the dried parcel thrust out, and a fresh parcel laid on in their place. A very small quantity of fuel is sufficient in this way, and any fuel will do, for the smoke never comes at the hops. There is a very great improvement still upon this method of drying hops, used by some people; this is the making a wooden cover, of the size of the Tin-floor; this is covered with plates of Tin nailed on, and is suspended over the kiln in such a manner, that it may be let down at pleasure, when the lower parts of the hops are dry. This is to be let down within ten inches of their surface, and there it acts as a reverberatory, and drives back the heat on the upper ones, so that they are dried as soon as the lower ones: thus all the trouble of turning is saved, and the hops are much better dried than in any other way. *Mortimer's Husbandry.*

TIN-*hatch*, in mining, a term used by the people of Cornwall, to express the opening into a Tin-mine. They also call it a Tin-shaft.

They make several openings in the sides of the hills where they suspect veins of ore to be. All these, except that which opens on the head of the mine, are called essay-hatches; but that which does so, is made their entrance afterwards, and changes its name to that of the Tin-hatch.

TIN-*plates*, an article of manufacture very common among us, and vulgarly called Tin. It is iron plated over with Tin. The French call it fer blanc, white iron, as we sometimes do in England. It was once known under a distinct name, latin. See the article LATIN.

TINCTURE (*Dict.*)—A general rule for the properly making light Tinctures may be taken from the following bitter: take half an ounce of Sevile orange-peel shaved thin, half a drachm of gentian-root thin sliced, a scruple of the tops of Roman wormwood, half a drachm of cardamom-seeds, and the same quantity of cochineal, each of them lightly bruised; put these ingredients into a pint of French brandy, let them steep for

 one

one night, and filtre the liquor the next morning, and thus you have a fine light bitter.

These bitters are of the number of many other ſubſtances, where the goodneſs of a Tincture does not more depend upon the choice of the ingredients, than upon the manner of their being infuſed; for, if ſuch be ſuffered to remain too long in the menſtruum, or, if heat be uſed in extracting the Tincture, the groſs terreſtrial and nauſeous parts of the ingredients will be fetched out, and the Tincture will thus be loaded with a heavy indolent matter of little virtue. *Shaw's Lectures.*

A great variety of Tinctures may be given to common water, and many remarkable things occur in their changes on the addition of common menſtruums: take a large ſpoonful of the ſyrup of pomegranate-flowers, mix it with five ſpoonfuls of water; the mixture will be of a very lively and brilliant red: for a violet colour, take the ſame quantity of ſyrup of violets, and the ſame of water. When the Tinctures are thus prepared, have at hand a phial in which is a ſmall portion of oil of tartar, which will only look like water remaining after the waſhing of the phial.

Pour the red or the violet Tincture into this phial, and it immediately becomes a fine graſs-green. Diſſolve the quantity of a walnut of crude ſal armoniac in a glaſs of water, pour all out except three or four drops at the bottom, and pour into this glaſs the fine red liquor, and it immediately becomes black as ink. In order to change the purple liquor red, only have a ſmall quantity of ſpirit of vitriol in the bottom of a phial, and pour it into this; the violet water, immediately on this, becomes of a florid red.

Steep Braſil wood in common water, or in white wine twenty-hours; the liquor will then look of the colour of red wine; pour this into a glaſs waſhed with vinegar, and it becomes of a fine yellow like ſack. If this experiment be made with white wine, the wood and the vinegar make ſo little alteration in it, that it may be drank afterwards, and the whole proceſs ſeems a way of turning red port into ſack. Into this liquor when yellow, drop a few drops of a Tincture of benjamin made in ſpirit of wine, and it immediately loſes its yellow colour and becomes white. Beat ſome galls to fine powder, and rub the powder on a towel; then put into a baſon of water, in which any perſon is going to waſh their hands and face, a ſmall piece of common green vitriol, or copperas; after the perſon has waſhed, let them have this towel to wipe on, and the hands and face will be as black as if waſhed with common writing-ink; the copperas in the water and the galls on the towel making real ink where they mix. This does no laſting injury to the ſkin, but will come off again upon waſhing with ſoap. *Philoſ. Tranſ.* N°. 238.

TINCTURE *of antimony*, tinctura antimonii, is thus made: take ſalt of tartar a pound, antimony half a pound, rectified ſpirit of wine a quart; reduce the antimony to a powder, and mix it with the ſalt by fuſion over a ſtrong fire. When it is cold, powder it, and pour on the ſpirit of wine; digeſt them together three or four days in a ſand heat, and then filtre off the clear Tincture for uſe. The ſalt of tartar yields a Tincture as well as the antimony.

TINCTURA *Fœtida*, the ſtinking Tincture, a form of medicine in the late London Diſpenſatory prepared in this manner: take aſſa-fœtida four ounces, rectified ſpirit of wine a quart, digeſt them together for ſome time, and then ſtrain off and filtre the Tincture through paper.

TINCTURA *Sacra*, a Tincture of aloes, called alſo hiera picra. The late London Diſpenſatory has ordered this to be made of only eight ounces of aloes, and two ounces of winter's bark powdered, and put into five quarts of white-wine, which is to be ſhook often, and kept in fuſion a week or more without heat, and then ſtrained off for uſe. *Pemberton's London Diſp.*

TINCTURA *Saturnina*, the lead tincture, a name given in the late London Diſpenſatory to the tincture before called Tinctura antiphthiſica.

It is made of ſugar of lead and green vitriol, each two ounces; of rectified ſpirit a quart. The ſalts are ſeparately to be reduced to powder, and then put into the ſpirit; then the whole is to ſtand ſome days without heat to extract the Tincture, and afterwards filtred through paper. *Pemberton's London Diſpenſatory.*

TINCTURA *Senæ*, a form of medicine preſcribed in the new London Pharmacopœa, and intended to ſtand in the place of the medicine commonly called elixir ſalutis, and Daffy's elixir. It is thus made: take ſtoned raiſins fixteen ounces, leaves of ſena a pound, carraway ſeeds an ounce and half, cardamom-ſeeds half an ounce, proof ſpirit a gallon; digeſt all together without heat, and, when the Tincture is well extracted, preſs off the ſpirit, and filtre it for uſe. *Pemberton's London Diſpenſatory.*

TINCTURA *Styptica*, a form of medicine made with very little trouble and apparatus, and ſerving to ſupply the place of that elaborate preparation the tincture of Helvetius; it is preſcribed in the late London Pharmacopœa, and is to be made by mixing a drachm of calcined green vitriol with a quart of French brandy, tinctured by the caſk; this is to be ſhook together that the brandy may turn black, and then ſtrained off for uſe. *Pemberton's London Diſpenſatory.*

TINCTURA *Thebaica*, a name now given to the tincture of opium, commonly called laudanum.

The method of making this is alſo much altered, as well as the name in the late London Diſpenſatory, where the ſaffron, being looked on as an uſeleſs ingredient, is wholly left out, and the medicine ordered to be prepared in the following manner: take of opium ſtrained two ounces, of cinnamon and cloves each a drachm, white wine a pint; infuſe without heat a week, and then ſtrain off the wine thro' rough paper. *Pemberton's London Diſpenſatory.*

TINCTURES, in heraldry, a word uſed to expreſs colours, red, blue, green, and the like.

TI'NGING *of marble.*—The art of doing this has in ſeveral people's hands been a very lucrative ſecret, though there is ſcarce any thing in it that has not at one time or other been publiſhed.

Kircher has the honour of being one of the firſt, who publiſhed any thing practicable about it. This author meeting with ſtones in ſome cabinets ſuppoſed to be natural, but having figures too nice and particular, to be ſuppoſed of nature's making, and theſe not only on the ſurface, but ſunk through the whole body of the ſtones, was at the pains of finding out the artiſt who did the buſineſs; and, on his refuſing to part with the ſecret on any terms, this author with Albert Gunter, a Saxon, endeavoured to find it out; in which they ſucceeded at length very well. The method is this:

Take aqua-fortis and aqua-regia of each two ounces, ſal armoniac one ounce, ſpirit of wine two drachms, about twenty-ſix grains of gold, and two drachms of pure ſilver; let the ſilver be calcined and put into a phial, and pour upon it the aqua-fortis; let this ſtand ſome time, then evaporate it, and the remainder will firſt appear of a blue, and afterwards of a black colour. Then put the gold into another phial, pour the aqua-regia upon it; and, when it is diſſolved, evaporate it as the former. Then put the ſpirit of wine upon the ſal armoniac, and let it be evaporated in the ſame manner. All the remainders, and many others made in the ſame manner from other metals diſſolved in their proper acid menſtrua, are to be kept ſeparate and uſed with a pencil on the marble, the ſeveral parts are to be touched over with the proper colours, and this renewed daily till the colours have penetrated to the deſired depth into the ſtone. After this, the maſs may be cut into thin plates, and every one of them will have the figure exactly repreſented on both the ſurfaces, the colours never ſpreading: the niceſt method of applying theſe, or the other Tinging ſubſtances, to marble, that is to be wrought into any ornamental works, and where the back is not expoſed to view, is to apply the colours behind, and to renew them ſo often till the figure is ſufficiently ſeen through the ſurface on the front, though it does not quite extend to it. This is the method that of all others brings the ſtone to a nearer reſemblance of natural veins of this kind. *Kircher's Mund. Subter.*

TINNU'NCULUS, in zoology, the name of one of the long-winged hawks, called by others cenchris, and in Engliſh keſtrel, ſtannel, or windhover.

It is about the ſize of a common pigeon. Its bill is ſhort, crooked, and very ſharp, and covered with a yellow ſkin at the top; near this the bill is white, elſewhere it is blue. Its tongue is bifid; its mouth very wide, and its palate blue. Its head is large and flatted, and is of an aſh-colour, with longitudinal ſtreaks of black. Its back and wings are brown, variegated with black ſpots; its rump is grey, with ſome tranſverſe black ſpots; and its breaſt and belly of a pale ruſt colour, with a few longitudinal ſtreaks of black. Its tail is long and pointed; its tip of a pale ferrugineous hue, with a broad tranſverſe ſtreak of black over it; and the reſt of the tail is a mixed grey and brown, with black ſpots and ſtreaks. Its legs and feet are of a fine yellow. It builds in hollow oaks, and lays four eggs, which are white, variegated with a number of ſmall red ſpots. It feeds on partridges and other birds. *Ray's Ornithol.*

TI'SRI, or TIZRI, the firſt Hebrew month of the civil year, and the ſeventh of the eccleſiaſtical or ſacred year.

The Hebrews call it roſh-haſhanna, that is, the beginning of the year. It anſwered to the moon of September. On the firſt day of this month was kept the feaſt of trumpets, becauſe the beginning of the year was then proclaimed by ſound of trumpets. On this day they refrained from all ſorts of ſervile buſineſs, and offered in ſacrifice a calf, a ram, and ſeven lambs.

TITHES (*Dict.*)—The cuſtom of giving or paying Tithe is very ancient: in Gen. xiv. 20. Abraham gives Abimelech the tenth of all the ſpoils he had taken from the four kings he had defeated: in Gen. xxviii. 22. Jacob makes a vow, at Bethel, to give the tenth of all the riches he ſhall gather, in that ſojourn, to God.

But theſe Tithes were free and voluntary; and, beſides, differed in divers other reſpects from what was afterwards called Tithe: what Melchiſedec received, was only the tenth of the ſpoils, not of Abraham's poſſeſſions; and this once, not annually; and beſides, not as maintenance, which Melchiſedec wanted not, but as homage: add, that this was only from one prieſt to another; for Abraham had not only a prieſt in his loins, but was a prieſt himſelf.—And as to Ja-

cob,

Printed for J. Hinton in Newgate Street.

cob, who was also a priest, what he did was the effect of a vow, voluntarily taken, to offer the tenth of all he should possess; not to any other priest, but to God himself upon an altar.

Under the new law, it is not Jesus Christ that established Tithes, as it was God himself did it under the old law by the ministry of Moses; the Christian priests, and the ministers of the altar of the new covenant, lived, at first, wholly on the alms and oblations of the devout.

In after times the laity gave a certain portion of their revenues to the clergy, but voluntarily, and not out of any constraint or obligation: the first instances we have of it, are in the IVth and Vth centuries.

This gift was called Tithe; not that it was really a tenth part of their income, or near so much: but only in imitation of the Tithes of the old law.

In the following age, the prelates in their councils, in concert with the princes, made an express law to the purpose; and obliged the laity to give a full tenth part of their revenues, their fruits, &c. to the ecclesiastics.

This the church enjoyed without disturbance for two or three centuries; but in the VIIIth century the laity got hold of part of these Tithes, either by their own authority, or by grants and donations of the princes; and appropriated them to their own uses.

Some time afterwards they restored them, or applied them to the founding of monasteries or chapters; and the church consented, at least tacitly, to this restitution.

In 1179, the third council of Lateran, held under Alexander III, commanded the laymen to restore all the Tithes they yet held to the church.

In 1215, the fourth council of Lateran, held under Innocent III, moderated the matter a little; and, without saying any thing of the Tithes which the laity already possessed, forbad them to appropriate or take any more for the future.

Fra. Paolo, in his treatise of Beneficiary Matters, is of opinion, that the custom of paying Tithes under the new law began in France; and affirms, that there are no instances of it before the VIIIth and IXth centuries: but he must be mistaken; for in the 2d council of Matiscona, held in 585, it is said expresly, that the Christians had a long time kept inviolate that law of God, whereby Tithe of all their fruits was enjoined to be given to holy places, &c.

In effect, Origen, Hom. XI. on Numbers, thinks, that the old laws of Moses, touching the first fruits and Tithes, both of cattle, and of the fruits of the earth, are not abrogated by the gospel; but ought to be observed on their ancient footing.

The Vth canon of the council of Matiscona orders Tithe to be paid to the ministers of the church according to the law of God, and the immemorial custom of the Christians, and that upon penalty of excommunication: which is the first penalty we find imposed on such as would not pay Tithe.—On which grounds it is that many among the modern clergy hold their Tithes to be jure divino.

Others, on the contrary, plead, that the recompence, to be given church ministers, is differently ordained by God, according to the differences he has put between his two great dispensations, the law and the gospel: under the law he gave them Tithes; under the gospel, having left all things in his church to charity and christian freedom, he has given them only what shall be given them freely, and in charity. That the law of Tithes is in force under the gospel, all the protestant divines, except some among the English, deny; for though hire to the labourer be of moral and perpetual right, yet that special kind of hire, the tenth, can be of no right or necessity, but to the special labour for which God ordained it: that special labour was the levitical and ceremonial service of the tabernacle, Numb. xviii. 21, 31. which was abolished: the right therefore of the special hire must be abolished too.

That Tithes were ceremonial, is evident from their not being given to the Levites till they had been first offered as a heave-offering to the Lord, ver. 24, 28.

He, then, who by the law brings Tithes into the gospel, brings in likewise a sacrifice, and an altar; without which, Tithes, by the law, were unsanctified and polluted, ver. 32. and therefore were never thought of in the first Christian times, till ceremonial altars and oblations had been brought back.

The Jews themselves, ever since their temple was destroyed, though they have rabbies and teachers of the law, yet pay no Tithes, as having no proper Levites to whom, nor altar whereupon, to hallow them; which argues, that the Jews themselves never looked on Tithes as moral, but merely ceremonial.

Add, that Tithes were not allowed to the priests and Levites merely for their labour in the tabernacle, but in consideration of this likewise, that they were not allowed to have any other part or inheritance in the land, ver. 20, 24. and who, by that means, for a tenth, lost a twelfth.

In effect, for the first three hundred years after Christ, no mention is made in all ecclesiastical history of any such thing as Tithes; though, in that time, altars and oblations had been recalled, and the church had miserably judaised in many other things. The churchmen confessedly lived all that time on free-will offerings; nor could the defect of paying Tithe be owing to this, that there were wanting civil magistrates to injoin it; since Christians, having lands, might have given out of them what they pleased: and the first Christian emperors, who did all things by advice of the bishops, supplied what was wanting to the clergy, not out of Tithes, which were never proposed, but out of their own imperial revenues. The first authority produced, setting aside the apostolical constitutions, which few of the patrons of Tithes will insist on, is a provincial synod at Cullen in 356, where Tithes are voted to be God's rent; but, before that time, divers other abuses and complaints had got ground, as altars, candles at noon, &c. And one complaint begot another; as its is certain that Tithes suppose altars.

It is alledged, that Tithes are of early and solemn force among us, having been paid by statute ever since the Saxon king Athelstan, anno 928: to which it may be answered, that Romescot, or Peter-pence, had been likewise paid to the pope by statute above 200 years longer, viz. from the year 725. And by the way it is to be noted, that these ancient Tithes, among our ancestors, kept a nearer analogy to their original in the Mosaic law; for the priests had but a third part, the other two thirds being appointed for the poor, and to adorn and repair the churches, as appears from the canons of Ecbert and Elfric.

TITHY'MALLUS, *spurge*, in botany, the name of a large genus of plants, the characters of which are these: the flower consists of one leaf, and is of the campaniform kind but globose, divided into several segments at the edge, and inclosed in two little leaves which seem to serve in the place of a cup to it. The pistil arises from the bottom of the flower, and is usually of a three-cornered shape; this ripens into a fruit of the same form, which contains many oblong seeds.

TOBA'CCO, (*Dict.*)—In the island of Ceylon, there are two kinds of Tobacco cultivated for profit. They call both kinds dunkol, which signifies a leaf, the use of which is to be smoaked. The one kind they call hingele dunkol, or singele dunkol; and the other dunkol kapada. The kapada Tobacco is much stronger and more intoxicating than the other; but both kinds are the produce of the same plant, only the single Tobacco has very little care taken of it, being, after the sowing, in a manner left to itself, while the other has great pains bestowed upon it during the whole time of its growth, and till it is fit for use, in the following manner: they clear a little piece of ground, in which they sow the seed of the Tobacco, and against the time that the young plants have got three leaves a piece, they chuse out another piece of ground into which to transplant them: this they hedge round, and turn their horned cattle into it, that their dung may fall upon it and sufficiently enrich it. The ground is then dug with a sharp hoe, or spade, in the form of a pick-ax, and the dung, by this means, thoroughly worked into it. When the earth is thus prepared, they take up the young plants, and set them in this new ground, at about a foot square distant from one another.

The manner of giving more or less strength to this Tobacco, is by suffering the plants to grow to a greater or less height before they top them, or cut off the stalk at the summit. The usual way is to cut off the top when the plant has fifteen leaves. If they intend the Tobacco to be a little stronger, they do this when it has only thirteen; and, when they would have it strongest of all, they do it when there are only eleven or twelve leaves. On the contrary, when they would have a milder Tobacco, they cut it not off till there be eighteen or twenty leaves; but, in this way of counting the leaves, they never reckon the three or four lowest, which do not grow so large and fine as the others. The cutting off the top prevents the juices of the plant from being wasted in flowers and seeds, which are of no value; and, in consequence of it, all being, after this time, employed to furnish the growth of the leaves, they grow four times as large and thick as they otherwise would do.

To prevent all unnecessary wasting of the sap, these plants are tended every day; and, as the young sprouts appear in the joining of the leaves and stalk, they are continually cut off: this is done once in three days, till the leaves have their full bigness, which is about that time when the flowers would have been ripe, had the plant been suffered to grow in its natural way: they are immediately to be gathered when they are full grown, otherwise they waste and decay. They cut down the whole plant, and bring them into their houses, laying them on a heap. When they have lain a little time together, they begin to sweat and grow hot: when they have been a little while fermenting, they turn them, bringing those which are in the middle to the surface, and placing those which were at the surface in the middle; by this means the whole quantity of leaves ferments equally. The longer they lie in this manner, the darker-coloured the Tobacco becomes. When they have left it thus to sweat as long as they judge necessary, they hang every stalk separately on cords; and, when the whole is thoroughly dry, they carefully take off the leaves, and lay them by in bundles, till they have occasion for them.

them. This is the manner of their preparing the kappada. The single Tobacco is sown in the same manner with this; but it is never transplanted nor tended, it grows as it pleases, and, when the flowers are ripe, it is cut down, and laid carelessly in heaps, where some of it ferments too much, and some too little. This is much weaker therefore than the kappada; and, as both kinds are common in the place, the natives smoak them either separately or together, mixed in different proportions, as they like. Some of the Ceylonese chew this strong Tobacco with their beetle, and some, who smoke it alone, use no pipe, but, taking a long leaf of it, they roll it up into a long form, and cover it with the leaf of the wattukan-tree; they then light one end of it, and smoak by the other, till the whole is consumed. *Philos. Trans.* N°. 278. *Plate* XLIII. *fig.* 4. represents the Tobacco plant; *a* is the flower, *b* the calyx, and *c* the seed vessel.

Adhesions of the TOES. It is a frequent thing to meet with new born infants with their fingers or Toes cohering or grown together, either by a strict adhesion of the flesh, or else by some loose productions of the skin, as in the feet of ducks and geese; and a disorder of the same kind is also sometimes found in adults, from accidents; as when the fingers and Toes have been neglected, after an excoriation of them by burns or wounds. In both these cases the surgeon's assistance is necessary, partly to remove the deformity, and partly to restore the proper use of the fingers.

These adhesions, according to the nature of the disorder, are to be separated two ways, either by cutting out the intermediate skin with a pair of scissars, or else barely by dividing them from each other with the same instruments. When this is done, to prevent their cohesions again, each finger must be invested separately with a spiral bandage about an inch broad, dipped in lime-water and spirit of wine.

Sometimes the fingers, instead of adhering to each other, grow to the palm of the hand, from wounds or burns, so that they cannot be by any means extended, or drawn back to open the hand. The method of relieving this disorder is first very carefully to separate the fingers from their adhesions to the palm, without injuring their tendons; then dress them with a vulnerary balsam, and scraped lint, and extend them on a ferula or thick pasteboard; and let them remain in this extended posture, separately to be dressed till they are perfectly healed; but at every dressing they must be gently moved, to prevent a rigidity or stiffness of the joints. *Heister's Surgery.*

TO'KENS, in pestilential cases, those livid spots, which appear in the several stages of the disease, and are certain forerunners of death.

TONGUE-*tied*, the popular name for a distemperature of the Tongue in children, when it is tied down too close to the bottom of the mouth, by a ligament connected all along its middle, and called its frænulum, which requires to be divided, to give the Tongue its proper motion.

This is sometimes the case in adults, but oftener in children, who cannot then exert their Tongues to suck. This is, however, by no means so common as the women usually imagine; not so much as one child in a thousand being afflicted with it; nor is the operation in cutting it of little consequence, since often bad accidents follow it, and sometimes the loss of a child's life. When the infant can put its Tongue out of its mouth, the frænulum wants no incision; but, when the Tongue cannot be extended beyond the teeth, the operation is necessary. *Heister's Surgery.*

TON'SÆ, among the Romans, the blades of oars, or that part of them which beats against the water. *Pitisc. in voc.*

TOP *of a ship*, a round frame of boards lying upon the crosstrees near the head of the mast; here they furl and loose the top-sail, &c.

TOP-*armours*, in a ship of war, are a kind of cloths hung about the round-tops of the masts for shew; and also to hide the men which are on top in a fight, who lie there to fling stinkpots, &c. or to fire small shot down on the enemy in case of boarding.

TOP-*masts*, in a ship, are four, which are made fast and settled unto the heads of the main-mast, fore-mast, mizzen-mast, and bow-sprit respectively.

TOP-*gallant-masts*, in a ship, are two, viz. main-top-gallant-mast and fore-top-gallant-mast, which are small round pieces of timber, set on their respective Top-masts; on the Top of which masts are set the flag-staffs, on which the colours, as flags, pendants, &c. hang.

TOP-*ropes*, in a ship, are those with which the Top-masts are set or struck; they are received through a great block which is seized on one side under the cap, and then are reeved through the heel of the Top-mast, where is a brass shiver placed athwart ships; after this they are brought up and fastened on either side the cap with a ring: the other part of them comes down by the ties, and so is reeved into the knight-head; and, when it is to be heaved, it is brought to the capstan. These Top-ropes belong only to the main and fore-mast.

TOP-*sails* and Top-gallant-sails, in a ship, are those belonging to the Top-masts and Top-gallant-masts.

TOP-*a-starboard*, on board a ship, a word of command to hale upon the larboard lift.

TOP *the yard-arms*, on board a ship, a word of command to make the yards hang higher or lower.

Counterfeit TOPAZ. To counterfeit the oriental Topaz in paste, take crystal prepared two ounces, ordinary minium or red lead seven ounces; put these into a crucible luted, and bake them twenty-four hours in a potter's kiln. If the mass is not sufficiently clear and fine, cover it up again and give a second baking, and it will come out of a fine Topaz-colour. *Neri's Art of Glass.*

TORCH-*thistle*, *cereus*, in botany, a species of plants belonging to the cactus genus.

This plant consists of a single stem or body, twenty, thirty, or more feet high, and about five inches diameter. It is of an angular figure, and armed with clusters of sharp firm spines, growing from tubercles placed along the ribs. The flowers, when open, are of the size of a large rose and consist of forty or more petals; the outer ones purplish, or greenish; the inner ones white.

It is a native of Surinam, and many parts of South America. It has gotten the name of Torch-thistle, from its being much used for Torches.

The propagation of all the kinds of this remarkable plant is by cuttings, which must be laid in a dry place ten days or a fortnight before they are planted, or, if it be three weeks, there is less danger of their miscarrying.

They are to be planted in small pots, filled in a light sandy earth, with a mixture of lime rubbish, laying some stones at the bottoms of the pots to drain off the moisture. The pots are then to be placed in a gentle bed of tanner's bark, and once a week are to have a gentle watering; this is best done in June or July: towards the middle of August, they must have air given them by degrees, and at the end of September they must be removed into the stove, where they are to remain the winter. They should always have a dry situation, and should never be exposed to the open air, even in the midst of summer. When the top of an old plant has been cut off for propagating, it always throws out several young shoots from its angles, which may be easily propagated in the same manner, that there will be a continual supply even from one stock. They may be brought in small pieces from the West-Indies packed up in straw, and will grow when planted here, as well as if cuttings from our own plants. *Miller's Gard. Dict.*

TORDY'LIUM, in botany, the name of a genus of umbelliferous plants, the characters of which are these: the flowers are of the rosaceous kind, being composed of several heart-fashioned petals of irregular sizes disposed in a circular order on a cup which afterwards becomes a fruit nearly of an orbicular figure, being composed of two flattish seeds with a high and usually denticulated margin which easily deposit their covering.

TORME'NTILLA, *tormentil*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the rosaceous kind, consisting of four leaves disposed in a circular form; the cup is of the shape of a bason, consisting of one leaf, divided into several segments; the pistil arises from this cup, and finally becomes a globose fruit composed of several seeds closely laid together, and covered by the cup.

TOU'CAN, in zoology, the name of a very remarkable Brasilian bird, a kind of magpie, of a middle size between our common magpie and the thrush, but having a beak, prodigiously thick and longer and finely variegated; this beak is hooked at the end, and is of a very thin substance, not exceeding the thickness of a membrane, and very light and hollow, yet bony in substance, and the colours very bright. It has a sort of toothed edge, which prevents its shutting closely, and, giving passage for the air, enables the bird to live without nostrils.

It is covered with a sort of scaly substance easily scraped off with a finger at the edge. Its head is large in proportion to its body, and is black on the crown; but the representation of this curious bird, *Plate* XLIII. *fig.* 6. will give a better idea of it than the most prolix description. The figure is taken from Mr. Edward's History of Birds: and as that ingenious gentleman drew it from nature, it may be depended upon as very correct. It is said that it feeds on pepper, and Thevet affirms that it devours it greedily and returns it again undigested, and that the natives gather up that pepper, and use it in their food, as less hot and acrid than the fresh pepper. *Ray's Ornithology.*

TOUCH-*hole*, or vent, in gunnery, is the small hole at the end of the cylinder of a gun or musquet, by which the fire is conveyed to the powder in the chamber. In a firelock, carabine, or pistol, it is called the Touch-hole, but in a piece of cannon it is more properly called the vent.

TOUCH-*needles*, small masses of gold, silver, and copper, each pure and simple, and, in all the different combinations, proportions, and degrees of mixture, prepared for the trying gold and silver by the Touch-stone, by comparison with the mark they leave on it.

The metals usually tried by the Touch-stone, are gold, silver, and copper, either pure, or mixed with one another in different degrees, and proportions, by fusion. In order to find out

out the purity, or quantity of baser metal in these various admixtures, when they are to be examined, they are compared with these needles, which are mixed in a known proportion, and prepared for this use. The metals of these needles, both pure and mixed, are all made into laminæ or plates, one twelfth of an inch broad, and of a fourth part of their breadth in thickness, and an inch and half long; these being thus prepared, you are to engrave on each a mark indicating its purity, or the nature and quantity of the admixture in it.

The manner of making the Touch-needles is by the proportions of the mark, a weight of half a pound, or eight ounces, being divided into sixteen half ounces, the half ounces each into four drachms, the drachm into four penny-weights, and this into two half penny-weights.

Silver TOUCH-*needles*, these must be only tempered with copper, and the proportion determined by the mark divided into half ounces and grains.

You must use therefore for this purpose one mark of such a weight that it may constitute a sufficient mass of metal for the making one needle, let it weigh for instance one drachm, then weigh such a mark of the purest silver, wrap it up in a small paper and upon this write sixteen half ounces, which will signify that the whole mark of this metal is the purest silver; make the first needle of this mass.

Next weigh fifteen half ounces of pure silver, and one half ounce of pure copper, wrap these both in a paper, and write on it fifteen half ounces, which will signify that there are in that small mass fifteen parts of pure silver, and one part of pure copper; make of this the second needle. In the same manner go on with the rest, add two half ounces of copper to fourteen half ounces of silver, mark it fourteen half ounces, make the third needle of this, and in the same manner proportion the small masses of silver and copper for making the other needles, and put inscriptions upon every one in the following manner:

For the needle	half oz. of silver	half oz. of copper.
1.	16	0
2.	15	1
3.	14	2
4.	13	3
5.	12	4
6.	11	5
7.	10	6
8.	9	7
9.	8	8
10.	7	9
11.	6	10
12.	5	11
13.	4	12
14.	3	13
15.	2	14
16.	1	15

When you have gone thus far, and have the metals in each of these proportions, wrapped up in its separate paper; put each separately into a new crucible never used for any operation, and adding a little borax melt them together in a very quick fire, which must be well kindled before with bellows; or, what is yet better, throw them suddenly into a hot crucible, and, as soon as they melt, stir them with a dry wooden peg, burnt at the end, and pour them immediately into an ingot. When this is done, wrap up each mass, when cold, in its own paper again, and weigh them singly, in a nice balance. If they still weigh a whole mark they are good; but, if there is any considerable deficiency in their weight, it is a sign that your fire having been of too weak, or of too long duration, has consumed as much copper as is wanting in the weight; therefore this mass must be esteemed useless, and another made in its place in the same proportion.

When this is all finished, make with a hammer, out of each these small masses, a needle, heating them a little; then engrave, on each of these needles, the number of half ounces it contains, as before marked on its paper; that is, upon the first 16, upon the second 15, and so on, and then pierce them at one end, and, running a silver wire through their eyes, collect them in order according to their different numbers. These are the silver Touch-needles, made of the different allays of silver and copper.

In Holland they make use of the mint mark, divided into grains for the making their needles. The first needle made of pure silver is said to be of twelve penny-weights. The second is made of eleven penny-weights and eighteen grains, by the addition of six grains of copper. The third is made of eleven penny-weights and twelve grains, by the addition of twelve grains of copper; and so on, the proportion of silver decreasing always six grains, that is, one quarter of a penny-weight at a time, and that of the copper being always increased in the same proportion, till at last the weight of the silver is reduced to one penny-weight, and that of the copper increased to eleven penny-weights, which proportion constitutes the last needle.

It is needless, however, to go through the whole series of the needles, by so small progressions to the very last, for very delicate proportions cannot be very accurately distinguished in the operation.

Gold TOUCH-*needles*. These must be mixed either with silver alone, or with silver and copper, variously intermixed. This mixture is called allaying or carracting, and is determined with a mark divided into carracts or weights of two sixth parts of an ounce. There is nothing to be observed about the making of these needles, besides what has been already said in regard to the silver needles; except that the proportions of the weights are determined in another manner. These needles are made according to the following division and order; and they all weigh one mark.

The first is entirely of pure gold.

	pure gold	pure silver.
2.	23 Car. 6 Gr.	6 Gr.
3.	23 Car.	1 Car.
4.	22 Car. 6 Gr.	1 Car. 6 Gr.
5.	22 Car.	2 Car.
6.	21 Car. 6 Gr.	2 Car. 6 Gr.
7.	21 Car.	3 Car.
8.	20 Car. 6 Gr.	3 Car. 6 Gr.
9.	20 Car.	4 Car.
10.	19 Car.	5 Car.
11.	18 Car.	6 Car.

The decrease goes on thus, by whole carracts, till the weight of the gold is arrived at one carract, and that of the silver at twenty-three; for after the ninth needle you cannot make so exact a distinction of the half carracts.

This mixture of gold and silver is called the white allay; but, when copper together with silver enters into the mixture of the gold, then it is called a mixed allay. The needles, for trial of pieces thus debased, are made of mixtures analogous to the former, except only that those portions which in the first case were pure silver, here consist of copper and silver mixed. Therefore you have a double series; for the mixture is either of two parts of silver, and one of copper, or of two parts of copper, and one of silver. For instance,

The first is of pure gold.

	of pure gold.	of pure silver.	of pure copper.
2.	23 Car. 6 Gr.	4 Car.	2 Gr.
3.	23 Car.	8 Gr.	4 Gr.
4.	22 Car. 6 Gr.	1 Car.	6 Gr.
5.	22 Car.	1 Car. 4 Gr.	8 Gr.
6.	21 Car. 6 Gr.	1 Car. 8 Gr.	10 Gr.
7.	21 Car.	2 Car.	1 Car.
8.	20 Car. 6 Gr.	2 Car. 4 Gr.	1 Car. 2 Gr.

and so on as in the foregoing.

If in this table you take pure copper instead of pure silver, and silver instead of copper, this gives you a third series of golden needles. And you may have a fourth by mixing with gold equal quantities of silver and copper in the same proportion. These allays of gold are much in use, but workmen may easily employ a multitude of other variations, which, compared with the already mentioned, will be distinguished in a thousand different ways by an experienced person, so that it is neither possible, nor necessary, to imitate them all.

But that these golden needles may not be too expensive, they may be made much shorter than those of silver, and afterwards soldered to plates of copper, that may be sufficiently long for use.

The use of these needles is by means of the Touch-stone; and arises hence, that every metal when pure must have its specific colour, that distinguishes it from the rest: but, metals being the most opake of all known bodies, the specific colour of every one appears most distinctly, when you rub it against a very black hard stone; and if the colours of two or more metals are expressed by large lively spots, made near each other on the same plane, by rubbing them against the surface of the stone, you will by that means easily discern their difference, or their likeness.

The stone adapted to this use, and called from its office the Touch-stone, must have the following qualities. It must be of the deepest black, lest the tincture of the metal should be altered by spurious rays of light shining among it: it must be capable of being pretty well polished, for, when too rough, the colours of the metals rubbed against it cannot be neatly or regularly distinguished; and, if it is too smooth, the metals are but faintly, and too slowly abraded or scraped by it, especially when gold is tried. It must also be neither too hard, nor too soft. Tripoli, coal-dust, and tin ashes are used in rubbing off the thin metalline crusts, and in a short time the stone, when very hard, is apt to acquire too smooth a surface; and, when it is too soft, it easily wears, throws off a dust, and contracts furrows.

The black rough marbles, and the softer black pebbles from the beds of rivers, are most proper for this use, and are to be made into the form of a quadrangular prism, about an inch thick, and two or three inches long.

The method of using your needles and the stone is this: when you meet with a piece of metal to be tried, first wipe it very well with a clean towel, or piece of soft leather, that you may the better see its true colour; for from this alone an experienced person will in some degree judge before-hand what the principal metal is, and how, and with what debased. Then chuse a convenient not over large part of the surface of the metal, and rub it several times very hardly and strongly against

against the Touch-stone, that, in case a deceitful coat or crust should have been laid upon it, it may be worn off by that friction. This however is done more readily by a grindstone or small file, if you have them at hand. Then wipe a flat and very clean part of the Touch-stone, and rub against it, over and over, the just mentioned part of the surface of the piece of metal, till you have on the flat surface of the stone a thin metallic crust, an inch long and about an eighth of an inch broad: this done, look out the needle that seems most like to the metal under trial, wipe the lower part of this needle very clean, and then rub it against the Touch-stone as you did the metal by the side of the other line, and in a direction parallel to it. When this is done, if you find no difference between the colours of the two marks, made by your needle, and the metal under trial; you may with great probability pronounce that metal, and your needle, to be of the same allay; which is immediately known by the mark engraved on your needle. But, if you find a difference between the colour of the mark given by the metal, and that by the needle you have tried; chuse out another needle, either of a darker or a lighter colour than the former, as the difference of the tinge on the Touch-stone directs; and by one or more trials of this kind you will be able to determine which of your needles the metal answers, and thence what allay it is of, by the mark of the needle; or else you will find that the allay is extraordinary, and not to be determined by the comparison of your needles.

