CHEMICAL LECTURES,

Publickly Read at LONDON,

In the Years 1731, and 1732;

And at SCARBOROUGH, in 1733;

For the IMPROVEMENT of

ARTS, TRADES,

AND

NATURAL PHILOSOPHY.

By *PETER SHAW*, M.D. F.R.S.
Fellow of the Royal College of Physicians in *London*,
And one of His MAJESTY's Physicians in Ordinary.

The SECOND EDITION, Corrected.

LONDON:

Printed for T. and T. LONGMAN, in *Pater Noster Row*; J. SHUCKBURGH, in *Fleet-Street*; and A. MILLAR, in the *Strand*.

MDCCLV.

TO THE

Right Honourable the

Lord Viſcount *Lonſdale*,

Lord PRIVY-SEAL, &c.

MY LORD,

AS your Lordſhip was pleaſed to honour theſe Lectures with your Notice in Manuſcript, I take the Liberty of laying them before you in Print; being deſirous the Publick ſhould know, that their Deſign was approved of by ſo unexceptionable a Judge.

For, besides your uncommon Skill in Civil Policy, the Laws, and all the Branches of Publick Business; you have, like the Illustrious Lord *Bacon*, a Talent for the Improvement of Arts, and a Pleasure, and Sagacity, in pursuing natural Enquiries.

Were I not, therefore, sensible, my Lord, that your Candour is as extensive as your Learning, I should be cautious of thus submitting these slender Enquiries to your View; as they are neither conducted in a Manner suitable to your correct and exquisite Taste; nor pursued to such a Length, as your great Knowledge in Philosophical Matters may justly require.

But this gives me farther Encouragement, that I do not know a more useful Subject, than the present, to a Trading Nation; nor a Person better qualified than your Lordship, to perceive its Tendency, and direct its Improvement.

I am

MY LORD,

YOUR LORDSHIP'S

Most obliged, and devoted humble Servant,

PETER SHAW.

Scarborough,
July 15. 1733.

ADVERTISEMENT.

THE following Lectures had the Honour to be read before a noble Audience, who candidly overlooked their Failings, and requested their Publication.

As the Design is of large Extent, little more than a Sample of the whole could at present be given; the farther Improvement of it being left to others.

The Experiments here employed, tho' many of them new, are generally simple; or performable with little Cost, and Apparatus: But if a few particular Instruments, and Trials, hereafter intimated, were to be made, and properly used, much greater Discoveries might be reasonably expected.

A GLOSSARY: OR Explanation of the TECHNICAL TERMS in this Work.

ACid. By *Acids* are meant all those Things that taste sour; as Vinegar, Tartar, Juice of Crabs, Lemons, *&c.* Spirit of Nitre, Spirit of Salt, *&c.* and which, when mixed with a due Proportion of an *Alkali*, constitute a neutral Body, wherein neither *Acid* nor *Alkali* prevails; whence it alters not the Colour of Syrup of Violets. *See* Alkali *and* Neutrals.

Adits. See Burrows.

Alcohol. Is pure and perfect Spirit of Wine, without the least Particle of Water, or Phlegm.

Alkali. Is a Word of extensive Signification, and chemically denotes a large Tribe of Bodies. For all Bodies may be chemically considered under three Tribes; or as being either *Alkalies*, *Acids*, or *Neutrals*. *Alkalies* have this essential Property, that when mixed, or united, with *Acids*, they constitute *Neutrals*. But a more common Mark of an *Alkali* is, that it turns Syrup of Violets green, as an *Acid* turns it red; whilst the Admixture of a *Neutral* Body does not alter the Colour of that Syrup. Thus Pot-Ash, Salt of Tartar, and all fixed vegetable Salts; as likewise all volatile animal Salts and Spirits, are artificial *Alkalies*; as Chalk, the teftaceous Bodies, *&c.* are natural *Alkalies.* And thus, in the vegetable Kingdom, Onions, Leeks, Garlick, Muftard, *&c.* are *Alkaline*; as Sorrel, Wood-Sorrel, the Juice of Lemons, Oranges, Verjuice, *&c.* are *Acid.* Their Difference alfo is manifeft from the Tafte, when the Habit of thus diftinguifhing them is acquired. *See* Acids *and* Neutrals.

Amalgamation. Is the Diffolution, or Mixture of any Metal with Quickfilver: But Iron, of all the Metals, will not amalgamate, or unite therewith.

Affaying. Is the Art of difcovering how much pure Metal is contained in any Ore, or Coin, affigned. Hence *to make an Effay*, is to produce a Lump, or Grain, of pure Metal, from any fmall Quantity of Ore, or Coin.

Axioms. By *Axioms* are meant a Kind of Corollaries, Confequences, or Refults, of certain Experiments, Facts, Obfervations, or particular Doctrines; fo as to recapitulate a certain ufeful Truth, contained in the preceding Partof the Work, and fet it in a clearer Light, with regard to Theory, or Speculation; As Canons, or Rules, regard Experience or Practice. *See* Canons.

Balneum Mariæ. Or Water-Heat, is no more than a Veffel of Water, fet in a Furnace, or over the Fire, with another Veffel put into the Water; which latter Veffel contains the Matter, or Subject, of the Operation.

Buddling Difhes. Are fhallow Difhes, like the Bafons of a Pair of Scales, for the wafhing of Ores by the Hand.

Burrows.

Burrows. In Mining, are the Paſſages leading into a Mine, and cut thro' the Sides of a Hill, or Mountain, ſo large that the Workmen may conveniently wheel out the Ore in Barrows, or carry it along in Baſkets.

Calcination. Is the burning of a Body in an open Fire, in order to diſcharge its more volatile Parts, or reduce it to Powder.

Canons. Are Rules of Practice, or Directions, for producing Effects, or performing Operations; and have the ſame Regard to Practice, as Axioms have to Theory. *See* Axioms.

Caput Mortuum. Is that Part of the Matter, which remains behind after Diſtillation, or Sublimation.

Cementation. Is the cloſe burning of a hard or metalline Body, with certain opening Powders, ſtrew'd betwixt its groſſer Parts; ſo as to ſoften, tinge, or impregnate them, with the Fumes of ſuch Powders; or it is the Introduction of any Mineral, or Metallic Fumes into the ſolid Plates of a Metal, by Means of a proper Heat, applied to a cloſe Veſſel, or double Crucible, wherein the Plates are laid, with the pulverized Matter ſtrew'd between them.

Clarification. *See* Depuration.

Concentrating. Is bringing the required Parts of a Subject cloſer together; as Salt-Water is concentrated by evaporating the aqueous Humidity; and Wine by freezing out, or ſeparating its Water, in the Form of Ice.

Copelling, or *Cupelling*. Is putting metallic Matters upon a cover'd Veſſel of Bone-Aſhes in a naked Fire, to try what Gold or Silver they will afford.

Cryſtallization. Is the Operation, whereby Salts diſſolved in Water ſhoot into Glebes, of particular

ticular Figures, according to the Nature of each Salt.

Decantation. Is the pouring off a clearer Liquor from a groſſer Sediment, after ſtanding.

Deflagration. Is ſetting exploſive Matters on Fire in a Crucible, or other Veſſel, and ſuffering them to burn out; as when Nitre, or Tartar, are thrown into a red-hot Crucible, or to any melted Matter, whilſt it continues in the Fire.

Depuration. Is the making of any Matter pure, or freeing it from the Droſs, Dirt, or other heterogeneous Parts, wherewith it may happen to be mixed: So Honey is depurated, or clarified, by heating it, and taking off the Scum that riſes to the Top.

Digeſtion. Is ſuffering ſolid and liquid, or groſſer and finer Matters, to ſtand together in a gentle Heat for ſome Time, that the Liquor may extract the Virtues of the ſolid Ingredients; or the whole become more ſubtile and uniform.

Diſtillation. Is the raiſing of Liquids into Vapour by Heat; and condenſing that Vapour into a Liquid again.

Elæoſaccharum. Is an intimate Mixture of any eſſential Oil, with Sugar; by grinding them together in a Mortar.

Elements. *See* Principles.

Elixation. Is the waſhing a Matter with Water, in order to get out what will diſſolve therein.

Empyreuma. Is a nauſeous Taſte, or Odour, proceeding from the Subject being ſcorched, or over-heated, in the Operation; as when Milk is burnt to, as they call it.

Eſſential, or *Chemical Oils.* Are the native Oils of Vegetables, drawn from them by Diſtillation with Water.

Evaporation.

Evaporation. Is the ſetting a Liquor in a gentle Heat, to diſcharge its ſuperfluous Humidity, or obtain its dry Remainder.

Faints. Are the Liquor that runs from the Still, upon diſtilling any inflammable Spirit, after all the Proof-Spirit is come over. *See* Proof.

Filtration. Is ſuffering any Liquor to paſs thro' Cap-Paper, or rather a peculiar Kind of filtring Paper, into a clean Veſſel, or Glaſs; the Paper being cut conically for the Purpoſe, and put into a Glaſs Funnel, or laid upon a Stone Colander, or Strainer.

Form. Is the particular Act, or Law of Nature, whereby a Thing is produced.

Flux. Is any Matter added to an Ore, or metallic Matter, in order to make it melt, or run the eaſier, and yield a greater Quantity, or a purer Metal.

Fulmination. Is the ſame as *Deflagration*, which ſee.

Fuſing. Is the ſame as Melting, being a Term generally applied to the melting of Metals, and metallic Matters, with a ſtrong Heat.

Inſolation. Is ſuffering Matters to ſtand and digeſt in the Heat of the Sun, inſtead of uſing the Heat of a Furnace.

Lac, or *Laque.* Is a Kind of Extract, or thick Body of Colour, prepared chiefly from vegetable Subjects, for Painters Uſe. Of theſe *Laques* there are ſeveral Sorts; but in a more particular Senſe, it ſignifies the *Red Laque* obtained by boiling *Stick-Lac* in Water.

Lavaderos. In Mining, are the Houſes, or large Troughs, where the Ore is waſhed.

Limation. Is the filing of a Metal, or metallic Subſtance, ſo as to reduce it into ſmall Parts, called the Filings of that Metal.

Lixivium.

Lixivium. Is the ſame Thing as Lee, or a Solution of Salts, by boiling any ſaline Matter in Water.

Load. In Mining, is the ſame as Ore.

Lotion. Is the waſhing of a Body in Water, to get out its Salt, or whatever elſe will diſſolve in Water.

Low-Wines. Are a weak Spirit, or the firſt Runnings of the Still, in diſtilling Brandies or Spirits, from Waſh or Wines, and mixed along with the ſecond Running, or more watry Part.

Menſtruum. Is any Body applied to another, ſo as to diſſolve it, and intimately mix its Parts with the Parts of the other : in which Reſpect the former may be called the *Solvent*, and the latter the *Solvend.*

Mercury. Is another Name for *Quickſilver.*

Metallurgy. Includes the whole Art of working Metals from the Ore to ſaleable Metal.

Muffle. Is an arched earthen Inſtrument made to cover a Teſt, in Cupelling, ſo as that the Coals, or Aſhes of the Fire, may not fall in upon the Subject. *See* Cupelling.

Muſt. Is the unfermented Juice of the Grape ; or any other liquid fermentable Subſtance, before it enters the Act of Fermentation. *See* Stum.

Neutrals, or *Neutral Bodies.* Are ſuch Bodies as manifeſt no Signs of either *Alkali*, or *Acid*, upon any of the Trials known, and allowed to diſcover them ; as particularly not by the Taſte, or the Admixture of Syrup of Violets, *&c.* *See* Acid *and* Alkali.

Per Deliquium. Is the running of diſſolvable Things into Liquor, by barely expoſing them to the open Air, or to the moiſt Air of a Cellar.

Phlegm. Is the ſame as Water, or aqueous Liquor.

Precipitation. Is the depositing of a Sediment; either by a Liquor standing at Rest, or when any Addition is used for the Purpose.

Principles. Are the different simple Matters, whereof a Body is composed.

Proof. In Spirits is meant of a certain Trial, or Way of examining their Strength, by the Bubbles that arise on their Surface upon shaking them in a Phial.

Quartation. Is the Separating of Gold from Silver, by Means of *Aqua-Fortis* or *Aqua-Regia.*

Quintessence Is the Mixture of an essential Oil with *Alcohol.*

Rectification. Is purifying a Subject, by repeating the Operations; as Brandy is purified, or separated, from its Phlegm, by repeated Distillation.

Reduction. Is the *reducing*, or recovering a Metal from its *Calx*, or *Ashes*; and may likewise be applied, when any Body destroyed, as to its natural Form, or Appearance, is made to assume that Form again.

Refrigeratory. Is a Vessel of cold Water, thro' which a winding metalline Pipe takes its Course, from the Hot Still, so as to bring off the Liquor cool, by Distillation.

Regulus. Is an impure, or imperfect metallic Substance, that falls to the Bottom of the Crucible in the melting of Ores, or impure metallic Substances.

Scoria. *See* Slag

Separating-Glass. Is a bellied Glass, open at top, and ending in a hollow Stem below; so that a Mixture of Oil and Water being put therein, and suffered to rest till they separate, the Water may be poured off from the Oil.

Slag. Is the Droſs, Cruſt, or *Scoria*, found at the Top of a melted Metal, or metallic Matter; being often in the Form of a vitrified Maſs, or Glaſſy Subſtance, and proceeding from the Flux employed, and united with ſome ſtony recrementitious Matter contained in the Ore. But when a large Proportion of a ſaline Flux is uſed, the Slag will relent, or even diſſolve in the Air.

Solvent. *See* Menſtruum.

Stum. Is *Muſt*, clarified by ſtanding and racking, then put up into matched Caſks, that is, Caſks impregnated with the Fume of burning Brimſtone, ſo as to be preſerved ſound in an unfermented State. *See* Muſt.

Sublimation. Is the raiſing of a dry Body by Heat into Flowers, or a ſolid Cake, at the Top of the containing Veſſel; being a Kind of Diſtillation ſuited to dry Bodies.

Subſidence. Is the ſuffering a Liquor to ſettle, and fine itſelf, by ſtanding.

Sulphur. Is another Name for Brimſtone; but in a more Technical Senſe, denotes the fat, unctuous, or oily Principle in Bodies; or that Part of them, which is truly inflammable.

Thermometer. Is an Inſtrument contrived to meaſure the Degrees of Heat. Thoſe made with Spirit of Wine, ſerve for the leſſer Degrees, and thoſe with Oil, or Quickſilver, for the greater.

Triture. Is the grinding, or rubbing any ſolid Body to Powder in a Mortar, or upon a grinding, or levigating Stone.

Torrefaction. Is the roaſting, or ſcorching, of a Body by the Fire, in order to diſcharge a Part either unneceſſary or hurtful, in another Operation,

ration; as Sulphur is discharged from an Ore, before the Metal can be obtained to advantage.

Turnsol. Is a red Colour prepared from the Juice of the Sun-Flower, and fermented Urine: which Colour being, in a fluid State, drank up by Linen-Rags, and dried, is the Thing sold by the Dry-Salters to the Dyers and the Wine-Coopers, for dying Cloths, and tinging Wines red.

Vitrification. Is the turning of a Body to Glass in the Fire.

Wash. Is the same Thing as fermented Wort, or any fermented Liquor, fitted to afford an inflammable Spirit, or Brandy, by Distillation.

LECTURE I.

CONTAINING

I. *An Account of the Office and Objects of* Chemistry.
II. *The* Chemical *Treatment of Bodies.*
III. Rules *for making new Discoveries in the Art.*

1. THE Design of these Lectures is to enlarge the Bounds of Chemistry, by applying it to the Advancement of Natural Philosophy, the Illustration and Improvement of the known Arts, and the Discovery of new ones. *The Design.*

2. In prosecuting this Design we would speak to the Eye, rather than the Ear; or indeed to the Understanding, rather than the Senses; and by means of apposite Experiments, scientifically explained, lead to the Discovery of *Physical Axioms*, and *Rules of Practice* for producing useful Effects, in the way of a *Philosophical Chemistry.* *The Manner of Execution.*

3. *Philosophical Chemistry* we define, a rational Art of (1) dividing or resolving all the Bodies within our Power (2) by means of all the Instruments we can procure; (3.) as well into integrant as constituent Parts; and (4.) joining these Parts together again; (5.) so as to discover the Principles, Relations, and Changes of Bodies; (6.) make various Resolutions, Mixtures, and Compositions; (7.) find out the physical Causes of physical Effects; and (8.) hence improve the State of natural Knowledge, and the Arts thereon depending. *Philosophical Chemistry defined.*

4. To

The Business of the Lectures. 4. To explain this Definition, in a concise general manner, is the Business of our first *Lecture*; and to illustrate it fully, will be the Business of all the rest.

5. Our Definition consists of eight Parts; the first whereof regards the *Objects of Chemistry*.

The Objects of Chemistry. (1.) These *Objects* are all the Bodies within our Power. We should therefore, if it were practicable, take a particular View of the Contents of the terraqueous Globe. To abridge the Labour, we shall single out the more capital and useful Sorts; and range them in some Order, by way of Specimen, or Sample, of that grand Repository of infinite Materials *.

Classed. The Productions of the Earth are divided into, I. *Minerals*. II. *Vegetables*, and III. *Animals*.

I. Minerals are subdivided into (1.) Metals and their Ores, (2.) Salts, (3.) Sulphurs, (4.) Stones, (5.) Earths, and (6.) Semi-metals.

CLASS I. The METALS are.

Gold,	Ranged according to their specific Gravities, and compared with their Ores respectively.
Quicksilver,	
Lead,	
Silver,	
Copper,	
Iron,	
Tin.	

II. SALTS. *Alum*,
Artificial Salt,
Bay Salt,
Borax,
Nitre,
Rock Salt, or *Sal-Gem*,
Sal Ammoniac.

* In the Course, a Set of Specimens was exhibited, in conformity with the following List.

III. SUL-

III. Sulphurs. *Amber,*
Arsenic, white, yellow, and red,
Auripigmentum,
Bitumen,
Brimstone, Common,
——— *Native,*
Coal,
Jet,
Petreol.

IV. Transparent Stones.

From the *Diamond* to *Crystal.* } Ranged according to their Hardness, which is their Criterion, as Gravity is of Metals.

V. Opake Stones. *Alabaster,*
Amianthus,
Emery,
Flint,
Hæmatites,
Loadstone,
Marble, and Porphyry,
Lapis Calaminaris,
Talc,
Tripoli, &c.

VI. Earths. *Bole,*
Chalk,
Marl,
Ore,
Ocre,
Ruddle,
Terra Lemnia, &c.

VII. Semi-metals.
The Vitriolic are,
Vitriol, green and blue, *viz.* of Iron and Copper;
White Vitriol, with other foreign kinds.

VIII. The Sulphureous Semi-metals are,
Antimony,
Bismuth,

Cinnabar, native,
Mundick,
Pyrites,
Zinck, &c.

II. VEGETABLES are divided into
Herbs, Berries, Flowers, Fruits, Grains, Seeds, Roots, Barks, Woods, Juices, and Excrescences.

Class I. HERBS. *Angelica, Baulm, Hyssop, Rosemary, Lavender, Sage, Tansy, Thyme, Wormwood,* &c.

II. BERRIES. *Bay Berries, Coffee, Kermes, Juniper,* &c.

III. FLOWERS. *Jasmin, Saffron, Lillies, Marigolds, Roses, Elder-Flowers, Violets, Flowers of Broom, Holly-Oak,* &c.

IV. FRUITS. *Cocoa-Nuts, Nutmeg, Jamaica-Pepper, Long-Pepper, Tamarinds, Cassia Fistularis, Pomegranate,* &c.

V. GRAINS. *Rice, Indian Wheat, Sago, Millet,*&c.

VI. SEEDS. *Beech-mast, Cardamom, Gran. Paradis. Mustard-Seed, Sun-flower Seed,* &c.

VII. ROOTS. *Alkanet, Galangal, Gentian, Liquorice, Madder, Orris, Turmerick,*&c.

VIII. BARKS. *Cassia, Cinnamon, Clove-Bark, Cortex Peruv. Mace, Oak-Bark, Winter's Bark,* &c.

IX. WOODS. *Cedar, Guaiacum, Logwood, Rhodium, Saunders,* &c.

X. JUICES are subdivided into natural, and artificial; or into *Tears*, and *inspissated Juices.*

Tears, or natural Juices, of the Sycamore, the Birch, *&c.*

In-

Inspissated Juices are divided into (1.) *Gums*, (2.) *Balsams*, (3.) *Rosins*, and (4.) *Sugars*.

(1.) GUMS. *Aloes, Gum Arabic, Assa Fœtida, Ammoniacum, Benjamin, Bdellium, Galbanum, Gamboge, Mastich, Myrrh, Gum Elemi, Opopanax, Gum Sandarac, Gum Lac, Gum Tragacanth*, &c.

XI. (2.) BALSAMS. *Balsam Capivi, Opobalsamum, Balsam of Peru, Tolu, &c.* The *Turpentines, Wax*, &c.

XII. (3.) ROSINS. *Camphire, Frankincense, Rosin of Guaiacum, Rosin of Jalap, Scammony, Burgundy Pitch, Common Rosin, Sang. Draconis, &c.*

XIII. (4.) SUGARS. *Honey, Manna, Sugar*, &c.

XIV. EXCRESCENCES. *Jews Ears, Agarick, Misletoe*, the *Mosses, Galls*, &c.

III. ANIMALS.

Class I. ENTIRE ANIMALS. *Ants, Bees, Cantharides, Cochineal, Millepedes, Vipers*, &c.

II. THEIR SOLID PARTS *Bone, Hart's-horn, Ivory, Cuttle Bone, Elk's Hoof, Human Skull, Castor*, &c.

III. CONCRETED ANIMAL JUICES.
Goat's Blood and human Blood dryed, Lard, Marrow, Sperma Ceti, &c.

IV. EXCREMENTS. *Album Græcum, Civet, Musk, Pigeon's Dung, Silk*, &c.

6. *Bodies* have been usually considered under three general Classes, called by the Names of the Vegetable, Animal, and Mineral *Kingdoms*. This Division is, perhaps, too scanty; as excluding many Particulars of the marine and atmospherical Regions. For in the Sea are found Coral, Shells, Spunge, Bitumen, Ambergrease, Mixtures of *Bodies how to be divided.*

Salt, Slime, Fæculencies, and the corrupted Parts of Fiſh, &c. which may poſſibly be irreducible to any of the three Kingdoms. And the Atmoſphere abounds with Air, Light, Water, Meteors, Exhalations and Effluvia of the Earth, differently combined; ſo as not to appear diſtinctly either of a Vegetable, Animal, or Mineral Nature.

7. The *Objects of Chemiſtry*, therefore, are taken from the three larger Maſſes, or Regions, of the Globe; *viz.* the *Earth*, *Water*, and *Atmoſphere*

The general Structure of the Earth. 8. Our Knowledge of the *Earth* reaches but a little below its Surface. So far as Men have dug, it appears a Compages of numerous ſolid Subſtances, ranged in a diſorderly manner; which may be phyſically neceſſary, to afford different Partitions, or Beds, of Soil, Gravel, Clay, Stone, Coal, Marcaſites, Ores, Gems, &c. each ſerving as a Matrix to the other.

Earth in particular. 9. By *Earth* is commonly meant the Soil, Mould, or Coat, wherein Vegetables grow. This Coat, which is but of little Depth, is the direct and immediate Seat of Vegetation. And with this Earth we chuſe to begin our Experiments; propoſing (1.) A general Analyſis of Garden Mould; (2.) The Preparation of a general kind of Flux, for the aſſaying of Ores. (3.) The general Method of aſſaying Ores for their Metal. (4.) A general Analyſis of common Water. (5.) A general Analyſis of the Air. (6.) A general Example of the Method of reducing Bodies to their integrant Parts. (7.) A general Example of reſolving Bodies into their conſtituent Parts; and (8.) An Example of Reduction, or the Method of recompoſing, or recovering, Bodies after Solution.

II.

II.

Experiment I.

The Analysis of Garden Mould, begun.

10. We took two Pounds of fresh, black and rich Garden Mould, and stirred it well in two Quarts of fair Water, gently warmed, then letting the grosser Part settle to the Bottom, we filtred the Liquor thro' Cap-Paper; and found that it passed considerably muddy, or impregnated with the finer Parts of the Earth; which it would not easily deposite upon many Days standing in a quiet Place *. *Earth analysed.*

11. The Design of the Experiment is to obtain a proper Liquor for discovering the Matter which the Earth affords to Plants in Vegetation, or the natural Juices, and natural Salts, of Garden Mould; because nothing seems capable of rising in Vegetation, but what is soluble in moderately warm Water, and will pass the Pores of Paper, somewhat in the same manner as it does the natural absorbing Vessels, or Strainers of a Plant. Whence the filtred Liquor of our Experiment may be examined by chemical Treatment; as by Evaporation, or the way of trying *Mineral Waters*, &c. as we shall see hereafter in our fourth Lecture.

12. Ores are the next useful Species of *Earth*; the general Treatment whereof, for obtaining their Metal, depends upon the Use of the *Black Flux*.

* See this Experiment carried a greater length in *Lect.* IV. *Exp.* I. and II.

EXPERIMENT II.

The Method of making the Black Flux, for the aſſaying of Ores.

The Black Flux. 13. We took one Part Nitre, and two Parts common Tartar; and reducing each to Powder, we mixed them together, and deflagrated the whole in a Crucible, by lighting the Mixture a-top; which thus turns to a kind of *Alkaline Coal*, that is to be pulverized, and kept in a cloſe Glaſs, to prevent its diſſolving, as it would do in a moiſt Air.

14. This Flux is of general Uſe; and to have it ready at hand, ſhortens the Buſineſs of making Aſſays in Metallurgy; and renders the Operation more exact, than when crude Tartar and Nitre are employed; becauſe the Deflagration might thus carry off ſome Part of the Ore, and defraud the Account. For the ſame Reaſon, the Mixture is here directed to be fired a-top; otherwiſe a conſiderable Part might be loſt in the Deflagration; which would prove much more tumultuous and violent if the Matter was thrown into a red-hot Crucible.

EXPERIMENT III.

The general Method of analyſing Ores.

Ores analyſed. 15. We took two Ounces of Copper Ore reduced to Powder, and mixed it, in a Mortar, with twice its Weight of the black Flux; then, in a Wind Furnace, fuſed it briſkly, that it might run thin, for about four Minutes: when, ſuffering the Crucible to cool, we broke it, beat off the Slag, and weighed the Metal.

16. This Experiment ſhews the Method of treating any unknown Ore, to diſcover, in the

way

way of Assay, or Proof, the Kind and Proportion of Metal it contains.

17. The *Cause* of the Effect depends upon a Separation of the terrestrial, sulphureous, or other heterogeneous Parts of the Ore, which are here either vitrified, or otherwise detained by the Flux; whose Property it is to vitrify Earth in the Fire, and strongly join with Sulphur; at the same time that it does not alter the Metal, but leaves it to its own nature; whence, by its superior Gravity, it sinks pure to the bottom of the Crucible; as being now made fluid, and set free from the heterogeneous Parts before mixed in among it *a*). *The Rationale of the Process.*

18. *Water* is generally divided into salt and fresh, with regard to the Ocean and Rivers. But it seems divisible into as many different Species, as the Earth is into Beds. Thus there are Mineral Waters of various kinds, according to the Mineral Substances they run over, and become impregnated with: tho' this Impregnation sometimes happens in the way of Vapour, or Exhalation. Water, therefore, in the general, may be as mixed a Body, as Earth in the general; and perhaps neither of them naturally exists in any considerable Degree of Purity *b*). *Water divided.*

Experiment IV.

A general Analysis of common Water.

19 (1.) We found that common warm Water throws up numerous Bubbles, and explodes, in the exhausted Receiver of the Air-Pump; and therefore contains what may, by way of distinction, be called Æther or Spirit. *Water analysed.*

a) See the Lect. on Metallurgy.
b) See *Lect.* V.

(2) It

(2.) It contains a merely aqueous part, diſtinct from Æther, and from the Sediment; as appears in diſtilling common Water.

(3.) It contains a dry ſolid Matter, which is either earthy or ſaline, as appears upon a full Evaporation; and alſo from the Inſides of Tea-Kettles, which, after long Uſe, are lined with a ſtony Matter, that beats off in Flakes or Cruſts.

20. That Water is accounted beſt and wholeſomeſt, which is lighteſt, moſt ſpirituous, and freeſt from earthy Sediment; and theſe Properties are uſually found in pure Rain Water: this being naturally diſtilled, or raiſed by the Sun's Heat, from the Ocean and Rivers, into the Atmoſphere, and from thence returned again, much after the manner of common Diſtillation *a*).

The Atmoſphere divided.

21. THE *Atmoſphere* is a kind of dry Fluid, no leſs eſſential to the Earth than the moiſt one. It ſeems as heterogeneous as the Earth or Water, tho' more rarified. It is diſſimilar in its Parts, like the Body of the Earth; and has ſomething analogous to Beds, or particular Portions abounding with different kinds of Effluvia, according to the Differences of the Countries and Places over which it extends. Thus over Mount *Ætna*, or other *Vulcanos*, it muſt neceſſarily be impregnated, after the manner of certain Mineral Waters, with the Fumes of burning Minerals; over the Iſland *Ceylon*, with Aromatic Effluvia; over *London* with the Smoke of Sea-Coal *b*), &c.

EXPERIMENT V.

A general Analyſis of the Air begun.

The Air analyſed.

22. A proper Analyſis of the Air, or any integrant part of the Atmoſphere, has hitherto ſcarce been attempted.

a) See *Lect.* V. *b*) See *Lect.* III.

(1.) That

(1.) That it is an elastic Fluid appears by its distending Bladders, and breaking Glasses, in the exhausted Receiver of the Air-Pump. (2.) That it is essential to Life, appears by Animals dying without it. (3.) That it may receive invisible Influences or Alterations, as well as visible Effluvia, appears from its becoming poisonous by passing thro' Fire; and by its containing gross Smoak, and the fine Particles of fermenting or putrefying Bodies: And (4.) that it is naturally a Compound, appears by the Water it deposites in dry Salt of Tartar; and by its changing the Colours of various Bodies, *&c.*

23. We shall hereafter attempt a more particular Analysis of the *Atmosphere*, in order to a Choice of the best Places for Health, Habitation, and the Exercise of particular Arts; on account of certain Properties in certain Places, arising from the different Mixtures, or Compositions, of the Air in different Parts *a*).

24. The *Instruments of Chemistry* are all those we can any way procure *b*). There are several Instruments continually at work, for the immediate Production of Effects, in the three larger Masses, or Kingdoms, of the Globe, *viz.* the Earth, Water, and Atmosphere. We evidently find, that Metals and Minerals are formed within the Earth; Vegetables on its Surface, shooting into the Air; Meteors in the Atmosphere; and Men, Beasts, and Birds in the Confines of the two: The *Physical Causes* of all which are to be diligently sought out, as so many *Rules of Practice.* *The Instruments of Chemistry.*

25. The principal physical Agents in Nature appear to be, (1.) Heat. (2.) Cold. (3.) Air, or the integrant Parts of the Atmosphere. (4.) Water. And (5.) proper Beds, or *Matrices*. This is *The physical Agents of Nature.*

a) See *Lect.* III. *b*) See above §. 3.

Matter

Matter of direct Obſervation; and might occaſion the eſtabliſhing of the four common Elements, Fire, Air, Water and Earth.

The Sun. 26. (1.) The *Sun* is the principal Source of Heat upon the Earth's Surface, and the Confines of the Earth and Atmoſphere. Without this, all the Bodies upon our Globe would doubtleſs grow rigid, lifeleſs, and fixed. 'Tis this that ſtirs within them, as the main Spring of their Actions. Hence Vegetation, and Animalization, are evidently promoted; and hence the Ocean and the Atmoſphere continue in a fluid State *a)*.

C[illegible]*d.* 27. (2) *Cold* is correlative to Heat; and tho' perhaps no more than a leſs Degree, or Abſence, thereof, yet has, in the natural State of things, an inſtrumental Efficacy; as in the condenſing of Solids *b)*, the coagulating of Fluids *c)*, the ſeparating of Salts *d)*, Spirits *e)*, *&c.* And by means of Cold and Heat, uſed alternately, it ſhould ſeem that ſome capital Operations of Nature are performed, eſpecially in the vegetable Kingdom, by the Reciprocation of Day and Night, Summer and Winter *f)*.

Air. 28. (3.) Air, or any integrant Part of the Atmoſphere, is an elaſtic Fluid, that expands with Heat, and contracts with Cold; ſo as apparently to generate Motion, and produce Effects. It animates Fire, and has a great Influence upon the Life of Animals: it alſo mixes in among, and unites itſelf with, Bodies; ſo as to conſtitute a material Part thereof *g)*. It is the great Receptacle of

a) See *Lect.* II. *paſſim.*
b) Which are rarified by Heat, but contracted by Cold.
c) As aqueous Liquors into Ice.
d) As Salt is ſeparated in the Freezing of Salt-Water.
e) As Spirit is ſeparated in the Freezing of Wine, urinous Spirits, and diſtilled Vinegar.
f) See *Lect.* III.
g) See *Lect.* III.

Effluvia

Effluvia from the Earth, the Matrix of Meteors, the continual Support of Birds, Beasts, Plants, and Men; and is in some degree nutrimental *a*).

29. (4.) *Water* is not only contained in the Earth, as in a Reservoir, but likewise floats in the Atmosphere. In both Cases it is actuated, rarified, and put in motion by Heat; so as to prove instrumental in producing Effects. Thus it produces Clouds, Rains, Dews, Springs, and Rivers. It refreshes the Earth, recruits Vegetables, and is the Support of Fish and other Animals, by conveying Nutriment to all their Parts. It is also the first and immediate Instrument of Fermentation, Putrefaction, Corruption, and Change, in all vegetable and animal Subjects *b*). *Water.*

30. (5.) Proper Beds, or *Matrices*, also appear to have an instrumental Agency in the Production of natural Bodies. Every Subject of an Operation is necessarily contained in something that may (1.) afford it a Lodgment, (2.) make some Resistance, and (3.) convey to it Heat, Cold, Water, or Air, or determine their Actions upon it. Thus in Vegetation, the Matrix Earth supports the Seed, resists its Swelling, and conveys a strained, or prepared, Moisture to it. The *Matrices* of Gems and Ores not only afford a proper Lodgment to the Subject-Matter, but also resist its Growth, by the Pressure of their Sides; which, however, give way a little, and at the same time strain and convey suitable Juices to the Subject. And something of this kind is observed of the *Fœtus in Utero*, the Hatching of Eggs, &c. insomuch that Closeness, moderate Resistance, or a slow yielding of the Sides of the Matrix, and a straining of the Juices through them (unless sup- *Matrices.*

a) As it adds to the Substance of Vegetables and Animals. See Mr. *Hale*'s *Vegetable Staticks*, and hereafter *Lect.* III.

b) See *Lect.* VII and XII.

plied

plied from within) seem requisite for the Formation and Production of all Vegetable, Animal, and Mineral Substances. Whence we are furnished with a capital Rule for the Improvement of Chemistry, natural Philosophy, and Arts; and taught that, in order to imitate Nature, Chemistry must not be confined to the sole Use of Fire, as its Instrument, but occasionally employ Water, Cold, Air, Earth, and proper *Matrices*, or Vessels.

Artificial Instruments of Chemistry. 31. But besides these *natural Instruments*, there is a great Variety of *artificial* ones belonging to Chemistry, which seem to raise the Power of this Art, in some respects, above the Power of Nature. Thus, by means of particular Menstruums, it performs Operations which Nature of herself does not: for instance, of all the Metals, only Iron and Copper are found naturally converted into Vitriol; whereas Chemistry makes Vitriols even of Gold, Silver, Tin, and Lead. And hence the Productions of Art may be much more numerous, than the Productions of Nature; indeed they may be increased at pleasure, to the great Enrichment of Arts, and the Enlargement of the Kingdom of Man *a*).

Vessels, Furnaces, Utensils. 32. Another Set of Instruments belonging to Chemistry are *Vessels*, *Furnaces*, and *Utensils*; of which there is a great Variety, for different Purposes, and capable of producing numerous Changes in Bodies, by Amalgamation, Cementation, Fusion, Fermentation, Putrefaction, Reduction, &c.

A new Set. 33. We add to the above-mentioned a new Set, *viz.* The *Air-Pump*, the *Condensor*, *Digestor*, *Microscopes*, *Burning-Concaves*, *Prisms*, *Lenses*, *Portable Furnaces*, and every other Instrument that can be invented, or procured, of advantage to the Art.

a) In this Light may the numerous Productions of the Chemical Trades be consider'd; such as the Effects of Fermentation, Distillation, Dying, Soap-making, the Art of Glass, Metallurgy, &c.

34. THERE

Two principal kinds of chemical Diviſion.

34. There are two capital Ways wherein Chemiſtry divides its Subjects, by the ſeveral Inſtruments above-mentioned; *viz.* into *integrant Parts*, and into *conſtituent* Parts. By *integrant* Parts we underſtand ſimilar Parts, or Parts of the ſame nature with the Whole; ſo Filings of Iron have the ſame Nature and Properties as Bars of Iron. Under this general Operation, fall thoſe particular ones of Triture, Filing, Solution, Amalgamation, Sublimation, *&c.* And by *conſtituent Parts*, we mean diſſimilar Parts, or Parts of a different Nature from the Whole; as when artificial Cinnabar is divided into Quickſilver and Sulphur: and under this general Operation come all kinds of Analyſes or Reſolutions.

Experiment VI.

A general Example of reducing Bodies into their integrant Parts.

Quickſilver rendered inviſible by a minute Diviſion into integrant Parts.

35. We took an Ounce of Quickſilver in a ſmall Glaſs, and poured upon it two Ounces of *Aqua fortis*; then ſet the Glaſs in a Sand-Heat to warm: red Fumes ſoon appeared; and the Mercury, or Quickſilver, diſappeared. We added a little more Mercury, till a ſmall Particle was left undiſſolved at the Bottom, that the Solution might be ſaturated. Then we decanted the clear Liquor: a Drop of which being viewed in a Microſcope no Particles of the Mercury appeared ſeparate.

36. Here we find the opake and heavy Body of Mercury tranſparently diſſolved, and equally diffuſed in a Fluid, at leaſt ten times lighter than itſelf; the Mercury ſtill remaining unaltered and recoverable in its priſtine Form, barely by Collection or Aggregation, as we ſhall preſently ſee *a)*: ſo that it is thus only divided into homo-

a) Under Experiment VIII.

geneous

geneous or integrant Particles, and not ſeparated into Particles of different Kinds.

EXPERIMENT VII.

A general Example of reſolving Bodies into their conſtituent Parts.

Brandy reſolved into its conſtituent Parts.

37. We gently diſtilled two Gallons of common Brandy by the *Balnæum Mariæ*, which reſolved it into Spirit of Wine and Water. For the Spirit of Wine, being the lighteſt Part, comes over firſt, and leaves a large Proportion, or about one half, of Water or Phlegm in the Still.

38. And thus Brandy is ſeparated into the two very different, or heterogeneous Parts, whereof it conſiſts. And hence, by the way, all Rums and Brandies contain one half Water, no way eſſential to them, that might commodiouſly be left behind upon their Tranſportation and Carriage. And this holds ſtill ſtronger of Arracks, which uſually contain three fourths Water, to one of Spirit *a)*.

Aggregates and Mixts, what.

39. Theſe two general Operations of Chemiſtry bear relation to two general Structures of Bodies, *viz*,. the *Aggregate* and the *Mixt*. Aggregates in their Reſolution conſtantly retain their Nature in every the ſmalleſt Part, or Atom; but when Mixts are reſolved, the Mixture is deſtroyed, and two or more new Aggregates are produced: thus when Brandy is reſolved, Spirit of Wine or *Alcohol*, and *Water* are produced.

Senſible Bodies compoſed of inſenſible.

40. Every ſenſible Mixt, or Aggregate, is compoſed of many inſenſible ones. Before Gold can become ſenſible to us, there muſt be a Collection of numerous Parts that are ſeparately inſenſible; yet all of them perfect Gold. The

a) See *Lect*. VII. Exp. IV. and *Lect*. XII. Exp. IV.

minuteſt

minuteſt Grain of Cinnabar has in it two different Parts, Sulphur and Quickſilver. The minuteſt Grain of Glaſs contains Sand and fixed Salt. And ſo when Quickſilver is diſſolved in *Aqua Fortis*, the leaſt aſſignable Portion of the Menſtruum contains a Quantity of Mercury proportionable to the whole.

41. (4.) Either he integrant or the conſtituent Parts of Bodies being once divided or reſolved *a)*, various Occaſions in Chemiſtry require them to be united again, for compoſing a Whole like the original Subject. This Operation is the Converſe of the former. Thus by ſimple Mixture we recompoſe Brandy from Alcohol and Water; and by Precipitation with a Copper-Plate, collect the Quickſilver diſperſed in *Aqua Fortis*. *Recompoſition illuſtrated.*

Experiment VIII.

An Example of the Method of recovering Bodies after Solution.

Quickſilver recovered.

42. Dilute part of the above Solution of Quickſilver *b)* with twice its quantity of fair Water; ſuſpend a Plate of Copper in the Liquor; the Quickſilver will ſoon fall in its natural Form to the bottom of the containing Glaſs, and being then taken out, well waſhed and dried, will be abſolutely indiſtinguiſhable from other Quickſilver that has never been diſſolved. The Effect is owing to this, that *Aqua Fortis* diſſolves Copper more eaſily than Quickſilver, and ſo lets the Quickſilver fall in proportion as it diſſolves the Copper. And this, by the way, is a general Example of *Precipitation*.

a) See above, §. 3. *b)* Exp. vi.

The Principles, Relations, and Changes of Bodies, how discoverable.

43. (5.) To discover the Principles and the Relations of Bodies, and the Changes *a)* produced in them by the Operations of Philosophical Chemistry, we must use all our Senses, assisted by proper Sets of Experiments, or particular Ways of Examination; otherwise we shall learn but little of the Powers of Nature and Art. In the Experiment of Quicksilver dissolved in *Aqua Fortis*, we find by a slight Expedient, *viz.* by putting a piece of Copper into the Solution, that the Quicksilver, tho' rendered invisible, is not destroyed; seeing it is thus recovered in its pristine Form and Properties.

44. By casual Experiment, *Glauber* discovered his Method of preparing mineral acid Spirits by means of Oil of Vitriol: for having once obtained this Oil, by an Analysis of Vitriol, he applied it to the Mineral Salts, and found that it expelled their volatile Acids in Fumes; and that these being more plentifully raised by Heat, and collected again, made the acid Spirits, so useful in Metallurgy, Refining, Dying, *&c.* Thus one new chemical Production may give Rise to many new Arts.

The Resolutions and Compositions of Chemistry.

45. (6.) The Resolutions and Compositions made by Chemistry *b)* are extremely numerous, and may be increased *ad infinitum.* We exhibited an Instance of Resolution in the Analysis of Brandy: And to this Class of Resolutions are referable all kinds of Depurations, Purifications, Separations, Clarifications, *&c.*

The Productions of Composition.

46. By Composition we produce all the artificial Vitriols, Soaps, Glasses, *&c.* and can compound these again in an almost infinite Variety. So that the Resolutions, Compositions, and Recompositions in Chemistry, seem to have

a) See above, §. 3. *b)* Ibid.

no

no Bounds; whence great room is left for new chemical Discoveries.

47. (7.) Whilst we carefully attend to the several Steps of chemical Operations, we are led into some sort of Knowledge of the *Physical* or *Material Causes* of the Effects *a*) produced, as may appear from our Attempts to assign the chemical *Causes* in the foregoing Experiments. Hence the more Attention and Diligence we employ, the juster Notions shall we have of these Causes, or the nearer Approaches shall we make to the Discovery of them; and they being once certainly found will afford us certain *Rules of Practice*, to be occasionally employed for producing the same Effects again. For to discover the Cause of an Effect, is to discover a Rule for producing that Effect.

The Physical Causes of chemical Effects.

48. (8.) The Improvement of natural Knowledge, of Chemistry itself, and of the Arts thereon depending *b*), must be the Consequence of a due Prosecution and Improvement of *Philosophical Chemistry*; which for Distinctness sake, we shall hereafter consider, as it more immediately relates to (1.) *Fire*, (2.) *Air*, (3.) *Earth*, (4.) *Water*, (5.) *Menstruums*, (6.) *Fermentation* and *Putrefaction*, (7.) *The Analysis of Bodies*, (8.) *The Synthesis of Bodies*, (9.) *Vegetable Curation*, (10.) *Vinous* and *acetous Fermentation*, (11.) *Distillation*, (12.) the making of *Oils*, (13.) *Salts*, (14.) *Colours*, *Dyes*, and *Stains*, (15.) *Pharmacy* and *Medicine*, (16.) *Mineralogy*, (17.) *Metallurgy*, (18.) *Pyrotechny*, and (19.) the farther *Uses of Chemistry*: so as to shew what has already been done on these Subjects, carry the View somewhat further, and recommend a fuller Prosecution to others.

The Advantages of improving Chemistry.

The Subjects to be treated in the following Lectures.

a) See above, §. 3. *b*) Ibid.

Three general Rules for conducting Philosophical Chemistry.

49. It was said in our Definition a), tha Philosophical Chemistry is a *rational Art*; by which we mean that it may be conducted by Rule, and need not be left to accidental Trial and casual Experiment. The Rule for duly conducting the Art we would endeavour to comprize under the following three.

III.

RULE I.

50. *When a Body is offered, in order to have new Properties discovered in it, different from those general ones of Figure, Gravity, Elasticity,* &c. *which come under Mathematical Consideration, let the Body be resolved, by degrees, into the simplest constituent Parts, which it is capable of being separated into by the Instruments above described: And let Trial be made with each particular part on a variety of Bodies, according to some Analogy of a previous Chemical Knowledge, leading from one thing to another, in a sure or probable Method of Ratiocination.*

RULE II.

51. *Let the several Parts, obtained by the preceding Analysis, be reunited, beginning with two, and proceeding gradually to the whole Number; using at first the gentlest, then the intermediate, and at last the highest Degrees of Heat and Cold. Thus, for example, join the fixed Salt and Oil of a Plant together, first by simple digestion, and afterwards by boiling; which affords a third Production dissimilar to all the rest, and known by the Name of* Soap. *So, again, melt the same fixed Salt with the Earth of the Plant; and this will afford Glass.*

a) See above, §. 3.

Let

Let the last Attempt be to reunite all the separated Parts of the Body; in order, if possible, to form the original Substance again.

Rule III.

52. *In every Operation performed let the greatest Diligence and Exactness of Observation be used, with regard to all the principal Phænomena and Effects produced; let these Phænomena be duly register'd, tabled, considered, and compared together, after the strictest Geometrical Manner; the Result whereof, if there be no considerable Errors committed, will lead to a Knowledge of the secret Springs, Motions, Instruments, and Means made use of by Nature for producing Effects. And thus, with proper Care and Application, just* Canons *or Rules of Practice may be formed.*

53. The Art of Chemistry having been but little cultivated in this view, all we can at present pretend to, is to make some Offers at forming such *Canons* or *Axioms*, and consign them over to further Experience and Observation, to be thereby *verified*, *amended* or *rejected*. But if a competent number of just *Axioms* and *Canons* were once formed in this manner, others of a still higher nature might be raised from them; till at length, Practice and Experience would lead us to a true Theory; and that Theory back again to a more extensive and useful Practice.

IMPERFECT AXIOMS, or CANONS, deduced from the preceding Enquiry, for promoting farther Diſcoveries and Improvements in chemical and natural Knowledge.

54. (1.) *We may learn from our preſent Enquiry, that a true Chemiſtry (as it may perhaps be juſtly called) is exerciſed by Nature in the Vegetable, Animal, Mineral, Marine, and Atmoſpherical Regions; and that by it all Bodies are produced, converted, renovated, repaired, and maintained: and that in the exact Diſcovery, Imitation, and Controul of this* natural Chemiſtry, *conſiſts the Perfection of the* artificial *a).*

(2.) *That neither the Eye, nor all the Senſes together, can give us any Information of the latent Properties of Bodies, their Natures and Uſes, without particular Tryals and Experiments, well attended to and conſidered b).*

(3.) *That Experiments are but inſignificant Facts, unleſs they have a direct Uſe in Life, or tend to the raiſing of* Axioms *and* Canons, *for improving our Knowledge, and extending our Power over the Works of Nature c).*

(4.) *That he who can chuſe fit Subjects, place them in proper* Matrices, *or including Veſſels, and ſupply them duly with Air and Water, Heat and Cold, may probably produce great effects in Imitation of Nature d).*

(5.) *That nature points out three Matrices for producing Phyſical Effects, different in Fineneſs,* viz. *Beds of Earth, Beds of Water, and Beds of Atmoſphere: Beds of Earth for Minerals, of Water for Fiſh, and of Atmoſphere for Birds,*

a) See above, §. 7, 8, 9, 21, 24, 25.
b) See above, §. 35, 36, 38, 39, 41.
c) Paſſim.
d) See §. 24, 25, 26, 27.

&c.

&c; *The Confines of the Earth and Atmosphere for Plants and Animals*; *and a rarified Mixture of all Matters for Meteors. a)*

(6.) *That Men may make use of the same Instruments as Nature does*, viz. *Fire*, *Air*, *Water*, *and Earth*, *and consequently produce the same kind of Effects*, *if Skill*, *that is*, *Knowledge*, *be not wanting. Whence to improve in Knowledge*, *is to improve in Arts b).*

(7.) *That Chemistry is not confined to the Use of Fire only*; *but*, *in imitation of Nature*, *may employ Cold*, *Air*, *Water*, *and Earth upon Matter*, *in various Degrees of Simplicity*, *Combination*, *and Mixture*; *which shews an extensive Method of enlarging the Bounds of the Art c).*

(8.) *That Fire is not only an Analyser in some Cases*, *but also a Mixer of Bodies in others*; *and this to the Advantage of Chemistry: For if it only separated*, *it could produce but few Effects*, *in comparison of that infinite Variety it now produces*, *both by Mixture and Separation d).*

(9.) *That it might be proper to try the Reciprocation of Heat and Cold in Chemical Operations*, *after the manner of Nature*, *in Day and Night*, *Summer and Winter e).*

(10.) *That Body*, *in all its Forms*, *is the Object of Chemistry*; *not considered mathematically*, *nor mechanically*, *but operatively and effectively f).*

(11.) *That the Atoms*, *or primary small Corpuscles of Bodies*, *are insensible to us*: *Thus the first Particles of Gold*, *Salts*, *Metals and Minerals may float in the Air*, *and not be perceived by us*,

a) See § 25. *b)* See § 25, 26, 27. *c)* Ibid.
d) See § 28—45. *e)* See § 25. *f)* See § 3. 5, 7, 49, *& alibi passim.*

till they aggregate or are collected together, and make a sensible Mass, or produce a sensible Effect a).

12. *That some Operation of the Mind is requisite to digest, methodize, and register Chemical Experiments and Observations; without which we cannot come to know the Laws observed by Nature in Physical Operations, nor be able to imitate them: The Chemistry, or regular Processes, of the Mind being here as necessary, as the corporeal Operations themselves b).*

a) See § 35, 36, 38, 39, 41.
b) See §. 3, 48, 49, 50, 51.

More *Canons* and *Axioms* might be drawn both from the present *Lecture*, and from all the following; but the Design of drawing any at all, is chiefly to recommend the Method, rather than the Matters brought a second time under consideration.

LECTURE II.

CONTAINING

I. *The Nature, Properties, Office, and Uſe of* Fire *in general.*
II. *The Nature of Celeſtial, Subterraneous, and Culinary* Fire.
III. *The Effects of* Fire *on the Atmoſphere, and Bodies of the terreſtrial Globe.*
IV. *The Degrees of Heat regulated.*

I.

1. OUR preſent Deſign is to ſearch into the Nature of Fire: This we ſhall attempt by means of Experiments, conducted after the manner laid down in our firſt Lecture. *The preſent Deſign.*

2. All the phyſical Knowledge we can have of a Subject muſt ariſe from attending to its Properties and Effects. But theſe Properties and Effects can never be diſcovered without the help of Experiments, which in phyſical Enquiries are the only Interpreters between our Senſes and our Reaſon. Whence all thoſe Notions of Fire ſhould be rejected as precarious and unſound, that are taken from the direct Teſtimony of the Senſes only, or from bare Reaſoning unaſſiſted by Experiments. In this Enquiry, therefore, the Mind is carefully to be kept unprepoſſeſſed, and to wait for a full and proper Information before it pronounce. *Preliminary Obſervation.*

3. By the general Name of *Fire* Men ſeem to underſtand a certain Senſation, or complex Notion *Fire, how underſtood.*

tion of Light, Heat, Burning, Melting, &c. This Notion ſhould be reſolved or analyſed, in order to ſee what Parts thereof are eſſential, and what precarious or arbitrary.

The Eye no judge of Fire. 4. We frequently find the Effects of Fire produced where no viſible Fire appears. Thus the Fingers are eaſily burnt by an Iron heated below the Degree of Ignition, or ſo as to be no way viſibly red-hot or fiery; whence the Eye is no Judge of Fire.

The Touch no true judge thereof. 5. So likewiſe the Touch gives us no poſitive notice of any Degree of Fire below the natural Heat of the Body, or of any ſo great as to deſtroy the Organ.

Burning, &c. not eſſential to Fire. 6. Again, the Effects of Fire are often produced without any manifeſt Signs of Burning, Melting, &c. as in Evaporations, Exſiccations, &c.

7. If this Method of Excluſion and Rejection were purſued to its due length, we ſhould perhaps find no Criterion, infallible Mark, or Characteriſtick of Fire in the general, but that of a particular Motion, ſtruggling among the ſmall parts of Bodies, and tending to throw them off at the Surface. If this ſhould prove the Caſe, then ſuch a Motion will be the *Form* or Eſſence of *Fire*, which being preſent makes Fire alſo preſent, and when abſent makes Fire alſo abſent. Whence to produce Fire, and to produce this Motion in Bodies, will be the ſelf-ſame thing *a)*.

8. But the following Experiments will afford us more Light, and ſhew, (1.) That, in general, both Solids and Fluids manifeſt an expanſive Motion upon being heated; (2.) That the direct inflammable Matter of Fuel is Oil, or an unctuous

a) See Lord *Bacon*'s Philoſophical Works, Engliſh Ed. Vol. II. pag. 433, &c.

Sub-

Subſtance; (3.) That no Fuel will burn or conſume without the Admiſſion of freſh Air; (4.) That the Air, which has once paſſed through burning Fuel, is of itſelf unfit to animate Fire again; and, (5.) That Flame exiſts only on the Surface of Fuel.

Experiment I.

That Iron expands with Heat.

9. We procured an Iron Ring to be made, juſt capable of admitting one end of a ſolid Rod of the ſame Metal; then heating that End in the Fire till it was red, and applying it to the Ring, we found the Rod ſo ſwell'd, that it would not now enter the Hollow which it fitted exactly when cold.

10. This Experiment directly ſhews no more than that Iron expands upon being heated; but as it has alſo been found to ſucceed in many other Solids, it may be made general, till the contradictory Inſtances are produced in the way of Exceptions *a)*.

Experiment II.

That Fluids expand with Heat.

11. We filled the ſpherical Cavity of a bellied Glaſs, having a long and ſlender Neck, at three different times, with (1.) Mercury, (2.) Water, and, (3.) Spirit of Wine, to the ſame height; then plunging the Glaſs, ſucceſſively, into Water (kept in the ſame Degree of Heat, in all the three Trials, as appeared by a Thermometer) we found that each Fluid ſwelled very remarkably, or roſe up to a conſiderable Height in the

a) Cedar Wood has, upon ſome Trials, been thought not to expand with Heat, or contract with Cold.

the Neck of the Glaſs, above what it ſtood at before the Glaſs was placed in the hot Water.

12. This Experiment ſeems to hold of Fluids univerſally: ſo that for the preſent we may allow the Motion of Expanſion, or Rarifaction in Bodies, to be inſeparable from Heat, or Fire in the general.

II.

Three Kinds of Fire.

13. We proceed to conſider this *general Fire* in its three Kinds, *viz. Celeſtial, Subterraneous,* and *Culinary.*

Celeſtial.

15. By *Celeſtial Fire* we principally mean that of the Sun, without regard to the Fire of the fixed Stars; tho' this perhaps may be of the ſame nature.

Subterraneous.

15. By *Subterraneous Fire* we underſtand that which manifeſts itſelf in fiery Eruptions of the Earth, Vulcanos, or burning Mountains; and by any other Effects it produces in Mines, or the more central Parts of the Earth.

Culinary.

16. By *Culinary Fire* we mean that vulgarly employed in all Chemical Operations, and the common Occaſions of Life.

The Sun's Heat.

17. The Sun's Heat appears to be the actuating Principle, or general Inſtrument of all the Operations of Nature in the Animal, Vegetable, Atmoſpherical, Marine, and Mineral Kingdoms *a).*

The Purity of the Sun's Heat.

18. Conſidered in itſelf, Fire ſeems to exiſt in greateſt Purity and Perfection in the Celeſtial Regions; at leaſt we are not ſenſible of any Smoke it yields: for the Rays of Light come to us from the Sun, unmixed with any of that groſs, terreſtrial Matter found in Culinary and Subterraneous Fires. But allowing for this Difference

a) See *Lect.* I. §. 16.

the

the Effects of the Solar and Culinary Fire appear to be the ſame.

19. The Effects of *Subterraneous Fires* will alſo be found nearly the ſame with thoſe produced by Culinary Fire. Burnt Coals, Cinders, and melted Minerals are thrown up by *Veſuvius*, and other Vulcanos. Warm mephitical Exhalations, natural hot Springs, Steams, Vapours, Smoke, *&c.* are found in ſeveral parts of the Globe, riſing much in the ſame manner as if they were produced by the Heat of a Furnace. Whence it can ſcarce be doubted that Subterraneous Fires are of the ſame nature with the Culinary. *Subterraneous Fire approaches the Culinary.*

20. And as all the three kinds agree in giving the Motion of Rarifaction to Bodies, it ſeems no way improper to reduce them to one; or to quit, for the preſent, the Celeſtial and Subterraneous, and keep to the Culinary Fire, which is more within our power, and every where ready at hand to be employed in Experiments. *The three Kinds have a near Agreement.*

21. All Culinary Fire requires ſome Pabulum or Fuel, wherein it either reſides or is collected. A leading Experiment therefore, in our preſent Enquiry, is the Analyſis of Fuel; to diſcover its conſtituent Parts, and learn which of them is more immediately adapted to receive or propagate Fire. *Fuel what.*

Experiment III.

That Oil is eſſential to Fuel.

22. We put a Pound of common Billet-Wood, reduced to ſmall Pieces, into an earthen Retort, and diſtilled with a naked Fire into a large Glaſs Receiver. There came over (1.) an acid Water, (2.) a rediſh tart Liquor, (3.) Smoke, and a groſs *A leading Experiment.*

grofs, black, burnt Oil. The fire being made and kept up ftrong at laft, no more Liquor or Oil afcended; but (4.) a black Matter, exactly refembling Charcoal, remained behind: this being taken out and burnt in the open Air, fell into Afhes; which by Diffolution in Water afforded (5.) a little fixed Salt, and (6.) an earthy Subftance.

That Coals owe their Inflammability to Oil.

23. This Experiment appears to be general, or to fucceed alike in all Wood, Coals, or folid Fuel. We feparated the acid Water or reddifh Liquor from the Oil by the Filtre; and then found that thefe aqueous Liquors would not burn in the Fire; no more would the Afhes, the Salt, or the Earth, either fingly or in compofition: fo that of all the Subftances thus obtained from the Wood, the black Coal and the Oil are the only inflammable ones. But the Coal remains inflammable merely upon account of the grofs Oil ftill lodged and clofely locked up therein, and according to its peculiar nature, fcorched, or turned black by the Heat employed in the Operation.

24. If farther Evidence be wanted to prove that the Oil remaining in the Coal gives it its Blacknefs and Inflammability; let it be confidered, (1.) That all fcorched Oils turn black; and that the more volatile Oil, which here comes over into the Receiver, is black. (2.) That no other part of the Wood, feparated by the Analyfis, is inflammable, befides the black Oil; not the Coal itfelf after it is become white or reduced to Afhes by open Fire and Air, which is an Operation fufficient to diflodge the grofs black Oil, that could not be raifed by a lefs Force. (3.) That no other chemical Caufe can well be affigned for this Blacknefs and Inflammability. (4.) That Wood, Pit-Coal, &c. prove lefs inflammable,

mable the more they are deprived of their Oil. (5.) And laſtly, that the Calces of Metals, rendered abſolutely uninflammable by Calcination, appear to attract this Oil out of burning Fuel, ſo as thence to recover their inflammable Principle and true metalline Form *a)*.

25. But without farther Proof we may venture, for the preſent, to conſtitute Oil the ſole Principle, or inflammable Matter in Fuel; and on this footing it will be proper to reduce our Enquiry to the more oily Species of Bodies, and make our Experiments chiefly upon thoſe.

Experiment IV.

That Fire will not conſume Fuel without the Admiſſion of Air.

26. Having exactly fitted a hollow Cylinder of Iron with a ſtrong Skrew at each end, we included a long Piece of Charcoal in the Cavity; then ſkrewing both ends tight, we detained the Cylinder in a ſtrong Fire for ſeveral Hours; letting it afterwards cool and taking out the Charcoal we found it ſtill black and no way apparently conſumed, altered, or diminiſhed.

27. This Experiment, compared with the common Obſervation that Fuel burns and conſumes quickly in the open Air, ſhews that Air is neceſſary to the Conſumption of Fuel; or that its burning and conſuming depend upon the Rarifaction, Diſlodgment, briſk Agitation, and Diſcharge of the Oil it contains; which is the phyſical Cauſe of the Effect. And hence we have the

a) Let proper Trial be made, whether the fixed Oil cannot be ſeparated from powdered Charcoal by a ſtrong Lixivium of Pot-aſh and Quicklime, ſo as to form a Soap, or otherwiſe exhibit this Oil to the Eye. See *Lect.* XVIII. §. 22.

reaſon

reaſon of the known Rule or Method of extinguiſhing Fire by ſmothering it, or keeping it cloſe from the Air.

28. But that the bare Motion of confined Air, or its paſſing ſeveral times through lighted Fuel, is not capable of conſuming it, appears by the following Experiment.

EXPERIMENT V.

That Air which has paſſed thro' Fire, *or ignited Fuel, is unfit to animate Fire again.*

29. We cauſed a wooden Box to be made, perfectly cloſe and tight, with Glaſs Windows on the ſides. At the bottom of this Box was a Perforation exactly fitted with a hollow wooden Plug, that joined to a tight leathern Pipe. This Pipe at the other end communicated with the Clack of a pair of Hand-Bellows, the Noſe whereof entered at a Hole on one ſide of the Box; ſo that by this Contrivance it was eaſy to draw the Air out of the Box into the Cavity of the Bellows, and return it into the Box again, without admitting any other Air beſides that originally contained in the Box. We now ſet a little Chafing-Diſh of live Coals in the middle of the Box, and ſecuring all the Joints tight from the external Air, we plied the Bellows; which, inſtead of increaſing, ſoon totally extinguiſhed the Fire; tho' the Coals were by no means burnt to Aſhes, but remained black and freſh when cold.

30. Hence it is manifeſt, that even a briſk Motion of ſuch Air as has already paſſed through burning Fuel, is ſo far from animating, that it deadens or quenches Fire *a*), in the ſame manner

a) Let a proper Experiment be deviſed, to ſhew what Alteration the Air ſuffers by paſſing through Fire.

as

damped or ſmothered; the Oil of the Fuel not being carried off for want of freſh Air.

31. This method of damping Fuel, or ſuffering it firſt to burn a little and then extinguiſhing it, teaches us a Method of rendering Fuel inoffenſive and fit for the more curious Uſes, by diſcharging its groſs Smoke, ſo as to leave a pure charred Coal behind. *Fuel, how charred.*

Thus for example, if Pit-Coal or Wood be burnt, not in the open Air, but with a cover'd, cloſe, or mouldring Heat, till it ceaſes to fume, and be then immediately quite ſmothered or quenched by throwing on it Mould, Sand, or Water, it becomes a charred Coal or Coak, fit for the drying of Malt, or other curious Operations in which groſs Smoke would be prejudicial.

32. Another Method of obtaining a pure Fuel is to chuſe ſuch an inflammable Matter as yields little or no Smoke from the firſt; ſuch, in particular, is Spirit of Wine; or, in the next Degree, Oil of Turpentine, or other thin *ethereal Oils*, as they are called; whereof Spirit of Wine is by the Chemiſts deſervedly reckoned the fineſt or moſt ſubtile *.

Experiment VI.

That Flame dwells and plays only about the Surface of Fuel.

33. We filled a Lamp-Glaſs with Spirit of Wine, and another with Oil of Turpentine; then ſetting fire to each it was viſible thro' the Glaſſes that both Liquors burnt or flamed on the Surface only; the Flame continually ſinking lower and lower in the Glaſſes as the Liquors conſumed.

* See *Lect.* VI. and XIII.

34. This Experiment holds alſo of ſolid Fuel, and appears to be univerſal. And hence again we are directed in the choice of our Fuel; which, to light quick, ſhould be furniſhed with a thin ſubtile Oil on its Surface. Upon this principle depend thoſe ſudden Methods of Illumination practiſed at great Entertainments or publick Rejoicings; and upon the ſame Principle we might eaſily invent quick, commodious, and inoffenſive Ways of lighting common Fires, *&c.*

III.

The Effects of Fire. 35. Having learned how to procure, prepare, manage, and improve our Fuel *a)*, we come next to conſider the Effects of Fire, produced by means thereof, on the Atmoſphere and Bodies of the terreſtrial Globe.

On the Atmoſphere. 36. All Fire rarefies the Air that is near it, as appears from a Bladder including a ſmall Portion of Air, and lying in a warm Place; for thus the Air is made to ſwell and diſtend the Bladder: Whence the Atmoſphere muſt needs be rarefied by the Sun's Heat, and produce Effects accordingly. The Air alſo imbibes Smoke and carries it aloft, at the ſame time that the Fuel diminiſhes or waſtes and falls into Aſhes. Whence the Air becomes a kind of Menſtruum, impregnated with Smoke or the matter of Soot, in Places where much Fuel is conſumed *b)*.

On particular Bodies. 37. The Effects of Fire upon particular Bodies can only be learned from particular Experiments; to make which, is the more immediate Office and uſe of Philoſophical Chemiſtry. Thus in ſome Bodies, as Ores, Fire procures Fuſion

a) See above, §. 25, 26, 27, 28, 29, 31, 32, 33, 34.

b) See *Lect.* III. *paſſim.* See alſo *Lect.* I. §. 16.

and

and Separation; in others, as Sand and Pot-ash, Fusion and Mixture; in some Dryness and Exsiccation, as in Clay; in others Softness and Pliability, as in Wax, &c. according to the Degree and Manner in which the Fire is applied. But for the Conduct to be observed in this Application certain general Rules are required. And first with regard to the kinds of Heat:

38. There are in Chemistry as many kinds of Heat as there are Mediums thro' which it may be conveyed, or Fuels that afford it. *The kinds of Heat in Chemistry.*

39. For common use, Heat is conveyed either thro' Water, Ashes, Sand, &c. or directly thro' the containing Vessel.

40. When Heat is conveyed thro' Water it is called the *Balneum-Mariæ*, or Water-Heat; when thro' Ashes, an Ash-Heat; when thro' Sand, a Sand-Heat; and when thro' no intermediate Substance at all, a naked Fire. Balneum Mariæ, *Sand-Heat*, &c.

41. Some Differences may be found in the Effects produced by these different Heats applied in the same Degree: but they have not perhaps been noted as they deserve.

42. In several Bodies 'tis evident that dry and moist Heats have different Effects; as we find remarkably in the common culinary Operations of boiling, roasting, baking, &c. And hence, where the Effects are required perfectly similar, the same kinds as well as degrees of Heat are to be used.

43. The purest Fire is that of Alcohol or perfectly pure Spirit of Wine; the next in Purity is that of distilled Oils; the next, that of Charcoal, or charred Turf; and the impurest, that of Pit-Coal: But all these have nearly the same Effect, when received thro' the same kind of Medium. *The Degrees of Purity in Chemical Fires.*

IV.

The Degrees of Heat. 44. The laſt thing to be conſidered is, how to regulate and aſcertain the Degrees of Heat in Chemical Operations, ſo as to produce the Effects required in every Caſe.

Uncertain. 45. The common Directions of the Chemiſts about this Matter are full of Uncertainty; their firſt, ſecond, third, and fourth Degrees of Heat, meaning no preciſe Degrees meaſured by any Standard.

How to be regulated. 46. To reduce this Affair to the neceſſary Accuracy proper Thermometers might be employed, filled either with Oil or Quickſilver, and graduated from the freezing Point, or any other fixed Point of Cold, up to the Degree of boiling Quickſilver. Thus would come in their reſpective Places, (1.) the Degrees of Heat beſt ſuited to Vegetation, which might be ſerviceable in regulating the Temper of Green-Houſes. And this temperate Heat is fit for extracting the native Spirits of odoriferous Vegetables with Oil; as of Roſes, Jaſmin, &c. and again, for making the more curious Inſolations, &c. *The firſt Degree.*

The ſecond. 47. (2). The next Degree of Heat may be accounted that of the human Body in a healthy State, which is always greater than that of the ambient Air. But when the Body is dead, it receives the ſame Degree of Heat with the ambient Fluid. This ſecond Degree of Heat is adapted to vinous and acetous Fermentation, Putrefaction, Excluſion of the Chick; the finer Digeſtions, the making of Tinctures and Elixirs; and the Adepts have uſed it for the firſt Digeſtion of their Mercury, by carrying the including Veſſel conſtantly in their Pocket.

48.

48. (3.) The third Degree of Heat in this Progression may be that of boiling Water, when the Atmosphere is in a middle State of Rarefaction. This Degree is required in the Distillation of simple and compound Waters, the essential Oils of Vegetables, and will coagulate or consolidate the Serum, Blood, and other animal Juices, and consequently destroy animals. *The third.*

49. (4.) A fourth Degree of Heat may be that wherein Quicksilver or Oil of Vitriol boils, distils, or becomes volatile. This Degree is suited to the melting of Lead, Tin, Bismuth, *&c.* the subliming of Sal Ammoniac and Sulphur; the calcining of Antimony, *&c.* *The fourth.*

50. (5.) A fifth Degree of Heat may be that wherein Iron is kept in thin Fusion. By this Degree all the other Metals are melted, *viz.* Gold, Silver, and Copper; Glass is made, and the unvitrifiable Stones calcined. *Fifth.*

51. (6.) The sixth and highest Degree of Heat hitherto known, is that of the burning Lens, or the Concave Mirror of M. *Villette*, *Tscirnhausen*, and others. The Focus of these Glasses will even volatilize what is called the Metalline or Mercurial part of Gold, and vitrify the more terrestrial. *Sixth.*

52. And thus much for regulating the Degrees of Heat to be employed in Chemical Operations. We must next consider by what means the preceding Degrees of Heat may be excited and preserved, as Occasions require. *The Degrees of Heat, how raised and preserved.*

53. (1). The Fuel must be chosen suitable to the Intention. The natural Sun in Summer suffices for Insolations. A Spirit-Lamp may be made to give a moderate, or a considerably strong Heat, according to the number of Wicks employed; and its Strength may be easily measured and adjusted by the Thermometer.

54. (2.) The lighter Fuels, ſuch as Straw, Leaves, Twigs, &c. come next in order after Spirit of Wine. (3.) Then Oils, Wax, Roſin, Pitch, &c. And, (4.) Laſtly, ſolid Wood, Coals and Turf; all which may have their proper Furnaces, ſo as to be burnt in the requiſite Quantity and with the requiſite Fierceneſs or Slowneſs.

The greateſt Heat with Fuel. 55. To excite the greateſt Degree of Heat in a Furnace the Rule is, to uſe the denſeſt Fuel, in the largeſt Quantity, and with Bellows all round the Furnace, inceſſantly blown, and directed to the central Point of the Fire wherein the Matter to be acted upon is lodged. And in this manner may be procured a Degree of Heat ſufficient for any of the known Operations upon Metals, Minerals, Glaſs, &c. that require the ſtrongeſt culinary Fire *a)*.

V.

AXIOMS *and* CANONS, *for the better Knowledge and Regulation of Fire.*

We learn from the preceding Enquiry;

1. That the direct Senſes afford but little Information as to the real Nature and eſſential Properties, or *Form* of *Fire b)*.