But, if the metal under trial has been altered by tin, arsenic, zink, or other such admixtures, the workmen may be deceived by the colour, so as to take for pure gold, or silver, that which is not by any means such. Deceits of this kind however are found out by the assistance of acid menstrua. Aqua-fortis answers this purpose, when the mass is of the colour of gold, and aqua-regia, when it is of the colour of silver; for the first of these menstrua dissolves all metals except gold, and the latter all metals except silver. In this case then you are to pour, upon your metallic streak on the stone, one small drop of either of these liquors, and extend it gently over it with a feather. If it is neither gold nor silver, the whole streak will be obliterated and consumed; but, if there is any gold or silver in it, this remains undissolved, and shews another colour, because the other parts have been separated from it by the solution. When these menstrua are used, great care must be taken that there is no oil in the way; for that would spoil and destroy their effects.

Besides, these the following particulars are to be observed: gold and silver when pure, whether separate or both mixed together, without the addition of any other matter, when made hot in the fire, not only preserve their colour, but, if they were tarnished before, they recover their splendor there, not losing the least part of their weight: and, by this quality in these two metals, the caratura alba, or white allay, made by the mixture of gold and silver alone, is distinguished from all the others. If you have not liberty to try the whole mass in the fire, you may make this experiment on a small piece of it with a blow-pipe.

If you find a needle of the same allay with the metal under trial, the streaks made by both upon the Touch stone must undergo exactly the same changes when aqua-fortis is poured on them; and this ought always to be made a part of the trial by the Touch-needles, that no fraud may be at the bottom.

All gold rendered brittle, when compared with the Touch-needles by the stone, will appear less pure than it really is; and on the contrary all silver, rendered brittle, has the whiteness of silver in a higher degree: nor is there any wonder in this, when rightly considered, since the bodies which make gold and silver brittle are only a few metals, and semi-metals, all of a very bright white colour, and necessarily adding to the whiteness of silver, and taking from the yellowness of gold; such are tin, lead, regulus of antimony, bismuth, zink, and arsenic. These dilute the yellow colour of gold or copper into a whiteness, so that the colour of copper mixed with the silver is hidden by admixtures of this kind, whereas gold on the contrary appears by them to have much more silver in it than it really has.

In a white allay, aqua-fortis does not discover the presence of silver from twenty-three to seven carracts, because aqua-fortis does not separate silver from gold, unless the mass contains three times more silver than gold.

Metallic streaks or crusts which have been left some time upon the Touch-stone, cannot be compared with fresh ones, with any degree of use, because their remaining long on the stone always alters their colour.

Silver when tempered with brass appears whiter than it would do with a like quantity of copper, and, as it may then be rendered sufficiently ductile by a proper operation, you will hardly be able to find out the fraud with the Touch-stone, unless you make a second time the same comparison with the streak of a needle of the same colour, having previously poured aqua-regia upon the metallic crust laid by rubbing on the Touch-stone; nor are Touch-needles, tempered with brass, of any great use on this occasion, since this artificial metal is sometimes more and sometimes less yellow.

Lastly, if the metal laid upon the Touch-stone by rubbing does not appear neat or distinct enough, lick it over with spittle that is not frothy; and the colours will be by that means more distinctly and livelily reflected. *Cramer's Art of Assaying.*

TOUCH-*stone* (*Dict.*)— The Irish Touch-stone, called basanes Hibernicus by Molyneux and some others, is a black marble found in the county of Antrim in that kingdom, in angular columns, forming that amazing pile called by the vulgar the giant's causeway.

This marble has the property of trying metals by the Touch beyond any other known stone; but it is not easily wrought into form, being so hard that it turns the edges of all the tools used to cut stones. Were it not for this, it is admirably calculated for building, and for ornamental works; but nobody has attempted to use it in this manner, any where, except in the church of Ballywellan in the neighbourhood; and here the trouble of cutting is avoided, for the joints are taken as they found them, and the church is built of these in their natural shape, piled one upon another. The outer surface of this stone is of a whitish colour like lime-stone, but this is only the effect of the weather upon it; for where-ever it is broken it is found to be of a fine iron grey, and when polished appears of a true and deep jetty black.

TOW-*chain*, in husbandry, a name given by our farmers to a chain, that makes a part of the structure of the plough, fastening the plough-tail to what they call the plough-head.

This is an iron chain of few links, and very strong; it is fixed at one end to a collar fastened to the middle of the beam of the plough, and at the other end passes through that part of the plough-head called the box, which is the timber through which the spindle of the two wheels run. The stake of the plough, which is an upright piece running parallel with the crow-staves, pins this in at the bottom, running through the link which comes out by the box; this stake is fastened by wyths or cords in two places to the left crow-staffs, and the chain is thus kept firm. *Tull's Husbandry.*

TOXICODE'NDRON, *poison-wood*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the rosaceous kind, being composed of several leaves disposed in a circular form. The pistil arises from the cup, and finally becomes a fruit of a roundish shape, dry, not juicy, and usually of a striated structure.

TOXO'TÆ, τοξόται, among the Athenians, bowmen, a sort of inferior officers, or rather servants, who attended the lexiarchi.

TRACHU'RUS, in zoology, the name of a fish of the cuculus kind, called in English the shad, and by several authors suro, saurus, and lacertus marinus.

TRA'CING, in husbandry, a term used by our planters in the method of preserving the maize or Indian corn. This, being a large grain, is apt to spoil, if not carefully preserved.

Some thrash out the corn as soon as the ears are gathered, and lay it up in holes of the earth, which are their granaries: but those who have not opportunities of doing this, trace it, that is, they leave it in the ear, and weave or fasten together a great number of ears by the ends of the husks: these traces of corn they hung up within doors, on such supports as will keep them from one another; and they will, in this manner, keep good the whole winter.

This is a method of our introducing; but their own of burying the clean corn was at least as good, and was the same practised by the Ægyptians of old, and by all the wisest nations of the East at this time. But whether we have improved their husbandry in this particular, or not, it is certain that we have greatly assisted them in the planting this corn, which we do by the plough, instead of the troublesome method they had of doing it with the hoe. The manner of our planting it is this: we plow single furrows the whole length of the field, and at about six feet distance one from another; we then plow others a-cross at the same distance, and then, wherever the furrows meet, the corn is thrown in; it is then covered either by the hoe, or by running another furrow behind it with the plough; and when the weeds begin to overtop the corn, they plow the spaces again, and by this means destroy and turn in all the weeds, and give the earth stirring that greatly assists vegetation.

TRA'INING, or TRACING, in minerology, a term used by our miners, to express the tracing up the mineral appearances on the surface of the earth to their head or original place, and there finding a mine of the metal they contain.

The principle on which this practice depends, is the change wrought in the face of the earth by the deluge, of the effects of which these remains are a very great proof. The superficial or upper part of veins, or loads of ore, is always the poorest, the richer ores lying deeper down, the poor ones only serving to lead the way.

TRANSPORTA'TION *of plants.* In the sending plants from one country to another great cautions are necessary. The plants, sent from a hotter country to a colder, should be always put on board in the spring of the year, that the heat of the season may be advancing as they approach the colder climates; and, on the contrary, those which are sent from a colder country to a hotter, should be sent in the beginning of winter.

The best way of packing up plants for a voyage, if they be such as will not bear keeping out of the earth, is to have boxes with handles,

handles, filling them with earth, and planting the roots as close together as may be; the plants should be set in these boxes three weeks before they are to be put on board, and in good weather they should be set upon the deck, and in bad removed and covered with a tarpaulin.

If they are going from a hotter country to a colder one, they must have very little moisture; if, on the contrary, they are going from a colder to a warmer, they may be allowed water more largely, and being shaded from the heat of the sun, they will come safe.

Very many plants, however, will live out of the earth a great while; as the sedums, euphorbiums, ficoides, and other succulent ones. These need no other care than the packing them up with moss in a close box; and there should be a little hay put between them, to prevent them from wounding or bruising one another, and holes bored on the boxes to keep them from heating and putrifying. In this manner they will come safe from a voyage of two, or three, or even four or five months.

Several trees also will come safely in the same manner, taking them up at a season when they have done growing, and packing them up with moss. Of this sort are oranges, olives, capers, jasmines, and pomegranate-trees. These and many others are annually thus brought over from Italy; and, though they are three or four months in the passage, seldom miscarry. The best way of sending over seeds, is in their natural husks, in a bag, or packed up in a gourd-shell, keeping them dry, and out of the way of vermin. *Miller's Gard. Dict.*

TRANSFORMA'TION *of insects.* It is well known that flies are not produced in that form, from the eggs of their parent fly, but undergo a change like that of the butterfly, and the like winged insects; the egg hatching into a worm; and this after eating, and performing all the operations of animal life for a certain time, enters into a state of rest, and thence is changed into a fly.

Though the general course of nature is the same in this respect in flies and butterflies, yet the means and manner of it are different; the butterfly makes its coat for this Transformation; the fly-worms of many kinds have only a shell of their own proper skin to undergo this change in.

All the fly-worms of the first and second, and many of those of the third class, have their case thus made only of their own skin; the different species afford indeed some varieties in the manner of this, but a general idea of the work may be had from observing the worm or maggot of the common flesh-fly in its several stages.

When this creature has arrived at its full growth, it finds it not convenient any longer to remain among the food it has till then lived upon; it quits it and now goes in search of a place where it may wait for its metamorphosis. To this purpose it creeps into the earth, where it remains two or three days without any change; at the end of this time, instead of its pointed figure, its white colour, and soft fleshy substance, it acquires the figure of an egg, and becomes of a chesnut colour, or somewhat reddish, and looks opake and crustaceous: it is in this state perfectly stiff, and destitute of motion, and the creature seems not only to have lost its form, but wholly to have lost its life also.

This however is not the case; all that is done, is that the creature has absolutely quitted its skin, which is now become hard and of a determinate figure, and is within it compleating all its changes. *Reamur's Hist. of Insects.*

TRA'NSUM, in gunnery, is a piece of wood which goes a-cross the cheeks of a gun-carriage, or of a gun, to keep them fixed together; each Transum in a carriage is strengthened by a bolt of iron.

TRAPE'ZIUM, in geometry, a plain figure contained under unequal right lines.

TRA'VERSE-*table*, in navigation, is the same with the table of difference of latitude and departure; being only the difference of latitude and departure ready calculated to every degree, point, half-point, and quarter-point of the quadrant; and for any distance under a hundred miles, though it may conveniently serve for more.

This table is one of the most necessary things a navigator has occasion for; for by it he can readily reduce all his courses and distances, run in the space of twenty-four hours, into one course and distance; whence the latitude he is in, and his departure from the meridian, may be found.

TREME'LLA, *laver*, in botany, the name of a genus of small and seemingly imperfect plants, the characters of which are these: they are a kind of plants seemingly of a sort of middle nature between the alga and conferva. These produce no flower, nor seed, so far as has been yet observed, but are throughout of one uniform and tender texture, pellucid and membranaceous, and frequently gelatinous; they, for the most part, live in the water, and consist of flat and plain leaves, often very broad, and sometimes tubular. *Dillen's Hist. Musc.*

TREE.—Heat is so essential to the growth of Trees, that we see them grow larger and smaller in a sort of gradation as the climates in which they stand are more or less hot. The hottest countries yield in general the largest and tallest trees, and those also in much greater beauty and variety than the colder do; and even those plants which are common to both arrive at a much greater bulk in the southern, than in the northern climates; nay, there are some regions so bleak and chill, that they raise no vegetables at all to any considerable height. Greenland, Iceland, and the like places, afford no trees at all; and what shrubs grow in them are always little and low. In the warmer climates, where Trees grow to a moderate size, any accidental diminution of the common heat is found very greatly to impede vegetation; and, even in England, the cold summers we sometimes have, give us an evident proof of this; for though the corn and low plants have succeeded well enough, and goosberries, currants, raspberries, and other low shrubs, have brought forth fruit in sufficient plenty, yet the production of taller Trees has been found very much hurt; and walnuts, apples, and pears, have been very scarce among us.

Heat is heat, be it from what cause it will, and acts as well upon vegetation one way as another. Thus the heat of dung, and the artificial heat of coal fires in stoves, is found to supply the place of the sun.

Great numbers of the Indian Trees in their native soil flower twice in a year, and some flower and bear ripe fruit all the year round; and it is observed of these last, that they are at once the most frequent and most useful to the inhabitants; their fruit, which hang always on them in readiness, containing cool juices, which are good in fevers, and other of the common diseases of that hot country.

Plantations of useful Trees might be made to very great advantage in many places in every country, and the country greatly enriched by it, while the public would be also benefitted by it, since it would raise a continual supply of timber used in ship-building, and on other public as well as private occasions.

We have, in many places, heaths, and other barren and uncultivated lands, of very great extent; and how great an advantage would it be to the public to bring these to be truly valuable? Many, if not all of these heaths, would be found on trial capable of producing Trees; and some of them are truly the remains of destroyed forests; and, though the profits to be reaped from the planting these would come late, yet the expence of doing it would be very trifling in comparison of that profit, and the means easy.

The authors who have given rules for planting, having employed themselves only about small spots of ground, the establishing orchards, or parks, are by no means to be supposed proper guides in attempts of this kind; and Monsieur de Buffon, who had a great opinion of the knowledge of our Evelyn and Miller, who seem to speak of every thing from their own experience, found, when he set about large plantations, that their opinions and rules were erroneous; and was obliged to have recourse to experiments only; which he varied a thousand ways: and, though many of them proved unsuccessful, yet they all gave hints towards others, by which the attempt might afterwards be brought to succeed.

This sagacious enquirer into the operations of nature in the growth of vegetables, having set apart a considerable quantity of land for the trial, and procured a number of young Trees, first divided the whole quantity into a number of small squares, and, having made a plan of it, examined the nature, depth, and other circumstances of the soil in each, and minuted the whole down on a proper part of the plan: that himself or whoever succeeded him might judge, from the different growths of a number of Trees planted in the same state in the different soils, the different advantages and disadvantages of every circumstance in the depth and nature of the ground, in regard to the growth of useful Trees. Different numbers of labourers were employed about different spots of this ground, and the acorns for the young growth planted at different seasons; but the result in general was, that what should seem the best methods succeeded the worst; and those pieces where many labourers were employed, and the acorns planted before winter, were much thinner of young oaks, than those where the least labour had been bestowed upon the ground, and where the acorns had been planted in the spring; but those places which succeeded best from the sowing, were those which had the acorns planted in holes made by a pickax, without any preceding culture of the ground. And those where the acorns had only been laid upon the earth, under the grass, afforded a great number of vigorous young Trees, though the greater part had been carried away by birds, and other devouring animals. Those spots of ground where the acorns were set six inches deep, were much worse furnished with young shoots, than those where they had been buried but at an inch deep; and in some places where they were buried at a foot deep not one shoot appeared, though in others where they had been buried at nine inches there were many.

Those acorns which had been steeped for eight or nine days in wine lees, and in the water of the common sewers, appeared out of the ground much earlier than those which were put in without this previous management.

But the most succesful of all the trials was that of planting in the spring such acorns as had been sown together in another place, and had time to shoot there; of these scarce any failed, and the plantation was perfectly flourishing, though the growth of these young shoots was not so quick and vigorous as those

of

of the acorns which had remained, when firſt ſown; which was probably owing to the injury the tender radicles received in tranſplanting.

Thus ſucceeded the experiments by ſowing, while, of thoſe made by planting young Trees, ſuch as had been brought out of woods, and places under covert, ſucceeded much worſe than thoſe which had grown in more expoſed places.

The young Trees of the ſeveral parts of the plantation kept on their growth in the manner they had begun to ſhoot, thoſe of the more laboured parts continuing more weak, and lower than thoſe of the leſs laboured.

Thus were a number of neceſſary experiments carefully tried, and the reſult of the whole was, that to make a plantation of oaks, on a ſoil of the common clayey or loamy kind, the moſt ſucceſsful method is this: the acorns muſt be preſerved during the winter in the earth in this manner: let there be made a bed of earth ſix inches deep, on this place a layer of acorns two inches deep, over theſe lay a bed of another half foot of earth, over that another layer of acorns, and ſo on ſucceſſively, till as many are employed as there will be occaſion for; the whole is then to be covered with a foot depth of earth, to preſerve all from the froſt. In the beginning of March, theſe beds are to be opened, and the acorns which will by that time have ſhot out, and are then in reality ſo many young oaks, are to be planted out at a foot diſtance each, and the ſucceſs of a plantation of this kind need not be feared. This is a manner of planting that is done at a ſmall expence, and even that might be in a great meaſure ſpared, were it not for the birds and other devouring animals; ſince, could the acorns be defended from theſe, they might be only laid on the ſurface of the ground under the graſs in autumn, and they would infallibly ſhew themſelves in ſo many young oaks the ſucceeding ſpring.

It is eaſy to continue the carrying the acorns, when taken out of their winter's bed, to the place where they are to be planted, without doing them much injury; and the ſmall ſtop the tranſplanting puts to their growth, is in reality rather an advantage than an injury; ſince it only retards the young ſhoots for about three weeks, or leſs than that: and by that means ſecures them from the few cold mornings that may be expected about the time of their natural appearance.

TRE'NCHING-*plough*, in huſbandry, the name of an inſtrument uſed to cut out the trenches, drains, and carriages, in meadow and paſture ground. It is alſo uſed for cutting the ſides of turf even, which are to be laid down again, either in the ſame, or in ſome other places.

It conſiſts of a long handle, with a knob or button at the end, and at the other end it turns upwards like the foot of a plough, to ſlide in the ground. In this part is placed a coulter of the length proportioned to the depth to the cut, and with a ſharp edge: this has two wheels to make it run eaſy, and does a great deal of buſineſs in a little time. *Mortimer's Huſbandry.*

TRIA'NDRIA *, in botany, a claſs of plants which have hermaphrodite flowers, with three ſtamina or male parts in each.

* The word is derived from the Greek τρεῖς, three, and ἀνὴρ, male. Of this claſs of plants are the valerian, ſaffron, a great many of the graſſes, &c. See *plate* XL. *fig.* 3.

TRIANGLE (*Dict.*) — Plutarch informs us, that Xenocrates the philoſopher reſembled the Deity to an equilateral Triangle, the genii to an Iſoſceles, and men to a ſcalenum. A Triangle has been ſince applied by Chriſtians to repreſent the Trinity, ſometimes ſingle, and at other times with additional lines, expreſſing a croſs. Thus we find them variouſly combined upon the medals of the popes publiſhed by Bonanni. And nothing was more frequent formerly with printers than to place theſe figures in the front of their books; at firſt, doubtleſs, with a religious intent, till at length, by common uſe, they became only preſs marks, and badges of diſtinction among the trade; as they now are with merchants, who mark their goods with them both here and abroad. *Phil. Tranſ.* N°. 474.

TRICHE'RIÆ *, in natural hiſtory, the name of a genus of foſſils, of the claſs of the fibrariæ, the characters of which are, that they are not elaſtic, and are compoſed of ſtraight and continuous filaments.

* The word is derived from the Greek τρίχες, capillaments or fibres.

TRICHE'STRUM *, in natural hiſtory, the name of a genus of foſſils, of the claſs of the ſelenitæ, but differing extremely in figure and ſtructure from the common kinds.

* The word is derived from the Greek τρίχες, hairs or filaments, and ἀστὴρ, a ſtar; and expreſſes a ſet of bodies compoſed of filaments arranged into the form of a ſtar.

The ſelenitæ of this genus are compoſed of filaments ſcarce any where viſibly arranged into plates or ſcales, but diſpoſed in form of a radiated ſtar, made of a number of disjunct ſtriæ. *Hill's Hiſt. of Foſſ.*

TRIEDRO'STYLA *, in natural hiſtory, the name of a genus of ſpars.

* The word is derived from the Greek τρὶς, thrice, ἕδρα, a ſide, and στῦλος, a column.

The bodies of this genus are ſpars, in form of trigonal columns, adhering by one end to ſome ſolid body, and terminated at the other by a trigonal pyramid.

TRIE'MERUS, *the three-day fly*, in natural hiſtory, a fly ſomewhat like the butterfly; it has four large yellowiſh wings, and a long body, with a head furniſhed with long antennæ, large eyes, and a ſpiral trunk. It is found among the nettles and mallows.

TRIEXAHÆ'DRIA *, in natural hiſtory, the name of a genus of ſpars.

* The word is derived from the Greek τρὶς, thrice, ἓξ, ſix, and ἕδρα, a ſide.

The bodies of this genus, are perfect, and pellucid cryſtalliform ſpars, conſiſting of thrice ſix planes, being compoſed of an hexangular column, terminated at each end by an hexangular pyramid.

TRIFO'LIUM, *trefoil*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of a papilionaceous kind: the piſtil which ariſes from the cup finally becomes a capſule, which remains covered with the cup, and uſually contains kidney-ſhaped ſeeds. To this it is to be added, that the leaves grow three on every ſtalk; though there are ſome inſtances of theſe plants truly of this genus, which have four or five on the ſtalk. See CLOVER.

TRIGONO'METRY (*Dict.*)—In ſolving the firſt caſe of oblique-angled plane triangles, the proportion is, as any one ſide is to the ſine of its oppoſite angle, ſo is any other ſide to the ſine of its oppoſite angle.

For take A *b* = C B (*plate* LVII. *fig.* 8. in the Dictionary) and upon A C let fall the perpendiculars B D, *b d*; which will be the ſines of the angles A and C, to the equal radii A *b*, C B. Now the triangles A B D, A *b d*, being ſimilar, we have as A B : B D (ſine of the angle C) :: A *b* (B C) : *a b* (ſine of the angle A.)—Alſo, in caſe 4, the proportion is, as the ſum of any two ſides is to their difference, ſo is the tangent of half the ſum of the two oppoſite angles to the tangent of half their difference.

For let A B C (*plate* LVII. *fig.* 9. in the Dictionary) be the triangle, and A B and A C the two propoſed ſides; and from the center A, with the radius A B, let a ſemi-circle be deſcribed, interſecting C A produced, in D and F; ſo that C F may expreſs the ſum, and C D the difference, of the ſides A C and A B: join F, B, and B, D, and draw D E parallel to F B, meeting B C in E.

Then, becauſe 2 A D B = A D B + A B D = C + A B C, it is plain that A D B is equal to half the ſum of the angles oppoſite to the ſides propoſed. Moreover, ſince A B C = A B D (A D B) + D B C, and C = A D B — D B C, it is plain that A B C — C is = 2 D B C; or that D B C is equal to half the difference of the ſame angles.

Now, becauſe of the parallel lines B F and E D, it will be C F : C D :: B F : D E; but B F and D E, becauſe D B F and B D E are right angles, will be tangents of the foreſaid angles F D B (A D B) and D B E (D B C) to the radius B D.—Likewiſe, in caſe 6, the proportion is, as the baſe is to the ſum of the other two ſides, ſo is their difference to the difference of the ſegments of the baſe.

For, let A B C (*plate* LVII. *fig.* 13. in the Dictionary) be the triangle; then on B as a center, with the radius B C deſcribe the circle C D E F, produce A B to D, draw the right-line B F, and let fall the perpendicular B G. Then, becauſe B is the center of the circle C D E F, therefore B E, B C, and B D are equal, and A D = A B + B C, and A E = A D — B C; and, becauſe the point A is without the circle, A C × A F = A D × A E (*by* 36 *of Euc.* 3.) which, being turned into an analogy, will be, as A C : A D :: A E : A F. Which was to be proved.

The meaſure of a ſpherical angle C A D (*plate* LVII. *fig.* 11. in the Dictionary) is an arch of a great circle intercepted by the two circles A C B, A D B, forming that angle, and whoſe pole is the angular point A. For let the diameter A B be the interſection of the great circles A D B and A C B, and let the plane, or great-circle D E C, be conceived perpendicular to that diameter, interſecting the ſurface of the ſphere in the arch C D; then it is manifeſt that A D = B D = 90°, and A C = B C = 90°, and that C D is the meaſure of the angle D E C (or C A D) the inclination of the two propoſed circles.

The firſt theorem for the ſolution of right-angled ſpherical triangles in the Dictionary may be thus demonſtrated:

Let A D L and A E L (*plate* LVII. *fig.* 10. in the Dictionary) be two great circles of the ſphere interſecting each other in the diameter A L, making an angle D O E, meaſured by the arch E D; the plane D O E being ſuppoſed perpendicular to the diameter A L, at the center O.

Let A B be the baſe of the propoſed triangle, B C the perpendicular, A C the hypothenuſe, and B A C (or D A E = D E = D O E) the angle at the baſe: moreover, let C G be the ſine of the hypothenuſe, A K is tangent, A I the tangent of the baſe, C H the ſine of the perpendicular, and E F the ſine of the angle at the baſe; and let I, K, and G, H, be joined.

Becauſe C H is perpendicular to the plane of the baſe (or paper) it is evident, that the plane G H C will be perpendicular to the plane of the baſe, and likewiſe perpendicular to the diameter A L, becauſe G C, being the ſine of A C, is perpendicular to A L. Moreover, ſince both the planes O I K and A I K are perpendicular to the plane of the baſe (or paper) their interſection

tion I K will alſo be perpendicular to it, and conſequently the angle A I K a right angle. Therefore, ſeeing the angles O F E, G H C, and A I K, are all right angles, and that the planes of the three triangles O F E, G H C, and A I K are all perpendicular to the diameter A L, we ſhall, by ſimilar triangles,

have { O E : E F : : G C : C H
{ O E : O F : : A K : A I }

that is, { Radius : ſine of E O F or (B A C) : : ſine of A C : ſine of B C.
{ Radius : co-ſine of E O F (or B A C) : : tang. A C : tang. A B. *Q. E. D.*

Hence it follows that the ſines of the angles of any oblique ſpherical triangle A D C are to one another, directly, as the ſines of the oppoſite ſides.

In the Philoſophical Tranſactions, Vol. XLVII. p. 441, & ſeq. the learned Francis Blake, eſq; F. R. S. has given us the following method of reducing ſpherical Trigonometry to plane.

It is obſervable, that the analogies of ſpherical Trigonometry, excluſive of the terms co-ſine and co-tangent, are applicable to plane, by only changing the expreſſion, ſine or tangent of ſide, into the ſingle word, ſide, ſo that the buſineſs of plane Trigonometry, like a corollary to the other, is thence to be inferred. And the reaſon of this is obvious; for analogies raiſed not only from the conſideration of a triangular figure, but the curvature alſo, are of conſequence more general; and, though the latter ſhould be held evaneſcent by a diminution of the ſurface, yet what depends upon the triangle, will nevertheleſs remain. Theſe things may have been obſerved, I ſay; but, upon reviſing the ſubject, it further occurred to me, and I take it to be new, that from the axioms of only plane Trigonometry, and almoſt independent of ſolids, and the doctrine of the ſphere, the ſpherical caſes are likewiſe to be ſolved.

Suppoſe, firſt, that the three ſides of a ſpherical triangle, *a b d* (*plate* XLI. *fig.* 5.) are given to find an angle, *a*; which caſe will lay open the method, and lead on to the other caſes, in a way, that to me appears the moſt natural. It is allowed, that the tangents, *a e*, *a f*, of the ſides, *a d*, *a b*, including an angle, *a*, make a plane angle equal to it; and it is evident, that the other ſide, *d b*, determines the angle made by the ſecants *c e*, *c f*, at *c* the center of the ſphere; whence the diſtance, *e f*, between the tops of thoſe ſecants, is given by caſe the fifth of oblique plane triangles (ſee Heynes's Trigonometry) which, with the aforeſaid tangents, reduces it to caſe the ſixth of oblique plane triangles alſo: and thus this eleventh caſe of oblique triangles, ſo intricate hitherto, becomes perfectly eaſy. The twelfth caſe is reducible to the eleventh, and the reſt, whether right-angled, or oblique, we are authoriſed to look upon as reducible to right-angled triangles, whoſe ſides are not quadrants, but either greater or leſs than ſuch. Conceive therefore, now, in a right-angled ſpherical triangle, *g k b* (*fig.* 7.) that the tangent, *g m*, and ſecant, *c m*, of either leg, *g k*, is already drawn; and in the point, *m*, of their union, draw a perpendicular, *m l*, to *c m*, the ſecant, directly above the other leg, viz. a perpendicular to the plane of the ſecant and tangent, that it may be perpendicular to both (Eucl. 4. 11.) for then will the tangent, *g l*, of the hypothenuſe, *g b*, drawn from the ſame point, which that of the leg was, conſtantly terminate in the perpendicular line, that the radius and tangent may make a right angle (Eucl. 18. 3.) Whence theſe tangents, *g m*, *g l*, and the perpendicular line, *m l*, together with the ſecants, *c m*, *c l*, will evidently form two right-angled plane triangles, *g m l*, *c m l*; and to one or other of theſe the ſpherical caſes are eaſily transferred. Thus, if in the ſpherical triangle, *g k b*, the hypothenuſe, *g b*, baſe, *g k*, and angle, *g*, at the baſe, be the parts given and required, when any two are given, the third may be determined by means of a plane triangle, and at a ſingle operation. We have, for inſtance, in the right-angled plane triangle, *g m l*, formed as above, the baſe, *g m*, and hypothenuſe, *g l*, to find, by caſe the fifth of right-angled plane triangles, the angle included, which is the ſame as on the ſphere. And then, if the baſe, *g k*, the angle, *g*, at the baſe, and perpendicular, *k b*, be the ſpherical parts given and required; or, if the angles, *g* and *b*, and the hypothenuſe, *g b*, be the parts given and required; we have only that former proportion of the hypothenuſe and baſe, and angle at the baſe, in the triangles, P N D, D F G, (*fig.* 6.) obtained by the complements, to transfer to the plane. But, ſecondly, ſuppoſe the ſpherical proportion is of the three ſides, any two being given, the third may be alſo found at a ſingle operation, in the ſecond right-angled plane triangle, *c m l*, formed as above. We have, for inſtance, the hypothenuſe and baſe, *c l*, *c m*, viz. the ſecant of the ſpherical hypothenuſe and baſe *g b*, *g k*, to find, by the fifth of right-angled plane triangles, the angle, *c*, at the center, which is the meaſure of *k b*, the ſide that was ſought. And then again, if the hypothenuſe, one leg, and the oppoſite angle be the ſpherical parts given and required; or, if the two angles and a leg be the parts given and required; we have only the former proportion of the three ſides in the triangles, P N D, D F G, obtained by the complements, to transfer to the plane. Whence, the ſix proportions of right-angled ſpherical triangles being comprehended in this method, it is fully demonſtrated, that all the caſes of theſe triangles are ſo to be reſolved.

The ſame might be deduced without the method of complements, but neither in ſo ſhort nor ſatisfactory a way, and it ſhall therefore be omitted. I have communicated this upon account of its perſpicuity, and ſuppoſing, that in an age ſo greatly advanced in mathematical learning, the leaſt hint of what is new would not be unacceptable.

TRILL-*hooks*, thoſe uſed to hold the ſides of a cart up to the horſe.

TRILLE'TO, in the Italian muſic, a little ſhort ſhake or quaver; it differs from trillo, only in point of continuance being its diminutive.

TRI'LLO, in the Italian muſic, is often found marked with a ſingle T, or tr, and often alſo by a ſmall t, as well in vocal as inſtrumental parts. It is deſigned to intimate, that you beat quick upon two notes in conjoint degrees, as *e f*, or *d e* alternately; beginning with the higheſt, and ending with the loweſt.

TRI'NGA, in the Linnæan ſyſtem of zoology, the name of a diſtinct genus of birds, of the order of the ſcolopaces: the diſtinguiſhing character of this are, that the feet have each four toes, and the beak is ſhorter than the toes. *Linnæi Syſtema Naturæ.*

TRINGA *minor*, in zoology, a name by which ſome authors called the bird commonly known in England by the name of the ſandpiper.

TRIPENTAHE'DRIA *, in natural hiſtory, the name of a genus of ſpars.

* The word is derived from the Greek, τρὶς, thrice, πέντε, five and ἕδρα, a ſide.

The bodies of this genus are ſpars compoſed of thrice five planes; being made of a pentangular column, terminated at each end by a pentangular pyramid. Of this genus we only know one ſpecies; this has a moderately long column, and very ſhort and broad pyramids; it is found in Derbyſhire, Yorkſhire, and Cornwall, and is very frequent about Goſſelaer in Saxony. *Hill's Hiſt. of Foſſ.*

TRI'POLI (*Dict.*)—The yellowiſh white kind is called by authors alana gleba, tripolis, and terra tripolitana; this is the produce of Germany, Saxony, and France; there is alſo ſome of it in the neighbourhood of Venice, but it is found in greateſt plenty in many parts of Africa. It is a dry hard earth, of a very pale yellowiſh white, of a firm texture, and moderately heavy; it is ſometimes found of itſelf, conſtituting a ſtratum; but is more frequently met with in detached pieces among ſtrata of other matter. It is of a rough, irregular, duſty ſurface; it adheres ſlightly to the tongue, is dry, hard, and harſh to the touch, is not to be broken between the fingers, and ſlightly ſtains the hands: it makes no efferveſcence with aqua fortis, and makes a ſlight hiſſing noiſe on being thrown into water. The reddiſh Tripoli is of our own production, though not peculiar to ourſelves; it is found in great abundance on Mendip-hills in Somerſetſhire, nor leſs plentifully in many parts of Germany. This is well known in the ſhops as a ſubſtance of great uſe in poliſhing braſs, but is not applied to any of the other uſes of the yellowiſh kind: this, like the former, is moſt frequently found in detached maſſes, and, while in the earth, is tolerably ſoft, and eaſily falls into flakes. When dry, it becomes of a conſiderable hardneſs; and is of a fine pale reddiſh white, of a looſe open texture, compoſed of a multitude of extremely thin plates or flakes laid evenly on one another, and conſiderably heavy; it is of a ſmooth and ſomewhat gloſſy ſurface; it adheres very firmly to the tongue, is dry and harſh to the touch, too hard to be broken between the fingers, and does not ſtain the hands: it makes no efferveſcence with acids, and burns to a paler colour, with ſome additional hardneſs. *Hill's Hiſt. of Foſſ.*

TRIPYRAMI'DES *, in natural hiſtory, the name of a genus of ſpars.

* The word is derived from the Greek, τρὶς, thrice, and πυραμὶς, a pyramid.

The bodies of this genus are ſpars, compoſed of ſingle pyramids, each of three ſides, ſtanding on no column, but affixed by their baſes to ſome ſolid body.

TRO'CHUS, in natural hiſtory, the name given by authors to a genus of ſhells; ſome of the ſpecies of which reſemble the figure of the Trochus, or top which boys play with. As there are many ſpecies of this ſhell, however, which are flatted and have nothing of this form, the whole ſeries are much better named, by a denomination taken from the ſhape of the mouth, which is of an oval figure, and is alike in all theſe ſpecies, and different from all other ſhells. They are therefore aptly charactered by a late French writer under the name of cochleæ ore depreſſo.

TROIS-*cinque*, in French diſtillery, a term uſed to expreſs their brandy when of a peculiar ſtrength, conſiſting of five parts alcohol, and three parts phlegm.

The method of diſtilling the wines into brandy, in France, is exactly the ſame with that uſed with us to draw the ſpirit from our waſh or fermented liquor of malt, treacle, ſugar, or whatever other kind. They only obſerve more particularly to throw a little of the natural lee into the ſtill, along with the wine; and the pooreſt wines are found to ſucceed beſt on the trial, making by much the fineſt brandies. We are apt to wonder, that we cannot from the wines of particular countries diſtil their particular brandies; but the whole myſtery conſiſts in this, that they do not ſend us over the ſame wines which they uſe in diſtilling, becauſe theſe latter would not be liked as wines, nor would keep in the bringing over. Sometimes, in Scotland, they meet with the poor and pricked wines, the ſame that the French diſtil their brandies from; and from theſe they diſtil a ſpirit, not to be known from the brandy diſtilled in France.

The lee, which the French add in the diſtillation, gives the brandy that high flavour for which we ſo much eſteem it; but they themſelves like it much the worſe for it. The French notion of a proof ſtrength, determined by the chaplet or crown of bubbles, is the ſame with ours; and all their fine ſpirits are found of this ſtrength.

But they have one particular expedient for thoſe brandies which prove foul and feedy, or retain the taſte of certain weeds which grow among the wines; they draw them over again, with a deſign to free them from that adventitious flavour. In this operation they always leave out the faints, or rather they change the receiver as ſoon as ever the ſtream comes proof; then mixing together all that run off before, they make a brandy ſtronger than the ordinary kind, and this is what they call Trois-cinque.

The diſtillers in France ſcarce ever bring their brandies higher than this; for they have the art to perſuade the foreign merchant, that the phlegm of French brandy is natural and eſſential to it: but the truth is, that the ſpirit alone contains the flavour and excellence of the brandy, and it might as well be reduced to half its bulk for exportation, and ſent over in the ſtate of alcohol, and then lowered with common water, to the proof ſtrength.

The French uſe no art in colouring their Trois-cinque, any more than their common proof-brandy, nor do they add any thing to give them an additional flavour. The thing which they principally value themſelves upon, both in regard to brandies and wines, being to make them perfectly natural: ſo that all the colour we find in their brandies, is acquired from the caſk, and the time they are left in it. This is often twelve or eighteen months, ſometimes two or three years; in this time they acquire a brown colour, and loſe their acrid taſte.

The greateſt adulteration of brandies is in England; the French have no temptation to do it, they having no cheaper ſpirit, ſince the prohibition of moloſſes in their country. The Dutch are in the ſame condition, having no moloſſes ſpirit; and only a very coarſe and nauſeous ſugar-ſpirit, and yet a worſe malt-ſpirit of their own manufacture; a ſingle gallon of which would ſpoil a whole piece of brandy. The French brandy alſo, paying no duty in Holland, is as cheap, or nearly ſo, there, as in France itſelf. The duties being high upon brandy, it is greatly adulterated, and that with all ſorts of ſpirits, &c. as malt, moloſſes, cyder, and ſugar-ſpirits; and, when this is done in a dexterous and ſparing manner, the cheat is not eaſily found out. *Shaw's Eſſay on Diſtillery.*

TRO'PHY, in architecture, an ornament which repreſents the trunk of a tree, charged or encompaſſed all round about with arms or military weapons, both offenſive and defenſive.