2. That the *Form* of Heat and Fire is a certain bridled or reſtrained Motion, excited, maintained, and ſtruggling in the minute Parts of Bodies, and tending to throw them off at the Surface *c)*.

N. B. *If this* Form *be rightly diſcovered, then to introduce ſuch a Motion among the Parts of any* Body,

a) If more be deſired upon this extenſive Subject, the Reader may conſult the Lord *Bacon*, Dr. *Hook*, Mr. *Boyle*, Mr. *Evelyn*, Dr. *Bohn*, M. *Homberg*, Dr. *Boerhaave*, and Dr. *Stahl*.

b) See above, §. 3, 4, 5, 6, 7, 33.

c) See §. 7, 8, 9, 10, 11, 26, 27, 28, 29, 32, 33, 34.

Body will be to introduce Heat; or, if the Nature of the Body be capable of it, Ignition or Inflammation.

3. That as the direct inflammable Matter in all Fuel is the Fat or Oil it contains *a*), the most oleaginous Fuel is the best or richest.

4. That Flame is the small Parts of an inflammable or considerably unctuous Body, actually set on fire, or briskly agitated and thrown off, with a certain vibrative Motion, at the Surface of that Body, into the open Air *b*).

5. That Flame cannot exist without Oil *a*). Whence it is that Ashes, Sand, Glass, Stones, and Earths do not flame upon Ignition, but rather damp and extinguish Flame.

6. That as Oil is the only inflammable Substance in nature *a*), this may direct us to the means of preventing Conflagrations; *viz.* by using such Materials in Building as contain little or no Oil. This Direction might be likewise extended to the making of incombustible Paper for valuable Books and Manuscripts; new Materials for Hangings, Furniture, *&c.*

7. That as all Flame catches and exists only on the Surface of inflammable Bodies *c*); we are hence led to invent Methods of casing, or otherwise defending, the Wood work of Ships and Buildings from Accidents by Fire.

8. That as the three capital kinds of *Fire* have a near relation, and may be very well reduced to one, for human Uses, *viz.* the culinary kind *d*); Men may have reasonable Hopes of performing considerable things by its means in

a) See above, §. 22, 23, 24, 25, 33, 34.

b) See above, §. 26, 27, 29, 33. 34.

c) See above, §. 33. 34.

d) See above, §. 13--20, 34, 36, *&c.*

imitation of Nature; as particularly in promoting and regulating Vegetation, the Ripening of Ores, &c. by artificial Heats.

9. That Fire and Flame are aboliſhed or extinguiſhed by Suffocation, or an Action contrary to Ventilation *a)*, as being deſtructive or preventive of that internal Commotion and Diſcharge of the oily Particles of the Fuel by means of the free Air, in which the nature of open and conſuming Fire and Flame conſiſts *b)*. Hence Fire and Flame are quenched by Water, or even by Spirit of Wine or Oil of Turpentine, if a live Coal or lighted Candle be ſuddenly plunged therein below the Surface of the Liquor. For the Degree of Heat which Water, Spirit of Wine, or Oil of Turpentine unfired, are capable of receiving, being much leſs than that of a burning Coal or Candle, the greater Heat is ſubdued by the leſs; juſt as Fire is quenched by boiling Water.

10. That Heat is Fire in a leſs Degree, and Fire only a greater Degree of Heat, on which Lucidity, and, if the Matter be unctuous, Inflammability *b)*, depend: as we ſee in hammering a Piece of Iron till it becomes red-hot; and in the firing of Wind-mills, or Coach-wheels, by their own violent Motion.

11. That Heat muſt aggregate and collect in a certain Proportion before it become cognizable to the Senſes, or produce any manifeſt Effects of Fire or Flame. Thus a Degree of Heat below that of the natural human Body is inſenſible, or paſſes for a Degree of Coldneſs; and the ordinary Motion of Wind-mills, Carriages, &c.

a) See above, §. 26, 27, 29, 30, 31. See alſo *Axiom* 2 foregoing.

b) See above, *Exp.* III, IV, V, and VI.

produces

produces no remarkable Heat; tho' when the Motion is greatly increased, or the Friction considerable, it soon excites Fire and Flame *a.)*

12. That all the Chemical Operations require a certain or determinate Heat, in order to their being performed to the greatest Advantage; and that this Heat may be assigned and obtained, in every case, to the great Improvement of Chemistry *b)*.

a) See above. §. 3, 4, 5, 6, 7.
b) See above, §. 44, 45.

LEC-

LECTURE III.

CONTAINING

(1.) *The general Properties,* (2.) *Ingredients,* (3.) *Nature,* (4.) *Office and Uſe of the Atmoſphere.*

(5.) *The Changes therein;* (6.) *The Effects it produces on the Terreſtrial Globe, and* (7.) *In Chemical Operations.*

I.

The Subject. 1. WE are now to enquire into the Chemical Nature, Properties, Ingredients, Office and Uſe of the Atmoſphere.

The Atmoſphere, what. 2. By the *Atmoſphere* we underſtand that whole Maſs of rarefied Matter, or dry Fluid which ſurrounds the Globe of the Earth to a conſiderable Height.

Its Import to Chemiſtry. 3. To diſcover the Nature, or the Influences and Effects of this Fluid, is of the utmoſt Importance to Chemiſtry; it being the general Fluid wherein all Animals, Vegetables, and Minerals grow, wherein our Fires burn, and every Chemical Veſſel and Subject is included.

To be examined in three States. 4. We ſhall examine it as exiſting in three States, *viz.* (1.) As it is an intire Maſs that ſurrounds the whole Terraqueous Globe; (2.) As it conſiſts of diſſimilar Parts, whilſt it either lies open and remains one with the reſt, or elſe is ſeparated therefrom by being included in our Glaſſes or Veſſels; and (3.) As it is united with, or fixed in Bodies. And from this Examination of the Parts

Parts of this general Fluid in different places we may infer the nature of the whole.

Experiment I.

That different Effluvia mix and form Clouds, or unite in the Atmoſphere.

5. We unſtopped a Bottle of ſtrong Spirit of Sea-Salt, and another of volatile Spirit of Sal Ammoniac; and ſetting the Bottles near each other, the Vapours inſenſibly ariſing from them met, and formed themſelves into a very groſs viſible Fume or actual Cloud, that continued for ſome time, but afterwards diſappeared, or mixed more intimately with the Air of the Room. *That the Atmoſphere receives Vapours.*

6. One of the Liquors here employed is an acid Spirit, and the other an alkaline one, which being mixed form a Species of neutral Salt or Sal Ammoniac. And as their Fumes are no other than fine Parts of the Liquors themſelves, that ſtill retain their Nature, they conſtitute this Kind of neutral Salt in the Air.

7. That ſomething of the ſame kind naturally happens in the Atmoſphere appears from hence, that all Vegetables produce a kind of volatile Salt by Putrefaction; that the volatile Salts of putrefying animal Subſtances, no leſs than the former, naturally go up into the Air, which contains likewiſe ſome Proportion of Sea-Salt raiſed from the Earth and Ocean: ſo that if theſe Particles meet they will neceſſarily make a kind of Ebullition, and unite into a neutral Subſtance, in the Atmoſphere; which may hence abound with a variety of acid, alkaline, and neutral Salts, the Signs whereof are evidently diſcovered by the Changes they produce in the Colours of different Bodies.

8. This

8. This Experiment therefore may ſhew to the Eye ſomewhat of the phyſical manner wherein Clouds and Meteors are generated in the Atmoſphere, and teach us that Salts naturally abound therein: whence again we have the phyſical Reaſon of many Effects produced by the atmoſpherical Air, in the animal, vegetable, and mineral Kingdoms, and in many Chemical Operations.

9. That the Atmoſphere not only ſupports Vapours or Effluvia raiſed into it from the Earth, but alſo preſſes upon terreſtrial Bodies by its Weight, appears from many Pneumatical Experiments; of which kind we need only produce two or three for the preſent.

EXPERIMENT II.

That the Atmoſphere preſſes upon Bodies by its Weight.

The Preſſure of the Air.

10. This was made ſenſible to the Hand applied cloſe on the top of a hollow metallic Cylinder or Ring, about two Inches in Diameter, ſet upon the Air-Pump; for the Air being drawn out of the Cavity underneath, the Hand was remarkably preſſed inwards, and felt a conſiderable Weight.

11. The Effect was likewiſe ſhewn in a different manner to the Eye, by the breaking of a piece of flat Glaſs applied cloſe to the top of the ſame metallic Ring: for the Air being drawn away from below, the Glaſs was immediately cruſhed to pieces and fell inwards, with a loud Noiſe and a conſiderable Force.

The Air's Elaſticity.

12. Beſides this Weight or Preſſure the Air or Atmoſphere has likewiſe an elaſtic Force which is no leſs conſiderable; as appears by many Examples, and particularly by the following.

Experiment III.

That Air is elaſtic, or capable of forcing, diſtending, or ſqueezing Bodies by its Spring.

13. We included a little Air in a Bladder, ſo as to leave it almoſt flaccid, and tying the Neck cloſe put it into a Receiver, out of which we then exhauſted the Air (but not out of the Bladder;) whereupon the Bladder immediately ſwelled and appeared as if full blown: but upon re-admitting the external Air the Bladder was preſently ſqueez'd up, or contracted to its former Dimenſions.

14. The ſecond and third Experiment therefore ſhew that the Air or Atmoſphere, both in its natural unconfined State, and when certain Portions thereof are included in Veſſels, continually exerciſes a gravitating and an elaſtic Power, capable of producing many Effects; as continually preſſing, by its Weight and Spring, all the Bodies we know. It perpetually preſſes upon the Surface of the Earth, with a Weight equal to that of a Column of Quickſilver whoſe Baſis is that Surface, and whoſe Height is about 29 Inches; as manifeſtly appears by the Barometer.

15. Hence the Atmoſphere will inſinuate itſelf into the open Pores on the Surfaces of all Bodies, capable of receiving its component Particles. So that the Pores of many Subſtances, though to our Senſes they appear Vacuities, are full of common Air; which thus produces the proper Effects of Air, in Diſtillations and many other chemical Operations.

16. The Atmoſphere alſo, as a Fluid, muſt by the Laws of *Hydroſtatics* preſs Bodies equally every way, and the internal Air of Bodies acting within, whilſt the external Air acts without, numerous

merous phyſical Effects are hence produced in that great Laboratory, the Earth; where Bodies are by natural Powers and Agents diſſolved, putrefied, changed, and carried off into that grand Repoſitory the Air.

The Effects and compounded Nature of the Atmoſphere.

17. And tho' the Atmoſphere itſelf be inviſible, yet we cannot but be ſenſible of the Effects it produces, ſeeing they are by means of proper Contrivances and Obſervation, made perceptible even by the Senſes, as in the preceding Experiments. And thus, tho' the Atmoſphere be a rarefied and moveable Fluid, ſo that Bodies eaſily paſs thro' it, yet broad Surfaces are greatly reſiſted by it. And hence its Force, as a reſiſting Fluid, becomes manifeſt in high Winds, by driving and diſſipating the Clouds, and all kinds of Vapours and Exhalations; which are thus mixed in with the Maſs of the Air, ſo as to form a heterogeneous Fluid, or Chaos of infinite Materials.

EXPERIMENT IV.

The Conſtruction, Nature, and Uſe of the common Thermometer.

Thermometers explained.

18. (1.) The common Thermometers are Glaſs-Tubes fill'd with tinged Spirit of Wine, and graduated, ſo as to ſhew, by the riſing or falling of the Liquor, the Degrees of Heat to which it is expoſed.

19. (2.) Spirit of Wine is choſen for this Purpoſe, becauſe of all known Fluids it is the moſt rarefiable with Heat, next to the Atmoſphere itſelf. Denſer Fluids might be employed, but the Diviſions would then be leſs; and Water is unfit for this Purpoſe, as freezing with Cold.

20. (3.) Theſe Thermometers are the exacteſt Inſtruments hitherto known for meaſuring the Degrees of Heat; being filled either with Alcohol,

Brandy,

Brandy, Oil, or Quickſilver, according to the ſeveral Purpoſes for which they are deſigned *a*).

21. (4.) The common Thermometer ſhews the Warmth of the Air; and that it always contains ſome Degree of Fire or Heat, more or leſs: for Spirit of Wine has never been found to freeze or congeal with any Weather, in any Climate; but riſes and falls in the Tube as the Weather is more or leſs hot; with regard to which alſo the Atmoſphere frequently varies.

Experiment V.

To determine the Proportion of Water contained in an aſſigned Portion of the Atmoſphere.

22. Having, by means of the Air-Pump and an exact Pair of Scales, found the Weight of a certain Quantity of Air contained in a large Glaſs Veſſel, we included therein a known Weight of well dried Potential Cautery (whoſe Property is powerfully to attract the Moiſture of the Air;) and kept this Veſſel cloſe ſtopped for ſeveral Hours, during which time the Potential Cautery was grown wet: in this ſtate we weighed it again and found a conſiderable Increaſe; which muſt be owing either to the Water attracted out of the Air in the Glaſs, or to a Condenſation of the Air itſelf into an aqueous Fluid: for ſuch a Fluid might now by Diſtillation be obtained from the Matter thus run *per deliquium b*). *Water in the Air.*

23. There is ſome room to ſuſpect that, if this Experiment were made in Perfection, a Weight of Water, almoſt equal to that of the Air included in the Veſſel, might be thus obtained; which would prove a very extraordinary Diſcovery, and

a) See *Lect.* II. §. 46.

b) The Experiment was not made with all the requiſite Exactneſs.

ſhew

ſhew what ſome have endeavoured to prove, that the Matter of common Air is little more than Water *a*).

24. That much Water muſt needs be contained in the Air appears evident from the Quantity daily exhaled by the Sun, from the Ocean, the Rivers, and the whole animal, vegetable, and mineral Kingdoms. And as the Water ſo raiſed into the Atmoſphere muſt neceſſarily mix and join with the ſaline and other Particles it there meets with, and is capable of diſſolving; hence the Water of all our Springs, Rivers, and the Ocean itſelf is impregnated with numberleſs Matters, that little appear in Water. And poſſibly to give the animating or vivifying Spirit to Water, it is phyſically neceſſary that it ſhould be perpetually refined or refreſhed by this Kind of Diſtillation, or recruited and new impregnated with the Effluvia or fine Particles of all the Bodies floating in the Atmoſphere; after the ſame Manner as a ſkilful Operator, to give his diſtilled Waters the finer Impregnation, ſuſpends a proper Mixture of Ingredients in the Head of his Still.

EXPERIMENT VI.

That a Refreſhment or Renewal of Air is neceſſary to Life.

Freſh Air required in Reſpiration.

25. If Animals or Plants be long continued in the ſame cloſe, unchanged, or unrefreſhed Air, they will languiſh and expire, much after the ſame manner as Fire would do, by a Kind of Suffocation *b*).

26. Hence it appears that the Air, which has once ſerved for the Reſpiration either of an Animal or Vegetable, is unfitted for the ſame Office

a) See the Lord *Bacon*'s Natural Hiſtory of Winds, *paſſim*.
b) See *Lect.* II. §. 29. & alibi *paſſim*.

again,

again, till it be recruited, as it ſeems to be, by mixing with the open atmoſpherical Air. Every Man is computed thus to deſpoil a Gallon of Air in a Minute; whence, if the Number of Animals and Vegetables on Earth be conſider'd, it ſhould ſeem that the whole Atmoſphere muſt in time be deſpoiled, unleſs ſome natural means were uſed to prevent it. Indeed, on weighing the matter attentively, one might ſuſpect that the Particles of numberleſs Materials, fermenting * together in the Atmoſphere, produce a certain *Spirit*, or fine vivifying Subſtance, that thus renovates and invigorates the whole Maſs, and renders it again fit for Reſpiration and the Suſtentation of all natural Bodies. And hence perhaps it is that no ill Effects are uſually felt from that immenſe Quantity of groſs Smoak continually diſcharged into the Atmoſpheres of large Cities. All Bodies ſuffer a kind of Tranſmutation, and may, by the eſtabliſhed Courſe of Nature, go the ſame rounds again. And hence alſo it is no wonder that Air, when ſo richly impregnated with Water, Soot, Smoak, Salts, Oils, Kitchen-Exhalations, *&c.* ſhould prove in ſome degree nutrimental.

Experiment VII.

That looſe Air is contained in Fluids.

27. We put Water, Small-Beer, and Brandy ſeverally into an Air-Pump Receiver, and exhauſting the Air obſerved numerous Bubbles to ariſe and eſcape from each Liquor, burſting upon its Surface. *Air in liquors.*

28. And in like manner is Air diſcharged from Liquors by boiling them over the Fire: This is practiſed upon Water, in order to make it

* See *Lect.* VII. *paſſim.*

it afford Ice without Blebs or Bubbles; and again upon Oil deſigned for *Thermometers*, &c. But ſuch Liquors as have been thus diſcharged of their looſe Air, will be found to recover it again by ſtanding open; as if looſe Air were a natural Ingredient in Liquor.

EXPERIMENT VIII.

That the external Air may promote Solution.

The Air may promote Solution. 29. We ſet ſome Spirit of Sal Ammoniac and Copper-Filings *in vacuo*, and compared this with a like Parcel ſtanding for the ſame time in the open Air: that *in vacuo* had not coloured its Menſtruum, whilſt that in the open Air afforded a rich blue Tincture. Hence it appears that the free Acceſs of the external Air may promote Solution in ſome Caſes; where it ſeems to act by increaſing the Motion or Action of the Menſtruum.

EXPERIMENT IX.

That the external Air does not promote Solution in all Caſes.

Yet in ſome Caſes only. 30. Upon two Drams of whole Crab's Eyes we poured *in vacuo* two Ounces of diſtilled Vinegar, having firſt boiled it to get out the Air. A great Ebullition was immediately produced, the Gage ſunk, and Air was generated.

31. Upon comparing this with the ſame Experiment made in the open Air, we found that the Ebullition was much greater *in vacuo* than in the open Air.

32. Hence we learn that Air may be generated upon the mixture of certain Bodies, where it did not appear before.

33. But

33. But Experiments of this Kind muſt be made with Caution; the Quantity of Air thus generated in ſome Caſes being able to raiſe the Receiver, and throw it to a conſiderable Diſtance.

34. There is wanting an Account of all the Mixtures that will produce Air in ſo violent a Degree; among them may be reckon'd *Oil of Vitriol* with *Oil of Tartar per deliquium*, *Aqua-Fortis* with *Iron Filings*, *Spirit of Nitre* with *Oil of Caraway*, *&c.*

35. And thus Air may be generated betwixt Solids and Fluids, and betwixt Fluids and Fluids, by bare Mixture. The following Experiment will ſhew that Air may be extricated out of Solids, and that it makes a conſtituent Part thereof.

EXPERIMENT X.

That Air enters the Compoſition of Solid Bodies.

36. We put a Piece of hard Tallow into an Iron Retort with a long Neck; then laying the large End of the Retort in a naked Fire, the ſmall one being plunged into Water, we diſtilled in the uſual Manner, and obſerved that large Bubbles of Air continually roſe and diſcharged themſelves thro' the Water into the Air of the Room. At length ceaſing the Operation, and collecting all the viſible Matter either left behind or come over into the Water, we found a very conſiderable Loſs of Weight, owing to the Air having been ſeparated or forced by the ſtrong Heat from the reſt of the Tallow *. *Air in Solids.*

37. If it be objected that the Loſs of Weight might, in great Meaſure, be owing to the Iron of the Retort, which when hot has the Property of drinking in Oil or Tallow; it may be obſer-

* The Experiment was not made with requiſite Care and Caution.

ved (1) That the Effect is nearly the ſame when an Iron Retort is employed that has been uſed for the ſame Operation before; (2) That the Experiment anſwers pròportionably when made in Glaſs; (3) That other Bodies beſides Tallow, particularly Hartſhorn, Bone, Tartar, &c. yield plenty of Air, when treated in the ſame manner; (4) As there is ſo large a Quantity of Air-Bubbles diſcharged in the Operation, and as Air is proved to be a ponderous Body *a)*, the Loſs of Weight may be fairly attributed to the eſcape of the Air. But (5) a proper Gage may be contrived to determine the exact Proportion of the Air thus ſeparated, with reſpect to the original Matter or Subject employed *b)*.

38. This Experiment is of great Importance in Natural Philoſophy and Chemiſtry. When fully verified and duly proſecuted it may ſhew (1) that all natural Bodies conſiſt of a very large Proportion of Air, as one Part of their original Compoſition; (2) That Air is neceſſarily required to the Formation and Growth of Animals, Vegetables and Minerals; (3) That when Bodies are diſſolved or reſolved a great Part of them turns into Air again; as when a Candle is burnt or Fuel conſumed; or as when Vegetables, Animals and Minerals ferment, putrefy or corrupt; or as when Bodies are chemically analyſed or treated by Heat.

39. (4) That the Matter which in the Diſtillation of Hartſhorn, Tartar, and many other things explodes and puffs thro' the Luting, or ſometimes, when confin'd, burſts the Glaſſes or Veſſels, is the Air ſet free by the Heat.

a) See above, *Exp.* II.

b) See Mr. *Hale's Vegetable Statics*, under the Analyſis of the Air.

40. (5) That the Air thus naturally condensed, confined, and intermix'd as a conſtituent Part in Bodies, has a great Share in their Diſſolution; for being violently rarified it breaks the parts in pieces and flies off.

41. (6) But leaving the Experiment to be further verified, and made general, if capable thereof, we ſhall anticipate no more, but proceed to reap the Fruits of the preſent Enquiry.

II

AXIOMS *and* CANONS *derived from the Enquiry.*

1. We learn from the preceding Enquiry that the Atmoſphere, conſidered as a Whole, and again as conſiſting of an infinite Number of Ingredients, is the Phyſical Cauſe of numerous Effects, not only in the Air itſelf, but likewiſe upon the Surface of the Earth, in the ſubterraneous Regions, in the Exerciſe of numerous Arts, and particularly in Chemical Operations *a*).

2. That it is the phyſical Office and Uſe of the Atmoſphere to aſſiſt in raiſing the Vapours and Exhalations of the Earth *b*), and to ſerve as a general Matrix for them *c*), wherein they are all blended together and fermented, or ſome way changed in their Nature, ſo as to perform new Offices, or recruit the vegetable, animal, and mineral Kingdoms, when ſuch enriched Vapours fall back again in Rain or Dew to the Earth *d*).

3. That it is the Nature of Air to inſinuate itſelf into Fluids *e*), unite and fix in Solids, ſo as

a) See above, *Exp.* II. III. IV. V. VI. VII. VIII. IX. X.
b) See *Exp.* I.
c) See *Lect.* I §. 16.
d) See §. 25, 26. & *alibi paſſim.*
e) §. 27, 28.

naturally to make a conſtituent Part of both *a*).

4. Hence may be conceived, in general, how all the Changes happen in this great Chaos the Atmoſphere; *viz.* according as floating Particles of different Kinds chance to meet, ſo as to form conſiderable Aggregates or Collections; and according as theſe are favoured by the requiſite Degrees of Heat, Cold, Dryneſs or Moiſture. So, for example, a Cloud of nitrous Spirit meeting with a Cloud of oily Particles might ſuddenly produce Corruſcations, as in the mixing of Spirit of Nitre and an eſſential Oil *b*). And in this manner may the Generation and Phænomena of all the Meteors be chemically explained. And thus the Occurſions of various Parts of different Bodies in the Atmoſphere may be the Cauſe of the Meteors, fiery Winds, Exploſions, Thunder, Lightning, the Aurora Borealis, and other Phænomena, which we can imitate by certain Mixtures, in the way of Philoſophical Chemiſtry *c*).

5. That the Atmoſphere is an univerſal Inſtrument, in the Hands both of Nature and of Art, for producing Effects, whether on the Surface of the Globe, in the Bowels of the Earth, in the Air itſelf, in the Laboratory, or in other human Works *d*). Thus it cauſes Fire to burn, and Bellows are but Engines to convey it thereto.

6. That as Air deſcends, and acts more forcibly in the ſubterraneous Regions, on Account both of its greater Denſity there, and of the ſubterraneous

a) §. 27, 28, 36, 37, 38.

b) See *Exp.* I.

c) See Mr. *Lemery*'s Philoſophical and Chemical Explanation of Subterraneous Fires, Earthquakes, Hurricanes, Thunder and Lightning, in the *French* Memoirs, *Anno* 1700,

d) See the whole *Lecture paſſim*. See alſo *Lect.* I. *paſſim.*

Heat;

Heat; hence Vulcanos and more violent Fires may happen there than upon the Earth's Surface *a*). And poſſibly this greater Heat and Power of the Air below is neceſſary to the Production of Minerals and Metals *b*).

7. Hence we may learn the phyſical Cauſe why in the open Air diſtilled aromatick Oils loſe their native Spirit, grow thick, and terebinthinate; why Wines grow flat or loſe their Briſkneſs; why pale volatile urinous Spirits grow red; why Mineral Waters loſe their Virtue; and how Air has in all reſpects a powerful Influence upon Liquors; as being a dry Fluid in briſk Motion, whereby it eaſily lays hold of and carries off all the moſt ſubtile and volatile Parts of Fluids, leaving the groſſer behind, and thus changes the Texture, Colour, and Conſiſtence thereof *c*).

8. That the Atmoſphere is, perhaps, the moſt compounded and diſſimilar Maſs in Nature; conſiſting of an elaſtic Part, and the Vapours and Exhalations ariſing from all the ſolid and fluid Bodies of the Globe, Salts, Oils, Minerals, Metals, &c. *d*).

9. That the Air is the Cauſe of numerous Effects, ill aſcribed to other Cauſes by the ancient Chemiſts, who for want of the Air-Pump and other Contrivances, were ignorant of the genuine Properties and Effects of the Air *e*).

10. That the component Parts of the Atmoſphere are coarſer than thoſe of Fire. For the

a) See *Lect.* II.

b) See above, *Exp.* X. See alſo the *Lecture* on Metallurgy hereafter.

c) See *Exp.* I. VI. IX. & §. 18.

d) See *Exp.* I. &c.

e) See *Exp.* VIII. IX. X.

component Parts of the Atmoſphere will not paſs thro' Glaſs *a*), Stones, Metals, &c. as Fire does. Alſo Water, Lixiviums, Oils, &c. paſs where Air cannot; as we ſee in Bladders, Wet-Leather of the Air-Pump, &c. Hence the Air may be artificially excluded from many Bodies. *b*).

11. That the Atmoſphere is continually at work upon all the Bodies Subject to its Power, in the way of a Menſtruum; whence Iron ſtanding in the open Air is corroded; imperfect Glaſs diſſolved; Salts and Sugars run into Liquor; and the Bodies of Animals, Vegetables and Minerals prey'd upon *c*).

12. That there is a continual Reciprocation betwixt the Earth and the Atmoſphere; they mutually diſtilling, as it were, or throwing off Matters from one into the other. Thus the Earth, by the Sun's Heat, ſublimes ſome Parts of all things into the Atmoſphere, and the Atmoſphere again precipitates them to the Earth *d*).

13. That the different Succeſs of Chemical Operations may be greatly owing to the particular Vapours or Effluvia floating in the Laboratory where ſuch Operations are performed *e*). Thus if Salt of Tartar be run *per deliquium*, where Vinegar is diſtilling, it becomes regenerated Tartar; a thing very different from the intended Oil.

14. As Air always adheres to the Surfaces of Bodies, and as the Surfaces of Bodies are enlarged by pulverizing them *f*); when we would exclude

a) See *Exp.* II. III. VII. VIII. IX.

b) See *Exp.* II. III. VII. VIII. IX.

c) See *Exp.* I. II. V. VI. VII. VIII. IX. See alſo below, *Ax.* 20.

d) See *Exp.* I. & *Lect.* I. *paſſim.*

e) See *Exp.* I.

f) See *Exp.* II.

Air

Air in Chemical Operations, the Subject ſhould not be pulverized.

15. That the open Air has a powerful Efficacy in many Chemical Operations, eſpecially in Mixture *a*), where it often acts mechanically by its Weight and Motion; as in the mixing of Oil of Turpentine with Salt of Tartar, which does not ſucceed *in vacuo*, or in high mountainous Places.

16. That the Acceſs of Air is not neceſſary to certain Fermentations, or Ebullitions, and Solutions; ſome of them proving more violent *in vacuo*, than in the open Air *b*).

17. That no Degree of Cold, or Condenſation, has hitherto been able to deprive Air of its Fluidity, or render it conſiſtent *c*). If there were ſuch a Power exerted in Nature, it would deſtroy all Animals and Vegetables, and perhaps ſtop the Growth of Minerals *d*).

18. By comparing the preſent Enquiry with the preceding, it appears that Fire cannot ſeparate Oil from Bodies, without the Admiſſion of the free Air. Whence in the roaſting of ſulphureous Ores, or obtaining of white Aſhes from Bones or Vegetables, we are directed to uſe an open Air, as well as a naked Fire.

19. That the Air is in a Kind of perpetual Motion *e*). Whence it performs all thoſe natural Offices, that cannot be performed in a *Vacuum*. Thus leaven'd Paſte will not ferment or riſe, nor Wine work, nor Fleſh putrefy, nor Fruit corrupt, after the uſual manner, when placed *in vacuo*.

a) See *Exp.* VIII.
b) See *Exp*: IX.
c) See *Exp.* IV.
d) See *Exp.* VI. & X.
e) See *Exp.* I. & IV. See alſo *Ax.* 12. & 17.

20. That

20. That as all kinds of Particles naturally float in the Air *a*), the Air may on this Account act as an univerſal Menſtruum, and in time diſſolve any Body expoſed to its Action; becauſe, in tract of Time, the Particles capable of diſſolving it muſt neceſſarily come at it *b*).

21. That many Arts may be aſſiſted, or carried on to better Advantage in ſome places than in others, by the means of certain Particles floating in the Air of one Place more than another. Thus 'tis ſaid that the Scarlet Dye is better ſtruck at *Leyden*, than in other Places of *Holland*, where the Water and Atmoſphere are not ſo impregnated with the Effluvia, Exhalations, or fine Particles of the Dye *c*).

23. Hence alſo we are directed to chuſe proper Seats for Health, and Habitation, as well as for Operations and the Exerciſe of Arts *d*).

a) See *Exp*. I. & *alibi paſſim.*

b) See *Ax*. II.

c) See *Exp*. I. & *alibi paſſim.*

d) There are various Methods of trying the Wholeſomeneſs or Unwholeſomeneſs of Airs and Places; as by finding their Degree of Moiſture ſeveral ways; by the Changes of Colour produced in white Linen, or ſtained Paper, left out in the Air; by expoſing Copper-Plates to ſhew the Colour of the Vitriol thereby made; and many other Expedients might be contriv'd for that Purpoſe. [See Mr. *Boyle*'s Natural Hiſtory of the Air.]

LEC-

LECTURE IV.

CONTAINING

The Solid or Earthy Matters of the Terrestrial Globe classed, and examined, under (1.) Garden Earths; (2.) Bolar Earths; (3.) Saline Earths; (4.) Sulphureous Earths; (5.) Stony Earths; and, (6.) Metallic Earths.

1. WE now come to enquire into the solid or earthy Contents of the Globe; more particularly into the Parts concerned in Vegetation. *The Subject.*

2. We shall begin with the Earth's Surface, and descend down gradually, so far as Men have hitherto dug.

3. The Earth's Surface is generally found covered with Verdure, or a Vegetable Coat, and in some Places with Sand, Dust, or Mud. *The Upper Coat of the Earth.*

4. Under this superficial Coat there usually lies a Bed of Mould, or Underturf-Earth, of different Depths, from one Foot to two, three, or more, in different Places. (1.) This Mould, or Underturf-Earth, is the proper Matrix of Vegetables, and will come to be first examined in Order.

5. We shall next proceed to the other Species of Earths that lie below, *viz.* (2.) the Bolar; (3.) the Saline; (4.) the Sulphureous; (5.) the Stony; and (6) the Metallic. For under these *The Species of Earths.*

six

ſix general Claſſes, we apprehend, may all the earthy or ſolid Matters of the Globe be ranged.

6. It will therefore be our Endeavour to give a general Example of the Method of treating every Species, ſo as to diſcover their Natures, Offices, and Uſes.

EXPERIMENT I.

The farther Analyſis of Garden-Mould or Underturf-Earth by Water a).

Mould analyſed by Water. 7. (1.) We took four Pounds of freſh, black and crumbly Garden-Mould, that was eſteemed the beſt ſort, and had lain, for a Year, expoſed to the Atmoſphere, without being exhauſted in Vegetation.

(2.) This Mould we elixated in fair and freſh boiling Water, till all that was capable of diſſolving therein was got out or extracted by the Water.

(3.) Having thus obtained a Lixivium or Solution of our Subject, we filtred it thro' thick doubled Paper, in order to have it tranſparent, and at leaſt free from any groſs terreſtrial Parts, that might otherwiſe lodge therein.

(4.) This Solution, therefore, contains all the Parts of the Subject that are ſoluble in boiling Water *b*).

(5.) To bring theſe Parts nearer together, that they might manifeſt themſelves to the Senſes, and particularly to the Taſte, we exhaled away the more aqueous Fluid in the Form of Vapour.

(6.) Then comparing the concentrated Solution, with a Portion of the former that re-

a) See *Lect.* I. *Exp.* I.
b) See *Lect.* I. *Exp.* I.

mained

mained unevaporated, we found it taſte manifeſtly ſtronger or more ſaline.

(7.) To gain a fuller Information, we evaporated a Portion ſtill higher, and ſet it to cryſtallize, if any Salt would ſhoot *a*).

(8.) To a Part of the filtred Solution we added Syrup of Violets, *&c.* to diſcover whether the Solution was acid, alkaline, or neutral; and found it rather the latter *b*).

(9.) We waſhed the remaining terreſtrial Matter in ſeveral Waters, every time decanting the upper muddy Liquor, after a little ſtanding, in order to procure the pure Sand contained in the Mould; and found the Sand to be a large Proportion of the whole.

8. This Experiment, or rather Combination of Experiments, ſhews us a Method of reſolving the matrix Earth of Vegetables into the conſtituent Parts thereof, without altering their natural Form and Properties. Whence it ſhould ſeem that a true Judgment might be formed of Moulds, both in general and particular, ſo far as this Information reaches, and a Rule be obtained for their artificial Mixture or Compoſition. Thus we find the Mould under Examination contains a certain Proportion of fine Earth, capable of being ſuſpended in Water; much more of a groſſer heavier Part that readily ſinks in Water; perhaps a little neutral Salt; and a large Proportion of Sand. Hence if this Mould had come from the Iſland *Ceylon*, for inſtance, having there ſerved for the Growth of Cinamon, we might be directed by this Analyſis to make or mix up a Mould that ſhould reſemble it, with a View to produce Cinamon

a) The Succeſs was not carefully noted.

b) See the Method of examining *Mineral Waters*, in the following *Lecture*.

in

in *England*. But to make the Experiment ſucceſsful, no leſs Regard muſt be had to the State and Ingredients of the Atmoſphere, than to the State and Ingredients of the Soil *a*).

9. To render the preſent Experiment more inſtructive and uſeful, for diſcovering the Principle of Vegetation, and the Nature of Earths and Plants, it were proper to compare it with a ſimilar Analyſis of certain vegetable Subjects. Thus by bruiſing a tender Plant, elixating all its ſoluble Parts with warm Water, exhaling the ſuperfluous Moiſture, and ſetting the Remainder to cryſtallize, we obtain the native ſaline part of the Plant, in the form of a ſolid Salt, which appears either of the tartareous or nitrous kind, according to the Nature of the Plant *b*).

10. Tho' any alkaline Plant, as Creſſes, were watered in its Growth with a Solution of Nitre, which upon Diſtillation affords much acid Spirit, the Plant would ſtill prove alkaline: and the ſame holds of every Plant and Salt hitherto tried *c*). Whence there appears to be in Plants a Power of changing any other Salt into their own. And hence we find, upon Experience, that Compoſts abounding in Sea-Salt, Nitre, or urinous Salts, all agree to promote Vegetation.