TROUT, a very valuable river-fiſh, the diſtinguiſhing characters of which are theſe: its body is long; its head ſhort and roundiſh; the end of its noſe or ſnout obtuſe and blunt; its tail is very broad; its mouth large; and each jaw furniſhed with one row of ſharp teeth; and in its palate there are three parcels of teeth, each of an oblong figure in the congeries, and all meeting in an angle near the end of the noſe; and the tongue has ſix, eight, or ten teeth alſo on it, and its ſides are beautifully variegated with red ſpots.

This delicious fiſh is obſerved to come in and go out of ſeaſon with the ſtag and buck; the time of its ſpawning is remarkable: moſt other fiſh do this in warm weather, but the Trout in October or November. Among the ſeveral kinds of Trout the red and the yellow are the beſt for the table; and, in the ſame ſpecies, the female has always the preference to the male; the head of the female is ſmaller, and the body deeper than in the male. They are known to be in ſeaſon by the bright colour of their ſpots, and by the largeneſs and thickneſs of their backs; which laſt is a general rule in regard to all fiſh, to know when they are in ſeaſon.

In winter the Trout is ſick, lean and unwholeſome, and very often is louſy. The louſe, as it is called, of the Trout, is a ſmall worm with a large head, which ſticks very faſt to the ſides of the fiſh; they live upon the juices of the fiſh all the time of the cold weather, while he is poor and lies quiet in the deep waters; but when the warm weather in the ſpring comes on, and the fiſh leaves his lazy life at the bottom, and comes up to the ſhallow gravelly places, where the ſtream is ſwift, he ſoon ſhakes them off.

The Trout, at his firſt coming into the ſhallow waters, may be ſeen to rub his body continually upon the ſharp gravel at the bottom; it is by this means he gets off theſe worms or lice, as they are called. From this time he begins to feed on flies; but, in May, the peculiar fly that he is fond of is produced, and, after feeding that whole month on this inſect, the fleſh of the fiſh becomes more red and firm, and its higheſt ſeaſon begins.

The general baits for a Trout, are a worm, a minnow, or a fly, whether natural or artificial: among worms, there are ſeveral kinds which this fiſh is fond of; ſuch are the earth-worm and dung-worm in particular; the lob-worm and brandling-worm are alſo eſteemed: but the beſt of all is the ſquirrel-tail-worm, which has a ſtreak down the back, a red head, and a broad tail. The brandling is commonly found in an old dung-hill, or under cow-dung, or elſe among tanners bark; the others are found in the earth, and under large ſtones or ſtumps of trees: whatever worm is uſed, the longer it is kept to ſcower firſt, the better the Trout will take it: they are to be kept in an earthen pot among moſs, which is to be ſhifted once in three or four days, or oftener, if the weather be very hot.

To take the Trout with a ground-bait, the angler ſhould have a light taper rod, with a tender hazel top; and may angle with a ſingle hair of three links, the one tied to the other, for the bottom of the line; and a line of three-haired links for the upper part: with this ſort of tackle, if the ſportſman have room enough, he will take the largeſt Trout in the river. Some fiſh with three-haired links at the bottom of the line, but there is very little ſport to be expected this way, for the Trout is very ſuſpicious, and very quick-ſighted. The angler muſt always keep out of ſight, and the point of the rod muſt be down the ſtream. The ſeaſon for fiſhing for the Trout with a ground-bait begins in March, and the mornings and evenings in general are the beſt times; but, if the weather be cloudy, the ſport may be followed all day long: there muſt be a plummet at ten inches from the hook, which the angler muſt feel always touching the ground, and this muſt be heavier, the ſwifter the ſtream is. The common worm is a good bait.

The minnow is a very good bait for the Trout, and with this the tackle need not be ſo ſlight, for the Trout will make at this bait with leſs conſideration, and ſeize it as ſoon as it comes in ſight; the upper part of the line with this bait may be of three ſilks and three hairs for the upper part, and two ſilks and two hairs for the lower; and the hook may be moderately large. The whiteſt minnows and thoſe of the middle ſize are the beſt bait for the Trout, and they ſhould be ſo fixed on the hook, as to turn round when they are drawn up againſt the ſtream.

The beſt way of baiting this fiſh is to put the hook in at the mouth and out at the gills, then drawing it through about three inches, to put it again in its mouth, and let the point and beard come out at the tail, and then to tie the hook and his tail with a fine white thread, letting the body of the minnow be almoſt ſtraight down to the hook; by this means it will turn, as it is pulled againſt the ſtream; and, the more and quicker it turns, the better: for want of a minnow, a ſmall loach or a ſtickleback will ſerve.

The moſt agreeable manner of fiſhing for Trout is, however, with the fly, when the ſportſman has found the true method of doing it; the rod in this caſe muſt be light and pliable, and the line long and fine; if one hair be ſtrong enough, as it may be made, by proper ſkill in the angler, there will be more fiſh caught, than where a thicker line is uſed; and the fly-fiſher ſhould have the wind at his back, and the ſun before him.

TRU'MPET-*flower, bignonia*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is compoſed of only one leaf, of a tubular form, wide open at the mouth, and ſeeming as if bilabiated: from the flower-cup ariſes a piſtil, which is fixed in the manner of a nail to the hinder part of the flower; this afterwards becomes a fruit or pod, divided into two cells by a longitudinal membrane, and containing flatted and uſually alated ſeeds.

TRU'MPET-*ſhell, buccinum.* See the article BUCCINUM.

TRU'MPETER, in zoology, a name given in England, to a particular ſpecies of pigeon, called by Moore the columba tibicen.

This ſpecies is of the middle ſize of the common pigeon, and made conſiderably like it; but it is pearly-eyed; is of a mottled black, and is feathered down to the legs and feet, and is turn-crowned like the nun, and ſome of the other ſpecies; ſometimes like the finnikin, but much larger: this ſeems to be the beſt ſort, as being the moſt melodious. The beſt character, to know them by, is a tuft of feathers growing at the root of the beak; and, the larger this tuft is, the more they are eſteemed. The reaſon of their name is, that they imitate in their cooing the ſound of the trumpet; but, to be often entertained with their melody, it is neceſſary to feed them frequently with hemp-ſeed. *Moore's Columbarium.*

TSIN, in natural hiſtory, the name given by the Chineſe to a ſtone which they make great uſe of in their manufacture of porcelain ware. It is of a deep blue colour, much reſembling Roman vitriol in appearance, and is found in lead mines, and ſuppoſed to contain ſome particles of lead; its effects being the ſame in the porcelain manufacture as thoſe of ceruſs or white lead, in making the other colours penetrate into the ſubſtance of the veſſels. The deep violet colour that we ſee

ſo

so beautiful on the China ware, is usually made with this stone. They find it about Canton and Peking; but the latter place affords the best, and it sells at greatly the best price. The painters in enamel melt this stone in their way, and use it very much; they form many beautiful works by laying it upon silver; but it is apt to come off in time.

When the Tsin is used in the porcelain manufacture, it it only used to the vases that pass a second baking, and are intended as the best kinds.

The Tsin is prepared by only beating it to powder, not roasting it in the common way. They mix the powder with large quantities of water; and, stirring it together, they let it subside a little to separate any earthy or extraneous matter that might be among it. They then let the powder subside. The water which is thrown away has no colour from this matter; and the powder itself is not of that fine blue it was in the lump, but of a pale ash-colour; but this recovers all its beauty, when it is laid on the China and baked.

The settlement taken from the water is dried and preserved in powder, and, when it is to be used, they only mix it up with gum-water, or a solution of glue, and lay it on with a pencil. *Observations sur les Coutumes de l'Asie.*

TU'BBER, or TUBBLE, in mining, a name given in Cornwall to that mining instrument, which is in other parts of England called a beele.

It is an iron instrument, pointed at each end, and having a hole in the middle for the handle.

TU'BEROUS, or TUBEROSE *roots*, among the botanists, such as are large and fleshy, thicker than the stalk of the plant, of an irregular figure, and wanting the characters of the bulbous.

TU'BERA, *truffles*, in botany, the name of a genus of plants, the characters of which are these: they are of a fungous fleshy structure, and are of a roundish figure, growing sometimes single, sometimes many together, and always remaining under ground. See TRUFFLE in the Dictionary.

TU'BULATED *Flower*, *tubulatus flosculus*, in botany, a term used by authors to express those smaller flowers, a great number of which go to compose one large compound flower. These are called Tubulated in distinction from another kind of them, which are, from their shape, called ligulated. The Tubulated floscules generally compose the disk, and the ligulated ones the radius of the compound flowers. The Tubulated ones are formed into a hollow cylinder, which expands into a mouth at the top, and is divided into five equal segments, which stand expanded, and in some measure bent backwards.

TU'BULUS *marinus*, or *canalis*, in natural history, the name of a genus of univalve shell-fish, the characters of which are these: it is of an oblong figure, terminating in a point, and hollow within; so that it resembles a tube of horn. They are also called by the older writers dentalia, for their resembling the tooth of a dog.

TUCK *of a ship*, the trussing or gathering up the quarter under water; which, if she lie deep, makes her have a broad, or, as they call it, fat quarter, and hinders her steering, by keeping the water from passing swiftly to her rudder; and, if this trussing lie too high above the water, she will want bearing for her works, unless her quarter be very well laid out.

TU'GUS, in botany, the name of a sweet aromatic plant, much esteemed in the eastern parts of the world, and supposed by father Camelli, who very strictly compared it with the accounts given by Dioscorides and the antients of their amomum, to be that very plant. The clustered manner of growing of the fruit, together with its oblong shape, and the aromatic taste of the seeds, seem greatly to countenance this opinion.

TU'LIP, *tulipa*, in botany, a large genus of plants, the characters of which are these: the flower is of the liliaceous kind, and is composed of six leaves, and somewhat of the form of a pitcher; the pistil occupies the center of the flower, and finally becomes an oblong fruit divided into three cells, which contain flat seeds, arranged in a double order; the root is tunicated, and the fibres grow from its bottom. The characters of a good Tulip are these: 1. It must have a tall and strong stem. 2. The flower should consist of six leaves, three within and three without; and the former should be larger than the latter. 3. The bottom of the flower should be proportioned to the top, and the ends of the leaves should be rounded, not pointed. 4. The leaves, when opened, should neither turn inward, nor bend outward, but stand erect; and the whole flower should be of a middling size, neither too large nor too small. 5. The stripes must be small and regular, and should all arise from the bottom of the flower: the chives also should not be yellow, but of a brown colour.

Tulips are generally divided into three classes, according to their times of flowering; the early, the middling, and the late.

The early ones are not near so high as the late, but they are valued for their earliness, as they flower in February.

The roots of these are to be planted in the beginning of September, under a warm pale or hedge. The proper soil for them is pasture land with the turf rotted among it, and a mixture of one-fourth part sand; this should be laid about ten inches deep, and should be renewed every year. If the weather is very severe when they first appear, they should be covered with mats; as also at nights, when they are in flower, if it be very frosty. When their flowering is over, and their leaves decay, the roots should be taken up, and laid in a dry place, and afterwards cleaned and laid up in a safe place from vermin, till the September following.

The late blowers are propagated from what they call breeders, which are plain flowers, brought over principally from Flanders, which is the great mart for flower-roots; and these, by culture, are changed into striped and variegated ones. They are also propagated by sowing the seeds; but this requires great care, as in the raising all the other fine flowers from their seeds.

The seeds must be saved from the choicest flowers, and sowed in shallow pans or boxes of earth, in September. The spring following they appear like the leaves of grass or young onions, and after standing two or three months those decay. The boxes are to be kept clear of weeds, and removed to different situations where they may enjoy the morning sun, and be defended from sharp winds and frosts; at the Michaelmas of the following year they are to be removed out of the boxes into beds, where they should be planted two inches deep, and at two inches diameter from one another. In October, an inch depth of new earth should be sifted on them, and they are to remain two years in these beds; at the end of this time they will flower, and the best of them must be marked with sticks, that their roots may be distinguished, when the leaves are decayed.

But there is no judgment to be passed either on Tulips, or any other flowers, on their first flowering; because, the next year, the good ones are often found to have degenerated, and the bad to have improved: after this, however, they may be concluded good or bad.

The breeders, as they are called, being thus raised, are to be shifted every year into fresh earth, and they will in time break out into very fine stripes. The earth they are planted in should be every year of a different kind, and the best general soil is made of a third part pasture land with the grass rotted in it, a third part of fine sea-sand, and a third part of lime-rubbish; these should be mixed half a year before they are used, and often turned. The beds must be laid eighteen inches deep with this earth. This should be laid in first ten inches thick, and on this the roots should be placed in regular order and at even distances; and then the other eight inches should be laid over these, the top of the bed being a little rounded to throw off the wet. Thus they are to remain till the buds appear, and then, if the nights are very severe, they are to be sheltered by covering them with mats. The flowers which break out into fine stripes here, should be separated afterwards from the rest, and if they hold on their beauty to the last, which the florists call dying well, they will never return to plain flowers again; and the off-sets from the roots of these will always produce such flowers, and often more beautiful than those of the parent-root.

When the Tulips have flowered, their heads should be broken off to prevent their seeding, which would make them flower much the worse the next year. *Miller's Gard. Dict.*

TULIP-*tree*, a very beautiful American tree, which produces flowers, supposed like those of the Tulip. These trees used to be kept in tubs, and housed in winter with great care; but, some of them having been planted out in the open air at Lord Peterborough's at Fulham, they throve much better than those which were so carefully nursed up, and soon produced abundance of flowers.

The tree is commonly found wild in all the northern parts of America, where its timber is of very great use. The flowers are not in reality much like those of the Tulip, though vulgarly said to be so. The flowers are succeeded by cones, which are often sent over from America; and the trees are frequently raised, with us, from the seeds contained in them. The seeds must be taken out of the cones in the spring, and sown in pots of light earth, which must be placed in a bark bed, and covered with mats, and frequently refreshed with a little water. When the young plants appear, they should be placed, during summer, in a shady situation; and in winter they should be put into a frame, where they may have the benefit of the open air, in mild weather, and be sheltered from the severity of frosts. In the spring following, the plants should be transplanted into small pots, and taken the same care of for four years, as while they were in the seed-pots; after this they will be strong enough to transplant finally into the places where they are to remain: it should be planted on a light loamy soil, near other trees, but not overshaded by them. Some raise them from layers, but they are two or three years before they take good root, and then never make such straight and regular trees. *Miller's Gard. Dict.*

TU'MBLER, a name given to a particular species of pigeon, called by Moore the columba revolvens.

It has its name from its peculiar property of tumbling, when it is in the air, which they are very fond of doing; and effect, exactly in the same manner as our posture-masters do it, by throwing themselves over backwards. It is a very small pigeon, and is always short-bodied, full-breasted, thin-necked, narrow-beaked, and has a small short head; the iris of the eye, in this species, is usually of a bright pearl-colour.

The English Tumbler is usually of one plain colour; black, blue, or white: the Dutch is much of the same make, but has different colours, and is feathered on the legs sometimes; it has also a larger head, and thin skin round the eye. Some of the finest pigeons of this sort are bred from a mixture of the Dutch and English kinds. These pigeons are remarkable for the height they fly to; they never ramble far from home, but will rise almost perpendicularly, till they appear no larger than a sparrow, or become quite out of sight; they will often keep at this height five or six hours, and then come gradually down again: they will never tumble when they are at any great height, but only as they ascend or come down again. There are particular times also, at which those birds will take much higher flights than at others; but they ought to be kept by themselves, and practised to it by the company of one of their own species; for if they mix, while young, with other pigeons, they will learn to fly as they do: a flight of a dozen of these birds sent out together will keep so close as to be all in a compass that might be covered with a handcherchief; but they should never be turned out in foggy weather, or in high winds; in the first case they lose sight of their home, and perhaps never find it again, and, in the others, they are blown away; and, if they return, it is not till another day: in the mean time, lying out, they are in danger of cats, and other accidents.

Lastly, the hen should never be turned out with egg, for she is then sick, and not fit for flying; and, besides, often drops her egg, and the breed is lost by it. *Moore's Columbarium.*

TU'NICATED *Roots*, among botanists, such as are formed of a multitude of coats surrounding one another.

TU'NNY, a name given by us to the Spanish mackarel, a larger fish of the scomber kind, called by authors thynnus and arcynus, by Salvian limosa, and pelamys by Aristotle, Ælian, and the other old writers.

It is properly a species of the scomber, and is expressively named by Artedi the scomber with eight or nine fins in the hinder part of the back, rising out of a furrow; and a furrow at the place of the belly-fins.

TU'RBAN-*shell*, *cidaris*, in natural history, the name of a genus of the echinodermata, which are of the hemispheric or spheroidal figure, and have their name from the Latin, cidaris, a Persian Turban, as in some degree resembling that head-dress.

TURBINI'TÆ, fossil shells of the turbo kind, or stones found in those shells. Among the people who have objected to the shells found buried in the earth being the remains of real animals, it has been alledged by some, that these, in particular, are always of a blackish or ash-colour, when found in chalk or clay, and white from the rocks, or when they have been bedded in stone.

TU'RBIT *pigeon*, a particular species of pigeon remarkable for its short bill, and called by the Dutch cort-bek, that is, short-beak. Moore calls it, in Latin, columba fimbricata: and its English name seems no other than a bad pronunciation of its Dutch one. It is a small and short-bodied pigeon, and has a beak no longer than that of a partridge; the shorter this is, the more the pigeon is esteemed: it has a short round head, and the feathers upon the breast open and reflect both ways, standing out like the frill of the bosom of a shirt. This is called by many the purle, and, the more the bird has it, the more it is esteemed. The tail and back are generally of one colour, as blue, black, red, yellow, or dun, and sometimes chequered. The flight feathers, and those of all the rest of the body, are white. They are a light nimble pigeon, and, if trained to it, will take very high flights in the manner of the tumblers. *Moore's Columbarium.*

TU'RBO, *the screw-shell*, in natural history, the name of a genus of shell-fish, the characters of which are these: they are univalve shells, with a long, wide, and depressed mouth, in some species approaching to a round shape, and in some having teeth, in others not. They all grow narrow towards the base, and are auriculated, and terminate in a very long and sharp point.

TU'RBUT, in ichthyology, a name given by us to the fish called by authors the hippoglossus, passer major, and passer Britannicus.

According to the new system of Artedi, this is a species of the pleuronectes, and it is distinguished by him by the name of the wholly smooth pleuronectes with the eyes on the right side.

TU'RNING (*Dict.*)—The lathe, or principal instrument used in turning, is composed of two wooden cheeks, or sides parallel to the horizon, having a groove, or opening between them; perpendicular to these are two pieces, called heads or puppets, made to slide between the cheeks, and to be fixed down at any point at pleasure: these have two points or center pins, between which the piece to be turned is fastened by the help of a screw. There is also a square piece of wood called a rest, which bears up the tool, and keeps it steady. The piece is turned round backwards and forwards, by means of a string put round it, and fastened above to the end of a pliable pole, and below to a treddle or board moved by the foot. This is the common lathe; but there is another used in hollow Turning, &c. very different from it.

This lathe is composed like the other of two cheeks, and has also two heads fitted to slide between them; but has no pole, being turned by means of a wheel and a pulley. The pulley is fastened on a kind of spindle called a mandrel, one end of which is pointed, and received into the center of the back-screw, which goes through one of the heads; and near the other end called the verge it moves in a piece called the collar; the end of the mandrel passes through the collar, and on it the piece to be turned is fastened. These descriptions will be rendered abundantly more easy from the two perspective views on *Plate* LIV, which represent both these kinds of lathes in so conspicuous a manner, that a full idea of both may be easily attained.

Fig. 1. is the lathe used by hollow turners, &c.

1. The lathe. 2. The groove. 3, 3. The heads or puppets. 4. The pulley. 5. The mandrel. 6. The collar. 7. The back-screw. 8. The rest. 9. The wheel. 10. The crank. 11. The treddle.

There are several kinds of mandrels, adapted to the different kinds of work; as

Flat mandrels which have three or more little pegs or points, near the verge, and are used for turning flat pieces on.

Pin mandrels, which have long wooden shanks, to fit into round holes in the work to be done.

Hollow mandrels, which are hollow of themselves, and used for Turning hollow work.

Screw mandrels, which are used in Turning screws.

There are a great variety of other instruments used in Turning, as chissels and gouges of different kinds, perspective views of most of which are represented in the figure. Thus, 12. Is a tool called a holdfast. 13. A point tool. 14. A broad chissel called a firmer.

Fig. 2. is a perspective view of the common lathe.

1. The lathe. 2, 2. The heads or puppets. 3. The pole. 4. The treddle. 5, 5. screws which fix the rest at a proper height. 6, 6. The rest. 7. The back-screw.

The workman stands, or is seated in his lathe, having one of his feet on the treddle to give the motion, which must be very moderate and equal; he places his tool on the rest, and approaches the edge of it gently to the piece, performing his work gradually, without leaving any ridges; and, when he meets with a knot, he must go on still more gently, otherwise he would be in danger both of splitting his work, and breaking the edge of his tool.

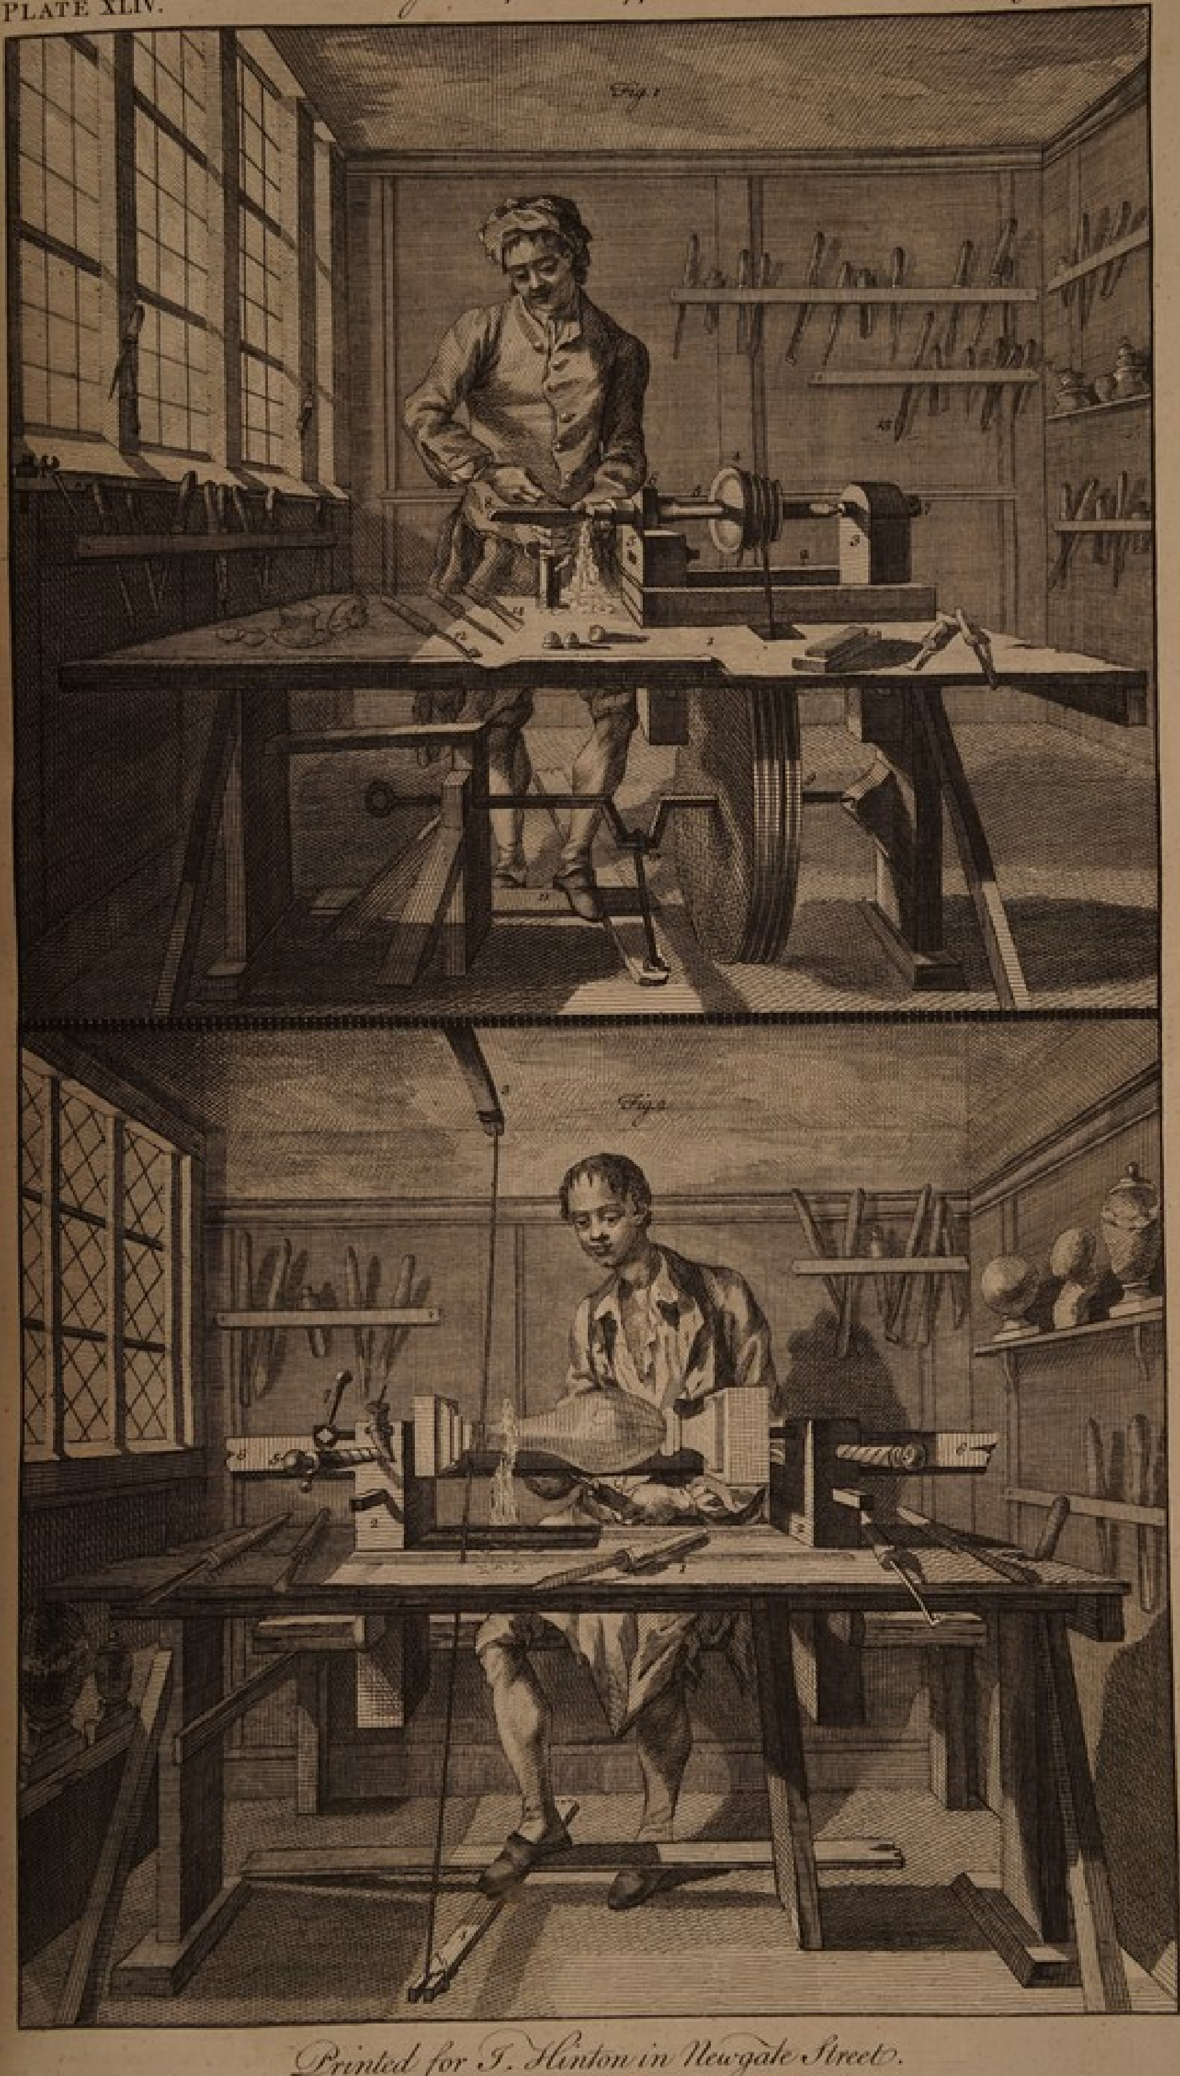
The two perspective views on the plate will give a better idea of the nature of Turning, than is possible to be conveyed by words. The first figure shews the nature of hollow Turning, and the second that for common work.

TUR'NSOL, a plant of considerable use by the colour prepared from it, and known under its name. The root of these plants is long and white; the leaves resemble in shape those of the xanthium, or lesser bur-dock; they grow on long pedicles, and are of a whitish or ash-coloured green. The flowers form a sort of cluster, and grow out of the alæ of the leaves; they are of two kinds on the same plant, barren and fruitful, or, as botanists express it, male and female.

The barren, or male flowers, occupy the top of every cluster, and are placed each in a cup, divided into five segments, and themselves consist each of five small yellowish leaves with a bundle of stamina in the middle. The female, or fruitful flowers, are placed at the bottom of the cluster, and are surrounded each by a cup, divided into ten segments; they are composed of five stamina, which surround a pistil which is furnished with three forked filaments. This pistil, which is fixed in the bottom of the cup, finally becomes a round fruit, of a rough surface, and green colour, its protuberances only appearing a little whitish. This fruit is divided into three cells, and each of these contains one round seed. The whole fruit is attached to the cup by a very long pedicle, so that when the flowers are withered, and it has arrived at its maturity, it is found hanging from the alæ of the leaves, and seems to have been produced without any flower; and this is what has led some writers into the error of imagining that the flowers and fruit of this plant grow on different stalks. Some have translated Turnsol by the English word sun-flower, which has led many to suppose, that the great yellow sun-flower which we keep in gardens, was the plant that afforded the Turnsol colour: but this is a mistake; and it is to be observed, that the true Turnsol plant here described is very common in the fields of France and Germany, but does not grow wild with us in England.

The juice of the berries of the Turnsol, rubbed upon paper or cloth, at the first appears of a fresh lively green, but presently changes into a kind of bluish purple. The same cloth, afterwards wet in water, and wrung out, will turn the water into a claret-colour: and it is to be observed, that these are the rags of cloth usually called Turnsol in the druggists shops. *Boyle's Works.*

TU'RNSTONE, in zoology, the English name of a bird called



Printed for J. Hinton in Newgate Street.

called by authors the morinellus marinus, or sea-dotterel. It is a little larger than the blackbird; its head moderately thick, and its body of a longish shape; its beak a finger's breadth long, thick at the base, and sharp at the point; and its head, neck, shoulders, wings, and the upper part of its breast, are of a brownish colour; its throat and belly are snow-white: the middle of its back has a very large white blotch, and its rump is variegated by a broad transverse streak of black; its legs are short, and of a reddish yellow or orange colour. *Ray's Ornithol.*

TU'RTUR, *the turtle-dove*, in zoology, a very beautiful little bird of the pigeon kind. The head, neck, and back, are of the bluish grey colour of the common pigeon, with some mixture of a reddish brown near the rump, and at the bottom of the neck. Its breast and belly are white; but its throat of a fine bright purple; and the sides of the neck are variegated with a sort of ringlet of beautiful white feathers, with black bases.

It feeds on hempseed, and other vegetable matters. *Willughby's Hist. Avium.*

TURTUR, *the turtle-shell*, in natural history, the name given by the collectors of shells to a very beautiful species of murex, common in the cabinets, but not found any where on the shores. This is owing to its having greatly altered its appearance in the polishing; for it is no other than the white and brown mouthed murex, which is common in its rough state, with its outer coat taken off. See the article MUREX.

TUSSILA'GO, *colts-foot*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the radiated kind. The disk is composed of floscules, and the outer circles of semi-floscules; these stand upon the embryo seeds, and are all contained in a scaly cup. These embryo's finally become seeds winged with down, and adhering to the thalamus of the flower. To this is to be added, that the flowers appear before the leaves. *Tourn. Inst.*

The common colts-foot stands generally recommended as a very great medicine in coughs, and all disorders of the breast and lungs. It is also sometimes used externally in inflammations.

TU'TTI, in the Italian music, is used to signify that all the parts are to play together, or to make a full concert.

In this sense Tutti stands opposed to soli or solo; which signifies one part playing alone.

V.

VA'NNING-*Shovel*, among miners, an instrument used for washing the ores of any metal, after being reduced to powder, thereby to discover the richness and other qualities of the ore. See the article SHOAD.

VA'POUR (*Dict.*) — *Fiery* VAPOURS, *halitus ignei*, a term used by some to express those exhalations from the earth, which either take fire of themselves on the bursting forth into the air, or are readily inflammable on the bringing a candle to them. Many of the supposed burning lakes are owing to these fumes bursting up through the water, and not to any quality of the water itself. Our famous burning well at Wigan, in Lancashire, is of this kind. The common people affirm, that the water of this spring burns like oil; but there is nothing of truth in this. There thrusts up a vapour through the earth in this place, which keeps the water bubbling, as if boiling over the fire, though it is not warm; and the stream of this breath may be felt issuing up in these places like a strong wind. This breath alone is inflammable, and takes fire at the approach of a candle, burning with a considerable violence for some time.

There are coal-pits in the neighbourhood, and the air is certainly of the same kind with that inflammable vapour, often met with in those places, and which may also be prepared from iron dissolved in a proper menstruum. The water itself, taken from the place, does not burn; and, if the bottom be made dry, the vapour which ascends from it will burn as strongly as if the water were there. The flame is not discoloured like that of sulphureous bodies, nor has it any bad scent; and the fumes, as they are felt bursting out of the earth, by the hand held over the place, are not hot. *Phil. Trans.* N°. 20.

VARI'ETIES, in natural history, a word used to express an accidental change in some body which is not essential to it, and therefore does not constitute a different species.

The naturalists of former ages have run into great errors, in mistaking the accidental varieties of plants, animals, and minerals for distinct species. Many of them have called a plant a new species, because its flower, which should have been blue or red, is white on account of the poorness of the soil, or some other such reason. Mr. Ray has established a very good test for Varieties in botany; he allows every thing to be a distinct plant which will propagate itself in its own form by its seeds, but such, as when sown, lose their difference, and run back to the old standard, he accounts Varieties, however great their distinctions may appear. In the history of fishes as much confusion has been introduced by mistaking Varieties for distinct species as in botany. Artedi is the only author who has rationally attempted to bring this part of natural history into order in this respect, and to settle regularly the rules by which to distinguish real and essential from accidental differences.

The principal grounds of the error of supposing Varieties distinct species of fish have been these: the variable and inconstant colour of fishes has been mistaken for a specific difference; in this manner Rondeletius has described many Varieties of the turdi, labri, and other fishes, under the names of distinct genera.

Others have paid the same too great regard to the more constant Varieties of colour; which are found only to differ in degree, in the several individuals of the same species; and their differences to be only in the degrees of the same colour, which is much more intense in some, and more remiss in others. These differences can only make Varieties of the same fish, the species remaining always the same. Of the same kind are the mistakes of those who esteem size or magnitude a specific character; and thus, out of the Varieties of the same fish, occasioned by scarcity or plenty of food, or other such occasions, make larger or smaller species. The place where fish are caught, is also another occasion of making new species, with this sort of authors; thus though the perca fluviatilis of Bellonius, and the perca marina of other authors, be the same fish, yet they are pretended to be different species. The time of spawning is also with some made a distinction of species; and thus we find the common pike divided into three species, according to its spawning in spring, summer, and autumn, which it does according to the heat or coldness of the climate.

All these differences are false and frivolous, and the utmost they can do, is to make what are properly called Varieties, though few of them are sufficient even for that. A salmon, caught at sea, is not different from one of the same brood caught in a river: and if the perca marina, falsly so called, be a little different from the perca fluviatilis, yet, if its spawn will produce regular percæ fluviatiles, its difference can only amount to a variety, not a distinct species.

The trifling nature of distinction by colour is seen by the Varieties we daily see in the colours of some of our most common fish; as the tench, the eel, the salmon, and some others, which vary more or less, from every change of the water; all the other distinctions, of size and place, are as frivolous; and the giant and the dwarf, the black and the white man, the Asiatic and the European, may as well be called distinct species of men, as these of fishes.

Finally, the time of spawning is no essential difference; for we daily see the change of climate make changes of that kind in all creatures; and even in the same climate, and under the same circumstances, the same species of birds will afford some individuals much earlier, or later, in laying their eggs than others.

China-VA'RNISH. The China Varnishes have been always famous; the manner of making which is said to be as follows: take crude Varnish sixty ounces, common water the same quantity, mix them well together till the water disappears; afterwards put this into a wooden vessel five or six palms long, and two or three broad; mix them together with a wooden spatula, for a whole day in the summer's sun, for two days if in winter, and afterwards keep it in an earthen vessel covered with a bladder. The water will not unmix itself again: this is called the sun-Varnish. The oil of wood, called by the Portuguese azeile de Pao, is made in the following manner; take twenty ounces of that oil, which they call oil of wood, and ten drachms of the oil of the fruit; boil these a little together, and the oil will look yellow; then let it cool, and add to it five drachms of quick-lime powdered. To make the first grounds called camiseca, take swine's blood and quick-lime powdered, of each an equal quantity; spread this mixture upon the wood, and, when it is dry, smooth it with pumice-stones.