11. But as there may be certain more fixed Parts naturally contained in Mould, than will diſſolve in boiling Water; and as theſe Parts may poſſibly be looſened, digeſted, and rendered capable of aſcending into Vegetables, by the

a) See *Lect*. III.

b) See M. *Homberg* on the Nature of Vegetable Salts. *Memoir. de l'Acad. An.* 1699.

c) I could wiſh the Experiment were tried with Sugar, Alum, Pot-Aſh, &c. both in Alkaline and acid Vegetables. But Care ſhould be taken not to uſe too much of the Salts, which in that Caſe would deſtroy the Nature of the Mould.

long-

long-continued Action of the Sun and Atmosphere; it may be proper to try a more powerful Analysis of the same Subject.

Experiment II.

The Analysis of Garden Mould by Fire.

12. Having weighed two Pounds of the same kind of Virgin-Mould as was used in the preceding Experiment, we put it into an earthen Retort, and committed it to a naked Fire, working by slow Degrees of Heat into a Glass-Receiver; and at last keeping the Retort ignited for some time. There came over (1.) a Water; (2.) an Oil; and (3.) a volatile Spirit almost like Spirit of Hartshorn, or as if the Subject had been animal *; and (4.) there remained behind a dry *Caput mortuum*, or apparently fixed and inert Earth. *By Fire.*

13. We elixated Part of the *Caput mortuum*, and then dried it; by Triture we reduced another Part into one similar, homogeneous Powder; with a design to put each Parcel into a separate Pot, and expose them to the open Air, for a Year, to try whether they would then prove fertile.

14. It appears by this Experiment, that our Garden-Mould was of a Vegetable or Animal Nature, in respect of the Salts or Juices it contained; and only Mineral, with regard to its fixed Matter. In both which respects it greatly resembles the natural Composition of Animals and Vegetables. And hence we see the physical Reason, why animal and vegetable Substances

* If it be supposed, that the Compost, which might have been used to this Mould, was not sufficiently rotted or changed, so as still to retain its own vegetable or animal Nature; let the Experiment be repeated with Earth, which has been known to have lain several Years fallow.

are

are proper Composts for Land. If we were to enquire how Mould comes to be of this Nature, it might in good Measure appear from our former Doctrine of the natural Contents of the Atmosphere; which being animal and vegetable, as well as mineral, continually fall upon the Surface of the Earth. And hence Gardeners find a manifest Difference between the Soil of *London* and that of open Country Places, on Account of the Quantity of Smoke daily precipitated out of the Air upon the Gardens of *London*. And the like is to be understood of other Cities and Countries respectively.

15. By comparing the present Process with the same performed upon a vegetable, an animal, and a mineral Substance; it appears that one simple *fixed Earth* is the Basis of all animal, vegetable, mineral, and earthy Matters; or the true *Stamen*, Support, and Skeleton of Flesh, Bone, Wood, Metals, and Earths, &c. being in itself of a fixed unalterable Nature.

16. We next proceed to *Bolar Earths*, which seem divisible into two Species, according as they are more or less tenacious; in which view *Loam* and *Clay* may represent them all. And even these two seem only to differ in respect of the Fineness or Coarseness of their component Parts, which renders them more or less tenacious, clinging, or adhesive.

EXPERIMENT III.

That Fineness of Parts in Earths may give Cohesion, Strength, and Solidity.

Loam made into Clay.

17. (1.) We mixed common Loam into a Mass with Water, and then dry'd it; to shew that, compared with Clay, it would easily break, crumble, and fall into Powder. But (2.) beating some

ſome Loam fine in a Mortar, and mixing it well with Water, it clung like Clay; and when dry'd, adhered much more tenaciouſly than before.

18. This Experiment not only ſhews that Loam and Clay, or all the Bolar Earths, are nearly the ſame thing, when their component Parts, or gravelly and ſandy Matters, are reduced to the ſame Degree of Fineneſs; but alſo ſupplies us with a Rule for the Improvement of Pottery, and the Imitation of *China* Ware. This Rule is to grind, or beat, the Earths employed, to an extreme Degree of Fineneſs: and accordingly Porcellane has been imitated in *Europe*, by Tobacco Pipe Clay and other Earths exceedingly fine ground, mixed into a Paſte with Water, and properly dried or baked. *Pottery hence improveable.*

19. The ſame Experiment may likewiſe inform us how Rocks are often produced, of different Degrees of Hardneſs, according to the different Fineneſs of the terreſtrial Particles depoſited upon any Eminence, or Declivity, as waſhed down by the Waters. *Farther Uſes of the Experiment.*

20. We recommend it to future Examination how far this mechanical Tenuity of Parts may reach, in cauſing Strength and Hardneſs in Bodies: and whether thoſe two Properties are not different in Glaſs, Cryſtal, Diamonds, &c. on Account of the different Fineneſs of their Parts. *.

21. Under this Tribe of Bolar Earths we rank all the hungry Garden-Earths, all the ſandy Field-Earths, all the Clay or Marly Earths, and all the Mixtures thereof. *Bolar Earths what.*

22. We next proceed to Saline Earths; by which are meant all thoſe wherein any Quantity of Acid, Alkaline, or Neutral Salt is evidently contained. *Saline Earths.*

* See Mr. *Boyle* on Gems.

23. If ſtrict Examination were made, perhaps no Earth would be found without ſome Proportion of Salt; which has pretty generally been thought the Principle that holds all Earths together. And there appears ſome Reaſon for the Opinion, as we endeavoured to ſhew by the following Experiment.

EXPERIMENT IV.

That a Saline Matter may give Tenacity and Firmneſs to Earth.

Quick-lime deprived of its Salt.

24. (1.) We ſlaked Quick-lime with a ſufficient Quantity of Water to bring it into a Kind of Paſte; (2.) Then ſuffered the ſuperfluous Moiſture to exhale gradually: Upon which, (3.) the Lime acquired a ſtony Hardneſs. (4.) We next poured a much larger Quantity of Water upon another Parcel of Quick-lime, than ſufficed to make it into a Paſte; then decanted the Water, which taſted manifeſtly ſaline. (5.) We afterwards elixated the remaining Matter with ſeveral Parcels of freſh Water, to get out all the Salt of the Lime; (6.) And now drying the Calx thus deprived of its Salt, we found it would not hold firmly together, but remained quite crumbly or duſty.

Uſes of the Experiment.

25. This Experiment ſhews us the Nature and Compoſition of Lime, which, mixed with Sand, makes the common Mortar uſed in Building. We ſee it is the Alkaline Salt contained in the Lime, and either extricated or produced in calcining the Lime-ſtone, that occaſions the Mortar to concrete and harden, And where the Salt is in its full Proportion, the Lime is ſtrongeſt, and the Mortar hardeſt and moſt durable. This ſaline Principle in Lime is alſo that which gives it the Advantage over Chalk, as a Compoſt for Grounds,

Grounds exhausted or drained of their natural Salt in Vegetation. For the Alkaline Salt of the Lime, by strongly attracting the Moisture of the Atmosphere, and other Particles that float therein, swells, dilates, crumbles, and opens the Earth with which it is mixed; whence the Atmosphere has the freer Action thereon, and in the mean Time the Alkaline Salt of the Lime becomes of a neutral, or nitrous fertilizing Nature.

26. Under the general Head of Saline Earths may be reckoned all those that are calcined or burnt in the Fire; as all the Kinds of Lime, Potash, Salt of Tartar, Soot, *&c.* these being but Mixtures of Salt and Earth: and to say the Truth, all Salts appear upon a rigorous Examination to be no other than Earths of different Natures; which, when reduced to a certain Degree of Subtility or Fineness of Parts, so as permanently to dissolve in Water, are then emphatically denominated Salts. *The Class of Saline Earths.*

27. The following Experiment regards the Sulphureous Earths, under which we reckon all those that will flame in the Fire; as Coal, Bitumen, Sulphur, certain crude Ores, Marcasites, *&c.* *Sulphureous Earth.*

28. By Marcasites we understand all those Mineral, Earthy and Sulphureous Matters, that are otherwise called *Pyrites*, Fire-Stones, Brass-lumps, Mundicks, or the like. For tho' these may be distinguished in respect of lesser Differences, yet in general they are all a Composition of Sulphur, un-inflammable Earth, and a small Proportion of Metal. *Marcasites what.*

EXPERIMENT V.

The Analysis of sulphureous Earths by an Example in Mundick.

Mundick analysed. 29. We took half a Pound of Mundick reduced to fine Powder, and put it into an earthen Retort, which being placed in a naked Fire, we fitted on a capacious Glass-Receiver, and luteing the Juncture well with a Mixture of Loam and Horse dung, we gave Degrees of Fire up to the strongest; then letting all cool and taking off, we found a small Proportion of an acid Liquor, exactly like the Spirit of Sulphur, made by the Bell, at the Bottom of the Receiver, and a considerable Quantity of Flowers of Sulphur sublimed to the Top.

30. The *Caput mortuum* being taken out, and flux'd with half its Weight of clean Iron Filings, afforded a little Lump of a Metallic Substance, or *Regulus*.

Uses of the Experiment. 31. Hence we see that Marcasites chiefly resolve into Sulphur, and a more fixed earthy Part, which being treated as an Ore yields a Proportion of Metal. And hence perhaps all the Pyrites, Brass-Lumps, Marcasites and Mundicks are but cruder Kinds of Ore, and if they could be brought to full Maturity, would prove real Ores.

Marcasites firing. 32. These Marcasites, upon long lying in the open Air, attract the Moisture thereof, thence grow hot, in some Measure dissolve, form an Efflorescence on their Surface, and by Degrees turn into a Vitriol, of the same Kind with the Metal they contain Thus if that Metal were Iron, the Vitriol becomes green or martial; if Copper, blue or cupreous. And on this is founded

founded the Artificial Method of making Vitriol, now practiſed in ſeveral Parts of *England*.

33. And from the heating, fuming, and firing of theſe Sulphureous Earths, by the Moiſture of the Air, we may perhaps learn the Origin of Hot Baths, Mineral Waters, Damps and Fires in Mines. For it is found, that a Pile of theſe Sulphureous Earths, being barely moiſtened, will at firſt ſmoke, and at length take Fire, and burn like glowing Coals *a*). *Whence Hot Baths, Damps and Fires in Mines, &c.*

34. Our preſent Experiment likewiſe ſhews us a Way of examining theſe Marcaſites, and of extracting the Metal they may hold, after having firſt ſeparated their Sulphur. Many ſkilful Metalliſts have been impoſed upon by the ſpecious Shew of theſe Marcaſites; for they uſually have a great ſpecific Gravity, and ſome of them a greater than real Ores: whence again they may poſſibly contain the Matter of Metals, tho' in a crude, imperfect, or unfixed State. But to bring this Matter to the Teſt, and to try the Validity thereof, requires more than a common Knowledge in Metallurgy *b*). *How examined for their Metal.*

Our next Species of Earths is the Stony. *Stony Earths.*

EXPERIMENT VI.

That Ignition may deſtroy the Tenacity or Coheſion of Stony Earths, ſhewn in Alabaſter.

35. (1.) We reduced two Pounds of Alabaſter to fine Powder; then put it into a flat Iron Pan, *Alabaſter calcin'd.*

a) See Dr. *Power*'s Experiments, *page* 63.

b) A ſmall Proportion of Silver has been obtained from certain Kinds of Mundick, after the Mundick had been fluxed with Iron Filings, and brought to a Regulus.

and apply'd a ſoft Heat, that the Matter might not glow, yet remain too hot to be touch'd. The Powder was thus brought to flow or run like Quickſilver, and being gently ſtirred, to boil and bubble. We let it continue thus, with a ſoft Heat, till it would run off a Spatula held almoſt horizontal; then removing it from the Fire, it grew cold, and was put into a Glaſs, kept cloſe ſtopped and ſet in a dry Place, under the Name of *Gypſum*, or calcin'd Alabaſter.

(2.) A Parcel of the *Gypſum* thus prepared being brought into a pappy Conſiſtence with Water, the humid Maſs became ſo hard and rigid, in a Quarter of an Hour, as to ring, or afford a clear Sound, when ſtruck with the Finger, or any more ſolid Inſtrument.

(3.) But a Parcel of the ſame Powder being kept in a State of Ignition for ſome time, before it was taken out of the calcining Pan, and then mixed with Water, acquired only a looſe, friable Conſiſtence, or a much leſs Degree of Hardneſs and Tenacity than the other. The un-ignited Sort alſo, by being kept in the open Air, loſes of its coagulating Virtue; and when once conſolidated with Water, becomes unfit for the like Purpoſe again.

Uſes of the Experiment.

36. Thus all the Stony Earths that do not vitrify in the Fire, are by Ignition reduced to fine Powder. So may Flints themſelves, by being often ignited and quenched in Water. And thus white Marble or Cryſtal is reduced to a Powder, fit for the making of pure white Glaſs.

37. This Experiment alſo ſhews us an earthy Matter, apparently fluid over the Fire, that will harden in Water, and ſerves to direct a farther Enquiry after cheap Bodies, that will grow ſtill harder under Water; which might be of

Service

Service in Bridge-works, Water-works, and the like *a*).

38. The preſent Uſe of the Preparation is ſufficiently known, for taking off Faces, Impreſſions and Figures, and the ſtopping of leaky Pipes, or Veſſels that tranſmit or contain Water.

39. The ſixth Claſs is that of *Metallic Earths*: For there are ſome Reaſons to judge, that even Metals themſelves are but a Species of Earths *b*), as they both burn into Aſhes, and melt into Glaſs; whilſt their metallic ductile Form ſeems owing to nothing more than a certain Proportion of Sulphur or Oil contained in them; which being burnt out, leaves them terreſtrial Calces, or certain Metallic Earths, of a nature peculiar to each Metal *c*). *Metallic Earths.*

40. And thus we may divide Earths into two general Tribes, *viz.* the *Brittle* or *Friable*, and the *Ductile* or *Malleable*. We have gone thro' the Friable Species; and ſhall proſecute the Ductile hereafter, in our Lectures upon *Mineralogy* and *Metallurgy*. *Earths reduced to two general Kinds.*

Axioms *and* Canons.

1. We learn from the foregoing Enquiries, that the Atmoſphere, with its Contents, is a chief Inſtrument in promoting the Fertilization of the Earth, whereby all Vegetables, and thence all Animals are fed, ſupported and maintained *d*); that this Mould may in ſome Meaſure be ſup-

LECTURE V.

CONTAINING

A Natural and Chemical Examination of Waters.

1. OUR present Busineſs is the Chemical Examination of Waters; with a view to manifeſt their Natures, their Uſes to the Earth, and all vegetable, animal, and mineral Subſtances; but particularly to Man, ſo far as we can diſcover them. *The Subject.*

2. By the general Name of Water we underſtand an extremely fluid, limpid, inſipid, and inodorous Liquor. This Definition is obvious, and taken from the direct Teſtimony of the Senſes; but by enquiring philoſophically into the Nature of Water, we ſhall find it poſſeſſed of many unexpected Properties. *Water defined.*

EXPERIMENT I.

That Water is contained in many ſolid and, to appearance, dry Bodies.

3. We took a Piece of the hardeſt and dryeſt Bone we could procure, and diſtilling it in an Earthen Retort with Degrees of Fire, obtained a very large Proportion of Water, along with much Oil, and volatile Salt *. *Found in dry Bones.*

* See this Experiment farther proſecuted in *Lect.* VIII. *Exp.* II.

4. This

4. This Experiment holds true even of the oldeſt Hartſhorn, the dryeſt and hardeſt Woods, Earths, and pulverized Stones. Whence it appears, that Water may lie concealed in ſolid Bodies, and make a conſtituent Part thereof; as we formerly ſhew'd of Air *a)*. For we do not here mean that Water inſinuates itſelf into the ſuperficial Pores of Bodies, as Wood, Skins, Leather, Parchment, Strings, *&c.* ſo as to ſwell them in moiſt Weather, and leave them ſhrunk in dry; but that it remains permanently intermixed as an eſſential Ingredient, or Part of ſolid Bodies, as in Stone, or Brick after baking, *&c.* Of this we gave an eminent Inſtance in our laſt Lecture *b)*, where we ſhew'd that *Gypſum*, with Water, preſently concreted to a ſtony Hardneſs.

5. If any doubt ſhould ariſe, whether the Liquor obtained from the Bone in our Experiment be truly aqueous, we might ſhew it to Satisfaction, by ſeparating the Oil, and turning all the volatile Salt contained therein to Sal-Ammoniac, by Means of a ſufficient Quantity of Spirit of Sea-Salt; then rectifying the Liquor by repeated Diſtillation, and bringing it over in Form of a pellucid, inſipid, and inodorous Fluid *c)*.

6. It

a) Lect. III. *Exp.* X.

b) Exp. VI.

c) To purify this Liquor abſolutely, is a very laborious Taſk; but as ſome of the firſt Drops come over limpid, and almoſt inſipid, before the Oil and Salt begin to riſe, this may afford a ſtrong Suſpicion that the ſucceeding Drops are alſo aqueous, only mix'd with Oil and volatile Salt. For tho' the Bone were ever ſo thoroughly dried by the Fire, and the Veſſels employ'd ever ſo free from Moiſture, a large Proportion of the aqueous Liquor would ſtill be obtained. Beſides, the foul and fetid Liquor has been ſo far cleared from the volatile Salt and Oil, as to appear limpid, and prove inſipid, and

6. It is therefore certain, that all Vegetables, and even the moſt ſolid Parts of Animals, naturally contain a large Proportion of aqueous Fluid, or actual Water, in their Compoſition; and that it remains in them unaltered in its own Nature, ſo as, when ſet free, to reſume the Form of Water, after having been detained, or circulated therein for numbers of Years. Whence it ſhould ſeem, that Water paſſes thro' all Natural Bodies, unchanged either by Accretion, Growth, Appoſition, Fermentation, Putrefaction, Digeſtion, Diſtillation, *&c.* being chemically recoverable again from Vegetables and Animals, Wines, Vinegars, and Spirits.

EXPERIMENT II.

That Water may be collected from the dryeſt Air, or in the hotteſt Climate.

7. (1.) We put half a Pint of common Water into a cylindrical Glaſs, wiped perfectly dry on the Outſide; then added to the Water, two Ounces and three Quarters of pulverized and dry Sal-Ammoniac. We now ſtirr'd them briſkly together; whereupon the Water floating in the external Air was, by the Coldneſs thus produced as the Salt diſſolved within, condenſed on the Outſide of the Glaſs, and trickled down in ſmall Veins into the ſhallow Baſon ſet underneath to receive it. *In the dryeſt Air.*

and inodorous. And as it approached nearer to common Water, after every Rectification, there is no doubt but, if a ſufficient Quantity were procured, it might by Degrees be brought exactly to reſemble common Water, diſtilled and treated in the ſame Manner. But the eaſieſt Way is to impregnate common Water with the Oil and Salt of the Bone; ſo as to make it reſemble the Mixture that comes from the Bone into the Receiver upon Diſtillation. See more to this Purpoſe in *Lect.* VIII. *Exp.* I. § 14.

The Experiment extended and applied.

1. This Experiment holds in all Climates and Places, of whatever Heights, where it has been tried. Whence, by the Law of Induction, we may make it univerſal, till any contradictory Inſtance appears. Thus therefore it may hold in the moſt parched Countries and hotteſt Seaſons, ſo as to afford an agreeable Method of cooling potable Liquors, and rendering them more refreſhing. For if the Glaſs containing the Salt and Water be ſet in any Liquor, the Liquor will become cooler as the Salt diſſolves. And if any conſiderable Improvement could be made in the Contrivance, it might ſerve in ſome Meaſure to ſupply the thirſty Traveller in parched Deſarts, and Sailors with freſh Water at Sea: nay, it has been a Practice among the latter to hang out Fleeces of Wool on the Sides of the Ship over Night, and to ſqueeze freſh Water out of them in the Morning.

9. The ſame Experiment, being carried higher, affords us a Method of procuring a Degree of freezing Cold, in the hotteſt Countries, at all Seaſons of the Year. For if a Quantity of dry and pulverized Sal-Ammoniac be ſeparately included in one well-cloſed Glaſs, and a proper Quantity of common Water in another, and if both theſe Glaſſes be put into the firſt Solution, whilſt the Salt is diſſolving, both the confined Salt and Water will ſoon acquire the ſame Degree of Coldneſs as the firſt Solution; and being then taken out, and mixed together, they will form a ſecond Solution much colder than the firſt. And thus by repeating the Experiment twice or thrice, with freſh Salt and Water, a Degree of freezing Cold may be ſoon obtained in the hotteſt Climate.

EXPERI-

Experiment III.
That an Earthy Substance is naturally contained in Water.

10. (1.) We filled three ſeveral Glaſſes with pure Rain Water, Spring-Water, and *Thames*-Water, and let them ſtand cloſe covered for ſome Days before they were exhibited: there was an earthy Sediment then depoſited in all three, but moſt in the *Thames*-Water, the Sediment whereof was not only larger, but alſo more foul and muddy than in the Rain-Water; tho' here alſo it was dirty, perhaps becauſe not carefully collected: whereas in the Pump-Water, it was white, ſcaly, flaky, and ſhining, like fine Spangles of Talc. *Water contains Earth.*

11. This Experiment alſo is univerſal, ſo far as it has been tried with Care, and holds true of the Waters of all Species, and all Countries; particularly in thoſe called Mineral Waters, from which an earthy Subſtance may uſually be precipitated by Art, in a conſiderable Proportion: For Example, by the bare Addition of Salt of Tartar.

12. Certain Experiments carefully made, and repeated, ſhew that the terreſtrial Matter naturally contained in Water, has a principal Share in the Growth and Increaſe of Vegetables; all the Plants that thrive in Water, appearing to enlarge their Bulk in Proportion to the earthy Matter furniſhed by the Water. Whence pure Elementary Water ſeems but a Kind of Vehicle to convey this nutrimental or ſubſtantial Part, and depoſite it in the Veſſels through which the Water moves, in order to its general Exit at the Surface of Vegetables *. Yet we are not here

* See Dr. *Woodward*'s Experiments to this Purpoſe, in the *Philoſophical Tranſactions*.

to

to exclude the Inftrumental Efficacy of the two other Elements, Fire and Air. Now this appearing to be the general Office of Water, in the whole Vegetable and Animal Kingdoms, *viz.* the Conveyance or Diftribution of the alimentary Matter to all their Parts, it may be proper to confider its Phyfical Properties, which wonderfully fit it for this Office.

Office and Ufe of Water.

Its Properties.

13. The Figure of its component Parts appears to be fmooth and fpherical, like thofe of Quickfilver, whence it becomes extremely moveable and penetrating. Thus it readily enters the Pores of Wood, Leather, Skins, Chords, Mufical Strings, &c. and thus it likewife becomes capable of moving and agitating Particles of Matter lefs active than itfelf, and fo proves the more immediate Phyfical Agent of Fermentation, Putrefaction, Solution, &c. And thus it alfo conveys earthy and faline Matters thro' our Filtres of Paper, Stone, &c. and even raifes fome Proportion of them in Diftillations.

14. Its Particles likewife appear to be extremely minute, and fo to have a large Share of Surface. Hence Water is admirably fitted for a Solvent, or for readily entring the Pores of Salts, and coming into full Contact with all their Particles. And thus it will pafs, where Air cannot, on Account of its Moifture, or lubricating Power, whereby it foftens mucilaginous Matters, and will therefore foak thro' the clofe Pores of a Bladder. And being thus qualified, it feems extremely well fitted to enter or flide thro' the fine Canals and Veffels of Plants; fo as to convey nutritious, faline, or earthy Particles along with itfelf; and having depofited them by the Way, and being now robbed of all that is ufeful to the Individuals, it at length perfpires into the open Atmofphere, in order to be there recruited and fitted

fitted for fresh Service. And the same kind of Office it performs in Animal Bodies.

15. Hence we may learn the physical Reason why River-water is more fertilizing than Rain, *viz.* because it contains more earthy Matter; and why such Meadow and Pasture Lands, as lie commodious to be overflowed by muddy Rivers, yield greater Crops than such as are watered by other Means. Hence the incredible Fertility of *Egypt* appears to proceed from the turbid Overflowing of the *Nile*, and the same is to be understood, in some Degree, of other Rivers, as the *Ganges*, the *Thames*, &c *a*). *That of Rivers why most fertilizing.*

Experiment IV.

That Water saturated with one Body will still dissolve another.

16. (1.) We took four Ounces of pure cold Rain-water, and dissolved therein as much dry common Salt, reduced to Powder, as it would take up. The Salt used being Part of a known Quantity, we weighed the Remainder, to find precisely how much had been employ'd, and found it about an Ounce; which therefore gave the Measure of the Power that the Water had to dissolve common Salt, with the Degree of Heat then present in the Atmosphere. To this saturated Solution of Sea-Salt we added about two Scruples of dry pulverized Nitre, and found that it dissolved therein, tho' no more common Salt could be taken up by the Water. *The dissolving Power of Water.*

17. This Experiment is only particular; for the dissolving Power of Water is different on

a) See *Boyle*'s Abridgment. Vol. I. *pag.* 248. *&c.* and *Lowthorp*'s Abridgment of the Philosophical Transactions, Vol. II. *pag.* 725. *&c.*

different Subjects *a)*. Whence a Set of Experiments ſhould be made, to ſhew this Power on all the Salts, and other Subjects, whether mucilaginous, gummy, earthy or others, that are capable of diſſolving in Water. Such a Set of Experiments might prove of conſiderable Uſe in phyſical and chemical Enquiries, and help to rectify the Mind, which is extremely apt to form general Rules from a few particular Inſtances. Whence Water has often paſſed for a Kind of univerſal Solvent; tho' there are numerous Bodies which it will not diſſolve *b)*. And from this erroneous Notion of a general diſſolving Power in Water, the Enquiry into Mineral Waters has been in great Meaſure either ſtopped, or perverted *c)*.

18. The limited Power which Water has, of diſſolving common Salt, appears remarkably in the Ocean; which we ſee, by our Experiment, may naturally contain about one fourth Part of ſuch Salt; or, with an additional Heat, conſiderably more; tho' its Charge is always limited by the Nature of the Thing, and cannot be above one certain Proportion. This, however, is found to differ in different Seas, or Bays; the Water of ſome being found to yield more Salt than others, according to the greater Heat or Exhalation of Vapor in thoſe Seas or Bays; or again, perhaps, according to the Opportunity which the Water has had of running upon a more ſaline Bottom *&c.*

19. But when Water has diſſolved its full Proportion of common Salt, we ſee, by the

a) As will appear hereafter. *Lect.* VI. *Exp.* I.

b) As Stones, Metals, Glaſs, Gems, Amber, Shells, Coral, Sponge, Cloth, *&c.* See hereafter *Lect.* VI. §. 15.

c) See the *Appendix* to *New Experiments and Obſervations* upon *Mineral Waters*, lately publiſhed.

Experi-

Experiment, that it may ſtill diſſolve ſome Quantity of another Salt. And how far this Power may extend, as to the Matters at the ſame time diſſolvable in Water, has not been hitherto ſufficiently aſcertained *a)*.

20. Nor is the Method, wherein different Salts range themſelves in the ſame Water, preciſely determined. That they do not intermix, ſo as inextricably to entangle and confound their Particles among one another, appears from Cryſtallization. For if ſeveral different Salts be diſſolved together in the ſame Parcel of Water, they may be made to ſhoot ſeparately out of it again, by repeated Evaporation and Cryſtallization, each in its own natural Form and Figure, or pure and unmixed with the reſt. But the Power of Water as a Solvent will again come to be conſidered in our next *Lecture upon Menſtruums b)*.

Experiment V.

The natural Ingredients or different component Parts of Water.

21. (1.) We took a Pint of the pureſt Rain Water, decanted from its natural Sediment, and put it into a bellied Glaſs, with a long ſlender Stem; then marked the Part of the Stem to which the Water roſe, and ſet it in the exhauſted Receiver, where we found it manifeſtly expanded, and diſcharged many Bubbles of Air. (2.) We put the ſame Water into a clean Glaſs Retort, and diſtilling with a gentle Heat into a Glaſs-Receiver, there came over a pure light Water, or merely aqueous Liquor; leaving a *The Contents of Water.*

a) See Dr. *Grew* and Mr. *Boyle paſſim.*

b) See *Lect.* VI. *Exp.* I.

 ſmall

ſmall Quantity of dry and whitiſh terreſtrial Matter behind.

22. This Experiment requires a farther, and much more exact Proſecution. We ſee it reſolves Water into three diſtinct, and, to appearance, different Parts; *viz.* (1.) Air, (2.) elementary Water, and (3.) Earth. The Truth of this Analyſis ſeems confirmed by other Experiments. For Water, by boiling, is alſo deprived of the Air it naturally contains. And ſo it likewiſe is by ſtrong Freezing, the Ice becoming gradually leſs porous, and more purged of its Air-Bubbles; alſo Water upon thawing always leaves a Quantity of earthy Sediment behind. But neither this Experiment of Freezing and Thawing, nor the Re-diſtillation of Water, has been carried ſo far as to ſhew, with Certainty, whether any, and what Proportion of the Water is thus actually convertible into Earth; or whether a Quantity of earthy Matter, before diſſolved or finely diſperſed in the Water, is thus only aggregated, or collected together and left behind, in a dry, ſolid, or earthy Form, upon Evaporation.

23. The Determination of this Point is of Conſequence to Phyſicks. The Circumſtances that tend to invalidate the Experiment by Diſtillation are, (1.) That the Water ſuffers a great Diminution of its Quantity in the Operation; ſome Part ſticking to the Sides of the Veſſels employed every Time, and ſome tranſuding thro' the Luting: whence the Account is defrauded. And (2.) that in tranſvaſing the Liquor, it every Time licks up the Duſt naturally contained in the Atmoſphere, and at the ſame Time loſes Particles of Water, which are thus carried off by the Air; whence, upon numerous Repetitions of the Experiment, a large Proportion of the Earth obtained

tained may proceed from the Duſt of the Atmoſphere *a)*.

24. The Experiment by Congelation ſeems attended with fewer Difficulties, and might perhaps be brought to determine the Point with leſs Exception, by uſing a Circle of Freezings and Thawings, alternately repeated, with Care to ſeparate the Earth each Time.

25. What we here term Elementary Water, is the pure aqueous Part which comes over in Diſtillation, commonly called by the Name of diſtilled Water. This diſtilled Water is found to be lighter and purer than the natural; provided it acquire no Foulneſs, or heterogenous Parts in the Operation. And it is obſervable that, if the Operation be ſtopped in the Middle, a groſſer Water remains behind than what came over. Whence, for all curious chemical and œconomical Uſes, the Water employed ſhould not boil too long; as particularly in the making of Tinctures, Tea, Coffee, *&c.*

Experiment VI.

The more commodious Methods of examining Water.

26. By Means of the Inſtrument called the Hydroſtatical Balance, we took the ſpecific Gravity of the Water propoſed, and directly judged of its Goodneſs by its Lightneſs. *Common Water examined.*

27. This Experiment is a good Subſtitute for ſeveral other Ways of examining the Purity and Goodneſs of Waters, both common and mineral. For it appears by numerous Inſtances, that light Waters are, *cæteris paribus*, the beſt, pureſt and wholeſomeſt.

a) See Mr. *Boyle*'s Philoſophical Works, and *Boerhaave*'s Chemiſtry.

28. But as the preſent Method requires the Uſe of a curious Inſtrument, and a conſiderable Degree of Accuracy and Attention, other more expeditious, tho' not more exact, Trials have been invented; particularly by the Uſe of *Water-Poiſes*; which are Inſtruments of Ivory, Glaſs, *&c.* made hollow-bellied, ſo as to float in Water, higher or lower, according as the ſpecific Gravity thereof is more or leſs: And the Inſtruments being graduated or divided by Lines on the Stem, readily ſhew to the Eye the Difference betwixt the ſpecific Gravities of any two Waters propoſed; tho' not with the utmoſt Exactneſs.

29. The Foundation of both Experiments is this, that the Bodies diſſolved or licked up by Water, in its paſſing thro' the Caverns, or ſuperficial Parts of the Earth, are generally either ſaline or earthy; which being both more ponderous than pure Water, it follows, that the ligheſt Waters are leaſt impregnated with them, and therefore fitteſt for the finer Uſes, where no ſuch groſs, ſaline, or earthy Matters are required; as they are not particularly in the healthy human Body, where the ordinary Office of common Water is to convey and diſtribute Nutriment to all the Parts, to dilute and waſh off the Over-proportion of animal Salts, as it evidently does in Sweat and Urine.

30. By Means of the preſent Experiment we find, that the pureſt Rain-Water is of nearly the ſame ſpecific Grav ty with diſtilled Water; neither of them, when obtained pure, precipitating any groſs earthy Matter upon the Addition of Oil of Tartar *per deliquium*, as many Spring-Waters do.

31. Common-Waters are diſtinguiſhed into *Hard* and *Soft*, and accordingly are uſed for different Operations. Thus ſoft Water is found beſt

for extracting certain Tinctures, freeing Metallic *Calces* from their Salts, &c. And hard Water is best for the tempering of Steel, the making of artificial Wines, and Malt-Liquors intended for long keeping.

32. Hard Waters are such as contain a foreign, saline or terrestrial Matter; and accordingly become softer by long standing, or by a small Addition of Salt of Tartar; both which tend to precipitate the terrestrial Substance out of them.

Experiment VII.

The more commodious Methods of examining Mineral Waters.

33. (1.) To half a common Wine-Glass of *Pyrmont* Water we added a Dram of the Syrup of Violets, whereby a greenish Colour was produced. (2.) To a like Quantity of the same Water we added a few Grains of scraped Galls; and first, a purple, then a blackish Colour presently ensued. (3.) We evaporated a Quantity of the same Water, and a small Proportion of an ochry Substance was left behind. (4.) We set a Glass of the same Water, cold, in the Receiver of the Air-Pump, and found, upon with-drawing the Air, that the Water sparkled violently, and discharged a numerous Quantity of small Bubbles at its Surface; like what happens in the Conflict of an acid and alkaline Liquor. *Mineral Waters examined.*

34. This Experiment holds in all the Cases of Chalybeate Waters only, and not of *Mineral Waters* in general. By Mineral Waters, in general, are meant all those wherein any Medicinal Virtues, besides those of common Water, are found. These Mineral Waters are of various Kinds: we may consider them under the general Titles of *Chalybeate*, *Purgative*, and *Alterative*.

35. The more uſeful and commodious Additions for examining theſe three Kinds of Mineral Waters, are, *Galls*, *Syrup of Violets*, and *Oil of Tartar per deliquium*.

36. *Galls* diſcover in them any ſmall Proportion of Vitriol or diſſolved Iron; as having the Property of immediately ſtriking a purple, or black Colour, in all Waters, where any ſuch Subſtance is lodged.

37. *Syrup of Violets* in the ſame Manner diſcovers any ſmall Predominancy of an Acid or Alkali therein; by changing the Water red, if an Acid, and green, if an Alkali preſides.

38. *Oil of Tartar* diſcovers any ſmall Proportion of earthy Matter, leſs capable of diſſolving in Water than that Salt; by precipitating ſuch earthy Matter, in Form of a white Cloud, to the Bottom of the containing Glaſs, where it collects, and appears like a ſubtile white Powder.

39. Theſe Particulars may be ſhewn, and proved ſatisfactorily, by adding to pure Water a little of a known Acid, Alkali, diſſolved Iron, and ſubtile Earth, or fine light Sediment of an earthy Water, and then applying the Syrup of Violets, Galls, and Oil of Tartar reſpectively.

40. Suppoſe, therefore, any unexperienced Water to be examined; firſt, drop into it a little Syrup of Violets, and if this does not alter its Colour, but keeps its full natural Blueneſs, the Water is neither Acid nor Alkaline. If Galls do not turn the Water black, it is not Irony, nor Vitriolic; and if Oil of Tartar does not precipitate a white Powder, the Water holds no conſiſiderable Proportion of earthy Matter.

41. The preſent Set of Experiments is capable of great Enlargement, by Means of many other Additions, fitted to produce a Change of Colour, or a Precipitation in Waters, according

as

they are impregnated with Matters of certain Kinds. Thus a Solution of Silver, by cauſing a Thickneſs or light Precipitation, diſcovers a minute Proportion of Sea-Salt contain'd in Waters. And there is ſcarce a Salt, an Earth, or a Mineral, hitherto known, but the Induſtry of the Chemiſt has found Means of diſcovering, if it be contained in any common or Mineral Water; eſpecially, if to this we add the Uſe of Evaporation, or the Way of bringing the ſolid Contents of ſuch Waters to a dry Form. So that if this whole Affair were to be properly conducted, we apprehend it might in a ſhort Time terminate in a certain Diſcovery of the Contents of all the Mineral Waters of the Kingdom; to the great Advantage of ordinary Life, and a conſiderable Improvement in the Art of Medicine, and many other mechanical Arts and Trades, depending upon the proper Choice and Uſe of Waters.

EXPERIMENT VIII.

That Mineral Waters are imitable by Art.

42. We took a Quart of the lighteſt and pureſt Water we could procure, and added to it about thirty Drops of a ſtrong Solution of Iron made with Spirit of Salt, a Dram or more of *Oleum Tartari per deliquium*, and twenty, thirty, or forty Drops of Spirit of Vitriol; but ſo as that the Alkali of the Oil of Tartar might prevail: we now ſhook all briſkly together, and poured out a Glaſs for taſting; upon which, it was found very remarkably to reſemble *Pyrmont-Water*. Pyrmont *Water imitated.*

43. This Experiment, tho' but particular, may afford us a general Rule for imitating any Mineral Water propoſed. The Rule is, by a proper Analyſis to find the Contents of ſuch a

Water,

Water, and their Proportions, by Evaporation, the Addition of tinging Ingredients, *&c.* as above mentioned *a)*; then, by Means of ſynthetical Chemiſtry *b)*, to compoſe a ſimilar Mixture. Thus, for Example, we learn, by a proper Analyſis, that the Ingredients or different conſtituent Parts of *Pyrmont*-Water *c)*, are a ſubtile aqueous Fluid, a volatile Iron, and a predominating Alkali; all joined together into one briſk, pungent, ſpirituous Water: And upon this Analyſis our preceding Imitation was founded, by means whereof, if the Proportions be juſtly hit, the artificial *Pyrmont* Water will greatly reſemble the natural, and produce ſimilar Effects in the Body; as has been found upon Experience *d)*.

44. The Imitation of this ſpirituous Kind of chalybeate Water is by much the moſt difficult; and may perhaps be rendered more perfect, if, inſtead of uſing the Solution of Iron in Spirit of Salt, the pureſt common Water be boiled in a cloſe Veſſel, with a ſmall Proportion of Okre, ſoft Iron Ore, or Pyrites; the reſt of the Proceſs being conducted as above ſet down.

Purging Waters imitated.

45. The Imitation of the common purgative Mineral Waters is facile: Thus *Epſom*-Water is imitated by barely diſſolving three or four Drams of *Epſom* Salt in a Quart of pure Water, made ſomewhat briſk or quick with a few Drops of Spirit of Vitriol and Oil of Tartar *per deliquium*, ſo as to let the Alkali prevail. And the ſame is to be underſtood of any other Water, the Contents of which are exactly known.

a) See *Exp.* VII. §. 35, 36, 37, *&c.*

b) See hereafter the *Lecture* on Synthetical Chemiſtry.

c) See above *Exp.* VII.

d) See New Experiments and Obſervations upon Mineral Waters.

46. And

46. And by a little farther Experience and Application, we apprehend that these Imitations might be brought to a great Degree of Perfection; so as to render the Trouble and Charge of importing foreign Waters, or going to drink them abroad, in a Manner unnecessary. *The Experiment extended.*

But the Imitation of the alterative Waters, such as those of *Bath*, *Buckston*, *Holt*, &c. has hitherto scarce been attempted; nor can be rationally, for Want of their respective just Analyses, upon which such Imitations should always be grounded.

Axioms *and* Canons.

1. We have seen, (1.) that Water is naturally contained in some of the dryest and hardest Bodies, and in the dryest Air; (2.) that itself naturally contains Air, and an earthy Substance; (3.) that it is the proper Menstruum of Salts, dissolving more of one and less of another; (4.) that one good Sign of its Purity and Wholesomeness is its Levity; (5.) that the Ingredients of a mineral Water may be discovered by chemical Experiments; and (6.) that mineral Waters are imitable by Art, guided by such Discovery *a)*.

2. That Water is of infinite Use in all the Works both of Nature and Art, as without it there could be no Generation, Nutrition, or Accretion performed in all the animal, vegetable, mineral, marine and atmospherical Regions. The Blood could not flow in the Veins, nor the Sap in the Vessels of Vegetables, nor the Particles of Minerals concrete and grow together, without Water. It is this that makes the largest Part of

a) See the *Lecture passim.*

our Blood, our Drink, and our Aliment. Without it there could be no Corruption, Fermentation, or Diſſolution carried on *a)*; no Brewing, no Diſtilling, no Wines, no Vinegars, no Spirits *b)*.

3. That we meet with Water under an infinite Variety of Forms, and in an infinite Variety of Bodies; as of Air, Vapour, Clouds, Snow, Hail, Ice, Sap, Wines, Blood, Fleſh, Bone, Horn, Stones *&c.* through all which it ſeems to paſs unaltered, as an Agent or Inſtrument that ſuffers no Alteration by Re-action, but remains capable of reſuming the Form of Water again upon Occaſion *c)*. In which reſpect it greatly reſembles that other *Proteus* Quickſilver, which we meet with in the Form of Fumes, Clouds, Sublimate, Precipitate, *&c.* from which it may be reduced to running Mercury again *d)*.

4. That Water, in its common State, appears to be a Combination of all the Elements together, as containing a Quantity of Fire, which keeps it fluid, a Quantity of Air, and a Quantity of Earth *e)*. Whence it can be no Wonder that Water alone, as it appears to the Senſes, ſhould ſuffice for Vegetation, in ſome Caſes where little Earth is wanted; or for ſupporting animal and mineral Life, where no great Degree of Nutriment is required. And hence it proves a *Gluten* or Cement to ſome Bodies, and a Solvent to others. Thus it conſolidates Brick, Plaiſter of *Paris*, Stone, Bone, *&c.* but diſſolves Salts, and ſubtile Earths approaching to Salts, and becomes the inſtrumental Cauſe of their Action *f)*.

5. That

5. That Water conveys Nouriſhment, or a more fixed and ſolid Matter, to the Parts of Vegetables, where that being depoſited the finer Fluid perſpires into the Atmoſphere *a)*; which gives us the phyſical Cauſe of the Dampneſs and Unwholeſomeneſs of woody Countries, which they remarkably find in *America*. For all large Vegetables act after the Manner of Pumps, continually drawing in large Quantities of Water at their Roots, and diſcharging it at their Leaves; which intimates a Method of collecting Water in dry Countries, and alſo of making Salt-Water freſh.

6. That the Water in paſſing thro' Plants, after having depoſited its more terreſtrial Part, does not always go off pure, but impregnated with the finer Effluvia, or more ſubtile Particles of the Vegetable; thus making an Atmoſphere round every Plant, odoriferous or otherwiſe according to its Nature: which ſupplies us with a Rule for procuring the odoriferous Waters of Vegetables by Diſtillation *b)*.

7. That the Particles, which are not fine enough to go off thus along with the Water, are left behind upon the Surface of the Leaves and Flowers of Plants; being now thickened or ſtrained from their moiſter Parts, and remaining in the Form of Honey, Manna, Gums, Balſams, *&c.* according to the Nature of the Vegetable *c)*. And hence appears the phyſical Cauſe of Plants proving more odoriferous and ſweet, when the Weather is both warm and moiſt; as immediately after a Summer's Shower.

8. That the chemical Operator ſhould form to himſelf an *Hygrometer d)*, for the Service of his

LECTURE VI.

CONTAINING

An Enquiry into the Nature and Use of Menstruums, or Solvents.

1. WE have now gone thro' the common Elements, Fire, Air, Earth, and Water: we next proceed to *Menstruums*, which make a large Branch of Natural Philosophy, and a more peculiar and immediate Part of Chemistry. *Introduction.*

2. By *Menstruums* we understand all those Bodies, which, in a fluid, or subtilized State, are capable of interposing their small Parts betwixt the small Parts of other Bodies, so as to divide them subtilely, and form a new uniform Compound of the two. *Menstruums what.*

3. Hence solid Bodies, as well as Fluids, are capable of becoming Menstruums, when their Parts are subtilely divided, so as to receive others uniformly between them; whether this subtile Division and joint Interposition of Parts be effected by Fusion, Triture, or the like. *Solid and Fluid.*

4. Thus when two Metals, being fused together, mutually interpose their subtile Parts between each other, and unite into one uniform Mass, they become Menstruums to each other. And so when common Sulphur and common Mercury are barely rubbed together, till the Mass becomes every Way uniform and similar, the Sulphur proves a Menstruum to the Mercury, and the Mercury a Menstruum to the Sulphur; and *The Definition illustrated.*

and both uniting form that black uniform Powder called *Æthiops Mineralis.*

5. Whence it appears, that the Term *Menſtruum* is equally applicable to both the Bodies concerned; the one being as much a Menſtruum as the other. So when Water diſſolves Sugar, it may as juſtly be ſaid that the Sugar diſſolves the Water; tho' Cuſtom, and the common Forms of Speech, which have little Regard to juſt and philoſophical Notions, do not authorize the Expreſſion.

The Menſtruums of Nature. 6. And hence it may appear that the common Elements, which we have conſidered in the foregoing Lectures, are in a proper Senſe the *Menſtruums of Nature*, which ſhe employs for producing her ordinary Effects. For Fire mixes uniformly among Bodies, and divides their Parts; ſo does Air, Water, and elementary Earth, as we have all along ſhewn. We ſuppoſe it will not therefore appear foreign, but directly conducive to our Purpoſe, to have beſtowed a Lecture upon each of theſe Elements, by way of Foundation for our Courſe; as theſe are not only the principal Agents of Nature, but are alſo concerned in every chemical Operation.

The Purport of the Experiments. 7. The preſent Buſineſs will be to ſhew, (1.) the different diſſolving Powers of Water, on different Bodies. (2.) The ſame of Alcohol. (3.) The ſame of Oil. (4.) The ſame of unlikely Subſtances. (5.) The ſame of Quickſilver. (6.) The ſame of the common Menſtruums, *Aqua Fortis* and *Aqua Regia*. And (7.) the ſame of the Digeſtor: thus proceeding gradually from the weakeſt up to the ſtrongeſt diſſolving Powers hitherto known in Chemiſtry.

EXPERI-

EXPERIMENT I.

That Water, as a Menſtruum, *diſſolves more of one Body, and leſs of another.*

8. We took three ſimilar and equal Glaſſes each containing two Ounces of the ſame Kind of Water, cold; into the firſt we put a certain weighed Quantity of *Epſom* Salt, *viz.* two Ounces, the greateſt Part whereof was ſoon diſſolved; into the ſecond we put a certain weighed Quantity of dry and pulverized common Salt, *viz.* five Drachms, which likewiſe ſoon diſſolved almoſt entirely; into the third we put a certain weighed Quantity, *viz.* eight Grains, of finely pulverized *Cream of Tartar*, whereof ſcarce any Part appeared to diſſolve in the cold. We ſet all the Glaſſes in *Balneo Mariæ*, till the Water of the *Balneum* boiled, and then obſerved that more of each Salt was taken up reſpectively. *The different Powers of Water, as a Menſtruum.*

9. It might be proper, for the further Improvement of Chemiſtry and Natural Philoſophy, to form a Table of the Time and Quantity wherein all the known Salts are diſſolvable in Water. *Epſom* Salt, we ſee, preſently diſſolves in about an equal Quantity of Water; common Salt diſſolves in about four times; Nitre in about five or ſix times; and Salt of Tartar in about twice its own Quantity of Water: but *Cream of Tartar* requires twenty times its own Quantity of boiling Water to diſſolve it. *The Experiment extended.*

10. Such a Table, regularly formed, might eaſe the Trouble of refining Salts, by ſhewing at once, without future Trial or Loſs of Time, how much Water each Salt required to diſſolve it; for Clarification, Filtration, or Cryſtallization.

11. It would likewiſe ſupply us with a ready and commodious Way of ſeparating any Mixture

of Salts, by ſhewing which would firſt ſhoot out of the Mixture upon Cryſtallization. For the Rule is, that *the Salt which requires the largeſt Proportion of Water to diſſolve it will ſhoot the firſt.* And thus Nitre, requiring a larger Proportion of Water to diſſolve it than common Salt does, the former is, in the ordinary way of refining, totally ſeparated from the latter by Cryſtallization. And unleſs this were to happen, the *Aqua-Fortis* prepared from Nitre would prove a kind of *Aqua-Regia*, and, inſtead of diſſolving Silver, would diſſolve Gold; For *Aqua-Regia* is made from a Mixture of Nitre and Sea-Salt, or Sal-Ammoniac, which contains the Spirit of Sea-Salt *.

12. The ſame Table might alſo direct us to a ready and commodious Method of ſeparating two Salts, without waiting for Cryſtallization. Thus ſuppoſe *Tartar of Vitriol* mixed with *Epſom* Salt, if Water be poured upon the Mixture, it will preſently diſſolve the *Epſom* Salt, leaving the *Tartar of Vitriol* untouched, ſo that it may be decanted clear from it; becauſe *Epſom* Salt eaſily and plentifully diſſolves in cold Water, whereas *Tartar of Vitriol* diſſolves ſlowly and ſparingly in it. And the ſame is to be underſtood of other Mixtures of Salts.

Accounted for.

13. If the phyſical Reaſon be demanded, why one Salt diſſolves more readily in Water than another, we recommend it to farther Examination whether all Salts do not diſſolve in Water with greater or leſs Facility, and in greater or leſs Proportion, according as they contain more or leſs of a groſs, unctuous Subſtance, unſuitable to the Nature, or to the Fineneſs and Lubricity of Parts required in Water. The comparing of

* See hereafter *Exp.* VI.

Epſom

Epsom Salt, Salt of Tartar, common Salt, *&c.* with Nitre, Alum, crude Tartar, *&c.* seem to make this more than a Conjecture.

14. Vitriols also, being a Species of Salts, thence become soluble in Water. But pure Water has not the Power of dissolving Metals, unless they are first reduced to a Saline or Vitriolic Form: Nor does Water act as a *Menstruum* upon Oils, Rosins, Amber, Sulphur, *&c.* Whence its Power, as a direct Solvent, is limited *. For Salts it seems the appropriated *Menstruum*; but, with the Assistance of other things, it may dissolve a great Number of other Bodies: Thus, by the Interposition of Wax, it will dissolve Oil by simple Triture; by means of the Yolk of an Egg it will dissolve Turpentine; and by means of acid Spirits it will dissolve Chalk, Earths, and Metals.

15. In our present Experiment we find the dissolving Power of Water increase with Heat; and this holds till the Water boils: after which, as the Heat remains the same, so does the dissolving Power, and as this Heat decreases, so does that Power, letting Part of the Salt fall down again. Whence it should seem as if Heat was the original Cause of the dissolving Power.

16. But on the other Hand, there are Experiments wherein the Power of Water, as a *Menstruum*, decreases, as the Degree of Heat increases; as in boiling the White of an Egg; where the Water, as it grows hot, coagulates the Subject which it would dissolve when cold. We also observe the same of Blood, a firm Mixture of Flower and Water, *&c.* The Instances of this Kind should therefore be collected, and go along with the former, to prevent the Mind from runn-

* See *Lect.* V. §. 17, 18, &c.

ing into Error, by concluding haſtily from too few Experiments, which has greatly prejudiced Chemiſtry and Natural Philoſophy.

EXPERIMENT II.

The diſſolving Power of Alcohol.

Camphire diſſolved in Spirit of Wine.

17. We took an Ounce of *Alcohol*, and by degrees added to it an Ounce of ſolid Camphire; all which it nearly diſſolved, in a very ſhort Time, without any Ebullition, or apparent Alteration of Fluidity or Tranſparency. We afterwards poured in a large Proportion of fair Water, which weakening the Solution, and uniting with the *Alcohol*, cauſed it to let go the Camphire; ſo that now it all roſe, white, ſolid, and perfect, to the Top of the Mixture.

Alcohol *what.*

18. *Alcohol*, or highly rectified Spirit of Wine, is a Liquor obtained from vegetable Subjects, by Fermentation, Diſtillation, and Rectification *a*). It appears related to Oil, becauſe totally inflammable; and when carefully examined, to be the eſſential Oil of the Vegetable, intimately broke, and ground in among the Particles of Water; ſo as to form one uniform Liquor, not eaſily ſeparable again into different Parts *b*).

19. We learn, by the preſent Experiment, that it has the Power of diſſolving about its own Weight of Camphire; which when duly examined, appears to be a particular Kind of volatile, or eſſential Oil, coagulated into a white and ſolid Subſtance *b*): And, as ſuch an Oil, it is here plentifully diſſolved in *Alcohol*.

Its Uſes.

20. This *Alcohol* is a capital *Menſtruum* in Chemiſtry, and fitted to diſſolve Roſins, as well

a) See the *Lecture* upon *Diſtillation* hereafter.

b) See hereafter *Lect.* XVI. *Exp.* III.

as

as Oils; tho' it does not thus mix inextricably with either, but leaves them separable again by the bare Addition of Water, which it dissolves more readily than either Oil or Rosin, and therefore lets them go to join with this, according to the Law of Precipitation. For *whenever one Body has dissolved another, if a third be added to the Solution, which third has a greater Relation to either of the former, than they have to each other, their Union is separated, and the third Body dissolved instead of the first or second; one of which is now at Liberty to rise, or fall to the Bottom, according to its specific Gravity:* as we saw remarkably in the present Experiment, where the Camphire, dissolved in the Spirit of Wine, was soon made to float upon the Surface, by the Addition of Water, which has a greater Appetite of Union, or Relation, to Spirit of Wine, than that Spirit has to Camphire. And the physical Reason hereof may appear from what was just now said of the Composition of this Spirit, or its being an intimate Mixture of Water and volatile Oil *.

21. Hence *Alcohol* is an intermediate Substance betwixt Oil and Water, and related to both, tho' participating more of Water than of Oil: And according to these Relations, its Action as a *Menstruum* may, we conceive, be properly explained.

22. By means of this *Menstruum* the Tinctures of *Myrrh*, *Gum Lac*, *Guaiacum*, most of the Varnishes, and many medicinal Tinctures, Elixirs, and Solutions are prepared; tho' for these Purposes it usually requires to be acuated with Salt of Tartar. But our present Business is to consider the Power of simple *Menstruums*, rather than of such as are mixed; for that were an infinite Field, and would lead us too far for the present.

* See §. 18.

Tho' the Discovery of powerful, yet innocent *Menstruums*, by means of Composition, should be earnestly recommended to the Diligence of every Chemist, as that on which the Improvement of numerous Arts depends.

EXPERIMENT III.

That Oil will intimately dissolve Lead.

Oil dissolves Lead. 23. We put two Ounces of crude Lead into an Iron Ladle, and added thereto twelve Ounces of Oil-Olive; then setting them over a clear Fire, the Lead evidently melted before the Oil began to boil, and at length the Lead disappeared, or united and became one with the Oil. By stopping the Operation at any time, we could easily learn how much of the Lead was dissolved in the Oil, both by the increased Consistence of the Oil, and the Diminution of the Lead.

The Experiment extended. 24. The same Experiment may hold also of Tin, and of Tin and Lead mixed. How far it is applicable to the other Metals has not been hitherto satisfactorily tried. Some have supposed that Oil will dissolve Copper and Iron: But it should be carefully examined whether the effect be not owing to an Acid concealed in the Oil; for it is the known Property of Acids to dissolve these Metals. This has been observed, that if Oil be well boiled, to get out its aqueous Parts, it is the better fitted to preserve Utensils of Iron, Brass, or Copper, from Rust. Whence Marrow is reckoned better for this Purpose, than other Fats or Oils more subject to harbour aqueous Moisture. And if a little Ceruse, or Black Lead, be added in the boiling, the Oil becomes still more proper for this Purpose. Now it is the Property of Ceruse, and black Lead, to drink up Acids; and therefore it may be hence concluded, that

that ſome acid Parts, naturally contained in Oils, are the Cauſe of their Ruſting or Diſſolving the Iron, Braſs, or Copper, on which ſuch Oils are laid.

25. The Preparation, or Subſtance, obtained in the preſent Experiment, being taken from the Fire at different times of the Operation, makes either a Balſam, a Cement, or a Plaiſter; and ſo is fit for various Uſes. As a Balſam, and a Plaiſter, it is ſerviceable in Chirurgery. As a Cement, it is excellent in Water-Pipes; and being laid upon hot Brick-work, or the like, fits it for holding Water. It alſo ſerves to hold crack'd Glaſſes together, ſo that they ſhall be as firm in the Crack, as in the Sound Parts. *Its Uſes.*

26. But a more phyſical Uſe of the Experiment is, to ſhew the great Affinity which the ſoft and fluid Body of Oils, as a *Menſtruum*, has with the ſolid Bodies of Metals, and how they may mutually, not only diſſolve, but diſguiſe and conceal each other; ſo that Metals ſhall be contained in Bodies where the Eye would never ſuſpect them.

27. The preſent Experiment alſo affords ſome Light in the Doctrine of Solders, or, the Mixtures of metalline Matters, that will run with a leſs Degree of Heat than the Metal propoſed to be ſolder'd, and tenaciouſly lay hold thereof. For Oil, or Greaſe, is an uſeful Thing to facilitate the running of theſe Solders; as we ſee in the Soldering of Lead and Tin, where the Plumber uſes his Tallow, as the Tinman does his Roſin; by means whereof the Solder and the Metal are the better ſoften'd, and in ſome Meaſure diſſolved and incorporated together.

The Relation betwixt Oils and Metals.

28. We deſire that this great Affinity betwixt Oils and Metals may be remember'd; as

being of extenſive Conſequence in the Buſineſs of Metals, and more particularly in the ſublimer Metallurgy; where certain Expreſſions, concerning the *Sulphur of Metals* may be underſtood to advantage, by taking them to mean an actually inflammable Subſtance, or Oil.

EXPERIMENT IV.

That innocent and unlikely Subjects may afford powerful Menſtruums, *ſhewn in Bread.*

Bread diſtilled. 29. We took two Pounds of common brown Bread, cut it into ſmall Pieces, and put it into a Glaſs Retort. We placed the Retort in a Sand-Heat, and luting on a Receiver, diſtilled with a moderate Fire, ſo long as any aqueous Liquor came over: at length ſuffering all to cool, we took off the Receiver, and by the Filtre ſeparated the Liquor obtained, to clear it of its Oil. This Liquor we rectified from its Phlegm in *Balneo Mariæ*, and afterwards diſtilled it over again in a Sand-Heat, ſo as to obtain a moderately ſtrong, acid, limpid Liquor, under the name of the rectified Spirit of Bread.

Uſes of the Experiment. 30 In this manner we obtain from common Bread a large Proportion of an aqueous Liquor, mixed with acid Parts, ſo as to be capable of extracting the red Colour out of Coral, or even Garnets. But to procure this Liquor in its greateſt Strength and Perfection, we ſhould make Uſe of Rye Bread, or ſome of the coarſer ſorts.

31. The Experiment being duly proſecuted, affords us the Analyſis of Bread; a Subſtance capable of recruiting and forming all the ſolid Parts of our Bodies. And no wonder, ſince it contains nearly the ſame Principles as animal Matters. For Blood, Fleſh, or Bone, upon their Analyſis, reſolve into Water, Oil, volatile Salt,

and

and Earth; the whole, by Decoction, making a Kind of mucilaginous, or gelatinous Substance with Water: And in the same manner Bread boils with Water into a gelatinous or mucilaginous Substance, and when distilled, resolves into Water, an acid Spirit, Oil, and Earth. The principal Difference between them is, that Bread affords a volatile *Acid* by Distillation, whereas Flesh, or Blood, affords a volatile *Alkali*. Whence it should seem, that there is in the Body a certain Power of Changing the Matter of an *Acid* into that of an *Alkali* *.

32. To gain a clearer Information from the present Experiment, we could wish it were repeated with such Bread as contains no Sea-Salt, which is a common Ingredient in the usual Kinds of Bread. For Sea-Salt affords a considerable Proportion of acid Spirit upon Distillation, and this Spirit may have a great Share in dissolving the Bodies supposed to be dissolved by the Spirit of the Bread. But however that Matter may prove, the Experiment shews a powerful *Menstruum* is obtainable from an innocent and unlikely Subject. And the same has been found to hold of many other Preparations; as Wine-Vinegar, tartarized Tartar, *&c.* Whence the like Experiments should be tried upon other common Subjects, such as the Yolks and Whites of Eggs; Rennet, Curd, Whey, Milk, Butter-Milk, Cheese, Urine, *&c.* in order to discover whether serviceable *Menstruums* might not be thus procured. *Extended.*

EXPERIMENT V.

That Quicksilver dissolves Metals.

33. We melted two Ounces of clean Lead in an Iron Ladle, and in another Ladle we heated *Amalgamation of Lead.*

* See more to this purpose in *Lect.* VII.

the ſame Quantity of Quickſilver till it juſt began to fume; then we poured the Quickſilver to the Lead, and ſtirred them both together with an Iron Rod: upon letting them cool, they made a white, hardiſh, homogeneous Maſs; a part of which, being ground with more freſh Quickſilver, readily and intimately mixed therewith.

The Experiment extended, with its Uſes. 34. This Experiment ſucceeds with all the Metals, except Iron; which therefore appears of a leſs mercurial Nature than the reſt. The Operation itſelf is called *Amalgamation*, that is, the intimate Mixing of a Metal with Quickſilver, and is the Foundation of Gilding and Silvering. For an Amalgam of Gold being rubbed upon a well poliſhed Plate of pure Silver, and the Plate afterwards expoſed to ſuch a Degree of Heat as will evaporate the Quickſilver of the Amalgam, the Plate is left gilt. The Caſe is the ſame when Copper is to be ſilver'd. And thus Gold, or Silver, is uniformly diffuſed through the Body of the Quickſilver; whence a ſingle Grain of Gold, Silver, Lead, or Copper, may be divided to an almoſt inconceivable Degree; or ſpread uniformly through a Maſs of a thouſand Pounds Weight of Quickſilver, every the ſmalleſt Particle of which ſhall contain a Quantity of Gold proportionable to the Whole. And hence it appears that Quickſilver is a true *Menſtruum* to all the Metals, except Iron; diſſolving them as perfectly as Water diſſolves Salt.

35. The preſent Experiment alſo ſhews us how Quickſilver may be adulterated with a Proportion of Lead: but the Fraud is eaſily diſcovered, by putting a little Quantity of ſuch debaſed Quickſilver into an Iron Ladle, and exhaling away all the Mercury which will thus leave the Lead behind.

36. We may likewiſe hence underſtand the fraudulent Tricks of ſome pretended Alchemiſts, who feigning an Occaſion for the Uſe of Mercury in their Proceſſes, do beforehand ſecretly diſſolve, or procure to be diſſolved therein, a certain Proportion of Gold or Silver; which not flying off along with the Quickſilver in the Fire, the credulous By-ſtanders are made to believe, that the baſer Metals employed are enriched with the nobler in the Operation. The Inſtances of ſuch Frauds are many, and have brought a great Stain upon the Art of *Alchemy.* But they are eaſily detected, by expoſing a Part of the Operator's Mercury to the Fire; for the Quickſilver going off in fume will leave the Silver and Gold behind.

EXPERIMENT VI.

That Aqua-Fortis, *or Spirit of Nitre, is the* Menſtruum *for Silver*; *and* Aqua-Regia *the* Menſtruum *for Gold.*

37. We took two Drachms of the fineſt Silver reduced to Filings, and poured upon it twice its Weight of proof *Aqua-Fortis*; then ſet the containing Glaſs in a gentle Heat, under a Chimney, till the Solution was perfectly made. *Gold and Silver diſſolved.*

38. We took ten Grains of Leaf-Gold, and poured upon it two Drachms of *Aqua-Regia*; then ſet the Glaſs in a Sand Heat to warm thoroughly. After the Gold was diſſolved we added a Grain or two more, till the *Menſtruum* was fully ſaturated, and then decanted the clear yellow Solution. We afterwards put a few Grains of Silver into *Aqua-Regia*, and a few Grains of Gold into *Aqua-Fortis*; and kept the containing Glaſs warm, in the ſame manner as before, but found no Solution enſue in either caſe.

39. Thus

39. Thus we ſee that Gold and Silver are perfectly diſſolved in their reſpective *Menſtruums*, neither of which will touch the other Metal. For if any Gold be contained in the Silver, it will fall to the Bottom of the Solution in the form of a black Powder; and if any Silver be contained in the Gold, it does ſo likewiſe.

Proof-Aqua-Fortis *what.*

40. The *Aqua-Fortis*, for the Solution of Silver ſhould be made *Proof*; that is, it ſhould be capable of diſſolving half a Grain, or a Grain of Silver immediately, without growing in the leaſt turbid; as it would do if it contained any Sea-Salt: in which Caſe it would be a Kind of *Aqua-Regia.*

How made.

41. *Aqua Fortis* is made by diſtilling purified Nitre with calcined Vitriol, or rectified Oil of Vitriol, in a ſtrong Heat, whereby an extremely corroſive acid Liquor is driven over in blood-red Fumes.

Aqua-Regia *what.*

42. *Aqua-Regia* is made by diſſolving a fourth part of Sea-Salt in the *Aqua-Fortis* above mention'd.

Uſes of the Solution of Silver.

43. If the Silver employed in the Solution were abſolutely pure, the Liquor will be pellucid: but if any Alloy, or Copper, remain mixed with it, the Solution will have a bluiſh or greeniſh Caſt. If a Solution of perfectly pure Silver be diluted with fair Water, it will ſtill remain pellucid, without letting any thing precipitate. But if any ſaline Matter be contained in the Water, the whole will now turn thick or milky. The Solution of pure Silver, when properly weaken'd with Water, may be commodiouſly uſed for ſtaining the Skin, or other animal Subſtances, black. And if white, grey, or red Hair be moiſtened with it, the Hair will ſoon become of a beautiful brown, or jet-black Colour. For which purpoſe it may be uſed with Safety, Care being taken not to touch the Skin therewith; for thus

thus a Blackneſs would be occaſioned, that requires many Days before it goes off again; but it diſappears at length, by the Scarf Skin peeling off, without cauſing any Pain, or leaving any Sore behind.

44. The Solution of pure Silver has an intolerably bitter Taſte; tho' to the Eye it be not diſtinguiſhable from fair Water: In which we have an eminent Inſtance how Metals may lie concealed from the Sight, or remain lodged in unſuſpected Liquors, and thence be introduced inviſibly into other Subſtances. Whence the greater Caution ſhould be uſed with all Pretenders to the Melioration and Tranſmutation of Metals.

45. This Solution of Silver is the Foundation of ſeveral medicinal and chemical Preparations; as the *Vitriol of Silver*, the *Lunar Cauſtic*, the *Silver-Pill*, &c.

The Silver how recoverable.

46. The Silver is recoverable from this Solution, barely by ſuſpending a Copper-Plate therein: For Copper being more eaſily diſſolved by *Aqua-Fortis* than Silver, the Silver is thereby precipitated to the bottom, in the form of a Powder, which being waſhed and melted comes into a metalline Lump again. And this is alſo to be underſtood of the Solution of Gold.

Uſes of the Solution of Gold.

47. But, on the other hand the Solution of Gold is yellow, or gold-coloured, and tinges the Skin purple, as the Solution of Silver ſtains it black. It may be further added, that if the Solution of Gold be precipitated with Salt of Tartar, and the Powder carefully dried, it makes the *Aurum fulminans*, ſo called from the violent Exploſion with which it goes off, when heated beyond a certain Degree *.

* See hereafter the *Lecture* upon *Pyrotechny*.

EXPERIMENT VII.

The dissolving Power of the Digestor, *an Instrument contrived at once to direct the Action of Water, Air, and Heat, in a high Degree, upon a Subject.*

The Structure and Use of the Digestor. 48. The *Digestor* is a strong Vessel made of Copper, or Iron, and fitted with a close Cover and Screws, so as to remain perfectly tight, in a considerable Degree of Heat; whilst Water, common Air, and the Subject of the Operation are contained within.

Ox-Bone soften'd. 49. We took a Pound of fresh Ox Bone in a single Piece, with two Quarts of common Water, and leaving a considerable Space for the Atmospherical Air, we screwed them all up together in the *Digestor*, and applied a moderate Degree of Heat to the Bottom thereof, for about a quarter of an Hour, or till a Drop of cold Water, let fall upon the Cover, would evaporate in a very few Seconds of Time: after which letting all cool, we opened the Vessel, and found the Bone soft and tender, so as to be cut with a Knife, the Water about it turned to a hard Jelly, and a large Quantity of Fat in a solid Cake at the Surface.

Rationale *of the Experiment.* 50. The Effects of this Instrument will not appear surprizing, if the Forces that act within it be duly consider'd. For, as we have formerly shewed the instrumental Efficacy of Fire, Air, and Water to be very great, even when separate, it is no wonder they should act extremely strong upon a Body in conjunction *.

Its Uses. 51. Hence the *Digestor* seems, of all the Instruments, or Vessels, hitherto invented, the most

* See the five preceding Lectures, *passim.*

pow-

powerful for increaſing the Action of *Menſtruums*. And if a ſuitable Method could be diſcover'd for ſtrengthening the Engine, ſo as to work ſafely with a very ſtrong Degree of Heat, we might reaſonably expect to perform ſome very extraordinary Operations by its means, in the way of Extraction, Decoction, Tincture, Solution, and perhaps even Deſtruction, or Tranſmutation *a)*.

52. But a Courſe of Experiments and Lectures upon this Engine alone, would ſcarce be ſufficient to ſhew and explain its numerous Uſes and Applications for improving the Doctrine of *Menſtruums*. And what Effects the common Solvents, as *Alcohol*, *Oils*, *Aqua-Fortis*, *Mercury*, and Metals themſelves, might have, when aſſiſted by this Engine, is not eaſy to foretel; and indeed it would require much Induſtry and Application to diſcover them.

Axioms *and* Canons.

1. We learn from the preceding Enquiry, that Water is a *Menſtruum* which, of itſelf, diſſolves little more than Salts *b)*; but, being aſſiſted by Acids, diſſolves Earths, and even Metals themſelves *c*). And hence might be drawn a *general Rule of Practice*, for making Water an almoſt univerſal *Menſtruum*. Thus, by the Addition of a fixed Alkaline Salt, it diſſolves Oil into a Soap; by the Addition of *Alcohol*, it extracts the reſinous Tinctures of Vegetables: and in this Manner it might be proper to run through the different Subjects of the vegetable, animal, and mineral

a) See Dr. *Papin*'s Treatiſe of this Inſtrument. See alſo the Lord *Bacon*'s Philoſophical Works, *paſſim*.

b) *Exp.* I. See alſo *Lect*. V.

c) *Exp.* I, VI.

neral Kingdoms, and form Tables of the ſolutive Powers of Water, ſimple and compounded.

2. That ſuch Tables may be readily formed of the diſſolving Powers of all the known *Menſtruums*, to ſhew by Inſpection, in what Time, in what Proportion, and with what Degree of Heat, all Solvents perform their Action; which being once reduced to a Certainty, would greatly facilitate and improve the Practice of Chemiſtry *a*).

3. That the Power of *Alcohol*, as a *Menſtruum*, is chiefly limited to Roſins and Oils; but, by certain Additions, may be extended, as was ſaid of Water, ſo as to become an almoſt univerſal Solvent *b*). Thus, by the Addition of Water, it becomes Brandy, or Spirit, which extracts many Tinctures that neither pure Water nor pure *Alcohol* will ſeparately extract. Whence we have a good Inſtruction for attempting a new Set of *Menſtruums* by Mixture, or the Compoſition of two or three ſimple Solvents. And if the requiſite Care and Skill were employed in this Matter, many uſeful Diſcoveries might be juſtly expected from it. Indeed, the mixing of two *Menſtruums* may ſometimes deſtroy the Virtue of both: thus Spirit of Nitre and ſimple Water will each of them ſeparately diſſolve the human *Calculus*, but when mixed they will not touch it. This Inſtance however is only particular, and there are a large Number producible on the contrary ſide; which may rationally recommend a farther Proſecution of this Enquiry.

4. That Metals are ſoluble in Oils, and in acid Spirits, ſo as not to be eaſily diſcovered therein *c*). Whence a Rule may be drawn for a prudent Suſpenſion of the Judgment, and a rational Diſ-

a) *Exp.* I. See alſo *Lect.* V.
b) *Exp.* II.
c) *Exp.* III, VI.

truſt

trust of the Senses in chemical Operations: And also, a Caution against being imposed upon by the vain Pretences of Alchemists *a*).