To make the black Varnish, take of the Varnish prepared in the sun sixty ounces; stone black alum (supposed to be a sort of copperas) dissolved in a little water, three drachms; and seventy drachms of lamp-oil, called, by the Portuguese, azeile de Candea. These things are all to be mixed together in a wooden vessel, putting the lamp-oil in at twice, and stirring the whole together with a wooden spatula.

The pitch-coloured Varnish is made in the following manner: take oil of wood, crude, forty drachms, called de Pao; of the lamp oil, called de Candea, crude, forty drachms; mix them together in the sun in a wooden vessel, in the same manner as the common Varnish, and water are ordered to be mixed in the first process.

To make the red Varnish, take ten drachms of cinnabar, twenty drachms of prepared Varnish, and a little lamp oil; mix them all together; and,

To make a Varnish of a musk colour, take of the red Varnish ten drachms, and of the black Varnish four drachms; mix them all together. *Philos. Transf.* N°. 261.

These are the accounts sent to the great duke of Tuscany, by the jesuits in China. Dr. William Sherard communicated them to the Royal Society; and to render the accounts useful to the world, he presented with them the several substances mentioned; these are deposited in the Musæum of the society, and may serve as instructions to all who are curious in this art.

VARNISH *for porcelain.* The Chinese have of late years discovered a new kind of Varnish for their ware: they call this tsekinyeou, that is to say, the brownish gold Varnish; it is of the colour of the brown images, or of what we call coffee colour. The novelty of this has made it much esteemed: it is made in the manner of all their other Varnishes, by dissolving the finer part of an earthy substance in water. The substance which they make it of is a common yellow earth; this they dissolve in water, and, letting the coarse parts settle, they pour off the yet thick liquor, and what afterwards subsides from this, is the pure and fine part, which they keep in form of a soft paste, or thick cream. They use this only to the thinnest and most delicate porcelain ware.

The manner of using it is this: they mix a quantity of this fine sediment with so much water as renders it thin and liquid, like to the common Varnish; this and the common kind are to be used together, so that care must be taken that they are nicely of the same degree of thickness; this the workmen try by dipping a petunse or brick of their earth into both, and seeing which comes out most covered; that which lies on the thickest, is to be diluted with more water, or the other to be heightened with more of the earth, to bring them to the same standard. They are both judged to be sufficiently liquid, when they enter the pores of the petunse. They then mix some of the oil of fern ashes and lime (*see the article* FERN-*oil*) along with the brown Varnish, and add as much of this mixture to the common Varnish as they find upon trial will give such a colour as is required. The common proportion for the brown colour, most esteemed at present, is two pints of the brown Varnish to eight pints of the common; and to four pints of this mixture they add one pint of the Varnish or oil of fern. It might puzzle a stranger to their terms to understand what these people meant by oil; but it is a word with them in use for any thing liquid; and they call all their Varnishes so, though made of the powders of earths and stones mixed with water. They apply this Varnish to the vessels by dipping them into it, and so completely covering them inside and out before they put them into the oven; and the baking gives a great brightness to the colour. This is the nicest part of the whole manufactory of the porcelain, and other wares of that kind. The Varnishes used by the Chinese are two; the one they call the oil of stones, the other, oil of Fern; which see. They mix these together, and with great caution and delicacy, for it requires an experienced artist, apply them to the vessels all over equally, with a steady hand and a fine pencil.

When the porcelain is very thin and fine, they give it two beds of the Varnish, the one over the other, when dry; these are to be very thin, and they answer to the single covering of Varnish given to the common good China, that is thick and strong. They give these coats by dipping, and use the foot of the vessel to hold it by; after this they hollow the foot, and paint the circle that we see round it, or mark it with some Chinese character.

The Varnish they lay on is so thick, that it often hides the colours, till the baking afterwards brings them out again: this is the case with the fine deep blues; we see none on the best China, it is all hid under the coat of white, and the vessel appears plain, till it has passed through the fire again; but then the colour appears deeper than when at first laid on. *Observ. sur les Coutum. de l'Asie.*

VAU'NING, in minerology, a term used by our miners to express a coarse and expeditious way of washing ores, for the examination of their nature and richness.

This instrument, called the vaun, is a long and moderately deep wooden shovel; into this they put the earthy or stony matter, which they suspect to contain the metal in powder; they then add water many times, and, shaking and stirring it thoroughly about, they throw out the water, and add fresh, till at last the matter is separated; the earthy part is washed away, and the stony and mineral matter only remain, the one at the hinder part, the other at the point of the shovel. This last is collected separate; and, on being examined either by the eye or test, they are able to judge very nearly of the general profit of the mine.

This method is often used with the stones and earths found in the shoads, or trains of mines. *Phil. Transf.* N°. 69.

VEGETA'TION (*Dict.*) — The great attention of all who study botany, is at present placed on the discovery of new plants; but we are yet unacquainted with many peculiarities in the most common ones, which may prove not a less worthy employment for our thoughts.

The irregularities in the Vegetation of the several parts of plants seems a subject well deserving our attention; and Mr. Marchand has laid before us an instance of this in one of our most vulgar plants, the common garden radish.

In the month of July, this gentleman observed a plant of this species, which had accidentally fixed itself in an open place, and was then full of flowers and pods. Towards the end of one of the branches, he observed a kind of tuberosity of an oblong shape, which looked somewhat like one of the pods of the plant, but that it was too long, and was very oddly twisted and contorted; this daily increased in size, and in a week was come to its full growth, which was, in the whole, about two inches and a half in length, and three quarters of an inch thick. It was of a very rough and knotty surface, and, like the rest of the stalk, had several pedicles of flowers growing on each side from it; it terminated in a smooth end, divided into three parts, which all turned upwards.

The longest of these points terminated in a green cartilaginous flower of the same substance with the protuberance which produced it; in this were all the regular parts of the flowers of the more perfect kind; there were four leaves which served for a cup; four more within these, which represented the petals; six other small bodies there stood in the middle of the flower, which represented the stamina; and among these another body which represented the pistil; so that here was, in this irregular Vegetation, a representation at large of every part of the perfect flower of the radish, excepting only the apices; but these were all very different, in their nature and structure, from their similar parts in the natural flowers, being all of a hard, thick, and tough cartilaginous substance, and in colour of a greenish brown.

The shortest of the three points which terminated this tuberosity, had also at its end a resemblance of a flower composed of all the parts mentioned in the former, and of the same colour and substance with it, only differing in being a little smaller: and the third point had no regular resemblance of a flower, but was of the same cartilaginous substance, and of a semi-circular figure, and had its upper surface ornamented with several irregular protuberances. This irregular Vegetation remained in vigour till October, when it gradually faded away, and there was no appearance of seeds in any part of it.

The radish, when its stalks are wounded by the pucerons, or other insects, will often throw out a protuberance of some irregular figure; but the resemblance of flowers, in this, was a singularity never before observed.

To explain this, it will be necessary to observe, that every organised part of a plant contains in it a number of invisible seminal principles, capable of producing plants like that to which they have owed their origin; and this is a truth of which the succeeding instances will all bring very familiar and obvious proofs.

The graft of a tree, which, from only one single bud, produces a tree like that from which it was taken, certainly acts upon this principle; for the whole tree is quite different from the stock on which it is grafted, which serves for no other purpose but merely to convey to it a proper nutritive juice from the developing its parts.

We very well know, that there are many roots, which being cut into little slices of only a quarter of an inch thick, each of these will propagate its species, and send up new plants like that which the root belonged to; and, some roots being split longitudinally into four quarters, each of these will in the same manner grow and flourish, and shoot out roots from one part, and stalks from another, so as to furnish perfect plants the same year: and how can this be, but by their having been seminal points in all these pieces and sections of roots, which being dilated, and put in action by the humidity of the earth, have grown into perfect plants. Several of the bulbous-rooted plants produce off-sets from the several scales of their roots, and from the sides of their stalks; these in three years time produce perfect plants with their flowers; and what are these but so many seminal points ready upon occasion to be developed?

Nothing is so obvious, as that the slips or cutting of trees, when planted in the ground, produce roots in one part, and buds for branches from another, and so finally become trees, like those from which they were cut; and this, though the piece that is planted, has no visible appearance of any bud in any part of it.

We also know, from daily experience, that many plants shoot out roots from their stalks as they grow, and that, though this usually happens in places where there is some solid substance for these new roots to fasten themselves to, yet it happens also in some plants where there is no such use for them; and what are these roots in a new part of a plant, but the

the effect of so many seminal points, ready to grow, both into roots and into branches, in all those places?

Among the thick and fleshy-leaved plants, as the opuntia, and other of the succulent plants of the Indies, there needs no more to produce a new plant, but to cut off a part of a leaf, and stick it into the earth, where it will at once take root, and produce a new plant in a very short time. A thousand other instances of this kind might be given; but these may be sufficient to prove, that there are, in almost all parts of plants, certain seminal points, which, like the plantula seminalis, inclosed in the perfect seed of each, need only humidity, and a proper degree of warmth, to develope and unfold themselves into perfect plants.

We are not therefore to wonder at the imitation of perfection in any irregular productions of vegetables, since it appears that there are numbers of perfect plants contained in every part of a growing plant, of the same kind. *Mem. Acad. Par.* 1709.

VEIN, among miners, is that space which is bounded with woughs, and contains ore, spar, canck, clay, chirt, croil, brown-hen, pitcher-chirt, cur, which the philosophers call the mother of metals, and sometimes soil of all colours. When it bears ore, it is called a quick vein; when no ore, a dead vein. *Houghton's Compl. Miner, in the Explan. of the Terms.*

The Veins of mines differ greatly from one another in depth, length, and breadth; some stretch obliquely, from the surface toward the central parts of the earth; and these the miners call deep Veins; others lie shallow and circular, so as to encompass a large space, and these are termed spreading Veins; others possess a great part of the space they lie in, both in length and breadth, and these are called accumulated Veins, being no more than a space possessed by a large group of fossils of one kind. To give the complete history of Veins and fibres, which are smaller Veins, their differences, their directions, their interstices, their discontinuations, their risings and fallings, and their goodness, would be a large work. Let it be observed, however, that these things seem all to proceed in a certain order, though that order, and the laws and rules of it, are not perfectly understood, so as to afford sure directions for practice; whence it sometimes happens, that, after a Vein has been successfully traced for some time, it dips, breaks off, or takes a different course, leaving the workmen as it were at a fault.

When the Vein is found, a pit is to be sunk upon it, and a crane fixed at the top of the pit for craning up the ore. Burrows, or adits, are also to be cut horizontally through the hill in one or more places, reaching to the mine, and serving to wheel out the ore, instead of craning it up. *Shaw's Lect.*

VELO'CITY (*Dict.*) — In the doctrine of fluxions it is usual to consider the Velocity with which magnitudes flow or are generated. Thus, the Velocity with which a line flows is the same as that of the point, which is supposed to describe or generate the line. The Velocity with which a surface flows, is the same as the Velocity of a given right line, that, by moving parallel to itself, is supposed to generate a rectangle, always equal to the surface. The Velocity with which a solid flows, may be measured by the Velocity of a given plain surface, that, by moving parallel to itself, is supposed to generate an erect prism, or cylinder, always equal to the solid. The Velocity with which an angle flows, is measured by the Velocity of a point, supposed to describe the arc of a given circle which subtends the angle, and measures it. See *Mac-Laur. Fluxions, B. I. ch.* 1.

All these Velocities are measured at any term of the time of the motion, by the spaces which would be described in a given time, by these points, lines, or surfaces, with their motions continued uniformly from that term.

The Velocity with which a quantity flows, at any term of the time, while it is supposed to be generated, is called its fluxion.

VEL'VET (*Dict.*)— *Colour of black* VELVET. The manner of giving this deep and fine colour to glass is this: take of crystalline and pulverine frit, of each twenty pounds; of calx of lead and tin four pounds; set all together in a pot in the furnace, well heated; when the glass is formed and pure, take steel well calcined and powdered, scales of iron that fly off from the smith's anvil, of each an equal quantity; powder and mix them well; then put six ounces of this powder to the above described metal while in fusion; mix the whole thoroughly together, and let all boil strongly together; then let it stand in fusion twelve hours to purify, and after this work it. It will be a most elegant Velvet black.

There is another way of doing this, which also produces a very fair black. It is this: take an hundred weight of rochetta frit; add to this two pounds of tartar, and six pounds of manganese, both in fine powder; mix them well, and put them to the metal while in fusion, at different times, in several parcels; let it stand in fusion after this for four days, and then work it. *Neri's Art of Glass.*

VENE'TA *Bolus*, a fine red earth used in painting, and called, in the colour-shops, Venetian red.

It is improperly denominated a bole, being a genuine species of red ochre. It is of a fine bright and not very deep red, approaching, in some degree, to the colour of minium, or red lead; and is moderately heavy, and of an even and smooth texture, yet very friable, and of a dusty surface; it adheres firmly to the tongue, is very smooth, and soft to the touch, easily crumbles to pieces between the fingers, and very much stains the skin in handling. It has a slight astringent taste, and makes no fermentation with acids. It is dug in Carinthia, and sent from Venice into all parts of the world, being an excellent colour, and very cheap; our colour-men, however, find too many ways of adulterating it. *Hill's Hist. of Foss.*

VENTILA'TOR (*Dict.*)— The noxious qualities of bad air have been long known, though not sufficiently attended to in practice; but it is to be hoped, that the indefatigable pains taken by Dr. Hales, to set the mischiefs arising from foul air in a just light, and the easy remedy he has proposed by the use of his Ventilators, will at length prevail over that unaccountable sloth or obstinacy, which, where particular interests are not immediately concerned, seems to possess the generality of mankind, and which rarely allows them to give due attention to any new discovery.

The Ventilator invented by that ingenious author consists of a square box of any size; in the middle of one side of this box a broad partition, or midriff, is fixed by hinges, and it moves up and down by means of an iron rod, fixed at a proper distance from the other end of the midriff, and passing through a small hole in the cover of the box. Two boxes of this kind may be employed at once, and the two iron rods may be fixed to a lever moving on a fixed center; so that, by the alternate raising and pressing down of the lever, the midriffs are also alternately raised and depressed, whereby these double bellows are at the same time both drawing in air, and pouring it out through apertures with valves made on the same side with, and placed both above and below the hinges of the midriffs. For a farther account of this machine we refer to the author himself, who gives a full detail of it, and of its manner of working. See *Description of Ventilators, by Stephen Hales, D. D. Lond.* 1743, 8vo.

VER-*puceron*, in natural history, a name given to a kind of insects which are fond of eating the puceron, and destroy them in vast numbers.

They are thus called, as the ant-eater is formicalis, from their destroying great numbers of them.

These Ver-pucerons are a sort of worms produced from the eggs of flies; and are of two principal kinds; the one having legs, the other none.

VER-*polype*, in natural history, a name given, by Reaumur and some other authors, to a species of water-worm, by no means to be confounded with the creature called simply the polype, and which is so famous for its reproduction of parts cut off, and for many other singular properties. See the article POLYPE.

This Ver-polype is a species of water-worm, produced from the egg of a tipula; and had its name given it from some remarkable productions, placed at the anterior and posterior parts of the body, which are supposed to have some analogy with the parts of the sea-fish called the polypus.

These worms are found in muddy ditches, usually either crawling upon, or buried in the mud. They are of various sizes, from more than an inch in length to a fifth of an inch, and are smooth and even on their surface; they are composed of several rings, as other insects of this kind, and have a brown scaly head, of a regular figure, and much harder than the rest of the body. Just below the head, on the under part of the body, there are placed two membranaceous productions which seem fragments of arms; they are considerably thick, and are cut off obliquely at the ends, and furnished with many hairs. At the other extremity of the body there are placed four other productions, resembling four pieces of cords; two of these are affixed to the middle of the lower side of the last ring but one, and the other two, at the joining of this, to the last ring. The anterior pair serve the creature greatly in its moving, and these hinder ones have their use in fixing that part of the body in the earthy case the creature sometimes makes for itself, while the head is at liberty to move every-where about in search of prey. These hinder ones are broadest at their insertion, and somewhat narrower at the point, and are very flexible and moveable every way.

The anus of the creature is placed near the end of the last ring of the body, and is of a square figure; it is surrounded with a number of rigid hairs or spines, and at each corner has a fleshy tubercle, which stands out a considerable way from the level of the body; the two under ones are much larger than the other two, and the creature evidently uses them to push itself forward in its moving about. Probably, however, these parts have some other more important use. The taking in of air or water is likely enough to be the use they are assigned for.

The cells which these creatures usually live in, are composed principally of fragments of a light and spungy earth, and to this they add the broken pieces of sticks and leaves, and other such substances as are just heavy enough to sink in water. Mr. Reaumur suspects that they have a method of spinning some glutinous fluid out of their bowels, to fix these things together with. But, though they usually reside in these cases, they

they often quit them, and are found swimming about the water, or with their tails at the top, and playing about with their bodies; or at the bottom, crawling on the surface of the mud.

When the creature has lived its destined time in this state, it changes into a nymph, in the case in which it had lived to the time of this change; it throws off the head, and the productions that served as arms, and to fasten it at the bottom of the case. Nature has generally made the nymph and crysalis state of animals a time of rest and incapacity of motion; but in this, as in the great worms, has given even the nymph a locomotive power, and that a very brisk one. The creature, in this state, had sufficient need of it, and could never arrive at its last change without it. When the time of this final change comes on, the nymph rises to the surface of the water, and, a crack opening on the back the winged insect begins to appear. The getting thoroughly out is a work of time; and this is the most perillous period of the creature's life; for, if the weather be windy, it is commonly blown into the water and drowned before the hinder parts are loose. *Reaumur. Hist. Inf.*

VERBA'SCUM, *mullein*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of a single leaf, rotated, and divided, into many segments at the edge. From the cup there arises a pistil, which is fixed in manner of a nail to the middle part of the flower, and finally becomes a fruit or case of an oval pointed figure, divided by an intermediate septum into two shells, which usually contain a number of small angular seeds fixed to a placenta.

VER'DETUM, the name of a green substance, used as a colour in painting. It is a very pure kind of verdigrease, being an ærugo of copper, produced by the vapour of vinegar.

VERO'NICA, *speedwell*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, and is rotated and divided into segments at the end. From the cup there arises a pistil, which is fixed in the manner of a nail to the middle part of the flower, and afterwards becomes a membranaceous fruit, divided into two cells, and containing usually small, but sometimes larger seeds.

VE'RVAIN, *verbena*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, and is of the labiated kind. The upper lip is erect, and divided into two segments, the lower into three; and these are so disposed, that, at first sight, the flower has not at all the appearance of a labiated one, but seems only divided into five segments. The pistil arises from the cup, and is fixed in the manner of a nail to the lower part of the flower: it is surrounded by four embryo's, which afterwards become four slender oblong seeds, which ripen in the cup, and fill it almost wholly up. To these marks it may be added, that the flowers of the Vervains grow in spikes, or sometimes in short heads, but never verticillately.

VESPERTI'LIO, *the bat*. In the Linnæan system of zoology, this animal makes a distinct genus; but that not as a bird, as the vulgar esteem it, but as one of the quadruped class. The characters of the genus are these: that the creature is viviparous, whereas all the birds are oviparous: that it has two paps: its feet have five toes on each; and the four feet are expanded into a sort of wings; Under this class, the author takes in canis volans and glis volans; the flying dog and flying dormouse, as they are called by other authors. *Linnæi System. Nat.*

VIBU'RNUM *Galls*, in natural history, the name of a species of galls, or small protuberances, frequently found on the leaves of the Viburnum. These are of a very singular nature, and seem to be composed of a different substance from that of the leaf. They appear in form of brown circular spots, of which there are sometimes forty or more on one leaf. These are about a fifteenth of an inch in diameter, and they rise a little above the surface of the leaf, as well on the under as the upper side; each of these has also a small prominence in the center, on each side of the leaf, looking like a nipple standing on the breast.

VI'CES, a term used by the dealers in horses to express certain faulty habits or customs in that creature, which render him troublesome to the rider, and are never to be worn off, but by attention to regular methods.

VI'CIA, *vetch*, in botany, the name of a large genus of plants, the characters of which are these: the flower is of the papilionaceous kind: and the pistil, which arises from the cup, finally becomes a pod, furnished with roundish or angular seeds; to this it is to be added, that the leaves stand in pairs on the rib, and that terminates in a tendril.

VIGORO'SO or *vigorosamente*, in the Italian music, is used to direct a performer to sing or play with vigour, strength, and firmness.

VINE (*Dict.*)— All the sorts of Vines are propagated either from layers or cuttings. The former is the method usually practised with us, but the latter seems much the better.

In order to propagate them by cuttings, let such be chosen as are strong and well ripened shoots, of the last year's growth, and should be cut from the old Vine, just below the place where they were produced, taking a knot of the two years wood, which should be pruned smooth.

The upper part of the shoot should then be cut off, so as to leave the cutting about sixteen inches long. These cuttings are to be placed with their lower part in the ground, in a dry place, laying some litter about their roots to prevent them from drying. In this place they should remain till the beginning of April, which is the time to plant them. They are then to be taken up and wiped clean, and, if they are very dry, they should stand with their lower parts in water six or eight hours. Then, having prepared the beds for them, they are to be set at about six feet distance from each other, and making their heads slant a little towards the wall. The cutting is to be so buried in the ground, that only the uppermost bud be upon a level with the surface; the earth is then to be well closed about the plant, and a little mould heaped up over the eye of the bud, to keep it from drying. After this, there is no more trouble necessary, but to keep the ground clear from weeds, and to nail up the shoot, as it grows, to the wall, rubbing off all the side-shoots.

The Michaelmas following, if the cuttings have produced strong shoots, they should be pruned down to two eyes. In the spring following the ground is carefully to be dug up about the shoots, and the stalks to be earthed up to the first eye. During the summer all the lateral shoots must be rubbed as they appear, and only the two from the two eyes which were left, must be encouraged; these, as they grow, are to be nailed up against the wall; and in the middle of July these should be shortened, by nipping off their tops, and this will greatly strengthen the shoots. At the Michaelmas following these should be pruned, leaving them each three eyes, if they are strong; but, if they are weakly, only two. The next summer there will be two shoots from each shoot of last year's wood; but if there should be two from one eye, which is sometimes the case, then the weaker is to be rubbed off. At Midsummer the ends of the shoots are to be pinched off, as before; all the weak lateral shoots are to be displaced, as in the preceding summer; and the whole management is to be the same. This is all the culture necessary to young Vines.

As to the management of grown Vines, it is to be observed that these rarely produce any bearing shoots, from wood that is more than one year old; the great care must therefore be always to have plenty of this wood in every part of the tree. The bearing shoots for the following year should be left at the pruning with four eyes each. The under one of these does not bear, and consequently there are only three which do. Many leave more eyes on the shoots, that they may have more fruit, which is the consequence; but then the fruit is much poorer; and this is so well known in the wine countries, that there are laws to direct that no more than such a number of eyes are to be left on each shoot, for the grapes would else be of a poor juice, and destroy the reputation of their wine. Each of the three eyes, left, will produce two or three bunches; so that each shoot will give six or nine bunches, which is as much as it can bring to any perfection. These shoots must be laid in at about eighteen inches asunder on the wall; for, if they are closer, when the side-shoots are produced, there will be no room to train them in upon the wall: and the largeness of the leaves of the Vine requires also that the shoots should be at a proportionable distance.

The best season for pruning Vines is the end of September or beginning of October. The cut is always to be made just above the eye, and sloped backwards from it, that, if it bleed, the juice may not run upon the bud; and, where there is an opportunity of cutting down some young shoots to two eyes to produce vigorous shoots for the next year's bearing, it should always be done. In May, when the Vines are shooting, they should be looked over, and all the shoots from the old wood should be rubbed off, as also the weaker, whenever there are two produced from one eye. During the month of May, the branches must be nailed up against the wall as they shoot, and towards the latter end of this month, the ends of the bearing branches should be nipped off, which will greatly strengthen the fruit. Those, however, which are to bear the next year, should not be stopped before the beginning of July.

When the fruit is all gathered, the Vines should be pruned, whereby the litter of their leaves is all removed at once, and the fruit will be the forwarder for this the succeeding year. *Miller's Gardener's Dict.*

The Vine is one of the trees most liable to be injured by frosts with us; its trunk is often split in frosty weather, and that most frequently when it stands in the warmest aspects. In the year 1683, the great frost split almost all our timber-trees; but this was owing to defects in them, by which the sap was detained in very large quantities in particular places, from their being wind-shaken, coltie, or otherwise distempered; but the Vines suffered the same accident, seemingly, from another cause. Those Vines were most split this year which were exposed to a south aspect, and planted against the warmest walls. The sun, their usual friend, now proved their enemy, and, daily thawing the sap in the trunk, it was again frozen every night. This, often bending and unbending, softening and hardening the

the vivid ſpirituous juice of this plant, deſtroyed it; and the ſap being the ſame year diſordered, and not gradually ſeaſoned, but even ſtopped before Michaelmas-day, and the freſh ſap wholly detained by the ſucceeding froſts from ariſing, the frozen and hard earth alſo denying its juices, even though the veſſels of the plant had been in a condition to receive them; the trunks and branches of the Vines were filled only with a thin, watery, and mortified ſap, and, this moſt of it extravaſated by the burſting of the veſſels it was frozen in, many of them ſuffered as much as if cut off from the root. Thus periſhed the greater part of the Vines expoſed to the ſun's action; while the other which ſtood in more ſhady places, not having their juices thawed and frozen daily, ſuffered but one change, and often eſcaped. It was alſo obſerved this year, that the red grape-trees eſcaped in general much better than the white, being hardier than they.

Other wall-trees, containing viſcous juices, eſcaped very well, while the Vines thus ſuffered, even though expoſed in the ſame manner. Among others, the plums, apricots, peaches, and wall cherries, had very little damage. It is eaſy to conceive why plants with viſcous juices ſhould ſuffer leſs by froſt, than thoſe with more thin ones; and we ſee that this is the caſe between theſe two ſorts of trees, the plums, &c. often exſudating their juices in form of gum-arabic; but the Vines, when they throw out any, ſhew that theirs is as thin as common water. The different kinds of trees have, doubtleſs, all their different conſiſtences, in their juices; and it may have principally been owing to that diverſity in others, as well as in the plum and Vine, that ſome eſcape, while others periſh by froſts. *Philoſ. Tranſ.* N°. 165.

VINE *Gallinſect*, an inſect of the gallinſect claſs principally found on the Vine, though capable of living on ſome other trees, and ſometimes found on them. It is much of the ſame ſhape, figure, and manner of life with the other animals of this claſs; but differs from them in this, that, as they lay their eggs all under their body, and continue abſolutely to cover them, till they are hatched, theſe protrude them from their body, and thus are found in prodigious abundance, lodged in a ſort of cottony or ſilky bags all over the ſtalks and branches of the Vines; the dead animal is ſometimes found covering them in part; but more frequently they are abſolutely naked, and often are ſo numerous as to appear like thin cobwebs hung one over another all over the Vine.

VINE *Grubs*, in natural hiſtory, a name given by ſome authors to the pucerons, or little inſects, which are uſually of a green colour, and are found often in prodigious numbers, ſticking to the leaves of trees and plants, and to their young ſtalks. Mr. Reaumur has been very curious in his inveſtigation of the nature of this inſect; but its manner of propagating its ſpecies was never clearly obſerved, till Mr Bonet diſcovered it.

VINEGAR (*Dict.*)— It is plain that the original component matter of Vinegar is ſugar, which, in the art of rectification, ſeems wholly converted into a fluid tartar; and, if the aqueous liquor be ſeparated from Vinegar, we find the Vinegar is thereby made the ſtronger, inſomuch that, if Vinegar were to be highly concentrated by congelation, it would become almoſt ſolid, or a kind of actual tartar.

Whence the rule is eaſy, that, in order to make an almoſt ſolid Vinegar, we ſhould endeavour to diſſolve tartar in an aqueous liquor, whence to perfect the art of acetification. The diſſolving of tartar largely with ſugar or treacle, and the ſtrongeſt Vinegar, by repeated imbibitions, that and a proper management is much to be recommended to the perſons concerned in this trade. *Shaw's Lectures.*

It is very well known that a large quantity of water, or mere inſipid phlegm, is contained in Vinegar, and that what we call Vinegar, would be infinitely ſtronger, if cleared of that. It is for this reaſon, that a great quantity of Vinegar will ſaturate but a very ſmall portion of an alkaline ſalt; and a great deal of this aqueous acid is, for the ſame reaſon, required to diſſolve a ſmall portion of metal. A pint of the ſtrongeſt Vinegar will ſcarce diſſolve more than two drachms of iron, and will not ſaturate more than the ſame quantity of pure ſalt of tartar.

It has been wiſhed by many, that ſome method could be contrived of concentrating Vinegar, ſo as to give it more ſtrength; this muſt depend alone on the extracting the aqueous humidity; and this has been attempted ſeveral ways. Of all others, however, that ſucceeds beſt which we find recommended by Stahl, which is by freezing. This method ſo far deprives Vinegar of its ſuperfluous water, and ſo far collects its acetous penetrating ſharpneſs, as to render it an extremely powerful menſtruum, throwing out five or ſix parts of phlegm, which ſcarce taſtes at all ſour, and having one ſixth or one ſeventh part poſſeſſed of all the virtues of the whole. Dr. Shaw aſſures us, that he has repeated this experiment, and found it to anſwer perfectly upon the trial.

This condenſed Vinegar, towards the end of the operation, or in the laſt congelations, lets fall a white ſhining powder, which is a tartar that, though diſſolved in great quantity in the whole aqueous fluid, could not be retained in this concentrated one. *Stahl, de Condenſat. Vini.*

The thicker Vinegar is, the leſs fit it proves for diſtillation, as there is always the greater danger of an empyreuma, or burnt ſmell, which would ſpoil the whole proceſs, and as it uſually in this caſe comes over oleaginous. And the pureſt white ſalt of tartar, ſaturated with this diſtilled Vinegar, being afterwards ignited, turns black, and yields a ſmell extremely like that of crude tartar in the calcination. *Shaw's Chemical Eſſays.*

Portable VINEGAR, a name given by the chemiſts to a ſort of Vinegar-powder, or Vinegar in a dry form. It is a preparation of tartar with Vinegar, and is made in this manner: take white tartar, half a pound; let it be carefully waſhed, then dried and powdered; infuſe this powder in the ſtrongeſt wine-Vinegar, then dry it, and infuſe it again, repeating this operation ten times. After this, the dry powder is to be kept for uſe; at any time a ſort of extemporaneous Vinegar may be made by diſſolving a ſmall quantity of this powder in any proper liquor.

VINOUS *Liquors* (*Dict.*)— All ſorts of Vinous and fermented liquors, both before and after the fermentation, conſiſt not of ſimilar, but heterogeneous parts, which are joined together in one certain and determinate order; thus, the action of fermentation being a ſeparation and deſtruction of the former connection of the ſubject, and tranſpoſing its parts anew, there muſt of neceſſity have been a kind of firm or durable texture in the ſubject ſo disjoined, ſeparated, and new ranged. For example:

Grapes being laid upon dry ſtraw, in a cold place, will, for ſome time after they are ſeparated from the Vine, preſerve that texture, which gives them their ſaline, unctuous, and ſlimy ſweetneſs; which the juice alſo retains after preſſing, and becomes a clear and tranſparent muſt, without ſeparating itſelf into parts, but continuing regularly and uniformly mixed, ſo as to preſerve the different matters it conſiſts of, intimately connected among themſelves. In this firmly connected ſtate they may be kept many months, if a caſk be filled with this juice, and ſet in a cool place, as we evidently ſee in ſtum. *Shaw's Eſſay on concentrating Wines.*

Wine, in the preciſe chemical or philoſophical notion of it, is a ſaline, clammy, oleaginous matter, diluted with a large proportion of water, whereby it is expanded, or ſet at diſtance from itſelf, while the ſaline parts are ſaturated with and interſperſed among the ſubtile earthy ones that make the ſliminess; thus, they together imbibe, detain, and hold the groſſer parts; beſides which there are other oily parts vaſtly more ſubtile, which, by means of the highly attenuated ſaline portion adhering cloſely to them, remain as much connected with the water as the reſt; and theſe are what we call the ſpirituous parts; but the connection of them all together is ſo ſtrong and durable, that they move for a long time as one body, without ſeparating, if carefully preſerved. An acquaintance with the true nature, hiſtory, and effects of Vinous fermentation, will fully explain and juſtify theſe poſitions.

If the ſpirituous part be once ſeparated and drawn away from the wine by diſtillation, though it were immediately to be returned back to the remaining maſs from whence it came, and ever ſo well ſhook again with it, the whole by no means retains its former taſte, odour, and durability, but turns to a confuſed turbid mixture, of a different and nauſeous taſte, and a diſagreeable ſmell; and, on the whole, approaches nearly to a ſtate of vapidity. The only objection to this general rule is, that if a new fermentation, or even but a fret be raiſed, when the ſpirit is newly joined to the remainder in the ſtill, the ſpirit may be thus reinſtated, and the wine rendered perfect. The proceſs is difficult and uncertain; but a nice management, and a proper intermedium, will bring it about.

If an inflammable ſpirit diſtilled from the ſame, or any other wine, be put to a parcel of wine which is too ſaline, or not ſufficiently ſpirituous, the bare addition, or tumultuous admixture thereof, very far from giving the fine and intimate ſoftneſs of a good wine, will rather manifeſt its own burning acrimony and nidorous flavour to the ſmell and taſte, and will add a nauſeous bitterneſs to the former tartneſs or acidity. This is an obſervation of Stahl's, and is allowed by Dr. Shaw to be true in general; but he obſerves, that, under a nice and proper management, a fine and taſteleſs ſpirit may be prepared and introduced into wines, and will, after a time, become intimately mixed with their other part, and remain abſolutely undiſcoverable to the taſte or ſmell, unleſs by the excellency and the ſtrength it gives. *Stahl's Schediaſma de Concentrat. Vini.*

VINI *Oleum*, *oil of wine*, a very precious liquid, kept as a ſecret in the hands of ſome dealers in ſpirits, and uſed to give the brandy flavour to ſpirits of leſs price. It is certain, that all the ſpirits we uſe take their flavour from the eſſential oil of the ſubſtance they are made from; that of malt is very nauſeous and offenſive, and renders the ſpirit horribly diſagreeable, if not carefully kept back in the diſtillation of it; that of the grape, on the other hand, is extremely agreeable, and is what gives the delicious flavour to French brandy: this, therefore is to be carefully brought over among the ſpirit in diſtillation.

This is that oil of wine ſo much celebrated among our diſtillers, and is for their uſe made ſeparate, being of ſuch effect, that half an ounce of it will determine a pure and clear malt ſpirit to be French brandy, ſo as to ſtand the teſt of the niceſt palate; and all the trials that can be invented, provided the oil and the ſpirit have both been carefully made.

8 M The

The manner of making the oil is this: they take the cakes of dry wine lees such as are used by our hatters, and, dissolving them in six or eight times their weight of water, they distil the liquor with a slow fire, and separate the oil by the separating glass, reserving for this nice use only that which comes over first, the oil that follows being coarser and more resinous. To render this business perfectly successful, there must be several things observed: First, the lee must be of the right kind, that is, of the same nature with the French brandy proposed to be imitated. Secondly, The malt spirit must be extremely pure. Thirdly, the dose of the oil must be very well proportioned: and, fourthly, the whole must be artificially united into one simple and homogene liquor. These cautions all regard only the taste, and besides these, in order to come up to a nice counterfeit, several other particulars must be attended to; such as the colour, proof, tenacity, softness, and the like; so that, in short, the operation has too much nicety in it to be bit off by every ordinary dealer. When this fine oil of wine is procured, it may be mixed into a quintessence, with pure distilled alcohol, or the totally inflammable spirit of wine, to prevent its growing distasteful, rancid, or resinous; and thus it may be long preserved in full possession of its flavour and virtues.

The still bottoms, or remaining matter after the distillation of this oil, will yield many productions to advantage, particularly tartar, and salt of tartar, as also an empyreumatic oil, and a volatile salt, like that of animals. Some kinds of lees afford all these in much greater quantity than others; the lees of canary and mountain wines yield very little of them, and, indeed, scarce any tartar or fixed salt at all; but the white French lees of those thin wines, that afford the ordinary brandies, yield them all very copiously, insomuch that sometimes a single hogshead of dry and close-pressed lees will afford, by this process, three gallons of this oil, forty pounds of clean tartar, a large proportion of empyreumatic oil, and volatile salt, besides full four pounds of good salt of tartar. It is not to be expected, however, that every parcel of this lee should yield fully in this proportion. *Shaw's Essay on Distillery.*

VI'NUM *extemporaneum*, a name given by Dr. Shaw and others to a sort of extemporaneous vinous liquor, made, without fermentation, from the melasses spirit, lemons, water, and sugar, in the following manner: some good sound lemons are to be cut into slices, rind and all, and put into a quantity of pure fine melasses spirit; when they have stood in fusion three or four days, the liquor is to be strained clear off, and filtred; and having before a very thin syrup of the finest sugar dissolved in spring-water, the two liquors are to be mixed together. The proportions of this liquor must be discovered by repeated trials, but, when once found, it will be easy to continue them; and a vinous liquor will thus be prepared not inferior to many foreign wines.