5. That the Power of a *Menstruum* is not to be judged of by its Innocency with regard to the animal Body. The acid Spirit of Bread is innocent and wholesome, yet capable of dissolving Coral and Gems *b*). Pure Oil-Olive will dissolve Lead and Tin. The White of an Egg, boiled hard, and suffer'd to run *per deliquium*, dissolves the tough Body of Myrrh. The Instances of this Kind are extremely numerous. They well deserve to be collected and tabled, that the Mind may be thereby cured of the Prejudice it has too readily imbibed, as if Corrosives only were Solvents.

6. That the Action of *Menstruums* depends upon a certain Secret and reciprocal Relation betwixt the Solvent and Solvend, scarce cognizable by the direct Senses, nor hitherto well made out by Instances and Induction. Alkali and Acid, Attraction and Repulsion, Sympathy and Antipathy, seem rather Words coined to express the Action, than to assign the physical Causes thereof. And hence the Action of new *Menstruums* cannot be determined, or rationally conjectured, beforehand; because it depends upon a Cause not hitherto known.

7. That *Menstruums* have not their full Action, unless reduced to a fluid or subtile State *c*). Water in the firm and solid Form of Ice does not act on Salts; but they soon begin to dissolve each other upon Contact. Metals do not act on Metals, in the Way of Solution, till they are fused: Nor does Sulphur dissolve Quicksilver, till they are both reduced, either to a fluid or very sub-

a) See above, §. 26, 33—36.
b) *Exp.* IV.
c) See the *Lecture*, *passim*.

tile State, by Triture, or by Melting. And this appears to be the Case in all Instances. Whence, in order to promote the Action of *Menstruums*, we are directed to reduce both the Solvent and Solvend to minute Parts, or as near as possible to a fluid State, whether by Heat, Triture, Fusion, or otherwise. And hence appears the physical Cause of the singular Efficacy of Fire, Air, Water, and Trituration in promoting the Action of *Menstruums* a).

8. That Quicksilver is a true Solvent of Metals, incorporating with them, as Water does with Salts b); by which Means one Metal may be readily united with another, in any Proportion, by simple Triture c). And hereby also many Operations in the sublimer Metallurgy are chiefly performed d).

9. That acid Spirits are not, equally, proper *Menstruums* to all the Metals; thus Spirit of Nitre, tho' it dissolves the rest, will not dissolve Gold e). So neither is Quicksilver itself a proper *Menstruum* to them all; for it does not dissolve Iron f). And the true physical Reason hereof seems not hitherto satisfactorily discovered, tho' numerous Conjectures have been made about it

10. That all the Bodies in nature may become *Menstruums* to one another, each of them being, by some Means or other, capable of having their small Parts uniformly interposed betwixt the small Parts of any of the rest. Thus even Metals may, by Art, be made to dissolve in Water; as we evidently see from numerous Solutions of Metals

a) See the five preceding Lectures, *passim*.
b) *Exp.* I and V. See also *Lect.* V.
c) See above, § 33, 34.
d) See hereafter the Lectures on *Mineralogy* and *Metallurgy*.
e) See *Exp.* VI.
f) *Exp.* V.

in

in acid Spirits: theſe Spirits being no more than Water charged with the fine or more volatile Parts of Salts.

11. That the Cauſe of Solution commonly aſſigned, *viz.* the Admiſſion of the fine Particles of one Body into the Pores of another, whoſe Figure is fitted for their Reception, is not juſt or adequate, but hypothetical and ill-preſumed, ſince we find that ſome Bodies will uniformly diſſolve their own Quantity of others *; as Water does of *Epſom* Salt, *Alcohol* of eſſential Oils, *Mercury* of Metals, one Metal of another, *&c.*; whereas the Sum of the Pores, or Vacuities, of every Body muſt be neceſſarily leſs than the Body itſelf; and conſequently thoſe Pores cannot receive a Quantity of Matter equal to the Body wherein they exiſt: for this were to make the contained Matter bigger than the Pores that contain it.

12. That the diſſolving Power of Water may be immenſely increaſed by means of the *Digeſtor*, an Inſtrument not hitherto introduced into Chemiſtry, tho' probably applicable to the great Improvement of that Art; as being a Contrivance, which at once determines the Action of a Solvent upon the Solvend, with all the Advantages of Heat, Air, and Water, briſkly agitated and confined, under a State of Compreſſure, ſo as to make them act like different Sets of Stampers upon the Matter to be changed. For this Engine at once employs all the four Agents required to make the greateſt Part of *Menſtruums* act with Advantage; *viz.* Fire, Air, Water, and Triture. Whence there are ſome ſolid Grounds of Hope, that it may, under a proper Regulation, greatly contribute to the Improvement of Chemiſtry, Natural Philoſophy, and Arts.

* *Exp.* I. II. V.

13 Upon the whole it ſhould ſeem, that many deſirable Improvements are derivable to Arts from an Improvement in the Buſineſs of *Menſtruums* *. The Diſcovery of that common *Menſtruum*, *Aqua-Fortis*, introduced the Art of Aſſaying, and the Scarlet Dye. That of *Alcohol* introduced the Arts of Varniſhing and Japanning, numerous Pigments for Painters, Colours for Dyers, Tan-Liquors for Tanners, the Staining of Bone, Horn, Ivory, Marble, various Kinds of Ink, Tinctures, and Solutions, in Medicine, Chemiſtry, and other Arts, have all reſulted from the Diſcovery of *Menſtruums*. Yet the Subject ſeems almoſt as new and rich as ever; ſo that numerous other Diſcoveries, of the ſame Kind, would not exhauſt it.

* See the whole Enquiry, *paſſim*.

LEC-

LECTURE VII.

CONTAINING

An Enquiry into the Nature, Office, and Effects of Fermentation *and* Putrefaction, *in the Vegetable, Animal, and Mineral Kingdoms.*

1. THE Purport of this Lecture is to enquire into the Nature, Effects, and Uses of Fermentation and Putrefaction, as they are the natural Means of converting one Body into another; in order to acquire a farther Knowledge in the *Chemiſtry of Nature*, and thence derive ſome ſerviceable Rules for the Improvement of *Philoſophical Chemiſtry*. *The Subject.*

2. But as the Subjects of Fermentation and Putrefaction ſeem to have been imperfectly treated by Authors, and to lie buried, as it were, in Obſcurity, we ſhall endeavour to let ſome Light in upon them by particular Experiments, and our Explanations of them; ſo as to ſhew the Steps of *Nature* and *Art*, in conducting and regulating theſe *capital Operations*, for altering and changing vegetable, animal, and mineral Subjects in the three grand Regions of Nature, *viz.* the *Earth*, *Ocean* and *Atmoſphere*.

3. That we may proceed the more clearly, we ſhall begin with *Fermentation* in vegetable Subjects, and trace it thro' all its Stages; till at length it terminates in *Putrefaction*, which reduces vegetable Subjects to an animal Nature. We ſhall next conſider the ſimilar Proceſs in animal *The Order.*

Subjects; and *lastly*, examine whether any Thing of the same Kind obtains among Minerals.

I.

To begin with vegetable Subjects:

EXPERIMENT I.

The Nature and Uses of vinous Fermentation; or the Way of changing the natural Juices of Vegetables into Wines.

Wine made from Raisins.

4. We took a Quarter of an hundred of whole, or unbruised, *Malaga* Raisins, and put to them seven Gallons of cold Spring-Water, in a wooden Vessel or Cask, which we set loosely cover'd in a warm Place, that the Contents might ferment for some Weeks. We found that the Water soaked thro' the Skins of the Raisins, dissolved their internal sweet or saccharine Substance, and became impregnated therewith, as a *Menstruum*; that the Liquor manifested an internal Struggle and Commotion of its Particles, throwing up numerous small Bubbles to the Surface, with a considerable hissing Noise; and that when the Fermentation was finished, the Liquor was become an actual new Wine, as appear'd by the Taste, Smell and Effects, having deposited a large Quantity of gross, earthy Sediment, called Lees, at the Bottom, different from the Husks, or Skins, and Stones of the Raisins.

The Experiment extended.

5. This Experiment is universal, or shews the general Manner of making Wines, and all other spirituous potable Liquors, or Drinks, by Fermentation. For, with a slight Change of Circumstances, it is applicable to the Brewing of Beer from Malt; Mead or Metheglin from Honey; Cyder and Perry from Apples and Pears respec-

refpectively; artificial, or made Wines, as they are vulgarly called, from Cherries, Goofeberries, Currants, Elder Berries, Blackberries, Plumbs, Oranges, or other Fruit; alfo, from the Tappings of certain Trees, as the Birch, the Maple, the Sycamore, *&c.* and more eminently from the Juice of the Sugar Cane, Treacle, or common Sugar and Water. For any of thefe vegetable Juices, being duly fermented, afford as real and perfect Wine, according to their feveral Natures, as the richeft Grapes of the beft Wine-Countries.

6. To bring any of thefe Juices into a found Wine, the Rule is to evaporate them, if they are naturally too thin, till they become of equal Richnefs with the Juice of the Grape, in Wine-Countries and in good Wine-Years. This may commodioufly be done, by Means of the common Water-Poife *, which fhews the Strength or Richnefs of Solutions to the Eye. And in general, any vegetable Juice, or Solution, is accounted fufficiently rich for making a ftrong Wine, when it will fupport a new laid Egg on its Surface. *And applied; with its Ufes.*

7. The Wines made at prefent in *England* lie under a Difrepute; the Reafon whereof feems chiefly owing, *firft*, to the inartificial Manner wherein they are ufually prepared, and, *fecondly*, to a certain Rumour fpread about them, as if they were unwholefome, crude, indigeftible, too lufcious, too tart or griping, and apt to occafion the Head ach, *&c.*

8. Thofe, who have never been in Wine Countries, nor otherwife made themfelves acquainted with the Nature and common Preparation of

* See *Lect.* V. *Exp.* VI.

Wines proceed in their Judgment of them according to Report, popular Notions, and the immediate Information of the Senſes. Thus, for Inſtance, Red-Port Wines, to pleaſe the common Palate, muſt be bright, deep-colour'd, rough, rich and racy, two or three Years old, *&c.* and when this or any other Notion comes once to be eſtabliſhed as the *Criterion* of Wine, the Cooper is thereby directed how to hit the general Taſte, and make a ſaleable Commodity.

Theory. 9. Upon the ſame Foundation *Philoſophical Chemiſtry* inſtructs us to imitate the Wine-Cooper, and from almoſt any ſweet and tart vegetable Juice, to make ſaleable Wines, even Sacks, Mountains, Sherries, or Ports; all of which by the way, are uſually mixed Liquors, tho' the Baſis of them all is the Juice of the Grape.

10. This Juice of the Grape being chemically examin'd and conſidered, proves to be no more than a large Proportion of real Sugar diſſolved in Water, with the Addition only of a certain Flavour in the Juice of the Grape, according to the Nature of the Vine. Whence we lay it down as an *Axiom*, and the Reſult of a careful Enquiry, that a *ſaccharine Subſtance is the Baſis of Wines.* For Sugar is not peculiar to the Sugar-Cane, but obtainable alſo from Grapes; and accordingly we often find large Grains thereof in dried Raiſins; particularly in thoſe of *Malaga*, that have lain for ſometime, and ſweated together, by which Means they run into Candy, a ſaccharine Efflоreſcence, and actual Grains of Sugar. So again, it is cuſtomary in *France* to evaporate the Juice of the Grape till it becomes coagulable in the Cold, and in this State to uſe it as a moiſt Sugar, under the Name of *Reſiné*. And the ſame Thing is to be underſtood as practicable in Malt,

or

or Wort, and the ſweet Juices of all Vegetables that afford a Wine by Fermentation *.

11. Hence therefore we may derive a Set of Rules, for boiling down, or otherwiſe procuring the eſſential Matter of Wines in a ſmall Bulk, and preſerving it ſound and ſerviceable for many Years, in order to the Making of all Kinds of Wines, Vinegars, and Brandies, even in Countries where no Vines grow. And this Diſcovery alſo affords great Light into the true Nature and Uſes of *vinous and acetous Fermentation*. *Rules.*

12. To illuſtrate and confirm this Diſcovery by an Example, upon the Footing of the preſent Experiment: Take two hundred Weight and a half of double refined Sugar; put it into a Pipe, or Wine Veſſel of two Hogſheads; fill the Veſſel within four Gallons of the Top with pure Spring-Water; ſet in a warm Place, or Wine-Vault; and three or four Pounds of freſh Ale-Yeaſt, or rather of new Wine-Yeaſt; and the Liquor in a few Months time will ferment into a ſound, colourleſs, and flavourleſs Wine, and remain ſuſceptible of any Colour or Flavour at Pleaſure; ſo as with the Stain called *Turnſol*, to be made of the true Claret-Colour; and with a little eſſential vegetable Oil, of any particular Flavour required. And this is here deliver'd as an Experiment that ſucceeds to great Perfection; ſo as to ſhew a rational and practicable Method of producing Wines in the Sugar Colonies, or elſewhere, that ſhall rival thoſe of *France*, *Italy*, or *Spain*; and if the Nature of Fermentation be well underſtood, the Proceſs may be greatly ſhortened in point of Time, as well as improved in other Reſpects. *Practice.*

13. And ſo much for the Uſe of our preſent Experiment, with regard to Trade, and Oeco- *Uſes to Trade.*

* See an Eſſay upon the Art of *Brewing* and *Diſtillation*. See alſo hereafter, *Lect. XI. paſſim*.

nomy;

nomy. Its philosophical Uses are no less considerable. And first, it shews that the proper fermenting Matter of every fermentable Subject is but small, compared with the Quantity of Wine it affords. Thus, for Example, we see that four Pounds of Raisins may be diluted, and fermented, with eight Pounds of Water, into what is accounted a tolerably strong Wine. And yet even Raisins themselves contain a large Proportion of Water, besides their directly saccharine Substance; which saccharine Substance is reducible to a dry Form, as we find in Sugar. And whoever would thoroughly enquire into the Nature, the Uses, and the Means of improving *vinous* and *acetous* Fermentation, cannot perhaps do better than to chuse Sugar for his Subject; a chemical Analysis whereof will shew the Principles necessarily required in this Operation. These Principles appear to be an acid Salt, an Oil, and Earth so united together, as to be capable of dissolving perfectly in Water.

To Philosophy.

14. Hence we also see the physical Cause of the fermentable Nature of River-Waters; which being kept in close Casks have been observed to ferment, and their Vapor, or Spirit, to take Fire at the Approach of a Candle. For much vegetable Matter, as Leaves, Grass, the Juices of Plants, &c. being by the Rains washed down into Rivers, such vegetable Matters must necessarily there run into a fermenting State, as Raisins do by the Addition of Water; the running or fluxible State of the Rivers being no Hindrance to this fermentative Motion, after it is once begun by Stagnation. For we see that Beer and new Wine will ferment afresh upon being shook, and carried upon Drays, or Carts.

15. All fermentable Bodies do not require *Ferments* to begin their Motion of Fermentation.

Raisins,

Raiſins, we ſee, require none; much leſs does the freſh expreſſed Juice of the Grape, or other vegetable Juices, in the Summer-Seaſon, or in a warm Air. But all ſweet vegetable Juices, that have felt much of the Fire, as Treacle, or Wort high boiled, Rob of Malt, Rob of Elder, or the like, uſually require a conſiderable Proportion of a vinous Ferment to make them work. In general, Ferments are no more than Matters already in the Act of Fermentation, or that ſoon run into this Act: Of the firſt Kind are the Flowers of Wine, Yeaſt, fermenting Beer, or fermenting Wine, *&c.* and of the ſecond, are the new expreſſed vegetable Juices of Summer-Fruits, *&c.*

16. Water, we find, is abſolutely neceſſary to begin and procure a fermentative Motion in vegetable Subſtances. For Raiſins, or Sugar, being kept dry, will never ferment. And this holds univerſally of all the Subjects of *vinous* and *acetous Fermentation*. Whence Water is an Inſtrument that muſt be neceſſarily employed in theſe Kinds of Fermentation, whether natural, or artificial *a*).

17. As the Water which naturally, and in large Quantities, perſpires from the Surface of Vegetables, eſpecially in hot Climates, does not go off pure, but carries along with it a conſiderable Proportion of fermentable Matter into the Atmoſphere *b*), there may be an actually vinous Fermentation begun and carried on in certain Parts of that Region, eſpecially where the Winds are ſtill, or the Air ſtagnant. And what phyſical Effects and Uſes this Fermentation in the Atmoſphere may have, ſcarce ſeems to have been conſider'd; nor ſhould they be raſhly judged of, till a more thorough Enquiry is made. At

a) See *Lect.* I. III. V. *paſſim.*
b) See *Lect.* V.

Schiedam

Schiedam in *Holland*, a larger Quantity of inflammable Spirit is ſaid to be obtained from Malt, than in any other Place, where there are fewer Malt-Diſtillers. This is probably owing to the Air of that Place being impregnated with the fermenting Vapours, that continually exhale from their numerous fermenting Backs and Stills. And the ſame is found to hold proportionably of Wines fermented in large Vaults or Cellars, where many Caſks of Wine are at once, or ſucceſſively, ſet to work.

18. Warmth, with the free Admiſſion of the external Air, is neceſſary to expedite the Action of vinous Fermentation; for if our Raiſins and Water were to ſtand either in a very cold Place, or to be kept entirely from the Acceſs of the common atmoſpherical Air, either no Fermentation, or a very weak and ſlow one, would enſue; as has been experienced.

19. The Lees remaining at the Bottom of the Caſk, in our preſent Experiment, are, if uſed freſh, a true Kind of *Ferment*, that will ſet any leſs fermentable Subject at work, and determine its Fermentation to the vinous Kind. They contain a large Proportion of eſſential Oil, and ſome Tartar. And hence we ſee that vinous Fermentation conſiſts, *firſt*, in an inteſtine Struggle or Commotion of the Fluid; and, *ſecondly*, in a Separation of a groſſer Part, which did not appear in that Form before.

EXPERIMENT II.

The Nature, Effects, and Uſe of acetous Fermentation; or the Method of turning vegetable Matters into Vinegar.

Vinegar made. 20. We took the Skins of the Raiſins, and the Sediment left behind, after a Wine was made in

the

the manner of the preceding Experiment, and poured three or four times their Quantity of boiling Water upon them, ſo as to make a thin aqueous Mixture. Then we ſet the containing Caſk, looſely cover'd, in a warmer Place than was uſed for the Wine, and found the Liquor, in a few Weeks time, became a clear and ſound Vinegar; which being drawn off from its Sediment, and preſerved in another Caſk, well ſtopped, continued long perfect and fit for Uſe.

21. This Experiment ſhews us a cheap and ready Way of making Vinegar from refuſe Materials; ſuch as the Huſks of Grapes, decayed Raiſins, the Lees of Wine, Grounds of Ale, Beer, *&c.* which are frequently thrown away as uſeleſs. Thus in many Wine-Countries, the *Marc*, Rape, or dry Preſſings of the Grapes are thrown in heaps, and ſuffered to putreſy unregarded; tho' capable of affording as good Vinegar, as the Wine itſelf would make. In ſome places they bury Copper-Plates in theſe Huſks, in order to make Verdigreaſe: but this Practice ſeems chiefly confined to the Southern Parts of *France*. Our preſent Experiment ſhews us how to convert them to another Uſe; and the Direction extends to all the Matters that have once undergone, or are fit to undergo, a vinous Fermentation; for all ſuch Matters will afford Vinegar. Thus all our Summer-Fruits in *England*, even Black-berries; all the refuſe Waſhings of a Sugar-Houſe, Cyder-Preſſings, or the like, will make Vinegar, by means of Water, the open Air, and Warmth. *The Experiment extended.*

22. The whole Proceſs, whereby this Change is effected, deſerves to be attentively conſider'd. And firſt, the Liquor to be thus changed, being kept warmer than in vinous Fermentation, in a few days begins to grow thick or turbid, and without throwing up Bubbles, or making any *The Proceſs phyſically conſider'd.*

any confiderable Tumult, as happens in vinous Fermentation, depofites a copious Sediment. The Effect of this Separation begins to appear firft on the Surface of the Liquor, which gathers a white Skin that daily increafes in Thicknefs, till at length it becomes like Leather; and now, if it be continued longer in this State, the Skin turns blue, or green, and would at laft grow folid, and then putrefy: therefore in keeping down this Skin as it grows, and thrufting it gently to the Bottom of the Veffel, confifts much of the Art of Vinegar-making, efpecially from Malt.

Larger Ob-fervation. 23. It is to be particularly obferved, that, if the Wine of our firft Experiment were not bunged down when arrived at its vinous State, but fuffer'd ftill to remain open and expofed to a warm Air, it would fpontaneoufly become Vinegar; and the fooner, if a fomewhat greater Degree of Heat, than ferved for the Making of Wine, were employed. Whence we might have ufed the Wine of our firft Experiment for this Purpofe, inftead of adding Water to the Hufks and Sediment, or Lees; but we chofe the latter Way, to fhew that even fuch refufe Matters will afford Vinegar; and again, to intimate how far the Art of Vinegar-making may be ftill improved, both in *England* where they brew a Wort from Malt, and in fome Wine-Countries where they make their beft Wines into Vinegars.

24. What we would chiefly obferve, for the prefent, is, that *acetous Fermentation* requires a ftronger Heat than the *vinous*; and that Wines having once finifhed their Fermentation, as Wines, do not naturally ftop there; but, unlefs prevented by the Care of the Operator, proceed directly on to *Vinegars*; where again they make

no

no Stop; but, unleſs prevented here alſo, ſpontaneouſly go on to Vappidity, Ropineſs, Mouldineſs, and Putrefaction. From which larger Obſervation we would deduce this Axiom: That, to ſpeak philoſophically, *the Intention or Tendency of Nature is, to proceed from the very Beginning of vinous Fermentation, directly, in one continued Series, to Putrefaction, and thence again to a new Generation*; which appears to be the grand Circle wherein all natural Things are moved, and all the Phyſical, or rather Chemical, Phænomena of the Globe produced.

25. And hence we ſee how, by the Interpoſition of Man, this general Proceſs of Nature may be ſtopped at different Periods, with different Views; ſo as to procure to ourſelves Wines, Vinegars, and, as will appear hereafter, * particular Salts and Oils.

26. Another Corollary from the larger Obſervation above laid down, is, That the Word *Fermentation* has been uſually applied to ſignify only a ſmall Part of this grand Operation of Nature. Thus one limits the Word to the Production of Wines; another, to the Production of Wines and Vinegars; and ſome would diſtinguiſh it from *Putrefaction*: whereas either the Term *Fermentation*, or ſome other, ſhould be made general, and denote the *Genus*, or *univerſal Operation*, whereof *Vinification*, *Acetification*, and *Putrefaction*, are only Species. At leaſt we ſhould thus attempt to follow and expreſs Nature, in the Facts that are obſerved, and not proceed, in an arbitrary, narrow, or inadequate Manner, to impoſe Terms, and dreſs out Nature according to our particular Hypotheſes and Conceits. But the Obſervation itſelf, on which *Corollaries.*

* See below, *Exp.* VI. VII.

this

this Doctrine is founded, being of moment to the right Underſtanding of the whole Affair of Fermentation and Putrefaction, we proceed to illuſtrate and confirm the laſt Part of it by an Experiment, as the two former Parts have been already *a*).

EXPERIMENT III.

That Wines and Vinegars, or all fermented vegetable Juices, have a natural Tendency to Putrefaction.

Vappidity and Putrefaction ſucceed Fermentation.

27. We took a Gallon of thick, muddy Vinegar, produced after the Manner of our ſecond Experiment, and letting it ſtand open, in a hotter Place than was required to make it Vinegar, it became in a few days a vappid, nauſeous, and putrefied Liquor, throwing up a large Quantity of a dry powdery Subſtance to the Top, and depoſiting a leſs Quantity of a groſſer Matter at the Bottom; ſoon after which the Body of the Liquor became clear again.

28. We might ſhorten the preſent Experiment, and ſave the Trouble of making either a Wine, or a Vinegar, to ſhew it. For if a Quantity of *Muſt* were ſet in an open Veſſel, in a hot Stove-Room, where the Air had free Acceſs, the Work would ſoon be performed, and the putrified Liquor be produced almoſt at once, without ſtopping at the State either of Wine or Vinegar; according to the larger Obſervation deliver'd above *b*).

Phyſical Uſe of the Experiment.

29. The preſent Experiment has a conſiderable philoſophical Uſe, as affording Light to the Underſtanding, and leading us far into a Knowledge of our Subject. And (1.) it gives us the phyſical Reaſon why Wines and Vinegars,

a) See *Exp.* I, II.

b) §. 24, 26.

unleſs

unleſs made exceeding ſtrong, will not keep, but corrupt and putrefy, in hot Countries. For the Heat being there ſo great, as to keep the lighter feculent Parts of thoſe Liquors ſuſpended for ſome time in the Body of the Liquor, Corruption (which proceeds from a tumultuary Motion of all the different Parts of a compound Body together *a*), neceſſarily enſues.

30. (2.) Hence alſo we learn the phyſical Reaſon why Wines and Vinegars require to be racked from their Lees, in order to preſerve them ſound, or keep them from running into Putrefaction, to which we find they are ſtrongly inclined; the Tendency of Nature being ever conſtant in urging them to that State. And the Caſe appears to be much the ſame in animal, and even mineral Subſtances; as we ſhall ſee hereafter *b*). *Practical Oeconomical Uſes.*

31. (3). This Experiment, therefore, furniſhes us with a Rule for preſerving vegetable Liquors from the laſt Stage of Fermentation, that is, Putrefaction or Corruption; *viz.* by firſt clarifying, and afterwards ſecuring and defending them from the open Air, and too much Heat. Thus, for example, we can preſerve the natural Juices of Quinces, Oranges, Lemons, Plants, *&c.* ſound and uncorrupt, by firſt clearing them of their groſſer Parts by the Filtre; or in ſome Caſes by Boiling and common Straining; then putting them up in Glaſſes, pouring Oil on the Top, and ſetting them in a cool Place. And in the ſame Manner we find ſome of the more delicate and curious Wines are long preſerved ſound and ſprightly: for the groſſer Feculencies being firſt removed, the Oil poured on the Top prevents the external Air from entering; and by keeping the Glaſſes

a) See §. 27. and hereafter *Exp.* VI. and VII. See alſo the Lord *Bacon*'s *Sylva Sylvarum paſſim.*

b) *Exp.* VII. VIII.

from the Sun, or open Day, too much Heat does not come at them.

Physical and Chemical Use. 32. (4) It is here remarkable, what a large Quantity of ſolid, earthy Matter is naturally contained in all fermentable Liquors. Thus, if a pellucid Solution of the fineſt Sugar in Water be expoſed to vinous Fermentation, it ſoon grows turbid, throws an earthy Skin to the Top, and depoſites much terreſtrial Matter at the Bottom in the Form of Lees. If the Wine be now drawn off clear and expoſed to acetous Fermentation, here again it throws off much terreſtrial Matter, both in the Form of a Skin at Top, and of Lees at the Bottom. Thirdly, if tranſparent Vinegar be expoſed to putrefactive Fermentation, here again it ſeparates a conſiderable Quantity of Earth, both at the Bottom and at Top. All which ſhews that the Separation of a groſs Matter is eſſential to theſe ſeveral kinds of Fermentation, and that a copious Earth may lie concealed in fermentable Juices, and tranſparent Fluids, till it finds an Occaſion of manifeſting itſelf to the Senſes.

The Changes produced by Fermentation. 33. Before we proceed to animal and mineral Fermentation, it is proper to examine what are the Changes wrought upon vegetable Subjects by vinous and acetous Fermentation. This we may find, in ſome Meaſure, by comparing Muſt, or a bare Solution of Raiſins in Water, with the Wine and Vinegar which the ſame Muſt, or Raiſins and Water afford, in Vinification and Acetification; and in this Light they may be compared by the bare Uſe of the Senſes: but their internal and eſſential Differences will better appear by a chemical Analyſis, or Diſtillation.

34. Muſt, or a Solution of Raiſins in Water, which makes a Kind of *Muſt* correſponding to the natural Juice of the Grape, is a ſweet, clammy

my and ſomewhat odorous Fluid, which being committed to Diſtillation affords not the leaſt inflammable Spirit. But after having paſſed thro' the Courſe of vinous Fermentation, it acquires ſeveral Properties it had not before. For example: it is more tranſparent and thin; loſes of its Sweetneſs; has ſome Degree of Acidity and Roughneſs; proves more odorous, and affords a large Proportion of *inflammable Spirit*; as appears by the following Experiment.

Experiment IV.

That vinous Fermentation produces an inflammable Spirit.

35. We took three Gallons of new Wine, procured from Raiſins and Water in the manner of our firſt Experiment, and committed it to the Alembic or Still, which being made to work gently, till the Liquor that came over, being thrown upon the hot Still-Head, would no longer take Fire by applying the Flame of a Candle to the riſing Vapour, we thus obtained a conſiderable Proportion of *Brandy*, and a weaker *Spirit*. *Inflammable Spirit obtained.*

36. This Experiment ſhews us the common Method of making Brandies in Wine-Countries, or a Spirit from Malt, Melaſſes, Cyder, &c. in others. For the fineſt *French* and *Rheniſh* Brandies, the Rums and the Arracks of the *Indies*, are obtained in the Manner of this Experiment; all of them being uſually diſtilled a ſecond time over, and *made up*, as they call it, with Water, or the weak aqueous Liquor of the ſecond Running, as in our preſent Experiment, to a certain Strength, or ſuppoſed Standard, termed ſaleable *Proof*. *Uſe of the Experiment.*

Proof in Spirits what.

37. This *Proof* is judged of by the Head, or Crown of Bubbles, riſing upon the Surface of the Liquor when ſhook in a long ſlender Vial, and by the Manner wherein theſe Bubbles vaniſh. For if they are too large and vaniſh too ſoon, the Spirit is deemed above *Proof*; if too ſmall, and they go off too ſoon, it is ſaid to be below *Proof*. But this is a fallacious Method of Judging; becauſe there are certain known Ways of making a Spirit bear this Trial, when it is in Reality either above or below Proof. For the proper Meaning of the Word is, that a Proof-Spirit ſhould contain about one half Water, and the other half Alcohol *a*).

Philoſophical Uſe.

38. The philoſophical Uſe of the Experiment is to ſhew, that an inflammable Spirit is produced by the Action of vinous Fermentation, from a vegetable Subject and Water, wherein no Signs of any ſuch Spirit before appeared. Inſomuch that this may be juſtly eſteemed the Criterion, or inſeparable Effect, of *vinous Fermentation*.

Spirit of Wine how btained.

39. The Ways of obtaining this inflammable Spirit, to the beſt Advantage, will be conſidered hereafter *b*). In the mean time it may be obſerved, that this Spirit being rediſtilled, ſo as to deprive it totally of its aqueous Part, is the *Spirit of Wine*, or Alcohol, whoſe diſſolving Power was ſhewn, in the laſt Lecture upon *Menſtruums c*); and this Method is the only one that is known of procuring it. For no Subjects but thoſe of the vegetable Kingdom are found to af-

a) See this Matter farther explained in *Lect.* XII. *Exp.* IV. See alſo *Lect.* I. *Exp.* VII.

b) *Lect.* XI. and XII.

c) See *Lect.* VI. *Exp.* II.

ford

ford it; and that only by means of a previous *vinous Fermentation*.

40. It ſhould likewiſe be obſerved, that this *Alcohol* is one of the moſt eſſential Parts of Wine; ſo that, when it is withdrawn, the Wine loſes its Nature; as we ſee by the Remains of the preſent Experiment. And when properly uſed, it is a certain Remedy for moſt Diſeaſes incident to Wines; as keeping them ſound and free from Corruption. Whence we have another Rule for preſerving vegetable and animal Subſtances from Putrefaction. For this Liquor proves a kind of Balſam to them all, and is accordingly uſed, with Succeſs, for preſerving even animal Subſtances; as we ſee in anatomical Preparations, &c. *The Uſe of the Spirit to Wine.*

Experiment V.

That acetous Fermentation aboliſhes the inflammable Spirit produced by vinous Fermentation.

41. We put a Quart of ſharp Vinegar into a Glaſs Retort, and diſtilled, in a Sand-Heat, with Degrees of Fire, into a Glaſs Receiver, but found not the leaſt inflammable Spirit come over; only an acid aqueous Liquor, commonly called *diſtilled Vinegar*; which, inſtead of burning, quenches Fire. *Vinegar yields no Alcohol*

42. Hence it appears, that acetous Fermentation has a very different Effect from the vinous; and that the inflammable Spirit produced in the former, is either concealed, altered, exhaled, deſtroyed, or ſome Way aboliſhed, in the latter. A part of this Spirit is unqueſtionably exhaled by the Heat employed in Acetification; yet Part alſo remains behind under a different Modification, ſo as to be recovered by Art in an inflammable Form; as we find by diſtilling the *Sugar of* *Use of the Experiment.*

 Lead,

Lead, which is only Lead diſſolved in Spirit of Vinegar.

43. Our Experiment affords us a Criterion of acetous Fermentation, as before we had of the vinous. For if an acid uninflammable Liquor comes firſt over by Diſtillation from a vegetable Subject, previouſly fermented, this will determine that Fermentation to have been of the acetous Kind.

44. Thus, therefore, we are plainly led to allow of two very different kinds of Fermentation, in the ſame vegetable Subject; and we conceive that ſome other Species may be found upon due Enquiry.

EXPERIMENT VI.

That vegetable Matters turn of an animal Nature by a hot Fermentation, or Putrefaction.

Putrefaction in Vegetables.

45 We took a large Quantity of freſh, green Cabbage-Leaves, and preſſed them hard down with Weights in an open Tub, bored full of Holes on the Sides and ſet in a warm Place. By ſtanding in this State for ſome Days, the Leaves conceived a Heat in the middle, which ſpread to the more external Parts, till at length nearly the whole was converted into a pappy, putrefied Subſtance, whoſe Conſiſtence would not well ſuffer it to ſeparate into a thicker and a thinner Part. This Subſtance being diſtilled in a Glaſs Retort, afforded the ſame Kind of volatile Salt and Oil, as if it had been an animal Subſta nce

The Experiment extended.

46. This Experiment is general, and ſucceeds alike in all tender, juicy, vegetable Subjects; ſo that both the acid and alkaline Tribe of Plants, the ſweet and the bitter, the aſtringent, and emollient, &c, reſolve into this ſame pappy, pu-

trefied

trefied Subſtance. We obſerve it alſo in Hay that is ſtacked wet; in Horſe-litter thrown on Heaps; in the Grape-Huſks, or Apple-Pumice, after preſſing for Wine or Cyder; and the larger the Heap, and the greater Weight the Matter ſuſtains, the greater the Heat; provided the Acceſs of the Air be not prevented.

47. Hence we ſee the Way employed by Nature for changing all *vegetable* into *animal Subſtances*, or of reducing the Matters of both Kingdoms to a Similarity; ſo that the one may be uſed for ſeveral Purpoſes inſtead of the other. And thus Nature annually makes large Quantities of Compoſt, from the refuſe Weeds, Leaves, Traſh of the Fields, Woods, and Gardens; for this vegetable Matter thus putrefying, and becoming ſoft and pulpy, is eaſily diluted by the falling Rains, and thence diſperſed over the Face of a Field, and carried into the Pores of the Earth. And thus the Chemiſt may, by Diſtillation from ſuch putrefied vegetable Subjects, procure volatile Salts and volatile Spirits, hardly to be diſtinguiſhed from thoſe of Hartſhorn, *&c.* at leaſt the volatile Salt and Spirit ſo obtained might ſerve together with Sea-Salt, for making of Sal-Ammoniac *a)*. For it appears that the Matter of the fixed Salt in Vegetables is, by this Operation, truly volatilized. Whence not a Grain of fixed Salt can be procured from the largeſt Quantity of this putrefied Matter, provided the Operation were compleatly performed. *In Uſe.*

48. This Experiment has various Uſes, not only in Trades, but alſo in natural Philoſophy and Medicine. And firſt, it ſhews an artificial as well as natural Method of converting any, or all of the different Subjects of the vegetable *In Trade.*

a) See *Lect.* XX. *Exp.* I.

Tribe into the ſame undiſtinguiſhable Subſtance, totally deſtroying all the ſpecific Differences which before diſcriminated that great Variety. And the ſame Obſervation reaches alſo to animal Bodies, as we ſhall ſee hereafter *.

In the animal Oeconomy. 49. It alſo throws conſiderable Light upon the Proceſs of animal Digeſtion, as performed in the Stomach and Inteſtines; it ſhews us the Nature of Gangrenes, Mortifications, and carious Bones in the Body; and the phyſical Reaſon why no fixed Salt is found in the Blood, Bones, or Fleſh; All which Particulars may be farther illuſtrated and confirmed, by conſidering the like Proceſs in an animal Subject.

II

EXPERIMENT VII.

That animal Bodies naturally undergo a Fermentation, or Putrefaction, after Death.

Animal Putrefaction. 50. If any large animal Body, as that of a Horſe or a Dog, for example, be expoſed in a dead State to the open Air and the Summer's Sun, it begins in a few Days to ſwell, purge, and emit a nauſeous Stench. At length the Form of the Carcaſs is deſtroyed by the Commotion, and reſolved into a putrid, fetid, ſtercoraceous Matter; a large Part in the mean Time flying off into the Air, ſo as to leave but a ſmall Proportion of a mucilaginous, pappy Subſtance, which ſoon grows dry, or turns to a Kind of Earth. But a Quantity of this Matter being collected before it grows dry, and diſtilled, it is ſaid to afford the burning *Phoſphorus*, as putrefied Urine is known to do.

* *Exp.* VII.

51. This

51. This Experiment or Obſervation is univerſal, and holds equally of Birds, Beaſts, and Fiſh. Whence Rivers, the Ocean, and the Atmoſphere itſelf, muſt neceſſarily be impregnated with fermenting, putrefying, and putrefied Particles, which mixing with other Matters, and being diſperſed through the immenſe Bodies of thoſe Fluids, they undergo therein ſuch Changes, whether by uniting with the Salts of the Air and Ocean, or otherwiſe, as prove not unfrequently deſtructive or noxious to the Creatures that inhabit thoſe Elements. For this putrefied Matter appears to be in itſelf a Kind of Poiſon, infecting the Air wherein it ſpreads; ſo as to occaſion peſtilential Diſeaſes near the Places where great Battles have been fought, when the unburied Carcaſes of the Slain thus reſolve and go off into the Atmoſphere. Many other Inſtances we have of the poiſonous Nature of putrefied animal Subſtances, in rotten Eggs, mortified Fleſh, and the like: whence this ſeems to be another particular Species of *Fermentation.* *Extended.*

52. It has been diſputed, whether there be a real Fermentation in the preſent Caſe. But ſuppoſing this not to be a Diſpute about Words, it ſhould ſeem that there is a proper Species of Fermentation, peculiar to animal Subjects, as there is one peculiar to Vegetables. Till this Point be ſettled, we ſhould not lay down vegetable Fermentation, as the Teſt and Standard of Fermentation in general, and ſo judge of all other Kinds according as they approach to, or recede from, this Standard. For want of diſtinguiſhing in this Caſe, all true Fermentation ſeems denied to the Blood and Juices, circulating in a living animal Body, as well as to the Sap of Vegetables. But were the Enquiry into Fermentation proſecuted in its full Latitude, and not arbitrarily *Fermentation determined.*

arbitrarily confined to any ſingle Species, perhaps many natural and artificial Operations would prove to be actual Fermentations. To ſay that there is no Fermentation in the Blood, becauſe it affords no inflammable Spirit upon Diſtillation, is in effect the ſame as to ſay that Blood is not Wine. Whereas the Queſtion is not whether there be a *vegetable Fermentation* in the Blood, but whether there be not an *animal one*; the Criterion whereof is the Production of a volatile urinous Salt, as the Production of an inflammable Spirit is the Criterion of vinous Fermentation.

Chemiſtry of Nature in Bodies.

53. And here is a Door opened for enquiring into the Chemiſtry of Nature, as it is exerciſed in the Bodies of Men; ſo as to diſcover the natural Means whereby vegetable Subſtances taken in at the Mouth, by the Way of Aliment, are prevented from running into vinous or acetous Fermentation; but are, on the contrary, changed into a balſamic, unctuous, and milky Liquor, or Chyle, that turns red in the Arteries, recruits the Blood, and nouriſhes the Body. For all this ſeems to be the Effect of a peculiar *animal Fermentation*, the Laws and Proceſs of which are little conſidered. And in this View, the ſeveral Juices of the Body, as the Saliva, Bile, Pancreatic Juice, *&c.* may be regarded as animal *Menſtruums*, acted upon, and made to act in the Body, by determinate Motions, for determinate Ends.

III.

EXPERIMENT VIII.

That there may be a Kind of Fermentation in mineral and metallic Bodies.

Mineral Fermentation.

54. We took an Ounce of Lead and as much Biſmuth, and melted them together in an Iron Ladle;

Ladle; then heating two Ounces of Quickſilver in another Ladle, we mixed all the three metallic Matters together as an Amalgam; which, when cold, appeared perfectly uniform or homogeneous, and totally paſſed thro' the Pores of Leather in a running Form. But this Mixture being ſuffered to cool, and ſtand quiet for ſome Hours, a groſs Matter ſeparated from it by Degrees, and floated upon the reſt; which was left ſo thin and fluid, as to paſs through Leather, leaving the groſs metallic Matter behind.

55. Hence it ſhould ſeem that even metallic Matters may have their peculiar Fermentations, as well as vegetable and animal Subjects. For when the preſent Experiment comes to be carefully conſidered, it appears to have all the Requiſites of Fermentation. For here is, (1.) a fluid Form, (2.) an uniform Matter, (3.) an inteſtine Motion, and (4.) an actual Separation of a groſſer Matter, leaving a thinner behind. All which Particulars we have found to hold in the ſeveral Species of Fermentation above examined. *The Experiment extended.*

56. There are many more Inſtances of an apparent Fermentation in mineral Bodies, one or two whereof it may be proper to mention. Thus, if an aqueous Solution of the common green Vitriol be expoſed to the Air in the Summer-time, and kept continually ſupplied with freſh Water as the former exhales, the groſſer metallic Part of the Vitriol will ſubſide, and the reſt gradually ſhoot upwards all round the Veſſel, in Form of an unctuous, cruſty Matter; till the whole Body of the Vitriol is thus ſucceſſively ſo altered that the Part ſhot into the cruſty, unctuous Form, will neither become Vitriol again, nor corrode any freſh Metal; and in all other Reſpects it appears a different Thing from Vitriol. And hence

hence feem to proceed the Complaints of the Makers of Vitriol, that in rainy, windy, and cloudy Weather, their Vitriol-Stones, which lie open to the Air, will not fometimes yield a folid cryftalline Vitriol, but only an unctuous Matter. This may therefore appear to be a Fermentation in all its Forms, as being attended with a fpontaneous inteftine Motion, a fpontaneous Separation of conftituent Parts, and a remarkable Alteration of the Subject.

57. It alfo makes to the prefent Purpofe that folid and hard Pyrites, or Vitriol-Stones, being expofed to the Air and moiftened with Water, will, like a vegetable Subject *a*), grow hot, fume, and even take Fire, as was obferved in our fourth Lecture, and afterwards afford Vitriol; a Thing very different from the Stones themfelves *b*). So that, upon the whole, we may conclude, that in a proper Senfe, there is an actual *Fermentation* exercifed, not only in the vegetable and animal, but alfo in the mineral Kingdom.

V.

AXIOMS *and* CANONS.

1. All the Inftances being duly confidered, and a large View of Things taken in, we may define *Fermentation*, in general, a fenfible internal Motion of the conftituent Particles of a moift, fluid, mixed, or compound Body; by the Continuance of which Motion, thofe Particles are gradually removed from their former Situations, or Combinations; and again, after fome vifible Separation is made, joined together in a different Order and Arrangement. And thus the

a) See above, *Exp.* VI.
b) See *Lect.* IV. *Exp.* V.

whole Procefs of Fermentation confifts of two different Operations, *viz.* an *Analytical* one, whereby the Particles are refolved, and a *Synthetical* one, whereby they are new ranged: So that whenever thefe two different Effects are found to be produced, in direct Sequence, with the Circumftances above defcribed, we need not fcruple to call the Operation by the Name of *Fermentation*, whether it happen in the Blood, or other animal, vegetable, or mineral Subftances *a*).

2. That all feparable, mixed, or compound Bodies may be the Subjects of this general Operation; but that the eafier they are feparable by Means of Water, Air, and Heat, the more readily they ferment *b*). Thus the fweet or faccharine Part of Malt, more readily diffolving in warm Water, ferments eafier than unmalted Corn, which is more clammy and will not diffolve fo foon. And hence the Flefh of animal Bodies putrifies fooner than the Bones. And this appears to hold in all Inftances *c*).

3. That this general Fermentation is divifible into many diftinct Species, particularly into *vegetable*, *animal*, and *mineral d*); the vegetable Kind again into *vinous*, *acetous*, and *putrefactive*; the vinous again into mucilaginous, mouldy, and putrefactive; and fo of the acetous, &c. Whence we may deduce a *Canon* for adjufting all the different Species of Fermentation; which being once fixed might put an End to infinite hypothetical Difputes upon this Subject, and lead to farther Difcoveries both in Nature and Art.

a) See the whole Lecture, *paffim.*
b) See *Exp.* I. VI.
c) See *Exp.* I. VI. VII.
d) See the whole Lecture, *paffim*,

4. That

4. That it is in the Power of Man to prevent, ſtop, and regulate theſe natural Operations at any aſſigned Point of Time. Indeed it is thus we come by our Wines and Vinegars; It is thus that Men diſcovered the Art of Embalming; It is thus we preſerve many vegetable, and animal Juices, in their natural or unfermented State; It is thus we preſerve Yeaſt, and Wine-Lees, Subjects extremely apt to putrefy; It is thus we can at any Time ſtop the Courſe of vinous Fermentation, and produce a ſweet, or half fermented Wine; It is thus we cure the Frettings, or other Diſeaſes of Wines; and thus we ſtop Mortifications in the Body, and Caries in the Bones. And moſt of the Artifices employed for theſe Purpoſes, depend upon a Knowledge and Regulation of the phyſical Cauſes and Inſtruments that produce the Change; which Cauſes and Inſtruments, as we above diſcovered, are chiefly, Heat, Moiſture, and the external Air *a)*.

5. That a ſaccharine Matter is the Baſis of Wines, Vinegars, and inflammable Spirits *b)*.

6. That a great variety of ſound, perfect, and wholeſome Wines may be made, in Countries that do not naturally afford Grapes, by a prudent Uſe of Sugar, or Raiſins and Water *c)*.

7. That the Matters called Ferments are of Uſe in beginning, regulating, and determining the Species of Fermentation *c)*. Thus freſh Yeaſt determines the Fermentation of Wheat-Flour to make our common Bread, which would prove of another Kind, if the Flowers or Lees of Vinegar were uſed. And thus ſpecific or de-

a) See the whole Lecture, *paſſim*.
b) See *Exp.* I. §. 15. &c.
c) See *Exp.* I.

terminate

terminate Ferments have their correſpondent Effects. If Sugar, Honey, Manna, Treacle, or new Wine be added to Vinegar, themſelves are ſoon changed into Vinegar, without ſtopping to make Wine; becauſe the acetous Ferment, or Vinegar, over-rules them. And ſo Vinegar is ſooneſt made in a Caſk that has before contained the ſame Liquor. And if the beſt Wine were put into a Caſk that had held putrefied Vinegar, the Wine would not now make Vinegar, but immediately run into Corruption. So great and ſo deciſive a Power have ſpecific Ferments; the Uſe whereof is therefore evident, and may afford conſiderable *Rules* in Chemiſtry, practical Philoſophy, and Arts.

8. That the Degrees of Fermentation differ with the Degrees of Heat employed *a)*. Thus we ſaw vinous Fermentation required a leſs Degree of Heat than the acetous; the acetous a leſs than the putrefactive; which latter may even conſiſt with a Degree of Ignition *b)*.

9. That a particular Kind of Fermentation may be carried on in the living Bodies of Animals and Vegetables, which are largely ſupplied with the requiſite Inſtruments of Fermentation, *viz.* Water, Air, and Heat: And in Fact both Vegetables and Animals appear to have an inteſtine Motion in all their circulating Fluids, which continually depoſite a groſſer Matter in the Canals and Parts they move through. Whence, by our Definition of Fermentation *c)*, this natural Act may be accounted a Species of Fermentation, producing a Change in the nutrimental Matter of Vegetables and Animals, and converting it into their own Subſtance.

a) See *Exp.* I, II, III, IV, V, VI.
b) See *Exp.* VI.
c) See *Ax.* I.

10. That

10. That when Vegetables or Animals die, there ſoon begins a different Kind of Fermentation in all their Parts; tending now not to the Repair, but to the entire Deſtruction, of their organical Veſſels, the confuſed Mixture of their ſolid Parts and Juices, and a Volatilization of their whole Subſtance *a)*.

11 That dry or ſolid Bodies cannot, in that State, undergo a proper Fermentation: for tho' they may in that State be ſeparated into minute Particles, yet they cannot range themſelves together in any new Order, nor depoſite a groſſer Part, without being agitated by ſome Fluid, or ſuſpended therein for ſome Time. And hence, in overheated Mines, the Ore is thus *analytically* deſtroyed, and cannot range itſelf into a metalline, or any other regular Order again, for want of the requiſite Moiſture or Fluidity; whence the Matter appears like a Heap of rotten Earth, or what the Miners call *Dead Metal b)*; of which we have a remarkable Inſtance in the over-heated or fired Mixture of Sulphur and Iron-Filings *c)*.

12. That the terreſtrial, marine, and atmoſpherical Regions have each their proper *Fermentation*, different in Kind, and ſubdiviſible into particular Species, whereby the Changes of all Bodies one into another are naturally performed *d)*; And that in Imitation hereof, by a thorough Knowledge of the natural Agents that produce theſe grand Effects, Art likewiſe may produce extraordinary Changes in Bodies *e)*.

LEC-

LECTURE VIII.

CONTAINING

Analytical Chemiſtry; *or, the Art of Analyſing Vegetable, Animal, and Mineral Subſtances, and reſolving them into different Parts or Principles.*

I.

1. THE whole of Chemiſtry may be comprehended under the Art of reſolving Bodies into their Principles, and of compoſing new Compounds from thoſe Principles, by Means of the common Elements, Fire, Air, Water, Earth, and particular *Menſtruums.* We ſhall accordingly in our preſent Lecture, endeavour to enquire into the Buſineſs of chemical Reſolution, in the vegetable, animal, and mineral Kingdoms, with a View to diſcover what uſeful *Principles* may be thence obtained; intending, in our next Lecture, to conſider the correlative Buſineſs of Compoſition: ſo that the two together may contain a ſummary Account of the Nature, Office, and Uſe, both of analytical and ſynthetical Chemiſtry; of which the one takes Bodies to Pieces, or reduces them to their component Matters, and the other, by putting theſe Matters or different Pieces together again, in various Manners, forms a large Set of new Productions, that would be unknown to Nature without the Interpoſition of Art. And ſuch Productions, for Inſtance, are, *Brandy, Soap, Glaſs,* &c. *Subject.*

2. But before we enter upon the Enquiry itſelf, it is neceſſary we ſhould diſtinctly explain *Principles what.*

what we mean by the Word *Principle*, about which many Diſputes have been raiſed. We muſt therefore obſerve, that the more intelligent among the modern Chemiſts do not underſtand by *Principles* thoſe original Particles of Matter, of which all Bodies are by the mathematical and mechanical Philoſophers ſuppoſed to conſiſt. Thoſe Particles remain undiſcernible to the Senſe, tho' aſſiſted with the moſt finiſhed Inſtruments; nor have their Figures and original Differences been determined by a juſt Induction. Leaving, therefore, to other Philoſophers the ſublimer Diſquiſition of primary Corpuſcles, or Atoms, of which many Bodies and Worlds have been formed in the Fancy, genuine Chemiſtry contents itſelf with groſſer Principles, which are evident to the Senſe, and known to produce Effects in the Way of corporeal Inſtruments. And theſe groſſer Principles are every Way ſufficient to anſwer the Purpoſes of philoſophical Chemiſtry, which conſiſts wholly in Experiment, and the Explanation of Facts and ſenſible Operations. Where, by the Way, it may be obſerved, that Chemiſtry is an Art extremely well ſuited to the Nature of Man, as it requires nothing more than the Uſe of ſuch Faculties as he evidently finds himſelf poſſeſſed of. But when once we leave the Oracles of Senſe, and introduce metaphyſical Speculations and Notions into Chemiſtry, it then becomes a corrupt Fountain of Hypotheſis and Illuſion. To rectify Chemiſtry, therefore, the Rule is to keep cloſe to the Information of our Senſes, the Laws of Induction, and the Uſe of material and ſenſible *Principles*.

3. Theſe ſenſible Principles, ſo far as we know them, are ſignificantly expreſſed by the common Words, *Water*, *Earth*, *Salt*, *Sulphur*, and *Mercury*: to which might be added the Air, if a Way were

were known to fix it, so as to render it more sensible, tangible, and corporeal *.

4. By *Water* we understand a sensible, transparent Liquor, without Taste or Odour; that freezes with a certain Degree of Cold, and liquifies from that State with a certain Degree of Heat; that extinguishes Fire, &c. By the Chemists this is otherwise called *Phlegm*. *Water.*

5. By *Earth* we understand an insipid, dry, powdery Substance, that will neither dissolve in Water, nor burn away in a strong Fire; but, with the Addition of fixed Salt, melts into Glass. *Earth.*

6. By *Salt* we understand any sensible Body that readily dissolves in Water, tastes sharp or pungent upon the Tongue, and has a great Disposition to unite with Earth, so as to appear in a solid Form; as in common Salt, Alum, &c. *Salt.*

7. By *Sulphur* we mean any Matter that will readily burn and disappear in the Fire, and that will not easily, or of itself, mix with Water. *Sulphur.*

8. And lastly, by *Mercury* we understand a sensible Body that has the Fluidity, Gravity, and Appearance of common Quicksilver. *Mercury.*

9. We do not lay down these as adequate Definitions, but only as sensible Marks whereby the Things meant may be readily known and distinguished for ordinary Use. Just Definitions can be drawn only from a full and perfect Discovery of the Nature and Properties of Bodies, which we are far from knowing; nor do we usually meet with any of these Principles in a pure and perfect State, unmixed with other Bodies. When they appear to the Senses to be thus far purified, they are the Principles we mean, or what we

* See *Lect.* III. *Exp.* X.

emphatically call the *Chemical Principles*; tho' they may be every one of them deſtructible, as to that Form: but then they ceaſe to be chemical Principles.

10. And thus we have endeavoured to ſettle the chemical Meaning of the Word *Principles*, and to lay down Marks or Criterions for diſcovering and diſtinguiſhing them, when we meet with them hereafter in the following Experiments.

11. Theſe Experiments we ſhall endeavour to make as general as we can, and give an Example in each of the three Kingdoms, as they are called, *viz.* the Vegetable, Animal, and Mineral.

EXPERIMENT I.

That Vegetables are reſoluble, by Fire, into four of the chemical Principles, viz. Water, Oil, Salt, *and* Earth.

Worm-wood analyſed.

12. We took two Pounds of common Wormwood cut ſmall, which we put into a Glaſs Retort in a Sand-Heat, and diſtilling with Degrees of Fire, and a frequent Change of Receivers, we obtained (1.) an aqueous Liquor, and (2.) an Oil. Then taking out the Remainder, and burning, or calcining it, in the open Air, it turned to a grey Kind of Aſhes; which being boiled in fair Water communicated thereto (3.) a Salt. This Salt we obtained in a dry Form, by letting the Solution ſtand at Reſt for ſome Time, then decanting the clear Liquor, and exhaling the ſuperfluous Water. And (4.) we found an earthy Subſtance remaining at the Bottom of the Water wherein the Aſhes were boiled.

The Experiment made general.

13. This Experiment being well attended to is very inſtructive, and ſhews that the *chemical Princi-*

Principles above-mentioned are not imaginary or fictitious Things; but Things palpable, and evident to the Senſes. For here we have a Water, an Oil, a Salt, and an Earth, all afforded us by a vegetable Subject. And the Experiment may be made general without much Variation: for all the vegetable Subjects hitherto examined, in this Manner, reſolve themſelves into the ſame general Principles, which differ only (1.) in Reſpect of the Kind of Salt; that being in ſome more volatile, in others more fixed; in ſome acid, in others alkaline; and (2.) in the Nature or particular Properties of the Oil; which in ſome Plants is thinner and more fluid, in others more groſs and viſcous; &c. But all the Principles thus obtained agree to the general *Definitions* above laid down *. So that there appears to be no Vegetable in Nature, but what is thus reſoluble into Water, Oil, Salt, and Earth.

The Water purified.

14. To obtain theſe Principles pure, we muſt (1.) ſeparate all the Oil that may chance to remain ſuſpended in the *Water*. This is effected, in a conſiderable Degree, by the Filtre; which being kept continually filling up, ſo as that the lighter Oil may not come in Contact with the Paper, the aqueous Part is thus tranſmitted tolerably free from Oil. (2.) But ſtill there may remain ſome ſmall Proportion of oily and ſaline Matter therein? If the ſaline Matter be acid, the way to deſtroy it is, to mix a little Chalk, or any pure and fixed alkaline Salt, with the Liquor. By this means alſo more of the Oil will be ſet free; ſo that being now filtred again, and gently diſtilled with a ſoft Heat, the aqueous Part will riſe much purer, and paſs for Water in the Judgment of the Senſes. (3.) If the Plant

* Sect. 4—8.

was alkaline, and an alkaline Salt abound in the aqueous Liquor, let it be made neutral with one that is acid; and thus again the Water may be ſeparated pure, by means of the Filtre and Rediſtillation. And this is the Method of manifeſting to the Senſes, that the chemical Principle *Water* is naturally lodged in, and may be ſeparated from all vegetable Subſtances *.

The Oil purified.

15. In order to procure the *Sulphur*, or oily Principle, pure, the unctuous Matter, obtained by this general Proceſs, may be waſhed from its adhering Salts and groſſer Earth in warm Water, barely by ſhaking them in a Glaſs together, and then ſeparating the Oil from the Water by means of the common ſeparating Glaſs; where, if the Oil be ſpecifically heavier than Water, it ſinks to the Bottom, and may be ſuffer'd to run out firſt; if ſpecifically lighter, it floats a-top, and may by the Finger applied to the Bottom of the Glaſs, or ſome other Contrivance, be kept behind, when all the Water and feculent Parts are run from it.

The Salt purified.

16. To obtain the ſaline Principle pure; (1.) if it be of the volatile urinous Kind, the Matter may be diſſolved in Water, and made to paſs the Filtre; then ſet in a gentle Heat to ſublime: for it will thus riſe and leave the Water behind, as being much more volatile than that. (2.) If it be required ſtill purer, the beſt Method hitherto known is, to ſublime it from finely pulverized Chalk; then to ſaturate it with a clean Spirit of Sea-Salt, ſo as to convert it into a true Sal-Ammoniac; which being mixed with Salt of Tartar, and again ſet to ſublime, the volatile Salt will riſe highly purified, ſo as long to retain its Whiteneſs. (3.) But if the ſaline

* See *Lect.* V. *Exp.* I.

Matter

Matter obtained be of the fixed Kind, the Method of purifying it is, to dissolve it in fair cold Water; suffer the Solution to subside; then decant the clear Liquor, and evaporate it in a clean Iron Pan or Glass Vessel, constantly stirring it, till it becomes dry and white: (4.) Or to purify it still farther and render it perfectly white, let it be put into a clean Crucible, and exposed for a while amidst the Flame of burning Charcoal, but without Melting it.

17. Lastly, to obtain the earthy Principle in its Purity, let it be thoroughly calcined, boiled in several Waters, in order to get out all its Salt; then dry it over a clear Fire, or in the Sun. And if these several Operations be performed in Perfection, we then obtain what we properly mean by the *chemical Principles of Vegetables*. *The Earth purified.*

18. And tho' it be not always necessary for the Purposes of Chemistry, or the common Calls of Life, to bring these Principles to the Degree of Purity here mention'd, yet there are many Cases that absolutely require them to be so purified; otherwise the Operations in which they are employed may easily miscarry: and this we desire may be noted as one considerable Reason of the Failure of particular Experiments and Operations, both in Chemistry itself, and in many of the chemical Arts; particularly the Art of Glass, Distillation, &c.

19. The Uses of this leading Experiment are numerous; we shall touch upon a few of them. And first, we may learn from it that these chemical Principles are found in different Quantities in different Vegetables, or in the same at different Seasons or Times of Growth. Thus, for instance, Olives, Almonds, Mace, &c. contain such an Over-Proportion of Oil, to the other *Uses of the Experiment.*

Principles, that it may be copiouſly got from them barely by Preſſure. The Vine in the Spring affords a larger Proportion of fixed alkaline Salt than at any other Seaſon; and the ſame holds of the Wood uſually burnt for Pot-aſh. And thus we find that the aqueous and ſaline Principles preſide in Vegetables in the Spring, but the oily in the Summer and Autumn; that all young Plants abound more with Water, than ſuch as are full grown; and that Oil is moſt plentifully contained in the oldeſt Trees, and thoſe of the colder Climates. Whence we are directed to the proper Times, Seaſons, and Places for felling the Timber deſigned for Pitch, Pot-aſh, Fewel, and Charcoal.

20. By applying this Experiment to different Vegetables it has been found, that Vegetables are naturally diſtinguiſhable into two grand Tribes, *viz.* the Acid and the Alkaline; the firſt affording a volatile Acid, and the other a volatile Alkali, upon dry Diſtillation. Thus Guaiacum, Cedar, Box, Cinamon, Cloves, Sorrel, Mint, Baulm, *&c.* afford an Acid; but Garlick, Leeks, Onions, Horſe-radiſh, Scurvy-graſs, Muſtard, *&c.* afford an Alkali; which, when rectified, is hardly diſtinguiſhable from that of animal Subſtances, ſo as nearly to reſemble the Spirit and Salt of Hartſhorn *a*).

21. This Experiment alſo ſhews us the Methods of making or procuring Tar, Charcoal, fixed Salt, and elementary Earth, from Vegetables; four capital Things in Arts and Trades. Tar is the ſcorched Oil of unctuous Wood, forced out by Fire, as the groſs Oil is in the *preſent Experiment b*). Charcoal is Wood burnt cloſe

a) See *Lect.* VII. *Exp.* VI.
b See alſo *Lect.* II. *Exp.* III.

to

to Blackneſs *a)*; Soap, a Mixture of fixed Salt and Oil; Glaſs, a mixture of Earth and fixed Salt; and elementary Earth makes all the Teſts and Coppels for refining of Gold and Silver.

22. Again, the preſent Experiment ſhews us the Nature of vegetable Fumes, by which, in the Way of animal Curation, Fiſh and Fleſh are long preſerved, free from Putrefaction or Corruption. For where-ever green Wood, or any acid vegetable Matter is burnt, the acid Particles riſe with the Smoke, and in this Form penetrate and lodge in animal Subſtances expoſed thereto; ſo that this Smoke acts upon them in the ſame Manner as the Fume of Spirit of Sea-Salt or Nitre would do. And whether it be not a nitrous Acid which thus tinges the Hams, Herrings, *&c.* red in drying, we recommend to farther Examination.

23. Our Experiment alſo confirms what was before obſerved *b)*, that the Force of Fire is not ſufficient to reduce a vegetable Subſtance to Aſhes without the Help of the Air, and that ſo long as the fixed Oil, which cauſes the Blackneſs, remains in a vegetable Coal, it will afford no fixed Salt by Decoction in Water *c)*. Whence for making Pot-aſh, and all the fixed Salts, to Advantage, we have this Rule, thoroughly to calcine the Subject, ſo as to leave no fixed Oil behind.

24. And hence we are alſo inſtructed in the phyſical Nature of a vegetable Coal, and ſee how it may have ſuch conſiderable Effects upon Metals, in the Way of a *Flux*; ſince we find it contains a fixed Oil, firmly united to the Matter of a fixed Alkali; whence, to uſe this Coal as a Flux, is the ſame Thing as to uſe a fixed Salt

a) See alſo *Lect.* II. III.
b) *Lect.* II. *Exp.* IV.
c) See *Lect.* II. *Exp*, IV.

in-

intimately united with a fixed Oil, which operates powerfully upon Ores, as we have formerly ſhewn *. And ſo much for the *Analyſis* of Vegetables.

II.

EXPERIMENT II.

That animal Matters are reſoluble, by Fire, into the four chemical Principles, Water, Oil, Salt, *and* Earth.

Bone analyſed. 25. We took four Pounds of animal Bones, that had been well boiled to get out their Marrow or Fat, and then thoroughly dried again; and breaking them into ſmall Lumps, we put them, dry as they were, into an earthen Retort, luted on a Glaſs Receiver, and diſtilled, with Degrees of Heat, in a naked Fire. There firſt came over in Drops an aqueous limpid Liquor, which we reſerved apart, by changing the Receiver. Then increaſing the Fire there came over white Fumes, a volatile Salt, and a Quantity of Oil. The Veſſels being ſuffered to cool, we found the Bones turned black in the Retort; but being calcined in a naked Fire, with the Admiſſion of the free Air, they turned to white Aſhes. Then boiling theſe white Aſhes in Water, we found by Evaporation that they communicated no fixed alkaline Salt thereto.

The Experiment extended. 26. This Experiment is general, or ſucceeds, with little Variation, in all other animal Subjects, whether they be Fleſh, Blood, Serum, Fiſh, Birds, Snakes, the Whites of Eggs, Horn, Hair, Hoofs, Silk, or the like; the principal Difference being only, that theſe Subſtances

* See *Lect.* I. *Exp.* III. See alſo hereafter the Lectures upon *Mineralogy* and *Metallurgy*.

respectively

reſpectively contain more or leſs Earth, Water, Salt, and Oil. Thus Blood being diſtilled in its natural State, or as it is drawn from the Vein of a healthy Perſon, will yield about ſeven-eighths of its Quantity in Water. And if any animal Subject be not well purged of its Oil, by boiling in common Water, before it is committed to Diſtillation, it thence affords a greater Quantity of a burnt empyreumatical Oil, that ſtrongly taints and impregnates the volatile Salt and Water, with a nauſeous Scent and Taſte; which are hard to get rid of, even by repeated Rectifications.

27. The Principles ſeparated by the preſent Experiment appear to be, in general, the ſame with thoſe before gained from a vegetable Subject. They may be ſeparately purified and made elementary, after the ſame Methods as we there laid down. And thus, by comparing the Productions of both Proceſſes together, we ſhall find that we have a Water, an Oil, a Salt, and an Earth in both Caſes. *Its Uſes.*

28. The two Waters ſeem ſcarce to differ, when reduced to the ſame Degree of Purity; no more do the Oils and the Earths; but all the Salt in the preſent Caſe is volatile; the Aſhes containing no fixed Salt at all: whence this appears to be the principal chemical Difference betwixt vegetable and animal Subjects, that the vegetable Kind yield a fixed Salt by Calcination, and the animal Kind, one that is volatile by Diſtillation. But this holds only of the acid Species of Vegetables; for the alkaline Species yields little or no fixed Salt upon Calcination. So that betwixt the alkaline Tribe of Vegetables, and the whole animal Kingdom, there ſeems to be little Difference; either in this, or any other chemical Reſpect *. But tho' ſome Difference

* See *Lect.* VII, *Exp.* VI.

ſhould

ſhould be found betwixt the animal and vegetable Oils, as there is thought to be in the Making of Soap, and ſome other Inſtances; yet the Principles of animal and vegetable Subjects may be juſtly reputed the ſame, as both equally agree to our general Definitions of Water, Oil, Salt and Earth a) But when the ſeveral Principles of Vegetables and Animals are reduced to the ſame Degrees of Purity and Fineneſs, there ſeems, ſo far as our Trials have gone, to be no ſenſible Difference between them. Thus the pure elementary Earth of Vegetables ſerves for the making of Teſts and other Purpoſes, as well as the elementary Earth of Animals; ſolid Soap is made of vegetable Oils, as well as of animal Fats; and the volatile Salt of alkaline Vegetables, or even of acid Vegetables when putrified, is not to be diſtinguiſhed from the volatile Salt of Animals, when both are thoroughly purged and purified.

The animal Principles how purified.

29. But the Labour and Difficulty required, to bring theſe Principles to a high Degree of Purity, has proved a chief Cauſe of their being thought different; for we ſee that the Oil tenaciouſly adheres to the volatile animal Salt, and thus adds ſome Qualities that do not properly belong to that Salt. But if a volatile animal, and a volatile vegetable Salt, be each ſeparately converted into Sal-Ammoniac, by Means of Spirit of Sea-Salt, no ſenſible Difference can be found betwixt them. And thus, if a vegetable Oil and an animal Oil were equally purified, ſubtilized, and freed from all the Matters that do not eſſentially belong to them, they would not ſenſibly differ. At leaſt, this ſeems confirmed by ſeveral Experiments b).

a) See above, §. 4—8.
b See Dr. *Cox*'s Papers in the *Philoſophical Tranſactions*.

30. And

33. And hence may ſome Advantages be derived to Arts and Trades, by making the Subjects of one Kingdom ſerve for thoſe of the other, where the one is cheaper than the other. Thus, as we before obſerved *, a volatile Spirit and Salt, like thoſe of Hartſhorn, may be drawn from the alkaline Species of Vegetables, and all putrefied Plants; at leaſt from Bones, purged of their Fat by boiling in Water. *Farther Uſes.*

31. The preſent Experiment has many other Uſes and among the reſt remarkably ſhews how a perfectly dry, inſipid, ſcentleſs, and ſolid Body may yield a great Variety of Taſtes and Odours, barely by being applied to the Fire. For the impure Water, the volatile Spirit, the Salt and the Oils, have each a particular Taſte and Odour. And tho' the Subject itſelf were fixed, we ſee it nevertheleſs affords ſeveral volatile Matters. And as this fixed Subſtance was originally compoſed of a fluid Matter, we are hence taught that the animal Solids and Fluids have the ſame common Nature; their Difference conſiſting only in a greater or leſs Proportion of Water and Earth. For Blood, upon the like Analyſis, affords more Water and leſs Earth than Bone.

32. This Experiment likewiſe ſhews us that a Bone may be entirely diveſted of its Water, Salt, and Oil, without loſing its priſtine Figure and Dimenſions. For after thoſe Principles are ſeparated from it, the elementary Earth, tho' abſolutely dry and friable, ſtill hangs together in the natural Form and Figure of the Bone; which thus remains exhauſted of all that Matter, which the Fire was able to carry off, without affecting the elementary Earth itſelf.

* See *Lect.* VI. *Exp.* VI.

Whence

Whence we evidently ſee that the Uſe of this elementary Earth, in vegetable and animal Bodies, is to afford a Lodgment, a Support, or Skeleton to the other Principles, which are much more diſſipable and deſtructible than itſelf.

33. And as our Experiment ſucceeds alike in all animal Matters, and even in the Jelly obtained from a Bone by long Boiling, till the elementary Earth is elixated, or drained of the other Principles; we hence learn that the Matter of theſe other Principles proceeds only from the Juices of the Body, where, as well as in the Jelly, they appear in an almoſt inſipid and inodorous State, yet are capable, by Diſtillation, of affording Subſtances ſo highly ſapid and odorous, as we find the volatile Salt and Oil to be. Whence this Concluſion naturally follows, that theſe Principles did not exiſt in a volatile State in the Body, as requiring even a greater Degree of Heat, than that of boiling Water, to ſeparate them.

34. We may farther obſerve that the preſent Experiment affords us the moſt volatile Subſtance hitherto known; for well-purified animal Salt is more volatile than Spirit of Wine, and riſes in Diſtillation before it, Hence this Salt readily evaporates in the open Air, and being laid upon the Palm of the Hand goes off inſenſibly, without any Effect; tho' if it were preſſed cloſe to the Skin, by a ſticking Plaiſter, it would prove corroſive; and in this Manner it is ſometimes uſed, for making Iſſues in Children, inſtead of the ſtronger Cauſticks.

III.

Experiment III.

That certain mineral or metallic Bodies may contain four of the chemical Principles, viz. Sulphur, Salt, Earth, *and* Mercury.