VI'OLA, *the violet*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the polypetalous, anomalous kind, much resembling the papilionaceous ones. The pistil arises from the cup, and finally becomes a seed vessel, usually of a trigonal form, which opens in three places when ripe, and contains roundish seeds.

Violet flowers, fresh gathered, are emollient and gently purgative. They are greatly recommended by authors in fevers, head-achs, pleurisies, and peripneumonies. A syrup of them, made in a strong infusion in water, is the only preparation kept in the shops: it is given to children as a gentle evacuant, and serves as a test to distinguish acids from alkali's, the former turning it immediately red, and the latter green.

VI'RGA *aurea*, *golden rod*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the radiated kind; its disk is composed of floscules, and its outer circle of semi-floscules. These are all placed upon the embryo fruits, and are contained in a common scaly cup: these embryo's finally ripen into seeds, winged with down. To this it is also to be added, that the flowers usually stand in long series towards the tops of the stalks.

The common golden-rod is an astringent, and its root is given in powder with great success in diarrhœas, dysenteries, and in hæmorrhages of all kinds; particularly in spittings of blood.

VI'RGIN'S-*bower*, *clematitis*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the rosaceous kind, and usually consists of four leaves arranged in a circular form, and without a cup. The pistil arises from the center of the flower, and finally becomes a fruit composed of several seeds arranged into a sort of head, and each ending in a long plume.

The several species of this plant make a very fine ornament in the quarters of gardens allotted to flowering shrubs. They are all propagated, by laying down their branches in spring, as is practised in vines and other such shrubs; and in a year's time they will have taken sufficient root, and may be taken up and removed to the places where they are to remain. This should be done in the spring, and a little mulch must be laid about their roots, and they must be watered in dry weather. In two years after planting they will make very strong shoots, which are to be trained up, to stakes, that they may not trail upon the ground. After this, they require no farther care, than to cut out their dead branches every year, and in the spring to shorten such branches as are too long and rambling. They may also be raised from seeds, sown either as soon as ripe, or in the spring; but this is a more tedious way, as they lie six or twelve months in the ground before they appear, and after that require two years care in a nursery-bed before they are fit to be planted out where they are to stand.

VI'TEX, *the chaste tree*, in botany, the name of a genus of trees, the characters of which are these: the flower consists of one leaf, and is, as it were, bilabiated, and tubular behind; the pistil arises from the cup, and is fixed in the manner of a nail to the hinder part of the flower; this finally becomes a roundish fruit, divided into four cells, each containing oblong seeds.

VI'TIS, *the vine*, the name of a genus of plants, the characters of which are these: the flower is of the rosaceous kind, and is composed of several petals, arranged in a circular form; from the middle of the flower there arises a pistil, which is surrounded by a number of stamina; this finally becomes a round, succulent, or juicy berry, containing usually four pear-fashioned seeds. See the article VINE.

VITIS *Idæa*, *the whortle*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, and is of the globose campaniform kind. The pistil arises from the cup, and is fixed in the manner of a nail to the hinder part of the flower; the cup finally becomes a soft umbilicated berry, juicy, and containing small seeds.

VI'TRIOL *of copper*. The glass-makers have a method of making this without corrosives, which was originally practised by Neri, and with which they make very fine colours in glass, particularly a fine sea-green.

The method of making the preparation is this: take little thin pieces of brass, and lay them stratum super stratum in a crucible, with powder of brimstone. When the vessel is full, set it luted and covered in an open wind furnace, with burning coals over it, and let it stand two hours; then let the furnace cool of itself, and take out the crucible; the mass within will be of a blackish obscure purple; powder and sift it fine, and then, mixing with every pound of it six ounces of powdered brimstone, take a round vessel of earth that will bear the fire, place it upon iron bars set across in an open wind furnace, fill it with coals, and then put in the powder; keep it burning and stirring about till all the brimstone is burnt up; then take out the pan, and powder the calcined mass again, sift it fine, and proceed with it thrice as before; the last time let it stand on the fire till it become red. Put a pound of this calcined copper into a glass body, with six pints of water; evaporate two pints or thereabouts in a sand heat; the water is then of a fine blue, and must be poured off clear; then filtrate it. Evaporate the water from the remaining sediment of copper left in the glass, and with new sulphur calcine it again and again; repeat this five or six times, and extract the blue tincture with water as before; filtrate all the waters, and put them together. Evaporate all to a fifth part or thereabouts, and set it in a cool place, and fine pointed crystals will be formed, resembling emeralds; separate these crystals, and evaporate the water again, till all the crystals be procured. Then put a pound of them into a glass retort, well luted and fitted to a capacious receiver; let the joints be well closed, and make a moderate fire for four hours; then make it violent for twenty hours, or till no more white fumes arise. The next day open the receiver, and separate the liquor into a glass, where it must be kept carefully sealed up. *Neri's Art of Glass.*

White VITRIOL. It has been disputed whether white Vitriol is any thing else than green Vitriol calcined. But it seems that white Vitriol is of a quite different species from either the green or the blue Vitriols.

In the condition in which white Vitriol is usually bought, it contains somewhat both of copper and iron; but, being purified by solution, filtration, and crystallisation, it is freed from both these metals, and appears to be a native Vitriol sui generis.

Blue VITRIOL, is made by evaporating ziment water to a proper standard; after which it is to be let out into coolers, where it shoots into regular, and beautiful crystals of a rhomboidal form and composed of ten planes. These have the same qualities with the water; and, being dissolved in common water, they make a ziment liquor, undistinguishable from the native kind. See the article ZIMENT *Water*.

VITRIO'LIC *Waters*, waters impregnated with particles of vitriol.—The countries which abound with mines of copper and iron usually afford a great many Vitriolic waters.

VIVACI'SSIMO, in the Italian music, denotes a degree or two quicker than vivace, and is much the same with allegro.

VIVES. A name given by our farriers to a disease of horses, which consists in the growth of certain flattish kernels in clusters, like bunches of grapes, beginning from the ears and creeping downwards, between the chop and the neck of the horse towards the throat.

U'LMUS, *the elm*, in botany, the name of a genus of trees, the characters of which are these: the flower is of the campaniform kind, consisting of one leaf, and containing a great number of stamina. The pistil arises from the bottom of the flower, and finally becomes a membranaceous or foliaceous fruit,

fruit, of a heart-like ſhape, in the center of which, there is placed a pear-faſhioned capſule, which is alſo of a membranaceous ſtructure, and contains a pear-faſhioned ſeed. See the article ELM.

UN'DERWOOD.—In the cutting the Underwood of coppices, when the ſtubs are great, they ſhould be ſtubbed up, for they only take up a great deal of room, and ſend up few ſhoots, their cracks and holes letting in water, and uſually half killing them. The taking up theſe ſhould be performed in winter, and the ſpaces they leave will be ſoon occupied by young trees; if not, a long branch of ſome neighbouring tree may be laid down, and will ſoon ſend up a ſufficient ſupply of ſuckers for the place.

In felling the Underwood, it is always proper to leave young trees enough. The worſt of theſe may be taken down the next fall, eſpecially if any of them grow near a great tree that will be fit to fell the next ſeaſon, becauſe they may be ſpoiled by its fall. When trees are at their full growth, there are ſeveral ſigns of their decay, as the withering or drying of their top branches, their taking in water at ſome of their knots, their being hollow or diſcoloured, and their making but ſmall ſhoots. If wood-peckers make holes in the body, it is a bad ſign, and, according to the appearance of one or more of theſe ſymptoms, it is very proper to cut down the tree before it decays farther. Large and ſpreading trees in coppices are often of more miſchief than advantage, as they ſpoil a great deal of the Underwood by their droppings.

The owner of a coppice muſt be very careful, when he fells the wood ſtanding, by the acre, to mark before-hand what ſtandards are to be left, becauſe otherwiſe the purchaſer ſeldom fails to cheat him, by felling ſome of them. *Mortimer's Huſbandry.*

Sea-UN'ICORN, in natural hiſtory, the name of a fiſh of the whale kind, remarkable for having a horn growing out at its noſe, in the manner of the ſuppoſed Unicorn's horn, as deſcribed by many too credulous authors.

This fiſh feeds on fleſh, or other fiſh, and is not only found in the main ſea, but ſometimes gets up into large rivers. In the year 1636 there was a large one caught in the river Oſte, near its diſcharging itſelf into the Elbe, in the duchy of Bremen; this place is four German miles from the ſea. The ſkin of this fiſh was ſpotted with dark brown ſpots upon a white ground; the epidermis was tranſparent, and under it was another ſkin very thin and ſpotted; but the true ſkin was brown, and near an inch in thickneſs. On the top of the head there is only a ſemilunar hole, as in the porpoiſes; this hole opens into the two channels, which run through the ſkull to the palate, and are called the ductus hydrogogi. The people who examined this creature, were not able to find any aperture in the body for the diſcharge of the excrements; whence it has been generally believed, that the creature voids them through this paſſage in the head.

Authors have differed in the name of the proceſs iſſuing from the head, ſome calling it a horn, others a tooth; for ſome are of opinion that it ſerves it to break the ice for air; but others pretend that it is an offenſive weapon, with which it wounds the common whale, and other large fiſh; and that, when it has plunged it up to the head in the whale's body, it ſucks the juices of that animal.

The fiſh was near twenty feet long, and about four feet in diameter. The horn ſtood on the fore-part of the head, juſt above the mouth, and was ſix feet long, white like ivory, and curiouſly wreathed or twiſted. The body was ſmooth and ſlippery, like that of an eel; the head, in proportion to the body, was ſmall, not exceeding ſixteen inches in length: the eyes not bigger than a ſix-pence. It had, on each ſide of the neck, two black fins, one above, another at a ſmall diſtance; theſe were two feet long, of the breadth of a hand, and about half an inch in thickneſs. *Phil. Tranſ.* N°. 447.

U'NIVALVE *Shells*, in natural hiſtory, a term uſed to expreſs one of the three general claſſes of ſhell-fiſh; the other two are the bivalves and multivalves. The Univalve ſhells are thoſe which conſiſt only of one piece, not of two or more joined together.

VOLU'TA, *the volute*, in natural hiſtory, the name of a genus of ſhells, the characters of which are theſe: they are Univalve ſhells, and have an oblong mouth, with a clavicle ſometimes erect, ſometimes depreſſed, and they are ſometimes coronated at the top.

VO'LVULA, in natural hiſtory, the name of an extraneous foſſil body, nearly allied to the entrochus, being compoſed of the ſame ſubſtance, and being, like that of a cylindric column, made up of ſeveral joints; the commiſſures of the joints are, however, much leſs viſible in the Volvulæ than in the entrochi, and they are not ſtriated, as in the entrochus, from the center to the circumference.

U'PLAND. The Uplands lie either on the tops of hills, or on their ſides, or on the ſlopes of riſing grounds. They ſometimes have a ſandy ſoil, ſometimes a rocky, gravelly, or loamy one; and ſometimes they conſiſt of tough clay, or a black mould. They are uſed by the farmers either for grazing or corn, as they happen to be more moiſt or more dry; and this difference depends upon their ſituation and nature.

Thoſe lands which lie flat upon the tops of hills are uſually the drieſt, and thoſe which form the ſlopes or ſides are uſually the moiſteſt, becauſe of the wet that is continually ouzing through them. The chalky, and eſpecially the clayey ſoils in theſe places, are moſt of all ſubject to be wet, eſpecially in winter, becauſe they retain the moiſture a long time; though they have alſo the inconveniencies of the ſandy and rocky lands in the ſame ſituations, chapping in ſummer. The black mould, and the hazely loams in theſe places, are the beſt for corn, as well as for paſture, eſpecially if the latter eſcapes the common misfortune of being full of worms. Theſe lands neither are waſhy in winter, nor parched up in ſummer.

The Upland meadows have ſome diſadvantages, as they often need mending or feeding, which thoſe that lie lower do not; but then they make amends for this in their hay, which is always much finer and ſweeter than that of the low-lands.

UPLO'PER, a name given to one particular ſpecies of pigeon, called by Moore columba gutturoſa faliens.

It was firſt brought to England from Holland, and much reſembles that kind of pigeon called the Engliſh powter, but that it is ſmaller: its crop is very round, and in this it buries its bill. Its legs are very ſmall and ſlender, and its toes are ſhort, and cloſe together, on which it treads ſo nicely, that, when moving, any ſmall thing might be put under the ball of its foot. The pigeons of this ſpecies are generally all blue, all black, or all white, ſeldom or never pyed. They are very ſcarce in England, and in Holland have been valued at five and twenty guineas a pair.

They have their name from the Dutch word oplopen, which ſignifies to leap up; and it was thus named from its manner of approaching the hen, which is always by leaping upon her. *Moore's Columbarium.*

URANO'SCOPUS, in zoology, the name of a fiſh of the cuculus kind, called in Engliſh the ſtar-gazer, and by ſome authors callyonymus.

URTI'CA, *nettle*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the apetalous kind, being compoſed only of a number of ſtamina placed in a cup. Theſe are barren, and the ſeeds grow on other plants of the ſame ſpecies, which have no flowers, and are contained either in round globules, or bivalve capſules, or in long tufts.

The roots of the common nettle are much recommended in medicine; they are powerful diuretics, and are ſaid to have great virtues againſt the ſtone and gravel. They cleanſe the blood, and are ſaid to be of great ſervice in hæmorrhages of all kinds, particularly in ſpittings of blood, and overflowings of the menſes. Authors add to this, that they are ſpecifics by way of antidote againſt the poiſon of henbane and hemlock; but this we are not ſo well aſſured of. The young ſhoots of the plant are eaten in the ſpring, as good againſt ſcorbutic complaints. *Dale, Pharm.*

URTICA *marina*, in zoology, the name of a remarkable genus of fiſhes, ſo called from their affecting the ſkin, on touching them, with a painful ſenſation like that of ſtinging of nettles. Theſe are an animal of the loweſt claſs, and have by many been reckoned among thoſe creatures called zoophytes, or plant animals, as ſuppoſed to partake of the nature of vegetables and of animals. Some of the ſpecies of this fiſh are found looſe upon the ſmooth ſhores, and ſome fixed to the rocks which are always covered with water. M. Reaumur obſerves alſo, that many of the ſpecies have no property of ſtinging, or cauſing any painful ſenſation of the fleſh.

VULNERA'RIA, in botany, the name of a genus of plants, whoſe characters are theſe: the flower is of the papilionaceous kind, and from its cup, which is of a tubular form and turgid, there ariſes a piſtil, which finally becomes a ſhort pod, containing roundiſh ſeeds; and being contained in a membranaceous bladder, which was before the cup of the flower.

VULPES, *the fox*. This creature has been long famed for its cunning, and is plainly of the dog kind.

It differs, however, from the common dog in the length, denſe diſpoſition, and ſoftneſs of its hair, eſpecially thoſe about its tail, and in its ſmell, which is peculiarly rank and diſagreeable. Its uſual colour is a reddiſh tawny, though it is ſometimes found white, and ſometimes black. Its manner of digging itſelf a hole in the earth, is alſo a cuſtom wholly different from all the dog kind, and it is far from the tameneſs of that animal, being with difficulty made to loſe its fierceneſs. Its internal parts, in general, are very much like thoſe of a dog. *Ray's Syn. Quad.*

W.

WALE, or WAIL, in a ſhip, thoſe outermoſt timbers in a ſhip's ſide, on which men ſet their feet when they clamber up a ſhip's ſide. They are reckoned from the water, and called her firſt, ſecond, or third Wale, or bend.

WALL. Of all the materials for building Walls for ripening fruit, brick is generally the beſt, as it reflects a great deal of heat, retains its warmth a great while, and affords, by the ſmalneſs of the joints, the convenience of faſtening up the trees with ſmall nails. If theſe Walls are coped with free-ſtone, and have ſtone pilaſters at proper diſtances, to break the force of the winds, and ſhelter the fruit-trees, they make the moſt advantageous, as well as the moſt beautiful of all Walls.

It is ſometimes an advantageous thing to build theſe Walls upon arches, that the roots of the trees may have room to ſpread under, and to the other ſide of them. This is neceſſary when the ſoil is a hard gravel; for, without this, when the roots of peaches, &c. have reached the gravel, they find not ſufficient nouriſhment, and the trees canker and die. But, though Mr. Fairchild had found great advantages from this way of building Walls, Mr. Miller diſapproves it. Some alſo have propoſed the building ſlanting Walls; but the ſame author gives many reaſons why the perpendiculars are preferable, and ſeems to think, that, if Walls could be eaſily contrived to ſlope a little forward, they would be even preferable to theſe. *Miller's Gard. Dict.*

WALL, in fortification, is that part of the parapet which is contained in one piece from end to end, and is about 2½ or 3 feet high.

The embraſures in the Wall ſhould as much as poſſible be cut perpendicular to the parapet; therefore the battery ſhould be parallel, or nearly ſo, to the object to be battered: for the direct ſhots have moſt force; and oblique embraſures weaken the merlons, or parts of the parapet ſtanding between the embraſures.

The embraſures are uſually about 2 or 2½ feet wide on the inſide, and about 9 or 10 feet on the outſide; whereby the cannon may be traverſed from the right to the left, ſo as to command a pretty large extent in front. The diſtance from the middle of one embraſure to the middle of the next ſhould be about 18 feet, in order to leave ſufficient room for the working of the guns, and the ſtowage of the ſhot and other neceſſaries.

WA'LNUT, in botany. See the JUGLANS.

The effluvia of Walnut-trees are ſaid to be hurtful to the head. Mr. Boyle aſſures us they cauſed the head-ach in himſelf. *Works abr. Vol.* 1.

WA'MPUM, a ſort of ſhells, ſeveral of which, being ſtrung upon threads, are uſed as money among the Indians.

It is made of a ſhell formed into ſmall cylinders, of about one quarter of an inch long, and a fifth of an inch over, and, being bored as beads, is ſtrung in great numbers upon long ſtrings. In this ſtate it paſſes among the Indians in their uſual commerce, as ſilver and gold among us; but, being looſe, it is not ſo current.

It is both white and black, and the meaneſt is in ſingle ſtrings, of which the white goes at five ſhillings a fathom, and the black at ten; or, by number, the white at ſix a penny, the black at three. The next in value to the ſingle ſtrings is that which is wove into bracelets of about three quarters of a yard long, black and white, in ſtripes, and ſix pieces in a row, the warp conſiſting of leather thongs, and the woof of thread; theſe the gentlewomen among them wear, wound twice or oftener about their wriſts.

The moſt valuable of all is that woven into girdles. Theſe are compoſed of many rows, and the black and white pieces woven into ſquares or other figures. Theſe girdles are ſometimes worn as their richeſt ornaments; but they are oftener uſed in their great payments, and make their nobleſt preſents, and are laid up as their treaſure. *Grew's Muſæum.*

WARD'S *Pill.* Some have conjectured that this medicine, which had ſo great a run, and to which a diminution of the numbers in the bills of Mortality, one year after it happened to come on vogue, was ſaid in a public advertiſement to be owing; it has been conjectured, I ſay, that this medicine was made of butter of antimony; others think it the glaſs of antimony, and cinnabar of antimony amaſſed with gum tragacanth. See Ward's Pills diſſected, and *Med. Eſſ. Edinb.*

Mr. Clutton mentions ſome caſes where they did ſervice, but relates the hiſtories of fifty caſes where they did great miſchief.

To diſcover the compoſition of theſe pills, he diſſolved the ſeveral ſorts of them, and then, viewing with a microſcope the powder which precipitated, he ſaw three different-coloured powders remaining of the blue pill; to wit, a yellow, red, and white powder; the yellow and red agreed exactly with the glaſs of antimony, and the white ones appeared to be common arſenic. Ward's pill being incloſed in copper, and expoſed to a ſtrong heat, made the copper white, and as hard as iron, which arſenic always does. He alſo obſerved in this blue pill another powder, which he judged to be zaffer, that is, calcined, incorporated with flints. He thinks the proportion of the ingredients in this blue pill to be, one-third glaſs of antimony, near two-thirds of arſenic, and a very ſmall part of cobalt, or zaffer, with ſome powder of blue.

The red pill appeared to be much the ſame compoſition as the blue, only red arſenic was made uſe of inſtead of the white, and the colouring of blue powder was left out.

The purple pills tinged glaſs blue, which cobalt or zaffer does; and therefore Mr. Clutton thinks them principally compoſed of cobalt, with a little glaſs of antimony, which left a yellowiſh border upon the glaſs.

WA'RREN. The word Warren is now generally applied to a piece of ground ſet apart for the breeding and preſerving of rabbets.

In the ſetting up a Warren, great caution is to be uſed for the fixing upon a proper place and a right ſituation. It ſhould always be upon a ſmall aſcent, and expoſed to the eaſt or the ſouth. The ſoil that is moſt ſuitable, is that which is ſandy; for, when the ſoil is clayey or tough, the rabbets find vaſtly more difficulty in making their burrows, and never do it ſo well; and if the ſoil be boggy or mooriſh, there would be very little advantage from the Warren, for wet is very deſtructive of theſe animals.

All due precautions muſt be taken, that the Warren be ſo contrived, that the rabbets may habituate themſelves to it with eaſe. Many would have it that Warrens ſhould be incloſed with walls; but this is a very expenſive method, and ſeems not neceſſary nor adviſeable; for we find but very few that are ſo, and thoſe do not ſucceed at all the better for it.

Mr. Chomel's opinion is, that it ought to be ſurrounded with a ditch. This indeed is no fence to prevent the rabbets from going out, unleſs there be water in it; but it marks the intended bounds of the Warren, and the rabbets generally confine themſelves within its circumference, though not neceſſarily compelled to do ſo. The ſpace proper for a Warren has no limits but the owner's pleaſure; but, in general, the larger it is, the more profitable it alſo proves; and the rabbets, when once accuſtomed to the place, will keep within its bounds, though they are neither hemmed in with Walls nor ditches, nor any other fence whatever.

WASH, the diſtiller's name for the fermentable liquor, made by diſſolving the proper ſubject for fermentation and diſtillation in common water.

With reſpect to the proper workings of this liquor, great regard is to be had to the containing veſſel. Its purity, and the proviſion for its occaſional cloſeneſs, are the things to be principally conſidered. Though it is neceſſary that the veſſel be perfectly clean, yet in the cleanſing it great care muſt be taken that no ſoap, or other unctuous body, be uſed, for this would check the fermentation in it; and for the ſame reaſon all ſtrong alkaline lixiviums are to be avoided. Lime-water, or even the turbid ſolution of quick-lime, however, may be ſafely uſed for this purpoſe; and this is indeed particularly proper to deſtroy a prevailing acid, which is very apt to be generated about the ſides and bottoms of theſe veſſels, if the warm air has acceſs to them, and thus prevents the order of the fermentation. All ſtrong alkaline lixiviums have as bad an effect on the contrary, and a ſpecial care muſt be had that no corrupt or putrified yeaſt, nor any remains of former fermented matters, hang about the ſides of the veſſels, for this would infect whatever ſhould be afterwards put into them. Foulneſſes of this kind, when of long ſtanding, are of all others the moſt difficult to be cured, and often are of great damage to the diſtiller.

WASHING *of ores*, the purifying an ore of any metal by means of water, from earths and stones; which would otherwise render it difficult of fusion.

The method of doing it is this: break the ore to a coarse powder in an iron mortar, weigh twenty or thirty docimastical centners of it, put them into the Washing trough, and pour some water upon them, that the ore may be thoroughly moist; then have a vessel full of water, the diameter of which must be a little larger than the length of the trough; take the trough with the left-hand by the top of the hinder part, and, dipping it horizontally into the water, move it gently with the right-hand from the fore-part of the trough, which is always to be made the shallower part of it, towards the hinder part, which is deeper; then take out the trough, and incline it a little on the fore-part, that the water may run out, and the heavier metallic part remain at the bottom; repeat this several times, till the remains at the bottom of the trough are quite pure. If the stone in which ore is lodged be too hard for powdering in its natural state, as the flinty and debased crystalline ones commonly are; the whole must be calcined, and quenched in cold water several times over, and afterwards powdered and washed in this manner: when it is thus washed, assay a centner of it, and, from the head of metal this yields, it will be easy to estimate the value of the ore. *Cramer's Art of Assaying.*

WASP. The Wasp has four wings and six feet; his body is yellow, with black triangular spots: the common Wasp breeds in the ground. There is another kind much more fierce, but very rare: these breed in woods and mountains; they are larger, and have broader bodies, and much more black about them; their sting is so large, that it seems disproportioned to the size of their bodies.

To these are to be added the ichneumon Wasps, which are smaller than the others, and have very slender bodies, but of the same colours with the common kind: they usually live in the holes of mud-walls, and make a sort of porch of mud before the doors of their habitations.

There is also another Wasp common about Vienna; this is three times as large as the common kind, and seems of two different species, the one having rough antennæ, and the other smooth; they are both variegated with black and a bright yellow. *Mouffet's Hist. Insect.*

WASP-*fly*, in natural history, a species of fly having very much the external figure of a Wasp, but harmless, without a sting, and with only two wings.

WASP-*tipula*, in natural history, the name of an insect described by Mr. Reaumur, and being properly a tipula, or long-legs, though greatly resembling a Wasp.

WASTE-*cloths*, in a ship of war, the cloths hung up on the uppermost work of a ship's hull, to shade the men from an enemy in the fight; and therefore by some are called fights.

WASTE-*trees*, in a ship, are those timbers which lie in Waste.

WATCH-*glass*, aboard a ship, runs four hours and is used to shift or change their Watches by. There are also half Watches, hour-glasses, minute, and half-minute-glasses; by which last they count the knots, when they heave the log, in order to find the ship's way.

WAVE (*Dict.*)— The great Mr. Boyle has proved by numerous experiments, that the most violent wind never penetrates deeper than six feet into the water; and it should seem a natural consequence of this, that the water moved by it can only be elevated to the same height of six feet from the level of the surface in a calm; and this six feet of elevation being added to the six of excavation, in the part whence that water so elevated was raised, should give twelve feet for the utmost elevation of a Wave. This is a calculation that does great honour to its author; for Count Marsigli measured carefully the elevations of the Waves near Provence, and found that, in a very violent tempest, they arose only to seven feet above the natural level of the sea; and this additional foot in height he easily resolved into the accidental shocks of the water against the bottom, which was, in the place he measured them in, not so deep as to be out of the way of affecting the Waves; and he allows that the addition of one-sixth of the height of a Wave, from such a disturbance from the bottom, is a very moderate alteration from what would have been its height in a deep sea, and concludes, that Mr. Boyle's calculation holds perfectly right in deep seas, where the Waves are purely natural, and have no accidental causes to render them larger than their just proportion.

In deep water, under the high shores of the same part of France, this author found the natural elevation of the Waves to be only five feet; but he found also that their breaking against rocks, and other accidents to which they were liable in this place, often raised them to eight feet high.

We are not to suppose, from this calculation, that no Wave of the sea can rise more than six feet above its natural level in open and deep water, for Waves immensely higher than these are formed in violent tempests in the great seas. These, however, are not to be accounted Waves in their natural state, but they are single Waves formed of many others; for in these wide plains of water, when one Wave is raised by the wind, and would elevate itself up to the exact height of six feet, and no more, the motion of the water is so great, and the succession of Waves so quick, that, during the time this is rising, it receives into it several other Waves, each of which would have been at the same height with itself; these run into the first Wave one after another, as it is rising; by this means its rise is continued much longer than it naturally would have been, and it becomes terribly great. A number of these complex Waves arising together, and being continued in a long succession by the continuation of the storm, make the Waves so dangerous to ships, which the sailors in their phrase call mountains high. *Marsigli Hist. Phys. de la Mer.*

WAVE-*offering*, among the Jews, a sacrifice offered by agitation or waving towards the four cardinal points.

WEALD, or WALD, in the beginning of names of places, signifies a situation near woods; and the woody parts of the counties of Kent and Sussex are called the Wealds, though misprinted wildes, in the statute 14 Car. II. c. 6.

The word Weald in Saxon signifies a wood.

WEAVER's *Alarm*. This contrivance is only a weight fastened to a packthread, which is placed horizontally, so that in a certain time a candle may burn down to it. Then, the flame of the candle setting fire to the thread, the weight falls, and awakens the sleeping person. See *Phil. Trans.* N°. 477, where we have a figure to explain the invention, which got its name from being in frequent use among the Weavers.

WEEDS. The farmer finds it impossible ever wholly to destroy the Weeds in his lands; and the reason seems to be, that in many kinds the seeds will lie many years in the ground, and successively grow, some one year and some another; so that the destroying the crop entirely, for one year, does not kill them for succeeding ones. The seed of red-poppy will lie twenty years in the ground, in a land all that time occupied by saintfoin; and, if it be, after that, plowed for corn, they will all grow, and fill the field.

The seeds of these plants will never all come up in one year, because they must have their exact degrees of depth, moisture, and covering; the seeds which want any of these one year, lie to grow up another. The best defence the farmer has hitherto found against these enemies, is to endeavour their destruction by a summer fallow. This, if the weather be propitious, does make some havock among them, but it never destroys them entirely. If the seeds lie so high that the summer's heat parches them up, or so deep that it cannot reach them, they do not germinate, and are by that means saved for another year. And another thing which saves a very great number of them, is their being able to bear the heat and moisture of the whole year without growing. Wild oats, and many other seeds of Weeds, are of this kind. If you gather these when ripe, and sow them in the most careful manner, watering them at times, and taking all the care of them that is necessary to the most tender plants, they will not grow till the spring come twelve-months after they were sowed, and sometimes not till the spring after that; that is, two years and a half after the time of putting them into the ground. It is plain from this, that no art can destroy these by fallowing, or other means, in one year.

The common way of weeding among the young corn turns out to very little good; if this is done while the weeds are young, the greatest part of them are only cut or broken off near the ground; this, instead of destroying them, gives them new vigour, and they shoot up with many heads in the place of one, and draw more nourishment than at first: if, on the other hand, it is done when they are grown up, the relief comes after the disease; for by that time they have robbed the corn of all the nourishment, or nearly all, they could. Hand-weeders also frequently do more harm in the corn by treading it down, than they do good by taking out the Weeds. This operation sometimes costs the farmer twelve shillings an acre, besides the mischief done, and yet there remain Weeds enough for a crop the next year from seeds.

The method of horse-hoeing is a very excellent way of curing lands of this disease, so long as it is carefully practised; one of the greatest advantages it will bring the farmer is, that no Weeds will grow up but those whose seeds are brought in the air, and these are but very few in comparison of the other kinds.

WEEDS, in mining, a term used by our English diggers to express any sort of unprofitable substance found among the ores of metals. They seem to have borrowed the phrase from the gardeners; and as every thing with them is a Weed, except what they have planted, and expect to gather; so every thing is a Weed with the miners, except the thing they are sinking for.

The principal substances known in our mines under the names of Weeds, are mundic or marcasite; this is of three sorts, white, yellow, and green; daze, a kind of glittering talcy stone, of the telaugium kind, which endures the fire, and is of various colours and hardnesses; iron-moulds or pyritæ; caul, which is brownish and spungy; and glister, which is a sort of talc. *Phil. Trans.* N°. 69.

WEEVIL, in natural history, the name of a small insect which does great damages in magazines of corn, by eating into the several grains, and destroying their whole substance.

This creature is somewhat bigger than a large louse, and is of the scarab kind, having two pretty, jointed, tufted horns,

and

and a trunk or piercer, projecting from the fore-part of its head: at the end of this trunk, which is very long in proportion to its body, there are a sort of forceps, or sharp teeth, with which it gnaws its way into the heart of the grain, either to seek its food, or to deposit its eggs there. By keeping these creatures alive in glass tubes, with a few grains of wheat, their copulation and manner of generation have been discovered. The female perforates a grain of wheat, and therein deposits a single egg, or, at the utmost, two eggs; and this she does to five or six grains every day for several days together. These eggs, which are not longer than a grain of sand, in about a week, produce as odd a sort of white maggot, which wriggles its body very much about, but is very little able to move from place to place: this, in about a fortnight, turns to an aurelia, from which is produced the perfect Weevil. This destructive creature is itself very subject to be destroyed, and when in the egg or aurelia state, is very subject to be eaten by mites. *Baker's Microf.*

WEIGHT, *pondus*, in mechanics, is any thing to be raised, sustained, or moved by a machine; or any thing that in any manner resists the motion to be produced.

In all machines, there is a natural ratio between the Weight and the moving power.—If the Weight be increased, the power must be so too; that is, the wheels, &c. are to be multiplied, and so the time increased, or the velocity diminished.

"The center of gravity F, *Plate* XLII. *fig.* 9, of a body IH, together with the Weight of the body, being given; to determine the point M, in which, lying on an horizontal plane, a given Weight G, hung in L, cannot remove the body I H out of its horizontal situation."

Conceive a Weight hung in the center of gravity F, equal to the Weight of the whole body IH, and find the common center of gravity M, of that and the given Weight G.—If the point M be laid on the horizontal plane, the Weight G will not be able to move the body H I out of its place.

WELD, the name by which our farmers commonly call the luteola or dyers weed. This is a very rich commodity among the dyers, and is the more advantageous to the farmer, as it may be raised on very poor land, and at a very small expence. Moderately fertile land does best for it; but it will grow upon the most barren; and, if this be but dry and warm, it will require no tillage. The seed may be sown with barley or oats, and only harrowed in with brush or furze, and rolled down with a wooden roller. It is a very small seed, and the greatest difficulty about it is the sowing it even. It is a slow grower; a gallon of seed is sufficient for an acre; and, though it makes but little progress the first summer, it begins to grow after the corn is cut, and the next year yields a good crop.

There is a great nicety required in the time for gathering it; for this should be when the stalk is full ripe, and the seeds not so ripe as to fall out; it is to be pulled up by the hand, and made up into little bundles to dry. The seed may be either threshed out, as soon as it is housed, or in the spring following; but the plant must be carefully kept dry. The seed sells at about ten shillings the bushel, and the dyers use it for deep lemon colour, and bright yellows. It is more cultivated in Kent than in any other part of England, and it there yields the farmer from forty shillings to ten pounds an acre.

WET *Couch*, a term used by the maltsters for one of the principal articles of malt-making.

In the making malt, the usual way is to soak the grain in water two or three days, till it becomes plump and swelled, and the water is brown; the water is then drained away, and the barley is removed to a floor, where it is thrown into a wet couch, that is, an even heap of about two feet thick.

In this heap the barley spontaneously heats, and begins to grow, shooting out first the radicle, and, if suffered to continue growing, soon after the blade; but, at the eruption of the radicle, the process is to be stopped short, by spreading the wet couch thin over the floor, and turning it once every four or five hours for two days, laying it thicker each time; after this it is thrown into a large heap, and there suffered to grow hot of itself, and afterwards spread abroad again and cooled, and then thrown upon the kiln to be dried crisp without scorching. *Shaw's Lectures.*

Toothed WHALE, *cetus dentatus*, a name given to a peculiar kind of Whale, called by Johnston, and many other writers, by the too general name of balæna.

This is distinguished from the common Whale which yields the Whale-bone, by having white and strong teeth in the lower jaw, which that fish has not. This is the species of Whale from which the sperma ceti was originally taken. It was first of all discovered on the coast of New England, being thrown on the coast there, and sperma ceti formed by the sun and air out of the oil of its head; but it is far from being peculiar to that place; the northern seas afford it, and it is not unfrequently taken on the western coasts of Ireland. One caught there, about fifty years since, measured seventy-one feet in length, which is nineteen feet more than the length Clusius allows to this fish.

WHEAT.—When Wheat is planted early, less seed is required to an acre than when it is planted late, because less of it will die; and poor land should always be allowed more seed than rich, because a greater number of the plants will perish on this land than on the other. The least quantity of seed is necessary for rich land, that is planted early; for, in this case, very few of the seeds will fail to produce a plant that will live and flourish. The use of the hoe causes every plant to send out a great number of stalks from the same root, and in these, more, than in the number of plants, consists the richness of a crop, as the ears on these are always largest and fullest.

Another thing to be considered, in order to find the proper quantity of seed to plant, is, that some wheat of the same species has its grains twice as large as others: in this case a bushel, containing but half the number of grains that it does in small-grained wheat, one bushel of the small-grained will plant just as much as two bushels of this; not the measure of the seeds, but the number of the grains being the thing to be considered in regard to the sowing.

It is a very natural thing to suppose, that a large-grained Wheat will produce larger and finer plants, and larger grain than a small-grained one; but experiments have proved, that there is nothing in this; for the smallest-grained Wheat produces fully as large plants as the largest, and those with as great ears, and as big seeds; but the young plants appear smaller and poorer.

Six gallons of middle-sized seed is the usual quantity drilled upon an acre; but on rich lands, planted early, four gallons will suffice; because then the Wheat will have roots at the top of the ground before winter, and tiller very much, without danger of the worms, and many other accidents, which the late planted Wheat is very liable to.

If it be drilled too thin, it will be in danger of falling, and, if too thick, it may happen to tiller so late in the spring, that some of the ears may be blighted; a medium therefore is best.

The depth to plant it at is from half an inch to three inches; for, if planted too deep, there is more danger of its being eaten off by worms between the grain and the blade. A Wheat-plant that was not sown early, sends out no root above the grain before the spring, and is nourished all the winter by a single thread, proceeding from the grain up to the surface of the ground: this is the thread of life to the plant during the winter, and, the longer that is, the greater danger there is of the worm, that creature much more easily finding a thread that extends by its length to five or six inches deep, than one which reaches but one inch; besides, the worms in winter do not inhabit very near the surface of the ground, and therefore they never naturally come in the way of the short threads, though the long ones are always in their reach.

It is very necessary to take care against the rooks, just at the time when the Wheat is shooting up. These mischievous birds perceive it beginning to sprout, before the farmer can perceive any thing of it, and are led by the shoot to pick it up; they must be carefully kept off the ground for a week or ten days at this season; for at the end of that time the blade will be grown up, and the grain so exhausted of its flower, that it will be of no value to them, nor will they give themselves any trouble about stealing it.

The rooks never molest such Wheat as is sown about Michaelmas time; for at this season there is so much grain of the late harvest scattered about the fields where it has grown, that they find it much more worth their while to pick it up there, than to search under ground for it in the sown crops, which therefore escape till too far grown for this animal. *Tull's Horsehoeing Husbandry.*

The season for sowing Wheat is in the autumn in moist weather. In the down countries the farmers begin sowing of their Wheat in August, if there happens rain; so that when they are in their harvest, if the weather stops them, they employ their people in sowing: for, if the corn is not forward in the autumn, so as to cover the ground before winter, it seldom succeeds well on those dry lands; especially if the spring should prove dry. But in the low strong lands, if they get their Wheat into the ground by the middle of November, the farmers think they are in good season: but sometimes it so happens, from the badness of the season, that in many places the Wheat is not sown till Christmas, or after; but this lately sown Wheat is subject to run too much to straw, especially if the spring should prove moist.

The usual allowance of seed-wheat to one acre of land is three bushels; but, from repeated experiments, it has been found, that half that quantity is sufficient: therefore, if the farmers have regard to their own interest, they should save this expence of seed, which amounts to a considerable article in large farms, especially when it is to be purchased; which most of the skilful farmers do, at least every other year, by way of change; for they find, that the seeds continued long upon the same land will not succeed so well, as when they procure a change of seeds from a distant country. And the same is practised by the husbandmen of the Low-countries, who commonly procure fresh seeds from Sicily every second or third year; which they find succeed better with them, than

than the feeds of their own country. In the choice of the feeds, particular regard should be had to the land upon which it grew; for, if it is light land, the Wheat which grew upon strong land is the best; and so vice versa.

There have been some persons in England curious enough to procure their seed Wheat from Sicily, which has succeeded very well: but the grain of this has proved too hard for our English mills to grind, which has occasioned their neglecting to procure their seeds from thence; nor do I think there can be much advantage in procuring the seeds from abroad, since the lands of England are so various, as to afford as much change of seeds as will be necessary. And, the less we purchase from abroad, the greater will be the saving to the public; so that it should be the business of skilful farmers to want as few seeds as possible; since, by exchange with each other, they may so contrive, as not to part with ready money for any seeds.

The land which is usually allotted for Wheat, is laid fallow the summer before the corn is sown; during which time, it is plowed two or three times, to bring it into a tilth; and the oftener and better the ground is plowed, and the more it is laboured with harrows between each plowing, the better will be the crop, and the fewer weeds will be produced. But in this article most of the farmers are deficient; for, after they have given their lands one plowing, they frequently leave it to produce weeds, which sometimes are permitted to stand until they shed their seeds, whereby the ground will be plentifully stocked with weeds: and, as an excuse for this, they say, that these weeds will supply their sheep with some feed, and the dung of the sheep will mend their land. But this is a very bad piece of husbandry: for the weeds will draw from the land more than the dung of the sheep will supply: so that it is undoubtedly the best method to keep the ground as clean from weeds as possible, and to stir it often to separate the clods, and render the land fine. And, where the land can enjoy a winter's fallow, it will be of much greater service to it, than the summer: and, by thus labouring of the land, it will be of equal service to a dressing of dung. Therefore, if the farmers could be prevailed on to alter their method of husbandry, they would find their advantage in it: for the expence of dressing in some countries is so great, as to take away the whole profit of the crop.

There is also a very absurd method in common practice with the farmers, which is the carrying of their dressing, and spreading it on the land in the summer; where it lies exposed till the sun has dried out all the goodness of it, before it is plowed into the ground; so that the dressing is of little value: but the dung should never be laid on the land faster than it can be plowed in; for one load of dung, so managed, is better than three in their usual method.

As Wheat remains a longer time upon the ground than most other sorts of corn, it requires a greater stock of nourishment, to lengthen and fill the ears: therefore, if the dressing is exhausted in winter, the corn will have but short ears, and those but lean, nor will the grain afford much flour: so that it frequently happens, that a light dressing of soot in the spring, at the time when the Wheat is beginning to stalk, proves of greater service to the crop, than a dressing of dung laid on the land before it is plowed; especially if the dung is not very good. Deep plowing, where the staple of the ground is deep enough to admit of it, will also be of great service to the corn; for the small fibres of the roots, which are the mouths that supply the nourishment, extend themselves very deep into the ground. I have traced many of them upwards of three feet, and do believe they spread much farther where the ground is light; therefore it is of great advantage to the crop to have the ground stirred and loosened to a proper depth.

Of late years, many composts have been advertised for the steeping of the seeds of corn, in order to improve their growth: some of these have been sold at a dear rate: but as so great success was assured by the inventors, to those who should make use of them, there were numbers of persons who made the trial; but, so far as I have been able to get information of the experiments, they did not succeed so well, as to encourage the use of these compositions. For in some trials, which I made myself with great care, it was found, that the Wheat which had been steeped in the composition, came up sooner, and grew much ranker in the winter, than that which had not been steeped: but in the spring the unsteeped Wheat had a greater number of stalks to each plant, and the ears were better fed, than those which had been steeped: therefore these sorts of composts have been found of no use to the crop.

I have before observed, that, in general, the farmers sow more than double the quantity of corn on their lands than is necessary: therefore there is a great waste of grain, which, in scarce years, amounts to a considerable sum in large farms. But I fear, whatever can be said to prevent this, will have but little weight with the practitioners of agriculture; who are so fond of old customs, as rarely to be prevailed on to alter them, though they are extremely absurd. But, if these people could be prevailed on to make the trial with care, they must be soon convinced of their error: for, if they will but examine a field of corn sown in the common way, they will find but few roots with more than two or three stalks, unless by chance, where there may be some few roots which have room to spread; upon which there may be six, eight, or ten stalks, and frequently many more. I have seen a field of Wheat which had not a greater allowance than one bushel of corn to an acre, where the produce was much greater than in any which was sown with the common allowance. And if the land is good, and the roots stand at a proper distance from each other, there will be few roots which will not produce as many stalks as I have here mentioned, and the ears will be better nourished.

But, if the land is not covered with the blades of corn by the spring, the farmers think they shall have no crop; whereas, if they had patience to wait till the roots put out their stems, they would soon be convinced of the contrary; especially if they could be prevailed on to draw the roller over the Wheat in March, which will cause it to spread, and produce the more stalks. But, before this operation, it will be proper to have the corn cleaned from weeds; for, if these are permitted to grow, they will draw away much nourishment from the corn. And, if at this season the land is made clean of weeds, the corn will soon after spread, and cover the ground, whereby the growth of weeds will be greatly lessened.

There is not any part of husbandry which requires the farmer's attention more, than that of keeping his land clean from weeds; and yet there are few who trouble themselves about it, or who understand the proper method of doing it. Few of them know those weeds which are annual, so as to distinguish them from those which are perennial; and, without this knowledge, it will be much more difficult for a person to clean his land, let his industry be ever so great: for annual weeds may be soon destroyed, if taken in time; whereas, if they are neglected, their seeds will soon ripen, and scatter; after which it will require three times the labour and expence to get rid of them, as would have been sufficient at the beginning; and then the crop would have had no bad neighbours to rob it of its nourishment. There is also another great advantage in keeping of corn clean from weeds, which is, that the corn is not so liable to take the smut, as when it is full of weeds, as I have frequently observed; so that cleanness is as essential to the well-doing and growth of vegetables, as in animals. And the changing of the seed annually is also as necessary, as the change of air is to all sorts of animals: for, where this has been carefully practised, there has rarely happened any smutty corn on the farms.

Brining of the seed-wheat is what the farmers generally practise, to prevent the smut; which in most years answers very well: but there is nothing which contributes more to this, than keeping the plants in good health: which is better effected in the drill-husbandry, than in the common method of sowing in broad-cast: for, by stirring of the ground with the hoe-plough between the rows of corn in the spring, the roots will be better supplied with nourishment: for, in strong lands, where the water may have lain in the winter, the ground will bind so hard on the first dry weather, as to stint the corn, and frequently cause it to change colour. When this happens, the roots seldom put out many stalks; and those which are put out, are weak: but, where the ground can be stirred to loosen the parts, the corn will soon recover its colour and strength, and cover the land with shoots: and this corn will be much less in danger of being lodged by wet or wind, the stalks being very strong.

Indeed the horse-hoeing husbandry has many advantages of the common method; but it is not likely to be brought into general practice by the present set of husbandmen: so that, unless the gentlemen who have lands in their hands introduce it, and encourage young persons to undertake it, who are not so much attached to the old practice, there is little hope of seeing this sort of husbandry spread in England.

The produce of an acre of Wheat is various, according to the goodness of the soil. In some of the shallow down-lands, where there have been near four bushels of corn sown, I have known the produce not double of the seed: but, when this is the case, the farmer had much better let his land lie waste, since the produce will not defray the expence; so that more than the rent of the land is lost. And, although these sort of crops are frequent on such lands, yet such is the passion for plowing among the husbandmen at present, that, if they were not restrained by their landlords, they would introduce the plough into every field, notwithstanding they are sure to lose by it.

But, although the produce of these poor downs is so small, as before related; yet, upon good land, where the corn has stood thin upon the ground, I have known eight quarters reaped from an acre, over the whole field, and sometimes much more. And I have been informed by persons of great credit, that on good land, which was drilled and managed with the horse-hoe, they have had twelve quarters from an acre of land; which is a great produce: and this is with greater certainty, if the seasons prove bad, than can be expected by the common husbandry.

The price of corn varies continually; and this variation is often very great in the space of one or two years: so that from

from being so cheap, as that the farmers could not pay their rents, in the compass of a year the price has been doubled. But this might be so managed by an honest administration, by purchasing from the needy farmers in times of plenty, at a moderate price, and laying it up in public granaries, until there is a scarcity, as to supply the poor; whereby the public will never be in danger of wanting the staff of life, nor will the farmers suffer by having too great plenty. For, when the Wheat is sold much under four shillings the bushel, the farmer cannot pay his rent, and live; nor can the poorer sort of people afford to purchase good bread, when the wheat is sold at a price much higher than five shillings the bushel: therefore, when it is at a medium, between these, there can be no great cause of complaint. *Miller's Gard. Dict.*

Buck WHEAT. See BUCK *Wheat*.

WHEEL (*Dict.*)—The Wheel is one of the principal mechanic powers.—It has places in most engines; in effect, it is of an assemblage of Wheels, that most of our chief engines are composed.—Witness clocks, mills, &c.

Its form is various, according to the motions it is to have; and the use it is to answer.—By this it is distinguished into simple and dented.

Simple WHEELS, are those whose circumference and axis is uniform, and which are used singly, and not combined.—Such are the Wheels of carriages; which are to have a double motion: the one circular about their axis; the other rectilinear; by which they advance along the road, &c. which two motions they appear to have; though, in effect, they have but one: it being impossible the same thing should move, or be agitated two different ways at the same time.

This one is a spiral motion; as is easily seen, by fixing a piece of chalk on the face of a Wheel, so as it may draw a line on a wall, as the Wheel moves.—The line it here traces is a just spiral, and still the more curve, as the chalk is fixed nearer the axis.

We shall add, that, in Wheels of this kind, the heighth should always be proportioned to the stature of the animal that draws or moves them.—The rule is, that the load and the axis of the Wheels be of the same heighth with the power that moves them: otherwise, the axis being higher than the beast, part of the load will lie on him; or, if it be lower, he pulls to disadvantage, and must exert a greater force. Though Stevinus, Dr. Wallis, &c. shew, that to draw a vehicle, &c. over waste, uneven places, it were best to fix the traces to the Wheels lower than the horses breast.

The power of these Wheels results from the difference of the radii of the axis and circumference.—The canon is this: "As the radius of the axis is to that of the circumference, so is any power, to the weight it can sustain hereby."

This is also the rule in the axis in the peritrochio; and, in effect, the Wheel, and the axis in peritrochio, are the same thing; only, in theory, it it usually called by the latter name, and, in practice, by the former.

Dented WHEELS, are those either whose circumference, or axis, is cut into teeth, by which they are capable of moving and acting on one another, and of being combined together.

The power of the dented Wheel depends on the same principle, as that of the simple one.—It is only that to the simple axis in peritrochio, which a compound lever is to a simple lever.

Its doctrine is comprised in the following canon, viz.—"The ratio of the power to the weight," in order for that to be equivalent to this, "must be compounded of the ratio's of the diameter of the axis of the last Wheel to the diameter of the first; and of the ratio of the number of revolutions of the last Wheel, to those of the first," in the same time.—But this doctrine will deserve a more particular explication."

1. Then, if the weight be multiplied into the product of the radii of the axis, and that product be divided by the product of the radii of the Wheels, the power required to sustain the weight will be found.—Suppose, for instance, the weight A, *Plate* XLII. *fig.* 8. $= 6000$ pounds, $BC = 6$ inches, $CD = 34$ inches, $EF = 5$ inches, $EG = 35$ inches, $HI = 4$ inches, $HK = 27$ inches. Then will BC, EF, $HI = 120$: and CD, EG, $IK = 32130$. Hence the power, required to sustain the weight, will be $6000.\ 120 : 32130 = 22\frac{1}{2}$ very nearly; a small addition to which will raise it.

2. If the power be multiplied into the product of the radii of the Wheels, and the factum be divided by the product of the radii of the axis; the quotient will be the weight, which the power is able to sustain.—Thus, if the power be $22\frac{1}{2}$ of a pound, the weight will be 6000 pounds.

3. "A power and a weight being given, to find the number of Wheels, and in each Wheel, so, as that the radius of the axis, to the radius of the Wheel: so, as that the power, being applied perpendicularly to the periphery of the last Wheel, may sustain the given weight."

Divide the weight by the power: resolve the quotient into the factors which produce it.—Then will the number of factors be the number of Wheels; and the radii of the axes will be to the radii of the Wheels, as unity to the several Wheels.—Suppose, for instance, a weight of 3000 pounds, and a power of 60, is 500, which resolves into these factors, 4. 5. 5. 5. Four Wheels are to be made, in one of which, the radius of the axis is to be the radius of the Wheel, as 1 to 4.—In the rest, as 1 to 5.

4. If a power move a weight by means of two Wheels, the revolutions of the slower Wheel are to those of the swifter, as the periphery of the swifter axis is to the periphery of the Wheel that catches on it.

Hence, 1. the revolutions are as the radius of the axis F E, to the radius of the Wheel D C.—2. Since the number of teeth in the axis F D is to the number of teeth in the circumference of the Wheel M, as the circumference of that, to the circumference of this: the revolutions of the slower Wheel M are to the revolutions of the swifter N, as the number of teeth in the axis, to the number of teeth in the Wheel M it catches into.

5. If the factum of the radii of the Wheels, G D, D C, be multiplied into the number of revolutions of the slowest Wheel M; and the product be divided by the factum of the radii of the axes which catch into them, G H, D E, &c. the quotient will be the number of revolutions of the swiftest Wheel O. For instance, if $GE = 8$, $DC = 12$, $GH = 4$, $DE = 3$, and the revolution of the Wheel M be one; the number of revolutions of the Wheel O will be 8.

6. If a power move a weight by means of divers Wheels, the space, passed over by the weight, is to the space of the power, as the power to the weight.—Hence, the greater the power, the faster is the weight moved; and vice versa.

7. The spaces, passed over by the weight and the power, are in a ratio compounded of the revolutions of the slowest Wheel, to the revolutions of the swiftest; and of the periphery of the axis of that, to the periphery of this.—Hence, since the space of the weight and the power are reciprocally as the sustaining power to the weight; the power that sustains a weight, will be to the weight, in a ratio compounded of the revolutions of the slowest Wheel, to those of the swiftest, and of the periphery of the axis of that, to the periphery of this.

8. "The periphery of the axis of the slowest Wheel, with the periphery of the swiftest Wheel, given; as also, the ratio of the revolutions of the one, to those of the other: to find the space which the power is to pass over, while the weight goes any given length."

Multiply the periphery of the axis of the slowest Wheel, into the antecedent term of the ratio, and the periphery of the swiftest Wheel, into the consequent term; and to these two products, and the given space of the weight, find a fourth proportional: this will be the space of the power.—Suppose, for instance, the ratio of the revolutions of the slowest Wheel, to those of the swiftest, to be as 2 to 7; and the space of the weight 30 feet: and let the periphery of the axis of the slowest Wheel be to that of the swiftest, as 3 to 8. The space of the power will be found 280.

9. "The ratio of the peripheries of the swiftest Wheel, and of the axis of the slowest; together with the ratio of their revolutions, and the weight, being given: to find the power able to sustain it."

Multiply both the antecedents and the consequents of the given ratio's into each other: and to the product of the antecedents, the product of the consequents, and the given weight, find a fourth proportional: that will be the power required.—Suppose, for instance, the ratio of the peripheries 8 : 3. That of the revolutions 7 : 2; and the weight 2000: the power will be found $214\frac{2}{7}$.—After the same manner may the weight be found; the power and the ratio of the peripheries, &c. being given.

10. "The revolutions the swiftest Wheel is to perform, while the slowest makes one revolution, being given; together with the space the weight is to be raised, and the periphery of the slowest Wheel; to find the time that will be spent in raising it."

Say, as the periphery of the axis of the slowest Wheel is to the space of the weight given; so is the given number of revolutions of the swiftest Wheel, to a fourth proportional; which will be the number of revolutions, performed while the weight reaches the given heighth.—Then, by experiment, determine the number of revolutions the swiftest Wheel performs in an hour; and, by this, divide the fourth proportional found before.—The quotient will be the time spent in raising the weight.

Centrifugal WHEEL, a name given by Dr. Desaguliers to a machine for extracting the foul air out of hospitals, ships, &c.

Plate XLII. *fig.* 10. represents a case D E C B, containing a Wheel of seven feet in diameter, and one thick; being a cylindrical box, divided into twelve cavities by partitions directed from the circumference towards the center, but wanting nine inches of reaching the center, being open towards the center, and also towards the circumference, and only closed at the circumference by the case, in which the Wheel turns by means of an handle fixed to its axis A, which axis turns in two iron forks, or half concave cylinders of bell-metal, such as A, fixed to the upright timber or standard A E.

From the middle of the case on the other side behind A, there

 comes

comes out a trunk or square pipe, which we call the sucking-pipe; which is continued quite to the upper part of the sick person's room, whether it be near or far from the place where the machine stands, in an upper or lower story, above or below the machine. There is a circular hole in one of the circular planes, of the machine of eighteen inches diameter round the axis, just where the pipe is inserted into the case, whereby the pipe communicates with all the cavities; and, as the Wheel is turned swiftly round, the air which comes from the sick room is taken in at the center of the Wheel, and driven to the circumference, so as to go out with great swiftness at the blowing-pipe B, fixed to the said circumference.

As the foul air is drawn away from the sick rooms, the air in the neighbouring apartments will gradually come into the room through the smallest passages: but there is a contrivance to apply the pipes which go to the sick room to the blowing-pipe B, while the sucking-pipe receives its air only from the room where the machine stands. By this means fresh air may be driven into the sick room, after the foul has been drawn out.

This machine would be of great use in all hospitals, and in prisons: it would also serve very well to convey warm or cold air into any distant room; nay, to perfume it insensibly, upon occasion.

Fig. 11. Represents the inside of the flat of the Wheel which is farthest from the handle, and next to the sucking-pipe.

1, 2, 3, 4. Represents the cavity or hole which receives the air round the axis, having about it a circular plate of iron, to hold all firm; which plate is made fast to the wood, and to the iron cross that has the axis in it.

g g g. Denotes, by a pricked circle, a narrow ring of thick blanketting, which, by pressing against the outside case, whilst it is fixed to the outside of the flat of the Wheel, makes the passage into the Wheel tight.

H H H, is another circle of blanketting, likewise fixed to the outside of the Wheel, and rubbing against the case, that the air, violently driven against the inner circumference of the case, may have no way out, but at the blowing-pipe.

There is on the outside of the other flat of the Wheel, where the handle is fixed, a ring of blanketting, like H H H, opposite to it; but none opposite to *g g g*, because the wood there is not open, but comes home close to the axis.

Fig. 12. Gives a vertical section of the Wheel and case a little forward of the axis, drawn by a scale twice as large as that of the other two figures.

A *a*, the axis separated by the irons A *a*, cylindrically hollowed except the upper part, where a pin keeps in the axis.

B D, the case with the sucking-pipe S *a*.

E A, the prop for one end of the axis.

1, 2. The opening into the wheel.

g g. The eminence of the wood, to which is fixed the small ring of blanketting.

The four black marks, one of which is near H, represent the sections of the two other rings of blanketting. *Desaguliers's Course of Philosophy.*

WHEE'ZING, a name given by our farriers to a distemperature in horses, in which they draw their breath with difficulty and noise.

The generality of people make this and pursiness in horses the same distemper; but the more judicious always distinguish it, as wholly different from that. Pursiness proceeds always from a stuffing or oppression of the lungs; but this Wheezing is only owing to the narrowness of the passages between the bones and gristles of the nose.

The horses that are most of all afflicted with this distemper, do not want wind; for, notwithstanding they wheeze excessively when they are exercised, yet all the time their flanks are not moved, but keep in the same condition that they were while the creature stood still. The dealers call these sort of horses blowers, and, though there is no real harm in the thing, it is a disagreeable quality, and few people will chuse them that have much service for them.

There are some horses that have a natural defect in their breathing, which makes it at all times attended with some difficulty, but not with the Wheezing before-mentioned; these are called thick-winded horses.

People who are careful in the buying horses, will purchase neither of these kinds; but then is this caution to be observed in regard to this defect, that it often seems to be in horses where it really is not. When a horse has been kept a long time in the stable without exercise, he will, at the first riding, be out of breath, and fetch it in a difficult and painful manner, though he be neither a blower or thick-winded; but all this will go off with a little exercise.

There are some temporary wheezers and blowers among horses: these, at times, rattle, and make a great noise through their noses in taking breath; but the complaint goes off and returns. This is only occasioned by a great quantity of phlegm, for their flanks do not redouble with it at the worst of times, nor have they any cough with it; so that there is no danger of their being pursy.

WHI'PLADE, in husbandry, a term used by the farmers in some places, for a particular sort of cart, whose hinder part is made up of boards, after the manner of a dung-cart, having also a head of boards, and shambles over the thills; this head being made so as either to be taken out or left in. The cart may be indifferently used to carry dung or other things; dung when the head is in, and corn, &c. when it is taken out.

WHIRL-*pool*. These, in rivers, are very common, from various accidents, and are usually very trivial, and of little consequence. In the sea they are more rare, but more dangerous. Sibbald has related the effects of a very remarkable marine Whirl-pool among the Orcades, which would prove very dangerous to strangers, though it is of no consequence to the people who are used to it. This is not fixed to any particular place, but appears in various parts of the limits of the sea among those islands. Wherever it appears, it is very furious, and boats, &c. would be inevitably drawn in and perish with it; but the people who navigate them are prepared for it, and always carry an empty vessel, a log of wood, or large bundle of straw, or some such thing in the boat with them; as soon as they perceive the Whirl-pool, they toss this within its vortex, keeping themselves out; this substance, whatever it be, is immediately received into the center, and carried under water; as soon as this is done, the surface of the place where the Whirl-pool was becomes smooth, and they row over it with safety; and in about an hour they see the vortex begin again in some other place, usually at about a mile distance from the first.

WHI'STLE-*fish*, a name given by the people of Cornwall to a species of gadus with only two fins on the back, otherwise called mustela fluviatilis.

WHITE *Land*, in agriculture, a tough clayey soil, naturally of a somewhat whitish hue when dry, especially when it has lain some time untilled, but becoming blackish after rain; this appears of a light greyish colour, when turned up by the plough, and slides off from the plough-share with ease, and with a smooth glossy surface.

It has often a yellowish hue with the grey, and is often veined with large parcels of a blue marly earth. *Moreton's Northamptonshire.*

WHITE *Throat*, in zoology, the name of a small bird, very common in our gardens and hedges, and seeming to have been described under the name of spipola by Aldrovandus and some others, though most approaching to the ficedula class.

WHITE *upon* WHITE, in the porcelain manufactory, a name given by the English merchants to a particular China-ware, which is formed of three different white substances, the body being of one, the flowers of another, and the varnish which covers these of a third.

The principal art, in the making this sort of China, is the finding the proper degree of dryness in the vessels for receiving the pencilling or upper coats. It is a fine art. And the principal colour is made of an earth called hoache, which is much of the nature of our steatites.

WHI'TING, in zoology, the English name of a common fish of the asellus kind, commonly distinguished by the writers in ichthyography, by the name of asellus mollis, though by some called asellus albus and merlangus.

The Whiting is distinguished from the other species of the cod kind by these characters: it is of a small size, seldom much exceeding a foot in length, and is thin and slender in proportion to its length, particularly about the tail. Its scales are very small, and its colour much more pale and whitish, than in any other fish of the cod kind, whence it has its English name. The belly is white, and the belly-fins behind the tail are spotted with small black dots. It has no beard. Its eyes are large, and its upper jaw longer than its under; so that its teeth, which are large and crooked, fall over, and are uncovered when the mouth is shut; and the inner part of this jaw is armed also with very small teeth. Its belly, or rather its breast-fins, are nearer the head than in any other species. It is common in the English seas and elsewhere. *Willughby's Hist. Pisc.*

WI'CKER-*tree*, a name given by the English to a tree common in China, and described by Kircher and others. It is, as it were, a rope twisted by nature, about an inch thick, and creeps along the earth often for above a hundred paces together, much embarrassing the way, but serving for cables of ships, seats, hurdles, beds, mats, and various other necessary uses. It endures no vermin, and is much valued for being cool and refreshing in the hot seasons. *Kircher's China Illust.*

WI'CRANGLE, in zoology, an English name for the mattagess, or greater butcher-bird, the lanius cinereus major of authors. *Ray's Ornithol.*

WICRA'NTUM, in natural history, a name given by the people of the East-Indies to certain fossil bodies, of the nature of the pyrites, of the size of pease, and formed into variously angular figures.

WI'LDERNESS, in gardening. There is nothing so great an ornament to a large garden as a Wilderness, when properly contrived and judiciously planted.

The Wilderness should always be proportioned to the size of the garden, and should never be situated too near the house; because the trees perspire so large a quantity of watery vapours, as make the air very unwholesome. They should never be so placed as to block up a good prospect; but, where the view naturally

naturally ends with the verge of the garden or little more, nothing terminates it so well as a fine plantation of trees. The size of the trees should be considered, and tall growing ones should be planted in larger places; smaller, in less extensive; ever-greens also should be kept by themselves, and placed most in sight, not mingled confusedly among the trees which cast their leaves.

The walks should be large, and not numerous; the large walk is best made serpentine, and this should not be entered upon the grand walks of the garden, but by some private walk. *Miller's Gard. Dict.*

WILDS, a term used by our farmers to express that part of a plough by which the whole is drawn forwards.

The Wilds are of iron, and are of the form of a gallows, whence they are by some called the gallows of the plough, but improperly, the gallows of the plough being properly that part formed by the crow-staves, and the transverse piece into which they are mortised at the top.

The Wilds consist of two legs, and a transverse top-piece: one of the legs and the top-piece are all of one piece of iron, and the other leg, which is loose, has a hole in the top, into which the end of the transverse piece is received; both these legs pass through the box of the plough, which is that transverse timber through which the spindles of the wheels run: these legs are pinned in behind the box with iron pins; the holes through the box at which these legs pass, are not made at right angles, but slanting upwards, so that the fore-part of the Wilds is higher than the hinder part; were it not for this, the upper part of the crow-staves would lean quite back when the plough is drawn.

The use of the notches in the Wilds is to give the plough a broader or narrower furrow; if the links are moved to the notches on the right-hand, it brings the wheels towards the left, which gives a greater furrow; and, on the contrary, a smaller furrow is made when the links are moved to the notches on the left. The legs of the Wilds should be nineteen inches, and their distance eight inches and a half; they must be made strong, and the links must be placed in different notches, that the front of the plough may be kept steady, and the wheels not be drawn one before the other. These links are of iron also, and are six inches and a half long, and to these are fastened the chains of the harness, by which the whole plough is drawn along. *Tull's Husbandry.*

WILLOW, *salix*, in botany, a genus of plants, whose characters are:

The leaves are entire; the flower, which is male, and grows on a separate plant, is amentaceous, spiked, and consists of a multitude of stamina. The ovary, which is found only on the female plant, is furnished with a long tube, adorned with four horns, is of a conoidal figure and constituted in such a manner as to become a spiked fruit, containing a multitude of capsules resembling horns, and gaping by maturity into two parts. These capsules are full of many downy seeds.

There are a great number of species to be found in England, especially of the sallows, as I have been informed by a very judicious basket-maker, there are at least thirty sorts, which they distinguish by name, commonly in use in their trade; and, besides these, there are a great number of mountain Willows, which grow upon dry grounds, and are cultivated as underwood, in many parts of England.

All the sorts of Willows may be easily propagated by planting cuttings or sets in the spring, which readily take root, and are of quick growth. Those sorts which grow to be large trees, and are cultivated for their timber, are generally planted from sets, which are about seven or eight feet long: these are sharpened their larger end, and thrust into the ground by the sides of ditches and banks, where the ground is moist; in which places they make a considerable progress, and are a great improvement to such estates; because their tops will be fit to lop every fourth or fifth year. The larger wood, if sound, is commonly sold for making wooden heels, and pegs for shoes; as also to the turners, for many kinds of light wares.

The sallows are commonly planted in cuttings made from strong shoots of the former year, and are about three feet long; these are commonly thrust down two feet deep into the ground, and are one foot above it. The soil should always be dug or plowed before they are planted, and the cuttings placed about three feet row from row, and eighteen inches asunder in the rows; observing always to place the rows the sloping way of the ground, especially if the tides overflow the place; because, if the rows are placed the contrary ways, all the filth and weeds will be detained by the plants, which will choak them up.

The best season for planting these cuttings is in February; for, if they are planted sooner, they are apt to peel, if it proves hard frost, which greatly injures them.

These plants are always cut every year; and, if the soil be good, they will produce a great crop, so that the yearly produce of one acre has been often sold for fifteen pounds; but ten pounds is a common price, which is much better than corn-land; so that it is great pity these plants are not more cultivated, especially upon moist boggy soils, upon which few other things will thrive.

WIND (*Dict.*)— The husbandman often suffers extremely by high Winds, in many different respects. Plantations of trees, at a small distance from the barns and houses, are the best safeguard against their suffering by Winds; but they must not be planted so near, as that their fall, if it should happen, would endanger them. Yews grow very slowly, otherwise they are the best of all trees for this defensive plantation. Trees suffer by Winds, being either broken or blown down by them; but this may be in a great measure prevented by cutting off great part of the heads and branches of them in places where they stand most exposed.

Hops are the most subject to be injured by Winds of any crop; but this may be in a great measure prevented by a high pale, or very thick thorn hedge; this will both keep off the spring Wind, which nips the young buds, and be great safeguard against other Winds that would tear the plants from their poles. The poles should always be very firm in the ground; and the best security to be added to this is a row of tall trees all round the ground.

Winds, attended with rain, do vast injury to the corn, by laying it flat to the ground. The best method of preventing this, is to keep up good inclosures; and, if the accident happens, the corn should be cut immediately, for it never grows at all afterwards. It should be left on the ground, in this case, some time after the cutting, to harden the grain in the ear. *Mortimer's Husbandry.*

WIND *flower*, in botany, the English name of the anemone. See the article ANEMONE.

WIND-*gall*, a name given by our farriers to a distemperature of horses. In this case, there are bladders full of a corrupt jelly, which, when let out, is thick, and of the colour of the yolk of an egg.

They vary in size, but are more usually small than large. Their place is about the fetlock joint, and they grow indifferently on all four legs, and are often so painful, especially in the summer-season, when the weather is hot, and the ground dry and hard, that they make the creature frequently stumble, or fall absolutely down.

The general method of cure is to open the swelling about the length of a bean, and to press out the jelly: when this is done, they apply a mixture of the oil of bays and the white of an egg, covering it with tow.

Another method is, after the jelly is all squeesed out, to wrap round the part a woollen cloath, and then applying a taylor's hot iron, this is to be rubbed over till all the moisture is carried away; it is then to be daubed all over with pitch, mastich, and resin, boiled together, laying tow in plenty over all.

The Wind-galls that are situated near the sinews, are much the most painful of all, and soonest make the horse lame.

The general cause of Wind-galls is supposed to be extreme work, or exercise in very hot weather; but it is to be observed, that those horses, which have long joints, will be Wind-galled, if they work never so little.

The worst Wind-galls are those of the hinder legs; all the above-mentioned will frequently miss of success in these, and nothing but fire will cure them.

WIND-*hatch*, in mining, a term used to express the place at which the ore is taken out of the mines.

The word hatch is the general term used by the miners to express an opening from the surface into the mine, or in the attempting to find a mine.

Thus the word essay-hatches signifies the openings made in search of the trains of shoad-stones; and the tin-hatch in Cornwall is the name of the opening by which they descend into a tin-mine.

The word Wind-hatch seems to be a corruption of winder-hatch; for at these places, they have a winder conveying two buckets, the one constantly up, the other constantly down; the man below fills the bucket that descends; and, when that which ascends full is emptied at the mouth of the hatch, the person who has the care of that part of the work, delivers it empty to go down again. *Phil. Transf.* N°. 69.

WIND-*sails*, in a ship, are made of the common sail-cloth, and are usually between twenty-five and thirty feet long according to the size of the ship, and are of the form of a cone ending obtusely: when they are made use of, they are hoised by ropes to about two-thirds or more of their height, with their basis distended circularly by hoops, and their apex hanging downwards, in the hatch-ways of the ship; above each of these, one of the common sails is so disposed, that the greatest part of the air, rushing against it, is directed into the Wind-sail, and conveyed, as through a funnel, into the upper parts of the body of the ship. *Phil. Transf.* N°. 463.

WIND-*shock*, a name given by our farmers to a distemperature to which fruit-trees, and sometimes timber-trees, are subject. It is a sort of bruise and shiver throughout the whole substance of the tree; but, the bark not being often affected by it, it is not seen on the outside, while the inside is twisted round and greatly injured.

It is by some supposed to be occasioned by high Winds; but others attribute it to lightning. Those trees are most usually affected by it, whose boughs grow more out on one side than on the other.

The

The beſt way of preventing this, in valuable trees, is to take care, in the plantation, that they are ſheltered well, and to cut them frequently in a regular manner, while young.

The Winds not only twiſt trees in this manner, but they often throw them wholly down: in this caſe, the common method is to cut up the tree for firing, or other uſes; but, if it be a tree that is worth preſerving, and if it be not broken, but only torn up by the roots, it may be proper to raiſe it again by the following method: let a hole be dug deep enough to receive its roots in the place where they before were; let the ſtraggling roots be cut off, and ſome of the branches, and part of the head of the tree; then let it be raiſed; and when the torn-up roots are replaced in the earth, in their natural ſituation, let them be well covered, and the hole filled up with rammed earth; the tree will, in this caſe, grow as well, and perhaps better, than before. If nature be left to herſelf, and the trees be not very large, the pulling off the roots will raiſe it. *Mortimer's Huſbandry.*

Venetian WINDOW, a very elegant Window, invented by the Venetians. *Plate* IV. *fig.* 1. in the Dictionary, repreſents a Window of this kind.

WINE (*Dict.*)—The method of converting white Wine into red, ſo much practiſed by the modern Wine-coopers, is this: put four ounces of turnſole rags into an earthen veſſel, and pour upon them a pint of boiling water; cover the veſſel cloſe, and leave it to cool; ſtrain off the liquor, which will be of a fine deep red inclining to purple. A ſmall proportion of this colours a large quantity of Wine. This tincture might be either made in brandy, or mixed with it, or elſe made into a ſyrup with ſugar for keeping. A common way with the Wine-coopers is to infuſe the rags cold in Wine for a night or more, and then wring them out with their hands; but the inconveniency of this method is, that it gives the Wine a diſagreeable taſte, or what is commonly called the taſte of the rag; whence the Wines, thus coloured, uſually paſs among judges, for preſſed Wines, which have all this taſte from the canvas rags in which the lees are preſſed.

The way of extracting the tincture, as here directed, is not only attended with this inconveniency; but it loads the Wine with water; and, if made into a ſyrup, or mixed with brandy, it would load the Wine with things not wanted, ſince the colour alone is required. Hence the colouring of Wines has always its inconveniencies. In thoſe countries which do not afford the tinging grape, which affords a blood-red juice, wherewith the Wines of France are often ſtained; in defect of this the juice of elder-berries is uſed, and ſometimes logwood is uſed at Oporto.

The colour, afforded by the method here propoſed, gives wine the tinge of the Bourdeaux red, not the port; whence the foreign coopers are often diſtreſſed for want of a proper colouring for red Wines in bad years. This might perhaps be ſupplied by an extract made by boiling ſtick-lac in water. The ſkins of tinging grapes might alſo be uſed, and the matter of the tournſole procured in a ſolid form, not imbibed in rags. *Shaw's Lectures.*

Any conſiderable heat, or even a degree of ſimmering, or tepidity, will, by its inteſtine and ſubtile agitation, that barely diſturbs the fine ſaline and ſpirituous parts, which are very ſuſceptible of heat, thereby diſjoin them from the reſt, and occaſion an alteration in the taſte, tranſparency and durability of the Wine, as much as if the ſpirit had been drawn off by diſtillation, and afterwards poured in again, in which caſe the whole ceaſes to be Wine, though it is poſſible to bring it to Wine again by bringing on a new fermentation.

It is a common accident, and a diſeaſe in Wines, to be kept too hot, and is not eaſy to cure when it has been of any long continuance, otherwiſe it may be cured by introducing a ſmall artificial fermentation, that new ranges the parts of the Wine, or rather recovers their former texture: but the actual expoſing of Wine to the fire, or ſun, preſently diſpoſes it to turn eager; and the making it boiling hot is one of the quickeſt ways of expediting the proceſs of making of vinegar.

On the other hand, Wine kept in a cool vault, and well ſecured from the external air, will preſerve its texture entire in all the conſtituent parts, and ſufficiently ſtrong for many years; as appears not only from old Wines, but other foreign fermented liquors, particularly thoſe of China, prepared from a decoction of rice, which being well cloſed down in the veſſel, and buried deep under ground, will continue for a long ſeries of years, rich, generous, and good, as the hiſtories of that country univerſally agree in aſſuring us.

The ſame is to be underſtood of vinegar which has once thrown off the ſuperabundant earthy parts, and many of the oily ones which preſided in it while it was Wine; whence the ſaline ones now get the aſcendant, and as it were ſubdue and preſide over the ſpirituous ones. In this ſtate it will continue perfect a long time; good and ſtrong vinegar, well ſtopped down, and placed in a cool place, preſerving itſelf unaltered for a long ſeries of years: but, if it be left open, ſo that its fine vapour exhales, or its ſubtile part be drawn from it, and again poured back; in either caſe it loſes its uniform conſiſtence, and particularly its durability, and immediately hurries into vapidity and corruption.

If either by fraud or accident a larger portion of water is mixed with Wine than is proper for its conſiſtence, and no way neceſſary or eſſential, this ſuperfluous water does not only deprave the taſte, and ſpoil the excellence of the Wine, but alſo renders it leſs durable; for humidity in general, and much more a ſuperfluous aqueous humidity, is the primary and reſtleſs inſtrument of all the changes that are brought on by fermentation. It may doubtleſs therefore be of uſe, and it is ſometimes abſolutely neceſſary, to take away this ſuperfluous water from the other part which ſtrictly and properly conſtitutes the Wine. This has been agreed upon on all hands as a thing proper; but the manner of doing it has not been well agreed on; ſome have propoſed the effecting it by means of heat and evaporation, others by percolation, and others by various other methods, all found unſucceſsful when brought to the trial; but the way, propoſed by Dr. Shaw from Stahl, is the moſt certain and commodious; this is done by a concentration of the Wine, not by means of heat, but of cold. *Stahl's Schediaſm. de Concentratione Vini.*

Condenſing of WINES, a phraſe uſed by Stahl, and ſome other writers, to expreſs what is more uſually called the concentrating them, that is, the freeing them from what ſuperfluous humidity they contain, and by that means rendering them more rich and noble, and freeing them from their taſteleſs part, reducing them to a ſmaller bulk, and by that means making them fitter for tranſportation, and finally rendering them more durable in their perfect ſtate, and much leſs ſubject to the various accidents that make them decay.

Various methods have been attempted for the effecting of this, and great objections found in the way of all of them, except the lateſt, brought into uſe by Stahl, and ſince recommended greatly to the world by Dr. Shaw in his Chemical Eſſays.

If any kind of Wine, but particularly ſuch as have never been adulterated, be in a ſufficient quantity, as that of a gallon or more, expoſed to a ſufficient degree of cold in froſty weather, or be put into any place where ice continues all the year, as in our ice-houſes, and there ſuffered to freeze, the ſuperfluous water that was originally contained in the Wine, will be frozen into ice, and will leave the proper and truly eſſential part of the Wine unfrozen, unleſs the degree of cold ſhould be very intenſe, or the Wine but weak and poor. This is the principle on which Stahl founds his whole ſyſtem of condenſing Wines by cold.

When the froſt is moderate, the experiment has no difficulty, becauſe not above a third or fourth part of the ſuperfluous water will be frozen in a whole night; but, if the cold be very intenſe, the beſt way is, at the end of a few hours, when a tolerable quantity of ice is formed, to pour out the remaining fluid liquor, and ſet it in another veſſel to freeze again by itſelf: this is proper, for two reaſons; firſt, becauſe, the quantity of ice growing large, more of the concentrated Wine will be apt to lodge in it than ſhould, and it will require a longer time to drain and clear away from the ice. The making the experiment will ſufficiently explain this to any body; for, without breaking the ice, the unfrozen part will, barely by inclining the veſſel, find its own way out, and drain clear from the watery part, which is now converted into ice; ſo that, if the draining be perfect, the ice of the moſt perfectly red Bourdeaux claret will become nearly as clear and pale as water, and will reſolve by heat into an almoſt entirely colourleſs phlegm. This is no ſmall curioſity attending this experiment, and at the ſame time affords a criterion of its exact performance.

If the veſſel, that thus by degrees receives the ſeveral parcels of the condenſed Wine be ſuffered to ſtand in the cold freezing place where the operation is performed, the quantity lying thin in the pouring out, or otherwiſe, will be very apt to freeze anew; and, if it be ſet in a warm place, ſome of this aqueous part thaws again, and ſo weakens the reſt. The condenſed Wine therefore ſhould be emptied in ſome place of a moderate degree as to cold or heat, where neither the ice may diſſolve, nor the various ſubſtance mixed among it be congealed. But the beſt expedient of all is to perform the operation with a large quantity of Wine, or that of ſeveral gallons, where the utmoſt exactneſs, or the danger of a trifling waſte, needs not be regarded.

By this method, when properly performed, there firſt freezes one third part of the whole liquor, and this is properly the more purely aqueous part of it, inſomuch that, when all the vinous fluid is poured off, to be again expoſed to a concentration, the ice remaining behind, from this firſt freezing, being ſet to thaw in a warm place, diſſolves into a pure and taſteleſs water.

If the Wine, now once concentrated, ſhould, by a long continuance in the freezing cold, be again congealed to the utmoſt (unleſs the cold were very ſevere indeed) and then again be drained from its ice, there, ſoon after this, falls to the bottom of the veſſel a pure white powder or tartar, and even the icy part afterwards depoſits a little of the ſame ſubſtance after thawing; and, after the ſtanding two or three days, there is always more and more of this tartar precipitated, and that conſtantly the more, in proportion as the Wine was the more auſtere, or leſs adulterated with ſugar-candy, or the like, for theſe things contain no tartar.

The ice of the second operation on a quantity of wine differs in nothing from that of the first, provided only that the Wine was poured clear off from it, before the ice is set to melt, by which means it dissolves into a clear phlegm. This shews the excellency of the operation, as it loses not its efficacy upon repetition, but brings away mere water as well at last as at first, without robbing the Wine of any of its genuine or truly valuable parts. The remaining liquor, which has escaped being frozen in these two operations, is a real concentrated Wine, as appears by its colour, consistence, taste, and smell; for it now has all these properties in a much larger degree, than while it contained so much superfluous moisture of a merely aqueous kind. It therefore becomes a nobler and richer Wine, than could any way be procured without such a contrivance. For, as, by this means, two thirds of the quantity are taken away in the better sorts of Wine, and three fourths in the weaker, what remains must needs possess three or four times the strength and virtues of the same quantity of the crude Wine.

The benefit and advantage of this method of congelation, if reduced to practice in the large way, in the Wine countries, must be evident to every body. Concentrated Wines in this manner might be sent into foreign countries instead of Wine and water, which is what is usually now sent, the Wines they export being loaded, and in danger of being spoiled by three or four times their own quantity of unnecessary, superfluous, and prejudicial water.

The business is, how to perform the operation, for, Wine-countries being in general hot countries, the business of freezing will not be so easily carried on there as in the cold ones: but this is an objection easily solved by observing, that, in most of the Wine countries that we are acquainted with, there are hills and mountains, the tops of which are covered with snow all the year round; and all who are acquainted with natural philosophy, very well know, that, where there is snow to be had, there will be no difficulty about freezing.

The difficulty rests therefore not in the matter of freezing, but in the reducing the Wines, when thus concentrated, to their due and natural state again; for, though the addition of water alone does this in a tolerable manner, yet better means may certainly be found on farther trials. The way of using poor Wines, and such as in themselves are of little use or value, is always a good one, and is sufficiently advantageous; because what there is in the price of these above water, is made up to the proprietor in the quantity of the final produce; water could only give the same quantity of the Wine that there was originally, and before the condensation; but these Wines will bear to be mixed in so much larger a quantity, that the produce will warrant the gaining by the practice.

This method is not practicable to advantage in the Wine countries alone. Dr. Shaw assures us, that he has himself experimented it here, and with the use of proper freezing mixtures has reduced wines in England to a much smaller quantity, in proportion to the whole, than in the strongest of Stahl's experiments. It is evident that, by how much the quantity is smaller, by so much it is richer and stronger, provided that the operation has been properly performed. The doctor assures us, the noble essence or rob, thus prepared, is capable of working almost miracles, by turning water into Wine, and the like; but that, in order to its succeeding well, there requires great care in the operator, when the congelation is repeated the last times. *Shaw's Chemical Essays. Stahl's Concentrat. Vin.*

Diseases of WINES. All Wines, malt liquors, and vinegars, which are all well made, and perfect in their kind, will grow fine of themselves, barely by standing; so that, if they do not thus grow fine in a reasonable time, it is a sign that they labour under some disease; that is, they are too aqueous, too acid, too alkaline, or they tend to putrefaction, or the like. In all these cases, which may properly enough be called the diseases of Wines, suitable remedies are required before the Wines will grow fine. The most general remedy, hitherto known for all the diseases of Wines, is a prudent use of tartarised spirit of Wine, which not only enriches, but disposes all ordinary Wines to grow fine. *Shaw's Lectures.*

Low WINES, in the distillery, the term for the spirituous liquor distilled immediately from the fermented matter, and continued running so long, that the last of it was not at all inflammable. This liquor is afterwards rectified to a proof spirit of the strength of brandy, and thence to a rectified spirit called alchol, or spirit of Wine. *Shaw's Lectures.*

Pricked WINES. An easy method of recovering pricked Wines may be learned from the following experiment: take a bottle of red Port that is pricked, add to it half an ounce of tartarised spirit of Wine, shake the liquor well together, and set it by for a few days, and it will be found very remarkably altered for the better.

This experiment depends upon the useful doctrine of acids and alkalies. All perfect Wines have naturally some acidity, and, when this acidity prevails too much, the Wine is said to be pricked which is truly a state of the Wine, tending to vinegar: but the introduction of a fine alkaline salt, such as that of tartar, imbibed by spirit of Wine, has a direct power of taking off the acidity, and the spirit or Wine also contributes to this, as a great preservative in general of Wines. If this operation be dexterously performed, pricked Wines may be absolutely recovered by it, and remain saleable for some time: and the same method may be used to malt liquors just turned sour. *Shaw's Lectures.*

WINE-*fly*, in natural history, the name of a small black fly, found in empty Wine-casks, and about Wine-lees, and called by the Latins bibio.

It is produced of a small red worm, very common in the sediment of Wine.

WINGS *of butterflies*. The beautiful Wings of this genus of insects are distinguished from those of the fly-kind, by their not being thin and transparent, like them, but thicker and opaque. This opacity in them is owing only to the dust which comes off of them, and sticks to the fingers in handling them; and it is also to this dust that they owe all their beautiful variety of colours. — Authors, in general, call this dust feathers; but Mr. Reaumur more justly calls them scales.

WINGS *of gnats*. — These are of a very curious structure, and well worthy the use of the microscope, to see them distinctly. The wings of a gnat, like those of most other insects, are of a cartilaginous substance; friable, and transparent as a piece of talc, and the circumference, and inner substance of the Wing, are strengthened by slender, but firm ribs, which are divaricated into several ramification. These appear to us to be mere straight fibres; but they are probably hollow, and perform the office of vessels, for carrying the fluids or air necessary to the support of the Wing, as well as to strengthen it. In the wings of butterflies there are similar ribs, but all hid by the scales. In the Wings of gnats, they are almost, but not absolutely, naked; for the microscope shews that these nerves or ribs, with their several ramifications, resemble so many stalks of plants, covered with small oblong leaves. The latter are scales, but their number is very small, compared with that of the butterfly class; but they make a slighter and more elegant ornament. *Reaumur's Hist. Inf.*

WIRE (*Dict.*) — Iron-Wire is made from small bars of iron, which are called Osleom iron, which are first drawn out to a greater length, and to about the thickness of one's little finger, at a furnace, with a hammer gently moved by water. These thinner pieces are bored round, and put into a furnace to aneal for twelve hours. A pretty strong fire is used in this operation.

After this, they are laid under water for three or four months, the longer the better; then they are delivered to the workmen called rippers, who draw them into Wire through two or three holes. After this they aneal them again for six hours, and water them a second time for about a week, and they are then again delivered to the rippers, who draw them into Wire of the thickness of a large packthread. They are then anealed a third time, and then watered for a week longer, and delivered to the small Wire-drawers, called over-house men.

In the mill where this work is performed, there are several barrels hooped with iron, which have two hooks on their upper sides, on each whereof hang two links, which stand across, and are fastened to the two ends of the tongs, which catch hold of the Wire, and draw it through the hole. The axis on which the barrel moves does not run through the center, but is placed on one side, which is that on which the kooks are placed; and underneath there is fastened to the barrel a spoke of wood, which they call a swingle, which is drawn back a good way by the cogs in the axis of the wheel, and draws back the barrel, which falls to again by its own weight. The tongs hanging on the hooks of the barrel are by the workmen fastened to the end of the Wire, and by the force of the wheel the hooks being pulled back, draw the Wire through the holes.

The plate in which the holes are is iron on the outside, and steel on the inside; and the Wire is anointed with train oil, to make it run the easier. *Ray's English Words.*

WOAD, *isatis*, in botany. See the article ISATIS.

WOLF, *lupus*, in zoology. See the article LUPUS.

WOOD (*Dict.*) — The structure and organisation of Wood is a subject on which many have employed their thoughts; but perhaps none with greater success than the celebrated Monsieur Buffon, of the Royal Academy of Sciences at Paris.

This gentleman observes that the organisation of Wood is yet unknown in all its parts; and, that though the world is greatly indebted to the observations of Grew, Malpighi, and Hales, yet, when he entered on the subject, he found there was much more unknown than known, and determined to observe, from its first state, the growth of trees, and the formation of their woody part.

The seed of a tree, suppose an acorn, if put into the earth in the spring season, produces, after a few weeks, a tender shoot, of an herbaceous structure, which enlarges, extends itself, and hardens by degrees, and, in the first year's growth, has in it a slender filament of a woody substance. At the extremity of this young tree there is a little button formed, which opens the next year into leaves, and from which there is propagated a second a second shoot, in all respects like that of the first year, except that is more vigorous, grows faster, and hardens much more considerably. This is also terminated by a button like that of the precedent year, and in this is contained the shoot of the third year; and in this manner is the growth of the tree carried on, till it has acquired its whole height.

Each of these buttons is a sort of seed, which contains the shoot of the succeeding year, just as the seed itself did that of the first: and the growth of a tree in height is carried on therefore by a series of annual productions, exactly like one another; and the full-grown tree is, though perhaps a hundred feet high, composed only of a number of short trees, joined end to end, the longest of which is not above two feet in length. These little trees of the several years never at all alter their height or length, or even their thickness; they remain even in a tree of a hundred years old, of their original length and diameter, and suffer no change, but in becoming harder.

This then is the manner in which trees grow in height; how they grow in thickness is next to be inquired into.

The button which makes the summit of the tree of the first year, draws its nourishment through the very substance of that little tree; but the principal tubes or vessels which serve to convey the sap, are placed between the bark and the woody filament.

The action of this sap, in moving, dilates and enlarges these vessels, while the button, in raising itself up in growth, elongates them; the sap also, in continually passing them, leaves behind it certain fixed parts, which augment the solidity. Thus the second year's little tree contains in its middle a woody filament in form of an elongated cone, which is the production of the Wood of a former year, and a woody bed for it, which is also of a conic shape, and which surrounds the first filament, and reaches beyond it in length; and this is the production of the second year. The third bed forms itself altogether like the second, and all the succeeding ones are formed by the same law, and in the same order, and envelope one another in a continued succession or series, so that a large tree is composed of a number of woody cones, which enfold, cover, and envelope one another, as the tree increases in thickness.

When the tree comes to be cut down, one easily counts, in a transverse section of the trunk, the number of these cones, the sections of which make so many concentric circles; and the age of the tree is known by the number of these circles, for they are distinctly separate from one another; in a vigorous and well grown-oak, these lines are each of a sixth of an inch or more in thickness, and the substance of these lines or circles is very hard and firm, but the substance of the Wood, which lies between, and unites these to each other, is much less so. This intermediate matter is always the weak part of the Wood, and its structure and organisation is perfectly different from that of the woody cones, and depends entirely on the manner in which those cones are united to one another. This is explained in the following manner:

The vessels, which are longitudinally disposed in the Wood, and convey the nourishment to the button, not only are extended and hardened by the action of the sap in motion, and by the firm particles it deposits; but they are ever attempting also an extension of another kind; they are ramified all along as they go, and break into numberless extremely minute filaments, which issue from them like so many branches; these, on the one part, are destined to the production of the bark of the tree; and, on the other, are connected to the Wood of the preceding year, and from between the two woody beds a sort of spungy reticular work, which, when cut transversely, even to a great thickness, shews numberless little cavities and holes, resembling a sort of lace-work. The woody beds are therefore united to one another by a sort of net-work; this net-work, however, does not occupy nearly the space of the woody circles which it separated, and is usually indeed but about a sixth part of their thickness. This thickness is much the same in all the trees of the same species, whereas the woody beds vary in them very considerably in thickness; in the oak they are found from a sixth to a four and twentieth part of an inch in thickness.

By this easy exposition of the texture of Wood, it is easy to discover that the longitudinal coherence of the particles of it must needs be vastly greater than the transverse: one sees also that, in little pieces of Wood, as in a bar of an inch thickness, if there are fourteen or fifteen of these woody beds, there will also be thirteen or fourteen of these intermediate spaces; and consequently it will be much weaker than if there were but five or six of these woody beds in it, and consequently but four or five of these intermediate spaces.

It may also be observed, that in those little bars of Wood there are two or three of the woody beds wounded, which is often the case; the strength of the bar must be thence greatly impaired: but the greatest fault these small pieces of Wood are subject to, is the different disposition of these beds in the different parts of the same tree; and this difference is so great, that the force or strength of a large beam of any Wood cannot be computed by proportion, from that of a small piece of the same Wood; which, were it possible, would make calculations of this kind extremely easy. The ingenious author of this paper has from hence calculated the force and strength of timber used in building. *Memoirs Acad. Par.* 1740.

The people who work much in Wood, and that about small works, find a very surprising difference in it, according to the different seasons at which the tree was cut down, and that not regularly the same in regard to all species, but different in regard to each. The button-mould-makers find that the Wood of the pear-tree, cut in summer, works toughest; holly, on the contrary, works toughest when cut in winter; box is mellowest when it has been cut in summer, but hardest when cut about Easter; hawthorn works mellow when cut about October, and the service is always tough, if cut in summer.

WOOD-*cock*, a bird of passage, that comes into England about the middle of October, and goes away again in March.

During their stay with us, they ramble about from place to place, never remaining above eight or ten days together in the same Wood or meadow. They seldom or never fly in the daytime, unless disturbed by men, or by some beast. In whatever places they are put up, they always fly to the thickest Wood that lies near, and there hide themselves under the sturdiest and thickest trees, where they remain all day searching for earthworms, and other food, under the fallen leaves.

When night comes, they go out of the Woods, and generally resort to watery places, where they may wash their bills, fouled with the taking their prey, and thrusting into the earth; here they remain all the night, and, if there is tolerable shelter, they stay also the day under it; but, when there wants this, they fly away to the Woods in the morning. In their flight, they chuse the shadiest places, and will coast it away to a great distance in search of the highest Woods to retire to, that they may be the better secured, and there more defended from the annoyance of the Wind. While they travel under shelter, they always fly low; but when they come to any glade to cross, they mount to a considerable height; but, as soon as they have passed this, they sink again.

They hate flying high, and they are afraid to fly among trees, because, like the hare, they see but very badly straight before them; and it is owing to this imperfection in their sight, that they are so easily taken in nets spread in their places of resort.

The draw-net, in countries which are very woody, is extremely profitable in this sport, it being no uncommon thing to take ten or a dozen Wood-cocks at a time in it.

The method of using it to advantage is this: there must be chosen a proper place in some thick Wood, where these birds are found to resort, and a place must be cleared for them, and for the net. Supposing the Wood about three hundred paces long, in this case, towards the middle there must be cut a walk through it eight fathoms wide: near the end of this, two opposite trees are to be pitched upon, proper to support the two sides of the net; the boughs of these are to be all cleared away, and the nets fastened by logs and pullies.

When the net is thus placed, the sportsman must provide some covert in which he may stand concealed. This is easily made by half a dozen boughs of ever-green trees with their leaves; and the sportsman, when he has stuck these down in the ground, and interwoven their boughs together, may either stand behind it, or sit down on a bundle of dry fern, or any other such matter. At three or four feet distance from this stand, towards the net, there is to be a strong stake fastened into the ground, and on this the lines of the net are to be fastened when it is drawn up. When there comes a Wood-cock, the net is to be let down as soon as ever he is taken, to entangle him the more, for, otherwise, in the struggling he may chance to make his escape. The sportsman is then to run up, and break a wing, and crush his head. The net is then to be refitted again as quick as possible, for, when one is caught, there is great reason to suspect that many more are coming the same way, which will be all lost, if the sportsman is slow at his work.

If a hare, or any other creature worth the taking, come along the walk, the net is not to be immediately let down upon it, for in that case it would certainly start back, or run forwards, and in either case would probably make its escape: the net is to be drawn up five or six feet, that he may pass quietly under it without suspicion: as soon as he is gone by, the sportsman is to make a great shout, and let go the net; the creature will, on this noise, start back, and will thus be certainly taken in the net.

There are, in many places, great thoroughfares through some open piece of ground, by which Woodcocks pass in great numbers from one Wood to another. If there be in these two trees, naturally planted, so as to sustain the nets, they are by all means to be used; but, if not, the sportsman will find it worth his while to be at the expence of planting two trees deep in the earth, at proper distances, that they may stand all weathers. Nets spread between these are the most fatal of all others to these birds, for all that inhabit either one or the other of the Woods come this way at times, without suspicion of any danger or disturbance.

There is another method of taking these birds in high Woods, with those nets called hays, of the nature of the rabbets-hays, only with smaller meshes. The Woodcocks are to be driven into these, and there should always be at least two or three of them planted together. When the sportsman has provided

 himself

himſelf with nets, he is to take five or ſix perſons into the Wood with him. The proper Woods for this purpoſe are thoſe of ſeven or eight years growth; and the people are to go into ſome part of them, near the middle. The nets or hays are to be placed in the ſame manner as they are for taking of rabbets, but two or three joining together at the end, and hanging over ſlopewiſe that way which the Wood-cocks are intended to be driven.

The nets being thus fixed, let the company go to the end of the Wood, placing themſelves at about ten rods diſtance from one another; they muſt all have ſticks in their hands, and they are to move forwards ſlowly towards the nets, making a noiſe by ſtriking the ſticks againſt the trees and branches, and by hallooing with their voices: in this manner they are to move up to the net; and the Wood-cocks in that part of the Wood will all be terrified before them, but will not take wing, but run along upon the ground, and thus be driven along like a drove of beaſts, ſo that, when the company come up, they will find almoſt all of them in the net. When that part of the Wood is thus drove, the nets are to be turned the other way, and placed ſlopewiſe in the contrary direction, and the company, retiring to the other end of the Wood, are to drive the Wood-cocks that are in that part with the ſame noiſe, till they have ſent them into the nets in the ſame manner.

Thus all the Wood-cocks in the Wood may be taken with very little trouble, and this may be done equally at any time of the day.

Another way of taking this bird is, by means of nooſes or ſprings.

The Wood-cock and the ſnipe ore both eaſily taken alſo with bird-lime, when their places of reſort are known, but they are not ſo eaſily found as many other birds.

The cuſtom of the Wood-cock is uſually to be upon the banks under hedges, and by the ſides of ditches towards the ſun; and they will ſuffer the ſportſman to come nearer them in the daytime after a moon-ſhiny night, than after a dark one. The reaſon of which is, that, having fed well by moon-light, they are only fit for reſt in the day following; but, when the night has been dark, they are ſeeking food all the day long.

The ſnipes naturally lie by the ſides of rivers, when the plaſhes and ponds are frozen, and they always lie with their heads up or down the ſtream, never tranſverſely.

In order to take either of theſe birds by bird-lime, the ſportſman muſt be provided with a large number of ſmall and ſmooth twigs, neatly and evenly covered with good bird-lime. Theſe muſt be placed ſloping, ſome one way, ſome another, and the whole place about where they reſort muſt be covered with them. The ſportſman then muſt conceal himſelf very carefully, that the ſight of him may not frighten away the game.

Wood-*cock ſhell*, a name given by the Engliſh naturaliſts to a particular kind of the purpura. The French call it becaſſe.

Wood-*land*, in agriculture, a term uſed, by the farmers of many counties of England, for a ſort of ſoil, from its conſtant humidity and dark colour, reſembling the ſoil in Woods, which, of whatever nature it originally is, will always be made to appear thus from the continual dropping of trees, and the want of a free air and ſun, together with the fall of leaves, deſtroyed and waſhed to pieces by the wet.

This ſoil in the open countries has a conſiderable quantity of clay in it, and holds the water a long time that once falls upon it: in wet weather it ſticks firmly to the plough-ſhare, and, in dry, is very apt to crack. In uncultivated places it uſually produces ruſhes and ruſh-graſs. A moiſt and dripping year is extremely detrimental to this ſort of land. *Morton's North.*

Wood-*lark*, in ornithology. This is one of the ſweeteſt of our ſinging-birds, and is indeed very little inferior to the nightingale, when in good health; for we are not to judge by ſuch as are made feeble by improper food, or want of cleanlineſs in their cages.

It is one of the tendereſt birds we have, and yet it breeds the ſooneſt of any that we know of. They principally frequent gravelly grounds, and the ſides of hills, that are expoſed full to the ſun; and, if there be any ſtumps of oaks in theſe places, they always reſort to them.

The females couple with the males in the beginning of February, at which time, and never before, they part with their laſt year's brood; immediately after coupling, they betake themſelves to building their neſt.

They generally build in lay, or grounds, where the graſs is rank, and is grown brown. The principal material they uſe is dry graſs, and they always chuſe ſome place ſheltered by a good tuft for their neſt, to defend themſelves from the cold winds, which are very ſevere at that ſeaſon. They feed their young principally with a ſmall red worm; but it is very difficult to find this kind, to feed a neſt of them under our care, and they will not do well without it; ſo that they ſcarce ever come to any thing this way.

Wood-*mite*, in natural hiſtory, the name of a little animal frequently made the ſubject of microſcopical obſervation, and by ſome called the Wood-louſe; though that leſs properly, as there is another larger animal generally known by that name.

The Wood-mite is in ſhape and colour very like a louſe, and is frequently found running very nimbly, but always by ſtarts and jumps, on old books and rotten Wood. The eyes of this creature are of a fine gold colour, and can be thruſt out or drawn in at pleaſure; and when examined by the microſcope, the periſtaltic motion of the guts is ſeen very diſtinctly and beautifully; and, what is more wonderful, there is obſerved a very diſtinct and regular motion in the brain.

This probably is the ſame animal with the pediculus pulſatorius, deſcribed by Derham, as one of the death-watches. *Baker's Microſcope.*

Wood-*pucerons*, in natural hiſtory, a name given by Mr. Reaumur to a ſmall ſpecies of inſects of the puceron kind, of a greyiſh colour, and diſtinguiſhed by its two hollow horns on the hinder part of its body.

Theſe animals very much reſemble, both in ſhape and ſize, the pucerons of the alder; but, as thoſe live always on the ſurface of the ſtalk, theſe make their way deep into the wood of a tree.

WOOLLEN *Manufactory* (*Dict.*)—In order to ſet this uſeful mechanic invention in a true light, we ſhall add here the moſt uſual terms uſed therein, ranged in the ſame order as the various operations are performed.

The wool is waſhed; either in heaps, in ſtanding water; or in the coyriddle, in running water; or in tubs full of river water.

To prepare the bath or ſuds, is to let the wool ſoak in water, until it has thickened the water in the tub, by diſcharging its greaſineſs and ſalt in it. Thence it is, that inſects ſeek clean wool, and will not touch that which retains its natural moiſture.

Wool in the greaſe, is that which ſtill preſerves its natural greaſineſs. This is better for keeping, becauſe the moth will not get into it.

A waſhing of wool, is a heap of wool, taken out of the tub, and ſet to drain in the air.

To waſh the wool alive, is to waſh it on the ſheep's back before ſhearing.

The ſhears are ſciſſars made of one piece of ſteel, which forms the bow and two blades. The bow is a ſemicircle, from whence the two blades ſtretch forwards. Theſe are preſſed cloſe to each other, and cut the wool under the workman's fingers, and then fly back by the ſpring of the bow.

A tod of Wool is what is cut off the ſkin of the ſheep, beginning at the legs and ending at the head.

A fleece is the tod gathered up into a packet. Out of trade, a fleece ſometimes ſignifies a ſheep ſkin with the Wool on.

The puſhes are Wool finer than the reſt, which ſhoot out by little tufts in different places. They are plucked off the ſheep before ſhearing. In the province of Berry this laſt name is given to the wool taken off the thighs.

The breechings are thoſe which are ſo hard and clotted, that they are of the conſiſtence of felt. They are alſo called clottings, becauſe the beaſt, eſpecially when ſick, dirts and clots them by lying much on one ſide.

Pelled wool is that which comes off from ſcabby ſheep.

Sprazely or crudley wool is the young hungry wool which ſhoots out before the old is ſhorn.

Locks or breechings are long white hairs, as ſtiff as badger's hair.

All theſe ſorts of wool are bad or rejected. Yet it cannot be ſaid that they ought to be thrown away as uſeleſs. They are uſed in very coarſe works, ſuch as ordinary rugs.

Clipping is cutting off the coarſe ends of the wool, before it is waſhed. Thoſe ends are called locks.

The fleece wool is that which hath been ſhorn off the ſheep while alive.

The lambs wool is the wool cut off lambs.

The glovers wool is the wool, which the leather-dreſſer takes off the ſkin, after the ſheep is killed.

The fell wool is the wool ſtripped off ſheep, which died of ſome diſtemper. The uſe of this ſort is prohibited.

In ſorting Segovia wool, it is diſtinguiſhed into firſt, ſecond, and third. The ſame order is obſerved in ſorting Spaniſh wool.

As to other ſorts of wool, the only diſtinction that is made, is into the high wool, which is the longeſt, and is generally reſerved for combing; and the low wool, which is uſually carded. However the long wool, when it is to make cloth, is alſo carded, becauſe it does better ſo than when combed.

Fine wool unſcoured, is only fit for the market, and not for working. In order to work it, in ſome caſes they begin by waſhing and combing it; in others by getting out the greaſe by boiling, in order to waſh and comb it afterwards: and there are other caſes ſtill, in which it is firſt dyed, then carried to the river, and thence to the comber.

The ſcouring boiler, or copper, has a croſs bar in it, to ſupport the wool taken out of the water. There are alſo poles to ſtir the wool, peſtles to pound or beat it, hooks to draw it out, baſkets to hold and carry it to the river, where the cleaning of it is finiſhed.

Common wool, which has been waſhed on the ſheep's back, ought, before working, to be carefully examined, picked off the locks or clipped, and cleaned of all refuſe.

In ſome manufactories wool is wrought white, in others it is dyed before working.

For dying wool the ſame utenſils are requiſite as for ſcouring.

The

The ingredients are the preparatory and colouring materials.

Setting the copper is to put the neceffary ingredients into it.

Handling the wool is to open it, by ftirring it with the poles, in order to make every part of it take the colour equally.

Increafing the boiling is to enlarge the fire.

Cooling the wool is to fpread it out in the air.

If the wool has been only grounded or galled; that is, if it has only had its firft dip, or the firft tincture of Galls, copperas, or other ingredients, whether preparatory or colouring; then it muft be brought in from the airing to the copper, to be there revived by a fecond dip, which brightens the dye, or to be lowered by a new mixture, which either diminifhes its luftre, or gives it another teint; or in fine to give it a deeper caft of the fame colour.

To beat the wool, whether dyed or white, is to fpread it on a hurdle, and to open its texture by whipping it with fwitches, in order to make it fit for combing, or carding, and fpinning.

For combing wool they ufe

A little furnace, which ferves to warm the combs.

A vice and hook to fix the combs.

A pair of combs, which are two little boards, almoft fquare, ftuck with teeth of iron wire, fome a little longer than others. Each comb has its handle.

A hammer, to put in and take out thefe teeth.

A brafs hollow tube, to mend them when out of order.

A file, to point them when blunt.

A windlafs, to twift the wood foaked in foaped water, before it be put on the comb.

A tub, in which the foap is diffolved.

To comb in water, is to comb the wool that has been fprinkled with oil, in order to wafh it afterwards.

A certain quantity of wool is given by weight to the workman.

A beating, is a parcel of wool beaten on the hurdle.

A fliver is a proper quantity of wool put into the teeth of the comb.

To difcharge it, is to take out the fliver, after having moved the right comb backwards and forwards on the left, and the left on the right.

The carding is the quantity of wool that fticks to each comb, and is fufficiently combed after a certain number of movements of one comb on the other. There are always two cardings, as well as two combs.

A diftaff is two cardings joined together, which make up a fufficient quantity for the diftaff.

The fhort wool, which cannot be wrought together by combing, is not loft. It goes to the card.

To brimftone the wool, is to fufpend the feveral fkeins over the brimftone room.

The brimftone ftove is a little ftove well clofed and cemented at top, to whiten the wool by the fumes of brimftone burning in a pan.

When dyed wool is combed, they begin by mixing it according to the tafte and fkill of the mafter-worker.

The different colours are effaced by the judgment in mixing them, whereby there refults a new colour.

The comber follows a certain rule in the quantity of each colour he takes for each combing: on which depends the uniformity of the colour required.

Carded wool is broke in a different manner from combed wool. It paffes through two tools called cards, which are two little quadrangular pieces of board, three or four times as broad as tall, with a handle to each, and thick fet with fmall crooked wires. The cards are changed, beginning by the wideft, and ending with the clofeft, in order to break the wool, and mix the colours the better.

Spinning is of two forts.

Twifted thread is fpun by the fpindle or little reel, from combed wool, and ferves for the chain or warp, which is the ground of little ftuffs. The name of chain, or warp, is alfo given to the threads running lengthwife in a piece of cloth, and which make the ground of it.

The flack fpun is made by the great wheel from carded wool, and is called the wool or fhute. The wool croffes the threads of the warp, and may be called fhute with regard to a ftuff that has a pile.

The thread of the work in cloths is generally called back thrown, becaufe, being made from carded wool, as well as the woof, it is likewife fpun by the great wheel, but with the circumftance of croffing the wheel-ftring: which has a double good effect, viz. to make a thread fomewhat better twifted and ftronger, and to give it a different twift from that of the woof; whereby they thicken better in the fulling mill.

Stuffs may be divided into three forts, tammy, ferge, and cloth.

Tammy or ftuffs of two tammies, are made of thread of warp upon thread of warp, that is, the warp is of twifted thread, and the woof of the fame, both made from combed wool.

Serge is made of flack fpun, or carded wool, on a warp of tammy, or combed wool.

Cloth is made of two foft threads, that is, both the warp and woof are of thread fpun from carded wool, and very little twifted, in order to make a more fubftantial and woolly ftuff.

Thefe three fundamental forts are fubdivided into a vaft number of others, according to certain qualities added to them, and different ways of working.

To weave, is to work at the loom, or to make ftuff.

One weaver is fufficient for making tammy and ferge; becaufe as thefe little ftuffs are not wide, the fame workman can throw his fhuttle with his right hand between the threads of the warp, and receive it with his left, in order to throw it the contrary way. But cloths and blankets, being very wide, are wrought by two weavers, one of whom throws the fhuttle, the other receives and throws it back; and they go on thus alternately with as much regularity, as if the work was done by the two hands of the fame man.

The loom is compofed of feveral parts, whereof the chief are the loom-pofts and crofs-bars.

The three rolls or rollers, viz. the little one, the cane-roll. The warp is at firft faftened at one end of the loom on the leaft of thefe rollers, and at the other end is rolled on the fecond cylinder, which is thicker, and is called the cane-roll: according as the warp is filled with woof, the ftuff is to be rolled under the loom on the knee-roll; and at the fame time the fame length of the thread of the warp is unrolled off the cane-roll, as that of the ftuff rolled on the knee-roll.

The batten is a large moveable frame fufpended on two pins at the top of the loom, to move freely backwards and forwards, under the workman's hand, who, after every throw of the fhuttle or thread of the woof, ftrikes in this thread more or lefs with the batten and reed.

The reed or comb is made of two rods, with a long row of teeth of reeds, or brafs wire. It is placed at the lower part of the batten. Every thread of the warp paffes fingly between two teeth of the reed: that fo the batten may move without breaking the threads, and ftrike in the woof equally, without leaving any part of it irregular.

The lams are behind the reed. Each lam is compofed of two virgees or laths, whofe length fhould be the width of the ftuff, and of little ftrings ftretched from one virgee to the other, which are called leifhes. In the middle of each leifh there is a loop or little ring of thread, horn, or glafs, to receive one of the threads of the warp. Thofe threads of the warp, which pafs through the loops of one lam, pafs between the leifhes or threads of the other lam; and thofe which pafs through the loops of the fecond lam, play freely between the threads of the firft; fo as to be able to defcend, while the firft afcends: and thus thefe two lams being near their ends faftened to a common cord paffed round a pulley at top, and at bottom to another cord which fupports a treadle, lying under the workman's feet; if he lowers the fore lam with his left foot, the other lam muft rife up. The reverfe happens upon a contrary motion. If there are a greater number of lams to vary or figure the ftuff, certain parcels of threads are thus raifed and lowered at a time, whereby divers openings are made to receive the throw of the fhuttle. As often as the foot is changed, and the warp receives a new throw of the woof, the batten clofes it more or lefs according to the quality of the ftuff. When the increafe of the ftuff hinders the play of the batten, there is as much of the warp rolled off the cane-roll, as of the ftuff rolled on the lower great cylinder. Concerning the manner of guiding the threads of the warp through the rings of the jack on the warping mill; of managing the feparation of the threads of the portee; of uniting feveral portees in one chain; and of making one entire warp of them all; of brufhing or moiftening it with fize, to make the threads glide eafier in working; of mounting it on the loom, by faftening it in a grove of the little roller; of paffing the threads in good order through the teeth of the reed, and then dividing the fame threads, and making fome of them go through the loops of one lam, and between the leifhes of the next; and others between the leifhes of the firft, and through the loops of the fecond; of fixing and maintaining the divifions of the threads, by the infertions of feveral rods which prevent their mixing; of facilitating, in fine, the unwinding and play of the warp and woof by the ufual precautions and proper tools. Thefe operations are eafily comprehended at firft fight. But their number is fo great, that if the workmen did not ufe great difpatch, by every one conftantly plying to his own part; fheep's wool either would never be converted into cloathing, or would bear too high a price for the common people. Let us not remain unacquainted with what fhews the greateft induftry, after the play of the lams.

The fhuttle is a piece of hard wood, that runs tapering to a point at both ends, and has a cavity in the middle, called the box or chamber, for receiving the quills.

The quill is a fmall pipe of reed, on which a proper quantity of the thread of the woof has been wound, and which plays on the fhuttle pin.

The fhuttle pin is an iron wire, which runs through the quill, and with it is fet in the chamber of the fhuttle. It is put in, fecured, and taken out, by the different action of a fpring at the end of the chamber, where the fhuttle pin is placed.

As the fhuttle runs through the warp, the thread of the woof, which flips through a hole or eye in the fide of the fhuttle, and has been faftened to the lizier, muft run off the quill, which runs round as the ſhuttle goes on. When this quill is emptied, another is put in its place; and the ends of the thread of the two quills are laid cloſe to one another without knotting; only taking care to manage the throw of the ſhuttle, ſo as to be ſure of keeping both theſe ends of the woof together.

The head of the piece are ſome few inches of the ſtuff, made with a different ſort of woof from the reſt. The names of the workmen and place are wrought in it: and afterwards the lead-ſeals are put to it, which are a teſtimony of its being examined and found to be of good materials, and of the breadth and quality required by the laws for the reſpective ſorts.

The temple is compoſed of two flat notched rulers, ſecured one over another by a ſliding ring, and having pins points at their ends. The workman faſtens the two ends, full of points or ſpikes, to the two liziers, or liſts, which are the outer threads of the width of the ſtuff; and, by bringing the virgers or laths more or leſs forward, he keeps the ſtuff conſtantly of an equal breadth. If he did not take care to temple his ſtuff, the woof would ſhrink unequally, and bring the threads of the warp nearer together in ſome places, and in others farther aſunder. But by removing his temple from time to time, to keep it near the laſt throws of the woof, he ſtrikes the woof in upon a ſquare, and ſo as to make it receive the ſtroke of the batten equally in every part.

The workman continues to throw the ſhuttle, to temple, and to wind off alternately. When he is come to the end of the piece, he takes another ſort of thread for the woof, as he had done at beginning it, and makes a ſtripe of a different colour, for the names and ſeals, as above. Theſe two ends are called the head and the fag-end.

To ſteam a little ſtuff, as is done at Amiens, Rheims, and La Mans, is to render it ſopple, by expoſing it to the ſteam of boiling water in a ſquare kettle or copper, where it is laid, ſtill on its roller, with other pieces. This operation diſpoſes it for dreſſing well.

The fullery is a water-mill for working great mallets on ſtuffs, either to clean them, or thicken them to the conſiſtence of felt.

The ſtocks, or fuller's pots, are hollow veſſels to hold the ſtuffs, which are continually turned under the ſtrokes of the mallets.

The levers, or prominent bars, are the ends of pieces of timber, that run through the axle-tree or arbor of the wheel, and which, as they paſs, catch the heads of the mallets, raiſe them up, and let them fall as they go off.

To earth the ſtuff, is to rub it with fuller's earth.

To beat it in the earth, is to full the ſtuff with the earth on it, letting a water-cock run on it at the ſame time.

To ſcour cloth, is to full it after ſoaping it with black ſoap, which carries off all ſpots.

To clean-ſtuff, is to full it with a great deal of water, to carry off any remains of dirt, and to rince it.

To beat it dry, is to full it without water, till it has acquired the utmoſt thickneſs it is capable of, and beyond which it runs into a pap.

When ſtuffs come from the fulling mill, they are aired, that is, hung out.

The pieces, brought from off the poles or tenters, ought to be made up, that is, properly folded on a table; then gummed at every fold, by ſprinkling the backſide with a ſolution of gum arabic in water.

To ſtretch the ſtuff, is to paſs it from one roller on another, keeping it conſtantly of the ſame breadth, over a braſier, by means of an iron bar, on which it ſlides; whereby the heat penetrates, and breaks its ſtiffneſs. And, by thus paſſing ſeveral times from one roller on another, it is rendered pliant in every part alike.

There are ſome ſtuffs that are unrolled and rolled without fire. But it is always allowed to ſuch as are to be dreſſed very well.

The effects of this ſtretching are, firſt, to ſmooth or take out the bad folds; ſecondly, to gum the whole piece equally by the fire's ſpreading the moiſture every-where, which evaporates, and leaves the gum behind. Thirdly, to ſtretch the whole in an uniform manner: which is of vaſt conſequence in the wear of ſtuffs.

They are folded near a good fire.

They are leafed, by putting a leaf of paſteboard hot, between every two folds.

They are put between two thick boards of box, which take in the whole pile of folds.

They are left ten or twelve hours in a ſtrong preſs: and this is repeated three or four times.

They are viſited for the laſt time, and after drawing out the two ends, called the head and fag-end, the lead-ſeals, tickets, and other marks are put on which denote the quality, breadth, length, dye, and other things preſcribed by the laws: then they are put into the preſs again, and ſtitched, by ſecuring the folds looſely with threads run through the liziers.

There are ſome other practices peculiar to different manufactories; but they all tend to the ſame end.

Cloth is not ſtretched on the rollers; but, after having been fulled, teazled, tentered, or hung on the rack, ſhorn twice, cottoned, and the pile laid ſmooth one way, it is gummed or folded on leaves, put to the preſs, the leaves are changed, and, inſtead of thick coarſe paſteboards, others thinner and ſmoother, called cards, are put between the folds: it returns to the preſs, or elſe to the calender, which gives it its laſt gloſs. *Spectacle de la Nature, Tome VI.*

WORD (*Dict.*)—Simple and primitive Words have no natural connection with the things they ſignify; whence there is no rationale to be given of them: it is by a mere arbitrary inſtitution and agreement of men, that they come to ſignify any thing. Certain words have no natural propriety or aptitude, to expreſs certain thoughts, more than others; were that the caſe, there could have been but one language.

But, in derivative and compound Words, the caſe is ſomewhat different.—In the forming of theſe, we ſee, a regard is had to agreement, relation, and analogy: thus, moſt Words that have the ſame ending, have one common and general way of denoting or ſignifying things; and thoſe compounded with the ſame propoſitions, have a ſimilar manner of expreſſing and ſignifying ſimilar ideas in all the learned languages where they occur.

For the perfection of language, it is not enough, Mr. Locke obſerves, that ſounds can be made ſigns of ideas; unleſs theſe can be made uſe of, ſo as to comprehend ſeveral particular things; for the multiplication of Words would have perplexed their uſe, had every particular thing needed a diſtinct name to be ſignified by.

To remedy this inconvenience, language had a farther improvement in the uſe of general terms, whereby one Word was made to mark a multitude of particular exiſtences; which advantageous uſe of ſounds was obtained only by the difference of the ideas they were made ſigns of: thoſe names becoming general, which are made to ſtand for general ideas; and thoſe remaining particular, where the ideas they are uſed for are particular.

It is obſervable, that the Words which ſtand for actions, and notions quite removed from ſenſe, are borrowed from ſenſible ideas; as, to imagine, apprehend, comprehend, underſtand, adhere, conceive, inſtil, diſguſt, diſturbance, tranquillity, &c. which are all taken from the operations of things ſenſible, and applied to modes of thinking.—Spirit, in its primary ſignification, is no more than breath; angel, a meſſenger. By which we may gueſs what kind of notions they were, and whence derived, which filled the minds of the firſt beginners of languages; and how nature, even in the naming of things, unawares, ſuggeſted to men the originals of all their knowledge: whilſt, to give names that might make known to others any operations they felt in themſelves, or any other ideas that came not under their ſenſes, they were forced to borrow Words from the ordinary and known ideas of ſenſation.

The ends of language, in our diſcourſe with others, are chiefly three: firſt, to make our thoughts or ideas known one to another.—This we fail in, 1°. When we uſe names without clear and diſtinct ideas in our mind. 2°. When we apply received names and ideas, to which the common uſe of that language doth not apply them. 3°. When we apply them unſteadily, making them ſtand now for one, and anon for another idea.

Secondly, to make known our thoughts with as much eaſe and quickneſs as poſſible.—This men fail in, when they have complex ideas, without having diſtinct names for them; which may happen either through the defect of a language, which has none; or the fault of the man, who has not yet learned them.

Thirdly, to convey the knowledge of things.—This cannot be done, but when our ideas agree to the reality of things.—He that has names without ideas, wants meaning in his Words, and ſpeaks only empty ſounds.—He that has complex ideas without names for them, wants diſpatch in his expreſſion.—He that uſes his Words looſely and unſteadily, will either not be minded, or not underſtood.—He that applies names to his ideas, different from the common uſe, wants propriety in his language, and ſpeaks gibberiſh; and he that has ideas of ſubſtances, diſagreeing with the real exiſtence of things, ſo far wants the materials of true knowledge.

Watch-WORD, in an army, or garriſon, is ſome peculiar Word, or ſentence, by which the ſoldiers know and diſtinguiſh one another in the night, &c. and by which ſpies and deſigning perſons are diſcovered.

It is uſed alſo to prevent ſurprizes.—The Word is given out in an army every night by the general, to the lieutenant, or major-general of the day, who gives it to the majors of the brigades, and they to the adjutants; who give it firſt to the field-officers, and afterwards to a ſerjeant of each company, who carry it to the ſubalterns.

In garriſons it is given, after the gate is ſhut, to the town-major, who gives it to the adjutants, and they to the ſerjeants.

WORK-HOUSE, a place where indigent, vagrant, and idle people are ſet to Work, and maintained with cloathing, diet, &c.

Meal WORM. There are two very different inſects found in our meal or flour; the one is ſo ſmall, that it is only to be ſeen by the microſcope: all that the naked eye can diſcover of it is, that ſomething is alive in the place, from the whole ſubſtance of the flour being in motion.

The

The other meal-Worm is larger, and more frequently offers itself to our observation; it consists of eleven rings, and has three pair of legs. The mouth of this Worm is made into a kind of forceps, and from this arise, on each side, a great number of small spinulæ; these serve instead of teeth, and the animal feeds by means of them. They are found sometimes very soft and tender, sometimes hard and firm, and at other seasons they are very brisk and lively; at others they have scarce any life in them.

The most remarkable thing, in regard to these worms, is, that they are always exactly of the colour of the flour which they live among. Ray has observed, that the white flour breeds white ones; the coarser flour breeds larger and greyer ones; and that flour which has the bran among it breeds brown ones, of the same colour with itself. This is a provision of nature for the safety of the animal, since, were it of a colour different from that of the flour, it must be easily discovered among it, and would be picked out and thrown away. The caterpillar tribe are thus preserved, by being of the colour of the leaves they feed on; their green usually suiting itself exactly to that of the tree or plant. *Deslandes, Trait Phys.*

Worms, in husbandry.—These creatures are very prejudicial to corn-fields, eating up the roots of the young corn, and thereby destroying great quantities of it.

Sea-salt is the best of all things for destroying them.—A decoction of wood-ashes, or walnut leaves, will answer the same purpose; and any particular plant may be secured, both from worms and snails, by strewing a mixture of lime and ashes about its roots. It is a general caution among the farmers to sow their corn as shallow as they can, where the field is very subject to Worms. *Mortimer's Husbandry.*

Worms, in medicine (*Dict.*)—Tin is often recommended as a good remedy against Worms, particularly of the flat kind. Dr. Alston, in the Med. Ess. Edinb. Vol. V. Art. 7, directs an ounce and an half of the powder of pewter-metal to be mixed in half a Scotch mutchin, or about half a pint English measure of treacle, for children; but, to grown persons, he gives two ounces of the powder of pure tin, put through the finest hair-sieve, and mixed with eight ounces of treacle. As to the administration of this medicine, the original receipt directs half of it to be taken the Friday before the change of the moon; the day after, half of the remainder, and the rest on Sunday. On the Monday a purge is to be taken. The doctor thinks there is probably nothing in the particularities of the day: but says, the medicine succeeds well in several species of Worms. The Memoirs of the French Academy give a very remarkable account of an obstinate pain caused by a Worm in the nose, a place where few persons would have suspected such an animal for the cause of it.

WRECK, in metallurgy, a vessel in which the third washing is given to the ore of metals.

In Cornwall, when the tin-ore has been twice washed, they take the head tin, or that part of the tin ore that lies uppermost out of the bubble, and, throwing it into this vessel, they pour water on it, and work it about with wooden rakes, till it is cleared from whatever other extraneous matter there may still have remained mixed with it, and is, after this, fit for the melting-house, to be run into metal. *Ray's English Words.*

WRITING. To make new writing appear old, moisten it with oil of tartar per deliquium, more or less diluted with water, as you desire the ink to appear more or less decayed. *Boyle's Works.*

We may write without ink or its materials: for this purpose, take a fine powder of calcined harts-horn, of clean tobacco-pipes, or rather of mutton bones burnt to a perfect whiteness, and rub it upon the paper, and then write with a silver bodkin or the like.

The discharging of ink out of parchment, paper &c. is commonly done by aqua fortis diluted sufficiently with water, that it may not destroy the paper. The like may be done with oil, or spirit of vitriol diluted. The juice of lemons, or strong vinegar, will take ink out of linen more safely, as the mineral acids are apt to destroy the linen, unless great care be used in diluting them.

We may write on iron with corrosive sublimate wetted with common water: for this purpose, the parts of metal we would preserve untouched should be covered with wax, and that taken off in the proper places to make way for the corroding substance.

The like may be practised by means of aqua fortis.

Mr. Boyle mentions a method he had of copying a whole page of writing at once. But we do not find his description of it any where.

The same author informs us of a method of imitating writing, on copper-plates. The copy to be engraved is to be wrote with a peculiar kind of ink, and the copper-plate, being moderately warmed, is rubbed over with a white varnish, and suffered to cool; then the paper being gently moistened, that it may readily communicate its ink, the writing is applied to the prepared surface of the plate, and passed through a rolling-press; by which means the ink, adhering to the varnish, leaves the letters very conspicuous. And hence it is easy with a needle to trace the strokes through the varnish upon the plate, which being afterwards cleaned, the letters are finished with the graver, and the work printed off in a rolling-press as common cuts.

Mr. Boyle does not mention what the varnish nor ink, used by the artificer from whom he received this method, was; but he tells us that he himself used the purer sort of virgin's wax, for a varnish; and for his ink he took fine Franckfort black carefully ground, with water, till it obtained the consistence of common ink; but no gum was added, lest it should hinder the ink from coming off. He also observes, that written characters may be taken off without the help of a press, by laying the moistened paper smooth upon the varnished copper, and rubbing it on hard with a convex piece of glass. *Boyle's Works.*

WYCH-*house.*—In the places where there are salt-springs, and salt-works are carried on at them, the work-house where the salt is made, is always called the Wych-house; and hence we may naturally conclude, that Wych was an old British word for salt; which is the more probable, in that all the towns in which salt is made end in Wych; as Namptwych, Droitwych, Middlewych, &c. *Ray's English Words.*

X.

XANTHIUM, in botany, the name of a genus of plants, the characters of which are these: the flower is of the flosculous kind, being composed of a number of floscules, each having one stamen. The seeds are produced on other parts of the plant, and finally become oblong and usually prickly fruits, divided into two cells, and containing each several oblong seeds.

XERANTHEMUM, in botany, the name of a genus of plants, the characters of which are these: the flower is radiated; its disk is composed of floscules standing upon the embryo seeds; but the outer circle is composed of plane flat petals, which are not affixed to embryo's, but are contained in the same cup with the floscules which make up the disk. The embryo's finally ripen into seeds, which are furnished with a foliaceous head.

We have several species of this plant cultivated in our gardens, and known in English by the name of everlasting flowers; a name common to all the species of this plant, and of the amaranthoides.

These flowers are of so dry and durable a structure, that, if gathered just when they are ripe, they will last many years in perfection, and appear as fresh as while growing; they are also capable of several tinges, and hence are often seen of fine blues and greens, colours not natural to them.

They are all propagated by sowing their seeds in August, in a warm border, observing to water and shade them till they are come up, if the weather proves over dry.

When the young plants are two inches high, they should be removed to another warm border under the shelter of a wall, and there planted at five inches distance from each other. They will here stand the winter very well, and in spring will be ready to grow up for flowering without any farther transplanting; they are only to be kept clear of weeds, and in June they will flower; the flowers should be gathered in July for drying, and some of the finest should be suffered to stand for seed; for the plants perish as soon as they have perfected their seeds, and must be renewed by sowing every year. *Miller's Gard. Dict.*

XIPHION, in botany, the name of a genus of plants, the characters of which are these: the flower is liliaceous, consisting only of one petal, and much resembling the iris flower. The pistil is in the manner of the iris also, ornamented with three petals, and the cup becomes a fruit of the shape of that of the iris; but the root wholly differs from that of the iris, being bulbous, and composed of a number of coats.

We have several species of this beautiful plant cultivated in our gardens, where they are called bulbous iris's; and, besides these, a vast number of varieties or new flowers, as the florists

rists call them, are frequently raised by those who propagate them from seeds. The culture of these being the same with that of several other plants of the same sorts, which are much valued for their flowers, it may not be amiss to give it at large.

There should be great care taken to save the seeds of the finest and strongest flowers, and in September some shallow pans or boxes must be placed with holes at their bottom to let out the moisture, and then filled with light and fine earth. On this the seeds must be sown pretty thick, and as evenly as may be; half an inch of the same earth must be sifted on these, and the boxes must then be set where they may have the morning sun; and, if the weather proves very dry, they must be gently watered at times. They must remain in this situation till October, and then must be removed to a place where they may have the benefit of the sun as great a part of the day as may be; here they must stand the winter, keeping the boxes very carefully clear from weeds.

In the spring the young plants will appear, and they should then be removed to their first situation, where they may have only the morning sun; and, if the weather be dry, they must be watered at times. In June their leaves will decay, and they must then have half an inch of fresh earth sifted over them, and be left in their situation till October, when they must be removed to the same place as before for the winter.

In the spring the leaves will appear again, and, when they are again perished, the earth must be taken out of the boxes, and sifted to separate the roots, which must then be planted at three inches distance on a bed of the same light earth; they must be buried three inches deep, and in the spring following must have about half an inch of fresh earth sifted over them; the leaves will this year appear and decay as before; and, the following year in June, they will most of them flower; when the finest flowers should be marked, that their roots may be taken particular care of. The following year the remainder, which did not flower at first, will produce their flowers; such of these as are finer than the rest, should be marked in the same manner, and the roots of these choice kinds be preserved with particular care. Whatever fine or new flower is thus raised from seed, may be afterwards propagated by off-sets from the roots, which, being planted out, will flower the second year, and often produce even finer flowers than the mother-root.

The roots of these flowers should be taken out of the earth only every other year; this should be done just when the leaves are decayed, and they should not be kept out of the earth above a fortnight.

The earth in which these flowers thrive best, is a light sandy loam; and, if it be taken up with the turf and the grass rotted among it before it is used, it will be so much the better. They do not delight in a rich dunged soil, nor should they be placed where they are too much exposed to the sun; for, besides that the flowers soon fade in these places, the roots are also always found to decay; but in an east border, where they may have the sun till eleven o'clock, and where the ground is not too moist nor over dry, they will stand a long time in flower, and thrive extremely well. *Miller's Gard. Dict.*

XY'LON, *the cotton-tree*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, and is of the bell-shape, very wide at the mouth, and divided into many segments. From its bottom there arises a pyramidal tube, usually loaded with stamina; and from the bottom of the cup there arises a pistil, which is fixed in the manner of a nail both to the hinder part of the flower, and to the tube. This ripens into a roundish fruit, divided into four or more cells, opening at the top, and containing numerous seeds wrapped up in a stringy white substance, which is called cotton.

The cotton is a woolly or downy substance, which incloses the seeds, and which is contained in a brown husk, or seed-vessel. It is from this plant that most of the cotton we use is produced, the difference of the several sorts of it being owing to the different soil and climates it has grown in, and the different culture it has received.

The cotton in the wool, as it is usually called, is what we have from Cyprus. Damascus cotton is called cotton in the yarn; and the Jerusalem cottons, which are called bazzes, are the finest kinds of all.

All the kinds of cotton plants are propagated with us from seeds, which must be sown on a hot-bed early in the spring; and, when the young plants are come up, they should be transplanted each into a separate pot of light earth, which is to be plunged into a moderate hot-bed of tanner's bark, observing to water and shade them till they have taken root; after this they should be watered at times, and have as much air as the season will permit. As they enlarge in size, they must be shifted into larger pots; but they must be kept in the stove, where the herbaceous kinds will annually flower in autumn; but they will seldom bring their pods to any perfection. *Miller's Gard. Dict.*

Y.

YEAST.—Common ale Yeast may be kept fresh and fit for use several months, by the following method: put a quantity of it into a close canvas bag, and gently squeeze out the moisture in a screw-press, till the remaining matter be as firm and stiff as clay. In this state it may be close packed up in a tight cask, for securing of it from the air; and will keep fresh, sound, and fit for use for a long time.

This is a secret that might be of great use to the brewers and distillers here; who, though they employ very large quantities of Yeast, seem to know no method of preserving it, or raising nurseries of it; for want of which they sustain a very considerable loss; whereas the brewers in Flanders make a very great advantage of supplying the malt-distillers of Holland with Yeast, which is rendered lasting and fit for carriage, by this easy expedient. *Shaw's Lectures.*

YE'LLOW (*Dict.*)—The Chinese are famous for their Yellows in dying, which never change with washing. They make this dye of the flowers of the acacia, in a manner in which we might use several of our own productions to great advantage. It is thus: they gather the flowers before they are perfectly ripe, and dry them in an earthen vessel over a gentle heat, till they crisp up in the manner of tea-leaves; they then add to them the ripe seeds of the same tree in different proportions; and then, boiling them in river-water with alum, they give the Yellow in any degree that they please.

They have three kinds of Yellow, which they distinguish by the names of Ngo-hoang, King-hoang, and hoang alone.

The first of these is the brightest Yellow; to dye five or six ells of silk of this colour, they use a pound of the flowers of the acacia, about two ounces of the seeds, and four ounces of alum.

The King-hoang is a somewhat deeper Yellow: to dye this, they use the same ingredients in the same proportion as in the former case; and, when the silk is dry from the dipping in this, they give it a second dipping in a slight tincture of Brazil-wood; this brings it to the fine strong Yellow we see.

The hoang, or pale Yellow, is made of the same ingredients as the first, only, instead of four ounces of alum, they put in but three ounces: river-water is found to be greatly preferable to any other, for the extracting these colours; but, even in that, there is great difference, some doing the business much better than others.

The Chinese are so expert in judging on this occasion, that they can tell by the taste of water, whether it will or will not do; and, if it taste faint, they know it is faulty; but they dip the pieces twice into it instead of once, and then the colour succeeds well.

The flowers of the acacia, when they have been prepared by roasting in this manner, may be kept all the year round, and employed in dying as occasion requires, only there is to be longer boiling for the dried flowers than the fresh ones; and it is always found that the fresh flowers give the brightest colour. *Observ. sur les Coutumes de l'Asie.*

YELLOW-*hammer*, in zoology, the name of a very common English bird, called by authors emberiza lutea; and by some hortulanus, by others luteus, and by others chloreus.

It is a little larger than the chaffinch, and is very beautifully variegated with a greenish or greyish brown, and a fine bright yellow.

There is besides this another kind, which is much smaller and of a browner colour on the back; this is called by some authors zivolo. *Ray's Ornithol.*

YEW, *taxus*, in botany, the English name of a genus of plants, and also a term used by the salt-workers of Limington and other parts of England, to express the first rising of a scum upon the brine in boiling.

YU'CCA, or MANIHOT, in botany, the name of the Indian corn.

We have three or four sp cies of this plant preserved in the gardens of the curious; a .d the common kind, when grown strong and hardy, will endure the cold of our climate in the open air, and produce its flowers with us. All the species may be propagated either from seeds sent from abroad, or from off-sets off-sets or heads taken from the old plants in the manner of the aloe. When they are to be raised from seeds, these are to be sown in a pot of light fresh earth, which being plunged into a moderate hot-bed, the young plants will appear in five or six weeks; and, when they are two or three inches high, they are to be removed, each into a separate pot, which is to be plunged again into the same hot-bed, where they are to be watered and shaded, and to have air given them, as the season and the heat of the bed will permit. In July they must be hardened by degrees to the open air, into which they must be removed soon after to harden them against winter. They must be placed in a defended situation, and remain abroad till October, when they are to be removed into the green-house, and placed among the hardier sorts of aloes. They are here to be treated exactly as those plants; and, when they are grown sufficiently strong, they may be removed into common borders, where they will remain through our winters, and flower very beautifully.

When they are to be raised from the off-sets, these must be laid in a dry place for a week or ten days, before they are planted, that the wound where they were taken off from the old plant, may heal; else, like the other succulent plants, they are apt to rot in the earth, and miscarry. *Miller's Gard. Dict.*

YUCCA-*bread*, or *Cassada-bread*, made in many parts of the West-Indies, and eaten there; and sometimes brought over as a curiosity to us. It is made of the root of this plant, known among the botanists by the name of manihot. This grows to five or six feet high; the stalk is woody and full of knots, and has a large pith in it; the leaves are digitated or divided into a number of segments, like so many fingers; the flowers are composed of one leaf, and are as large as our narcissus, and are succeeded by a fruit of the size of a hazel nut. The root is very large and thick, and of a dark colour without, but very white within. It grows wild, common enough in some places; but it is generally cultivated for use, setting it in large furrows. Its juice is poisonous, though the dry powder of the root is perfectly innocent and wholesome; but there is a kind of it which may be eaten raw, and which is now getting into use, instead of the other, which is a speedy poison, if eaten with its juice.

The manner of making the bread from these roots is this: they peel them, rasp them, and putting them into bags squeeze out the juice; then they dry the remaining matter over the fire, and, when it is sufficiently dried, either in the sun, or by artificial heat, are the Cassada-bread; which is very nourishing, and will keep without moulding, as well as biscuit.

The use of it is apt to contract the throat, if eaten dry, and sometimes brings on a danger of choaking; the best method is to moisten it in broth, or otherwise, before it is eaten, or else to have a bottle of water at hand to wash down every mouthful.

The juice, expressed in preparing this root for bread, will kill any animal that drinks it crude: but it may be boiled over the fire till a great part is evaporated, and the remainder, if it be far evaporated, will be sweet, and serve in the place of honey; if less evaporated, and set by to ferment, it will make a very good and wholesome vinegar. The juice of the roucou is said to be a counter-poison for the juice of Yucca. *Lemery, Dict. des Drog.*

The thicker cakes of Yucca-bread are called cassavi, or cassada, and are eaten by the poorer sort. The thinner are called sciam, and are eaten by the rich. *Grew's Musæum.*

Z.

ZA'FFER, or ZAFFRE, in chemistry, the name of a blue substance, of the hardness and form of a stone; and generally supposed to be a native fossil.

It is in reality, however, a preparation of cobalt; the calx of that mineral being mixed with powdered flints, and wetted with water to bring it into this form. *Hill's Hist. of Fossils.*

To prepare this for use in the glass trade, put it in gross pieces into earthen pans, and let it stand half a day in the furnace; then put it into an iron ladle to be heated red-hot in the furnace; take it out while thus hot, and sprinkle it with strong vinegar; and, when cold, grind it on a porphyry to an impalpable powder, then throw this into water in glazed earthen-pans, and, when it has been well stirred about, let it settle, and pour off the water; repeat this washing often, and the foulness of the Zaffer will be thus wholly separated. Dry the powder and keep it for use.

ZA'RNICH, in natural history, the name of a genus of fossils, the characters of which are these: they are inflammable substances, not composed of plates or flakes, but of a plain, simple, and uniform structure, not flexile, nor elastic, soluble in ore, and burning with a whitish flame, and noxious smell like garlic.

ZEBLI'CUM *marmor*, in natural history, a name given by several authors to a soft green marble variegated with black and white; and though the authors who have described it have not observed it, yet it no ways differs from the white ophites of the antients. *Hill's Hist. of Foss.*

ZIBELLI'NA, *or the mustela Zibellina*, in zoology, the name of the creature whose furr is the sable, so much valued among us.

It is an animal of the weasel-kind, of the size of a cat, and of a dusky yellow colour, with a mixture of deep brown; the anterior part of the head, and the ears, are of a brownish grey, and the hairs about its eyes, nose, and mouth, very long. *Ray's Syn. Quad.*

ZIBE'THICUM *Animal*, in zoology, the name of the creature commonly, but very improperly, called the civet-cat; for it does not at all belong to the cat kind; but wholly to that of the dog; the head and nose are plainly of the figure of the dog's; and the figure, number, and disposition of the teeth, are plainly the same as in the wolf, fox, and dog.

Its colour varies very much; its more usual one, however, is that of a pale grey, variegated with long black streaks, though in the females it is often yellowish, and sometimes whitish, and the spots black and round, like those of the leopard, or cat of mountain.

The whole shape of the creature approaches to that of the wolf or dog; its snout is long and small; its ears are small and roundish; its hairs are like those of the badger, but very soft. Its body is thick and fleshy, and something resembles the shape of a hog's; its feet are small, and its legs very short. The bags which contain the civet are placed between the anus and pudenda, and are found equally in the males and females; but in the male they are twice as large as the female; they have a large cavity in their internal part, and their orifice is small and cartilaginous. The perfumed liquor which is found in these bags, seems to be secreted from a number of glands, which lie between the two skins of which they are composed. It is remarkable, that in this creature, as in the badger, its nose and belly are black, whereas in almost all other animals these parts are either whitish, or much paler than the rest. These creatures copulate backwards.

ZI'MENT-*water*, or *copper-water*, in natural history, the name by which some have called water found in places where there are copper-mines, and lightly impregnated with particles of that metal.

The most famous spring of this kind is about a mile distant from Newsol, in Hungary, in the great copper-mine called by the Germans herrn grundt.

It is not easy to say at what time these waters were discovered, since there is no authentic account of it. Kircher, Brown, Toll, and others, mention them as well known in their times; but it is probable that they were not discovered in the days of Agricola, since he no where makes the least mention of them; and it is not probable that so great a curiosity, and that so immediately in his own way, would have escaped him, if known at that time, especially as he has commemorated the like virtue in the Schmolnich waters, much less famous for it, and of much less power than those of Newsol. The water in this mine is found at different depths, and is received into basons, for the purpose of separating the copper from it: in some of these it is much more highly sated with this metal than in others, and will make the supposed change of iron into that metal much sooner. The most common pieces of iron, used in the experiments, are horse-shoes, nails, and the like; and they are found not very much altered in shape, after the operation, except that their surfaces are more raised. *Phil. Trans.* N°. 479.

ZI'ZYPHUS, *the jujube-tree*, in botany, the name of a genus of trees, the characters of which are these: the flower is of the rosaceous kind, being composed of several petals arranged in a circular form; the pistil arises from the cup, and finally becomes a fruit of the shape of an olive, and of a fleshy substance, including a stone divided into two cells, each of which contains an oblong seed.

The species of jujube, enumerated by Mr. Tournefort, are these: the cultivated jujube, with large oblong fruit. And, secondly, the wild jujube. *Tourn. Inst.* See the article JUJUBE *in the Dict.*

ZODI'ACAL *Light*, a brightness resembling that of the milky-way, and which is sometimes perceived in the heavens, at certain times of the year, after sun-set, or before its rise. The form of this light resembles that of a pyramid, lying lengthways

lengthways in the zodiac, within which its point and axis are always inclosed, its base being placed obliquely with respect to the horizon. This phænomenon was first discovered, described, and named by Mr. Cassini the elder.

The Zodiacal light is nothing but the solar atmosphere, a rare and subtile fluid, either luminous by itself, or made so by the rays of the sun surrounding its globe; but in a greater quantity, and more extensively about its equator, than any other.

The Zodiacal light is more or less visible according to circumstances: but the solar atmosphere is not always visible by means of this light, though it be always seen about the globe of the sun in total eclipses.

One of the most essential circumstances for the perception of the solar atmosphere by the Zodiacal light, is its having a sufficient length on the zodiac; for, without this, its brightness is entirely hid from us by the twilights.

Mr. de Mairan says, it may be proved from many observations, that the sun's atmosphere sometimes reaches as far as the earth's orbit, and, there meeting with our atmosphere, produces the appearance of aurora borealis. See the article AURORA BOREALIS.

The length of Zodiacal light varies sometimes in reality, and sometimes in appearance only, from various causes.

The oblique position of this light, little different from that of the plane of the ecliptic, does not permit us to see it distinctly, and sufficiently elevated above the horizon; but some time after sun-set, towards the end of winter, and in spring, or before sun-rising in autumn, and towards the beginning of winter. Several causes hinder our seeing it, any more than the milky-way; such as moon-light, and strong twilights, among others.

Mr. Cassini often mentions the great resemblance of the Zodical light to the tails of comets. Mr. Fatio has made the same observation; and Mr. Euler has lately endeavoured to prove them owing to similar causes.

Mr. Euler observes, that, if the sun has an atmosphere, the force of the impulse of light, issuing from that globe, must drive particles of that atmosphere before it; but, as gravity is very strong at the sun, this impulse would never drive those particles beyond the limits of their atmosphere, were it not for the centrifugal force arising from the sun's motion round its axis. This being opposite to the action of gravity, and diminishing its effects, the impulse of the light may considerably dilate the figure of the solar atmosphere, from what it would be if it arose from the gravity and centrifugal force of its particles only; and this dilatation will be very considerable near the sun's equator, and very small towards its poles. The action of light thus diminishing the action of gravity, Mr. Euler attempts to calculate how far this diminution of gravity may increase the extent of the sun's atmosphere about its equator. He finds a cubic equation, the roots of which express the semi-axis, or greatest amplitude of this atmosphere. He adds, that, this equation having three real roots, it is possible that the solar atmosphere may become a ring surrounding the sun's globe, as the ring of Saturn surrounds the body of that planet.

ZOO'LOGY, (*Dict.*) — This makes one of the three kingdoms, as they are called, of natural history; the vegetable and the mineral being the two others: in these, however, there is this difference made by writers, that, while vegetables and minerals are treated of together, as all of a piece in each, the subjects of Zoology are divided, and it is made to compose, as it were, several kingdoms. Whoever is to write on plants and minerals, calls his work a treatise of botany, or minerology; and we have no words to express any subdivision of them into kingdoms; but, in Zoology, we treat, as different subjects, the different parts of it; and the history of birds is separated by some from the rest under the name of ornithology; that of quadrupeds under the name of tetrapodology; and we have, for the rest, the words entomology, amphibiology, and the like, expressing these things which are properly but the parts of Zoology, and so many distinct and separate studies.

This may easily be amended, by our considering the animal world as we do the vegetable and mineral, and dividing it, as we do the others, into its proper families; it will then be found that these are no better distinctions than those of the families of these things, and that the authors may as well set up separate studies under the names of bulbology, umbelliferology, and the like, as those.

A natural division of the subjects of Zoology, on this principle, will afford six several families of its subjects. 1. The hairy quadrupeds. 2. The birds. 3. The amphibious animals, such as serpents, lizards, frogs, and tortoises. 4. Fishes. 5. The insects. And, sixthly, those lowest order of animated beings the zoophytes. *Artedi Ichthyol.*

ZU'RNAPA, in zoology, the Arabian name of an animal of a very singular kind, and seeming properly to belong to no known genus of animals, but to be perfectly sui generis. It is also called camelopardalis by Latin authors, and geraffa by eastern nations.

ZYGÆ'NA, in zoology, the name of a fish of the shark kind, called in English the balance fish, or the hammer-headed shark.

ZYMO'LOGY, in chemistry, a term used by some writers, to express a treatise on fermentation, or the doctrine of fermentation in general.