35. We took two Ounces of native Cinnabar reduced to fine Powder, and mixing it with ſix Ounces of Quick-lime, we put the whole into an eathern Retort, and diſtilling into a Baſon of Water, we found a conſiderable Quantity of running Mercury at the Bottom thereof *. The Matter remaining behind in the Retort being boiled in a *Lixivium* of Pot-aſh, and the Solution precipitated with Allum, lets fall a fine Kind of Brimſtone called *Lac Sulphuris*, which will ſublime into true Flowers of Brimſtone, that may be melted, and run into a Roll. This Brimſtone being burnt, in the common Method, under a Glaſs Bell, reſolves into an acid Liquor, leaving an uninflammable, ſcurfy, terreſtrial Matter behind; which being treated as an Ore, ſometimes affords a ſmall Proportion of Metal, either Iron or Copper. *Cinnabar analyſed.*

36. We have here an inſtructive Experiment, which being fully explained might lead to conſiderable Diſcoveries. It ſhews that a true running Mercury may lie concealed in metallic Ores, or ſtony Earths; for native Cinnabar is but an Ore of Mercury, conſiſting, as we ſee, of two different Matters, Sulphur and Quickſilver, which

* We endeavoured to ſeparate the Sulphur from the Cinnabar, by boiling ſome pulverized Cinnabar in a ſtrong *Lixivium* of Pot-aſh and Quick-lime, expecting the Mercury ſhould fall to the Bottom in a running Form; but had no Succeſs at the End of two or three Hours.

ſilver;

ſilver, which are ſeparable by Diſtillation with Quick-lime or Iron Filings; and ſometimes by long Boiling in a ſtrong alkaline *Lixivium*.

The Experiment whether extendible

37. It were highly proper, if poſſible, to render the preſent Experiment general; and, if the Nature of the Thing would admit thereof, apply it to extract a running Mercury from Metals, as we have here done from a native Ore or mineral Subſtance. For the more intelligent Chemiſts agree, that the true Analyſis of metalline Minerals depends upon what is called their *Mercurification*; that is, the obtaining Mercury from them. And for this Purpoſe there are three Methods propoſed. The firſt is by Means of a certain Mercury, ſo prepared as to have a diſſolving Power, and to take up the Mercuries of Metals, in the ſame Manner as Water diſſolves Salt from Aſhes. The ſecond is by Means of certain regenerating Salts, particularly *Sal-Ammoniac*, which ſhall detain the more earthy Parts of Metals, and leave their Mercuries ſeparable from them by Sublimation or otherwiſe. And the third Method is by Means of a large *Lens*, or double Convex Glaſs; in the Focus whereof, if any Metal be applied, its mercurial Part is ſaid to ſeparate and go off in Fume, which when collected and condenſed appears to be running Mercury.

38. The firſt Method would be eaſy, if the proper Mercury for the Purpoſe could be readily procured. The ſecond is extremely laborious, and requires much Patience, and Reiteration. But the third ſeems eaſy enough, and practicable to Advantage, when a Glaſs of three or four Foot in Diameter is at hand, the Sky ſerene, and the Sun ſhines ſtrong *.

* See M. *Homberg*'s Experiments, with the Duke of *Orleans*'s Lens, in the *French Memoirs*.

39. Let

39. Let us not be miſapprehended as if we were here launching out beyond the Confines of genuine Chemiſtry, whoſe Office it is to keep cloſe to the Senſes, without indulging any Degree of Speculation and Hypotheſis: we only mean to give an Occaſion for proper Trials to be made, which alone can determine whether running Mercuries are obtainable from Metals, or whether a fixed Metal may not be obtained from running Mercury. Indeed we ſhould be wanting to the Art we are endeavouring to improve, if we did not, at a time when almoſt every Chemiſt in *England* is preparing the *Mercurius præcipitatus per ſe*, requeſt them to try whether a ſmall Portion of their fluid Mercury is not by the Operation fixed into a ſolid Grain of Metal; and if ſo, what Metal it is, and whether more of it be not procurable by grinding their Precipitate, expoſing it again to Digeſtion, and repeating this Operation for a Number of Times ſucceſſively, till it may happen that Part of it will bear the Cupel.

40. In the ſame View we recommend it, to thoſe who deſire the Improvement of Chemiſtry, that they would procure a double Convex-Glaſs, three or four Feet in Diameter, and try whether, when a Metal is expoſed to the Focus thereof, the metallic Matter which goes off in Fumes, being collected by a proper Veſſel dextrouſly applied and plunged in cold Water, may not be thus condenſed, and aſſume the running Form and other Properties of an actual Quickſilver. If theſe Experiments ſucceed, they may richly repay the Coſt, by uſeful Knowledge at leaſt.

41. But to proceed; we are farther to obſerve from the foregoing Experiment, that as common Brimſtone reſolves itſelf into an acid Liquor and an earthy Matter, we find that certain mineral

or metallic Subſtances will, by a proper Analyſis, afford the four chemical Principles above mentioned; *viz* running Mercury, Sulphur, Salt, and Earth. But it is not ſuppoſed to hold univerſally, that all mineral Subſtances ſhould afford a running Mercury upon their Analyſis; but only ſuch of them as are properly metallic.

Reſult of the Analyſis of Minerals.

42. So far as the Analyſis of Minerals has been carried, it ſhould ſeem that all Metals contain a running Mercury, fixed in them, as Water is fixed in dry animal or vegetable Subſtances *a*), and joined with a Sulphur, or an inflammable Part, and an Earth; beſides a little Salt in ſome of them *b*). The Foſſil Salts reſolve into a large Quantity of Acid, which is always united with ſome Sulphur, and a ſmall Proportion of Earth. Moſt Stones reſolve into a large Proportion of Earth, and a ſmall Quantity of aqueous and ſulphureous Vapour. And Earths reſolve into a mere terreſtrial Subſtance, a little aqueous Acid, and a ſmall Proportion of Sulphur.

43. Upon the whole therefore we may conclude, that the five Principles above laid down, *viz.* Water, Earth, Salt, Sulphur, and perhaps Mercury, are the true Chemical Principles of vegetable, animal and mineral Subſtances *c*).

AXIOMS *and* CANONS.

1. It appears from our preceding Enquiry, That genuine Chemiſtry conſiſts in a legitimate Uſe of the Senſes, keeping entirely to ſenſible

a) See *Lect.* III. *ad finem*.

b) See M. *Homberg* upon the Chemical Principles, in the *French Memoirs*.

c) No notice is here taken of Air as a Chemical Principle, for the Reaſon before aſſigned. See above, § 3. See alſo *Lect.* III. *paſſim*.

Things

Things, or the Law of Induction, for its Principles and Explanations a); but, if it once indulges hypothetical Notions, Fiction, Illuſion, and Darkneſs enſue, inſtead of ſure Rules, uſeful Diſcoveries, and Light to the Underſtanding.

2. That the common chemical Principles are juſtly ſaid to be Water, Earth, Salt, Sulphur, and Mercury; whereby many chemical Effects are explicable to common Senſe and Reaſon, ſo far as to afford Rules of working, to the Advantage of the Art and of ordinary Life b).

3. That as animal and vegetable Subſtances are reſolvable into the ſame Principles b), there is no Neceſſity for making more than two Diſtinctions or Claſſes of chemical Principles, *viz* the Vegetable and Mineral; which ſeem to differ chiefly in this, that the metallic Species of Minerals may afford a running Mercury, whereas the vegetable and ſimple mineral Species will not.

4. That the different Combinations of theſe five chemical Principles make all that vaſt Variety of natural and artifical Bodies, which have hitherto been analyſed by the Fire; the Difference of theſe Bodies appearing to ariſe from the different Proportions wherein theſe Principles are mixed. Whence, unleſs we except the Air, there ſeems no Neceſſity for introducing a larger Number of Principles, to account chemically for all the various Phænomena of Nature and Art.

5. That the correſpondent animal and vegetable Principles may in many Caſes be uſed for one another; ſo as to render volatile Salts and Oils cheaper, and leſſen the Expence attending their Uſe in particular Arts and Trades b).

a) See the whole Lecture, *paſſim.*
b) See *Exp.* I. II.

6. That in order to leſſen the Trouble and Expence of procuring the volatile Salts of animal Subjects, theſe Subjects ſhould be firſt purged of their Oil and unctuous Parts by boiling in Water: after which they may be made to afford volatile Salts and Spirits, as pure as unboiled Hartſhorn, or purer *a*). But care muſt be taken not to boil the Subject too long, otherwiſe a Jelly will alſo be drawn out of it; which Jelly plentifully contains the Matter of the volatile Salt.

7. That the unrectified volatile Salts of vegetable and animal Subſtances are true *Sales volatiles oleoſi*; that according to the Difference of the Oil abounding in them, they are properly diſtinguiſhed into Salt of Hartſhorn, Salt of Ox bone, Salt of human Blood, of Silk *&c.* But that when theſe Oils are totally ſeparated from them, they become one and the ſame undiſtinguiſhable volatile Salt *b*).

8. That the ſo called *volatile Spirits* of vegetable and animal Subſtances, conſiſt only of a large Proportion of Water, impregnated with ſome of the volatile Oil and Salt of the Subjects; and that they may accordingly be reſolved by Rectification into theſe three Principles; ſo that there is no Neceſſity for introducing a ſpirituous Principle *b*).

9. That it is the Admixture of Oil which gives the Colour to volatile Salts and volatile Spirits; for when this Oil is totally ſeparated from them, the Salt is permanently white, and the Spirit pellucid *c*).

a) See *Exp.* II.

b) See *Exp.* I, II.

c) See *Exp.* II.

10. That volatile Salts are obtainable from all Kinds of Land Animals, the amphibious and ſubterraneous Tribes, Birds, Fiſh, and Reptiles; from alkaline Vegetables without Putrefaction; from other Vegetables after Putrefaction; from Soot, Horns, Hoofs, and all refuſe animal and vegetable Matters, ſuch as the Pith of Horns, Urine, the Blood of Slaughter-houſes, *&c.* and that as pure and perfect as from Hartſhorn: Which affords a Rule for making volatile Alkalies and Sal-Ammoniac cheap in *England.*

11. That elementary Earth, a Subſtance fixed and of itſelf unalterable in the Fire, Air, or Water, conſtitutes the firm Baſis, or Skeleton, of all animal and vegetable Subſtances; and that Water, Salt, and Oil mixed, and wedged betwixt the Particles of this Earth, conſtitute all animal and vegetable Subſtances *a*).

12. That there is only one Kind of volatile alkaline Salt, when reduced to abſolute Purity; the apparent Difference betwixt the volatile Salts depending entirely upon the different Oils wherewith they are mixed *b*).

13. That by endeavouring to purify the chemical Principles too high, we do but deſtroy their Natures *c*), or loſe the Properties whereby they produce their ſpecific Effects. Thus Oils are, by numerous repeated Diſtillations, loſt in the form of Oils, and turned into Earths; volatile Salts fly away in repeated Sublimation; and fixed Salts turn to Earth by repeated Solution and Filtration *d*).

14. That animal Bodies naturally contain no fixed Salt, tho' the acid Vegetables, which are

a) See *Exp.* I, II.
b) See *Exp.* I, II. See alſo hereafter the Lecture upon *Oils.*
c) See *Exp.* I, II.
d) See Mr. *Boyle*'s *Sceptical Chemiſt.*

ufed as Food, contain it plentifully *a*). Whence there is lodged in the Body a Power of converting the Matter of fixed Salt into the Matter of volatile Salt.

15. That the volatile animal Salts, and the fixed vegetable Salts, differ chiefly with regard to their Volatility and Fixednefs, and the Effects thereon depending; but agree in other Refpects. Thus they both make an Effervefcence, and turn neutral, when faturated with Acids; they are both corrofive, hot and fiery, *&c. a*).

16. That a principal Reafon of the Difficulties attending the Analyfis of Bodies, is the natural Affinity, or Relation, which fome of the chemical Principles have to others; whence they cohere ftrongly together, fo as not to be well feparated pure *b*). Thus part of the volatile Oil of Animals ufually rifes with the fame degree of Heat as the volatile Salt, and intimately mixes therewith, *&c*: Whence, to improve Chemiftry, we fhould feek out for other analyfing Powers befides Fire. And fuch an one in the prefent Cafe is Water; which imbibing the volatile Salt, more ftrongly than it does the Oil, thus makes a more perfect Separation; whereas Fire chiefly acts as an Analyfer, when there is a confiderable Difference between the Volatility of Bodies; as in a Mixture of Water, Alcohol, and volatile Salt, all which rife feparately after one another; the volatile Salt firft, the Alcohol next, and the Water laft.

17. That the Mercuries of Metals may be real things, and procurable different Ways; and that poffibly thefe Mercuries, or the common running Mercury, may be convertible into Me-

cal

tal. But this Matter requires a farther Examination, and ſhould be brought under the direct Evidence of Senſe *a*).

18. Laſtly, that there are certain Inſtruments and chemical Operations, which though little attended to may afford great Light to the Underſtanding, and prove highly advantageous in chemical Philoſophy and Arts: we inſtance, for the preſent, the Mercurification of Metals, the powerful Furnace of the Sun, the artificial Uſe of the common Elements, *&c.* *a*) all which we recommend to the farther conſideration of chemical Philoſophers.

a) See *Exp.* III.

LECTURE IX.

CONTAINING

Synthetical Chemiſtry; *or, the Art of Recompoſing Bodies.*

The Subject. 1. IN our laſt Lecture we endeavoured to explain what the more intelligent Chemiſts underſtand by *analytical Chemiſtry*, or the Reſolution of Bodies; in the preſent we propoſe to give ſome Inſtances of Recompoſition, or the compounding of Bodies from their ſeparated Parts or Principles, ſo as to compoſe the Original whole again. This indeed is extremely difficult to effect univerſally; yet it may be done in ſome caſes ſo accurately, that the recompoſed Body ſhall be perfectly undiſtinguiſhable, by the Senſes, from that which had never been ſeparated by the Fire. And if the Art of Chemiſtry were perfect it would be able thus to recompoſe, at leaſt in ſome tolerable manner, all the Bodies it divides. At preſent it is far from this Perfection, eſpecially in the vegetable and animal Kingdoms; where, by reaſon of the vaſcular Texture of the Parts, ſuch a Recompoſition ſeems almoſt impracticable, unleſs the natural or organical Structure be ſome way or other preſerved, or artificially imitated. We are therefore carefully to diſtinguiſh betwixt the Regeneration of organized, and the Regeneration of unorganized Bodies. As the latter is much the more ſimple and eaſy, we ſhall begin with that, and aſcend by degrees to the more complex Kinds; ſo as to ſhew

ſhew where this Regeneration may be rationally expected, and where it is leſs to be hoped for; together with the ways of carrying this Part of Chemiſtry to greater Perfection.

2. This *Synthetical Chemiſtry*, taken in the ſtrict Senſe, for the Recompoſition of Bodies from their own Principles, is rather of philoſophical than ordinary Uſe. And it will doubtleſs be aſked, to what Purpoſe do we ſtudiouſly endeavour to recover thoſe Bodies by Art, which Nature affords us in plenty? We anſwer, it would ſhew an extreme Perfection and Power in Chemiſtry to be able to do this, and prove, either that Bodies might be taken to pieces by the Fire, without altering or injuring their natural Parts, or at leaſt that any accidental Alteration brought upon them by the Analyſis, might eaſily be rectified or aboliſhed by a Recompoſition. *Synthetical Chemiſtry.*

3. But here we are to guard againſt a Fallacy: for ſuppoſing the Art of Chemiſtry ſo far advanced as to reinſtate Bodies after their Analyſis, we muſt not thence conclude that Nature originally uſes the ſame Means to compoſe them. The Ways ſhe uſes for this Purpoſe would ſtill be a new Enquiry, and ought to be diligently proſecuted, for the farther Improvement of *Philoſophical Chemiſtry*.

4. Our firſt Example of Recompoſition is taken from Nitre, the ſecond from Brandy, the third from Cinnabar, and the laſt from Bone.

EXPERIMENT I.

The Regeneration, or Recompoſition of Nitre, from its own acid Spirit and fixed Alkali.

5. We took two Pounds of refined Salt-Petre reduced to Powder, and putting it into a Glaſs-Retort *Nitre analyſed; or reduced to a Spirit.*

Retort poured upon it a third of its own Weight of rectified Oil of Vitriol; then placing the Retort in a Sand-heat, and luting on a large Receiver, we distilled with degrees of Fire, up to the highest that Sand would give. Then suffering all to cool, we thus obtained a pure and strong *Spirit of Nitre*; which came over in red Fumes, and cannot, by any Experiment, be found to participate of the Oil of Vitriol used in its Preparation.

And a fixed Salt. 6. On the other hand, we took a Pound of purified Nitre reduced to Powder, and melting it in an earthen Crucible, cast little pieces of Charcoal into it successively, till the Deflagration ceased, and the Salt at the Bottom of the Crucible appeared sluggish, or would no longer keep fluid, with that Degree of Heat which melted it before. Then increasing the Fire, so as to make the Salt run again, we poured it out upon a clean metalline Plate, where it congeal'd into a Substance called *fixed Nitre*.

7. And thus, at two different Operations, we resolved the same Subject, Nitre, into two very different Parts; which being put together again, after a proper Manner, constitute the original Salt again, in all its Forms.

Recomposed. 8. For if the alkaline Solution of fixed Nitre in Water, be exactly saturated with the acid Spirit of Nitre, till no more Effervescence appears, and yet the Mixture be not made alkaline; this compound Liquor will, by standing, shoot into true and perfect Crystals of Nitre, as we found upon Trial. And the Experiment succeeds no less, if any other fixed alkaline Salt, as that of Tartar, Pot-ash, &c. be used instead of fixed Nitre.

9. And in the same manner may common Salt be regenerated from any fixed alkaline Salt, and

and the acid Spirit of Sea-Salt; or Alum, from any fixed alkaline Salt and Spirit of Alum; ſo as to afford us Inſtances of the juſteſt Recompoſition perhaps hitherto known in Chemiſtry.

10. It is remarkable in this Experiment, that the two Subſtances which compoſe the Nitre are extremely different; the one being highly odorous and volatile, the other inodorous and fixed; the one a violent Acid, the other a violent Alkali; but upon mixing, they unite into a neutral Salt, of the very ſame Nature and Properties with that which afforded them. *Uſes.*

11. From this Experiment ſome have ventured to affirm that Nitre is naturally generated in the ſame manner; but this ſhould not be allowed till it is ſhewn that ſuch an Acid and ſuch an Alkali are to be found diſtinct in the places where Nitre grows. And we cannot too well remember, that there may be ſeveral phyſical Ways of effecting the ſame Thing; all which Ways are not to be preſumed, but ſought.

12. To this Claſs of artificial Recompoſitions may be added the Reproduction of Sulphurs and Vitriols; tho' the Experiments do not commonly ſucceed in Perfection. Indeed, as we above obſerved that the Thing itſelf is chiefly of philoſophical Uſe, for that Reaſon very few have endeavoured to proſecute it.

13. In our preſent Experiment we may obſerve that the Nitre, tho' in both Caſes it ſuffers a great Violence of Fire, is neither ſcorched nor rendered empyreumatical; which in other Caſes, where the Subject is more oily, ſeems a principal Cauſe of the Difficulties found in the regeneration of Bodies; particularly ſuch as Sugar, Turpentine, Amber, &c. Whence we are directed to analyſe theſe unctuous Bodies, with ſuch a degree of Heat as ſhall not ſcorch their Oil, if we deſire

fire to recompofe them; or elfe to find out fome more proper Analyfer for them than the Fire; fuch as particular Solvents, capable of feparating, and others of reuniting their component Parts, without having this deftructive Effect.

14. The Solvents here intimated might have confiderable Ufes, if a competent Set of them were difcovered, as directly tending to the Improvement both of *analytical* and *fynthetical Chemiftry*. Thus Water in fome Cafes is a better Analyfer than Fire, as we fee particularly in the feparating of Salts from Earths; and thus fome Chemifts are faid to have a Method of recovering analyfed Amber, or Amber diftilled for its Salt and Oil; and that by means, not of the Fire, but of an artificial compound Salt; the Inftances of which Kind fhould be collected.

EXPERIMENT II.

Brandy refolved into its component Parts, and recompofed.

Brandy analyfed.

15. (1.) To a Pint of Brandy we added half a Pound of dry Salt of Tartar, then fet the containing Glafs in a gentle Heat of Sand; where we obferved the Salt to diffolve into a Liquor, by attracting to itfelf the Water of the Brandy, leaving a Spirit of Wine floating on the top. This Spirit we decanted upon a little more dry Salt of Tartar, and found that this fecond Salt fcarce relented. Then pouring the Spirit into a Glafs Receiver, we diftilled it gently over, and thus obtained a highly rectified Spirit of Wine. (2.) In the fame manner we diftilled the faline Solution left behind upon decanting the Spirit, and thus obtained the Water of the Brandy in confiderable Purity, leaving the Salt of Tartar behind,

in a dry Form. (3.) In the laſt Place, we mixed the Spirit and the Water together, and directly found the Brandy recompoſed, without any conſiderable Alteration. *And recompoſed.*

16. The Separation and Recompoſition is however leſs exact in the preſent, than in the preceding Caſe; becauſe ſome ſmall Part of the Salt will always come over in Diſtillation, both with the Spirit and with the Water: but when the Experiment is performed in Perfection, it may paſs for a tolerably exact Recompoſition.

17. To this Claſs may be added the Recompoſition of Wine, after its Spirit or Brandy has been diſtilled from it, and the Recompoſition of Vinegar from its Spirit and *Reſiduum*. Though both require a new Fret, or ſlight Fermentation. Yet if the Operation be dextrouſly performed, the Recompoſition appears to be juſt and perfect. To render the Operation perfect in either Caſe, we recommend the Uſe of a proper intermediate Subſtance, either fermentable, or actually in a fermenting State; ſuch as a little new Wine, Sugar, Juice of the Grape, or the like: for theſe Subſtances coming to work in the Liquor, lay hold both of their aqueous, ſpirituous, and ſaline Parts; ſo as to bring them into the State of Mixture or Arrangement, on which their Perfection, as Wines and Vinegars, depends. And how far this Method of Recompoſition may be extended ſeems hitherto little conſidered. *The Experiment extended.*

18. In our preſent Experiment for the Recompoſition of Brandy, there are only two conſtituent Parts concerned, *viz.* Alcohol and Phlegm; which renders the Separation and Combination ſo much the eaſier and the more exact: nor is there any Occaſion here for an intermediate Subſtance, to procure, or recover, the natural Union; becauſe Alcohol readily mixes with Water, barely by

by ſhaking, and that as intimately as is neceſſary to the Conſtitution of Brandy.

19. In Imitation of this Experiment, it is proper to enquire what other Bodies may be perfectly ſeparated into different Parts by the Way of Menſtruum, Abſorbent, or Precipitant; ſo as to leave the ſeparated Matters unaltered in their Natures, and fit to compoſe the original Subſtance again. This Enquiry depends upon finding out the ſecret Relations which exiſt between particular Bodies; and theſe Relations can only be diſcovered by particular Trials *a)*.

Farther Uſes. 20. This Experiment ſhews an uſeful Method of obtaining Spirit of Wine from Brandy, without Diſtillation, which may be practiſed to advantage in the large Way of Buſineſs; *viz.* by adding Pot-aſh to the Brandy once diſtilled, and brought to the Size commonly called *three Fifths*, that is, three Parts Alcohol and two of Water: For the Pot-aſh ſo employed is eaſily recoverable without much loſs, barely by boiling the Lixivium in an Iron Pot; by which Means being dried it will ſerve for the ſame Purpoſe again. This ſlight Experiment has proved of eminent Service, where large Parcels of Brandies have been to be rectified in a ſmall Compaſs of Time.

EXPERIMENT III.

Cinnabar recompoſed, by the Union of its two component Parts, Sulphur *and* Mercury.

Cinnabar recompoſ'd. 21. Having found, in our laſt Lecture, that native Cinnabar is compoſed of Sulphur and Mercury *b)*, we took four Ounces of common Brim-

a) See M. *Geoffroy*'s Paper to this Purpoſe in the *French Memoirs.*

b) See *Lect.* VIII. *Exp.* III.

ſtone,

ſtone, and melting it in a earthen Pan, over a dull Fire, added by Degrees twelve Ounces of crude Quickſilver, firſt made warm, and ſtirred them well together, till no Globules of the Quickſilver appeared; then ſuffering the Maſs to cool, we reduced it to Powder, and ſublimed it, with a proper Degree of Heat; and thus obtained an artificial Cinnabar, which being ground fine, and compared with the natural, appeared undiſtinguiſhable from it.

22. The regenerated or artificial Cinnabar has not the ſtony Form of the native; this Form being accidental in the Mine, and determined by the Circumſtances of the Place, as the Form of the regenerated Cinnabar is by the Figure and Make of the Veſſel wherein it was ſublimed. But if the two be compared together, in all other Reſpects there appears no Difference, when the Operation is juſtly performed. *Uſes.*

23. This Experiment ſhews us the common Method of preparing artificial Cinnabar, which may, in the large Way of Buſineſs, be thus ſublimed in a tall earthen, or coated Body, with its Head well luted on, and ſo placed in a Sand-Heat as to touch the Bottom of the Iron-Pot, whilſt the Sand riſes above the Matter contained in the Veſſel. And here it is a principal Caution to uſe a briſk Fire, that the Operation may be finiſhed in three or four Hours Time. And probably, if only one Part of Sulphur be uſed to about four Parts of Quickſilver, the Cinnabar will be the finer; for about thirteen Ounces of running Mercury may be recovered from a Pound of native Cinnabar.

24. And thus we have an Inſtance of a perfect Recompoſition, in a metallic Body, or Subject of the mineral Kingdom: for the Experiment ſucceeds alike, when the Sulphur and Mercury

of

of native Cinnabar is uſed *a*). To this Claſs might be referred the Reduction, or Recovery, of all the Calces of Metals to a metallic Form again, by the Addition of any inflammable Matter, which they loſe in their Calcination; as alſo the Regeneration of Antimony, by melting its Regulus with Sulphur; the Regeneration of Ores, by melting their Metals with Sulphur, ſtony Earths, *&c.* ſo as to mix them again; and all other Inſtances of this Kind.

25. The preſent Experiment is of conſiderable uſe, particularly in natural Philoſophy, and Metallurgy; as it ſhews us that a very large Proportion of fluid Mercury may, by Means of a very ſmall one of Sulphur, be fixed into a Body of a ſtony Hardneſs, ſuch as the native Cinnabar. Whence we ſhould not be over-haſty to conclude that Mercury cannot aſſume a metalline Form *a*). Some metallurgical Chemiſts contend, that Mercury is nothing elſe but a Metal, overdoſed with that Part which gives ductility and ſoftneſs, which remarkably belong to all the Metals when amalgamated with Mercury. In ſhort, whoever duly lays together all the Properties of Mercury, may perhaps find Cauſe to allow it a metallic Nature *b*).

EXPERIMENT IV.

An Attempt to recompoſe Bone from its Aſhes.

Bone recompoſed.

26. (1.) We took a large Ox-Bone, and made a ſtrong Jelly thereof with Water in the Digeſtor *c*); then (2.) in an open Fire we burnt and calcined the Bone to whiteneſs, without deſtroying

a) See *Lect.* VIII. *Exp.* III.
b) See the Place laſt quoted.
c) See *Lect.* VI. *Exp.* VII.

its

its external Figure; so that in other respects the Bone was reduced to mere Ashes, or separated from the Principles of Water, Oil, and Salt, which it originally contained. In this state we found it extremely brittle and crumbly; but (3.) putting it into the Digestor again with the Gelly, and warming them together over the Fire for some time, then taking the Bone out, and suffering it to dry in the open Air, we found that it gradually hardened, and recovered, in some tolerable Degree, the Appearance, or Colour and Consistence, of the natural Bone.

27. Gelly, by an Analysis, is found to yield the same Principles as Bone itself *a)*; or to contain the matter, not only of Water, but of Salt and Oil, and a little Earth: so that to use this Gelly, is the same thing as to use the Water, Salt and Oil; all which being thus together soaked into the Skeleton of the Bone, restores it in some Degree to its natural State.

28. But to use the direct volatile Salt and Oil of the Bone for this Purpose, were to use two things which did not exist in those Forms in the Bone; for to separate the volatile Salt and Oil from Bone, requires a much greater Degree of Heat than that natural to an animal Body; so that they are never thus separated in the Body, whilst that remains in its natural State. Yet a Degree of Hardness (with Discoloration, on account of the black and scorched Oil of the Subject) may be given to Bone-Ashes by the separated Oil, or even by Water, as we see in Tests.

29. We were farther encouraged to use the Gelly of the Bone in this Experiment, from observing by repeated Operations in the Digestor *b)*, that all the active Principles of the Bone might

a) See *Lect.* VIII. *Exp.* II.
b) See *Lect.* VI *Exp.* VII.

be got out and united with the Water added to extract them; ſo as to leave nothing but a little Earth behind, reſembling the Aſhes left upon a dry Calcination in a violent Fire. Whence we are plainly inſtructed in the Nature of animal Gelly, with its Uſes to the Body. And hence alſo we learn the Nature of Mucilages, Size, Glues, and may underſtand many things relating to Medicine, the animal Oeconomy and Arts.

Uſes. 30. This Experiment might be rendered more ſucceſsful, if we could procure the tenacious Glue or Cement, which obſtinately remains in the Pores of the Bone, even tho' long detained in the Fire. This Glue ſeems to be an intermediate Subſtance, of a middle nature betwixt Gelly and elementary Earth; whence it were proper to try whether, by grinding the elementary Earth fine and digeſting it with Gelly, ſome ſuch tenacious Glue could not be procured. This alſo might open the way to a Hiſtory of Glues, which is extreamly wanted in Chemiſtry, natural Philoſophy, and Arts.

31. If a promiſcous Maſs of elementary Earth be uſed, inſtead of that which retains its natural vaſcular Form, a Kind of *Callus* will be thus produced, inſtead of a regular Bone. Whence we may be enabled to judge of the Nature of the *Callus* formed in the Bones of Animals.

32. After the manner of our preſent Experiment, we might alſo attempt to recompoſe vegetable Subjects. But before any thing of this Kind is done to Perfection, Chemiſtry will require the Aſſiſtance of mechanical Contrivance, and many Improvements from the Anatomy of Plants; particularly it muſt learn to preſerve the native Spirits of Vegetables, upon the Analyſis, or elſe the artificial ways of imitating and introducing ſuch Spirits into the Subject. Theſe Spirits

rits are extreamely apt to fly off with Heat, yet may in good Meaſure be collected and preſerved by Art. And unleſs they are thus preſerved, the Subjects will want their native Taſtes and Odours, which depend upon theſe Spirits, or ſubtile, volatile Matters.

33. The higheſt Degree of Recompoſition is, when a Body is perfectly reſolved into its Principles, (ſuppoſe a Vegetable Subject into Water, Salt, Oil, and Earth) and theſe are again put together, ſo as to form a Subject undiſtinguiſhable from the Original. In order to attain this Perfection, let the thing be firſt tried in ſimilar, unorganized Bodies; as Glaſs, Turpentine, Amber, Vegetable Juices, Wines, Sulphurs, Ores, *&c.* proceeding by ſlow Degrees, up to the more diſſimilar and organical Bodies; ſuch as vegetable and animal Subjects. *Perfect Recompoſition.*

34. We have ſeen that, in many Caſes, a true Reſolution and Recompoſition are practicable; and as Chemiſtry improves, the Buſineſs of *Analyſis* and *Syntheſis* muſt likewiſe improve.

35. But let it be obſerved, that the Power of Chemiſtry is not limited to the Buſineſs of juſt Reſolutions and Recompoſitions: it can produce numberleſs Effects without going to this Exactneſs. Thus it already analyſes and recompoſes, or ſeparates and mixes, all the natural and artificial Bodies, in its own imperfect manner. And thus it has furniſhed us with all Chemical Medicines; as Tinctures, Extracts, Spirits, Oils, Waters, Eſſences, *&c.* and the ſeveral Commodities of Sugar, Wine, Alum, Salt, Pot-Aſh, Aqua-Fortis, Oil of Vitriol, Soap, Glaſs, *&c. &c. &c.* For without attempting a perfect Separation or Recompoſition of the chemical Principles, a groſs Separation or Mixture of two or three of them will frequently afford very uſeful *The Imperfect uſeful.*

ful Subſtances; ſo that Chemiſtry, tho' it remains imperfect, is ſtill highly ſerviceable.

AXIOMS *and* CANONS.

1. We learn from the preceding Enquiry, that we cannot ſafely conclude Bodies to have been originally compoſed of the ſame Principles, into which the Fire reſolves them *a)*.

2. That as the Fire, in many Caſes, proves a juſt Analyſer, and reſolves Bodies into their conſtituent Parts, without Alteration; ſo, in others, it quite perverts and changes their Nature and Properties; eſpecially by ſcorching the Oil of a Subject which abounds therewith *b)*.

3. That the perfect Regeneration of Bodies can take place in ſuch Caſes only where the Fire, or other Inſtrument, is a true Analyſer, without adding any extraneous thing of its own, or any way altering or ſubverting the Nature of the Parts ſeparated *c)*.

4. That the Buſineſs of Recompoſition is to be diſtinguiſhed into three Kinds, *viz.* mineral, vegetable, and animal, differing in Degree of Facility; the mineral Kind being the eaſieſt, and therefore to be firſt cultivated, in order to improve *Synthetical* Chemiſtry, and render it more advantageouſly practicable in organical Bodies *d)*.

5. That *Synthetical Chemiſtry* is more imperfect than the *Analytical*; or that the preſent Chemiſtry divides natural Bodies more perfectly than it puts them together again, for want of more proper Analyſers than Fire, and more

a) See §. 3. & *Exp.* I.
b) See *Exp.* I. See alſo *Lect.* VIII. *Exp.* II.
c) See *Exp.* I, II, III, IV.
d) See *Exp.* I, III, IV.

ſuit-

suitable Methods and Menstruums than are hitherto discovered *a)*.

6. That a new Composition is usually made in every chemical Resolution. Thus when Nitre is separated into an acid Spirit, its fixed Salt remains compounded with the Oil of Vitriol *b)*. When Mercury is separated from the Sulphur in Cinnabar, the Sulphur remains united with the Quick-Lime, or Iron-Filings *c)*. When Water is separated from Brandy, the Water unites with the fixed Salt, and leaves the Spirit to float separate *d)*. And this appears to be generally the Case; so that the Separation is made by some intermediate Body, which unites with one Part, and not with the other of the Subject *e)*. Whence we are directed to find out the *Mediums of Mixture* and *Recomposition*, as well as of *Separation*, in order to perfect *Analytical* and *Synthetical Chemistry*.

7. That Bodies endowed with a native Spirit are hard to recompose, unless this Spirit be some way artificially preserved *f)*. Thus for Instance, Seeds, Roots, Flowers, *&c.* may be dried in close Glasses, with blind Heads, set upon a gentle Sand-Heat; then taking the Subject out, and separating its Principles, the Oils and Salts being afterwards impregnated with the native Spirit of the Subject, remaining in the Blind-Heads, may thus serve to recompose the whole in some tolerable Degree.

8. That animal Gelly is a Mixture of all the Principles of an animal Subject, *viz.* much Water,

a) See the preceding Lecture, *passim.*
b) See *Exp.* I.
c) See *Lect.* VIII. *Exp.* III.
d) See *Exp.* II.
e) See *Exp.* I, II, III, IV.
f) See §. 31. *&c.*

a moderate Proportion of Oil and Salt, and a little Earth *a*). Whence we learn the phyſical Cauſe why Gelly is nutrimental; why animal Subſtances ſo much abound therewith; its Uſes in the Body; its reſtorative Nature, *&c.* And hence we have a Foundation for the natural and experimental Hiſtory of Gellies, Size, Glues, *&c. b*).

9. That the Buſineſs of Analytical Chemiſtry is deficient, which ought to afford the Rule of operating to Synthetical Chemiſtry *c*). Thus moſt of the Analytical Operations hitherto performed, are but ſuperficial Attempts to enter and open the Subſtances of natural Bodies; for which purpoſe, in ſome Caſes, long Digeſtions, repeated Reverberations, vaporous Mixture, exquiſite Triture, continued Fuſion, ſubtile Precipitation, *&c.* are required. Whence the Improvement of Synthetical Chemiſtry will greatly depend upon the Improvement of the Analytical.

10. That another way of improving *Synthetical Chemiſtry* is carefully to obſerve what Steps Nature takes in ſupplying and recruiting the Bodies of vegetable, animal, and mineral Subſtances; and whether there be any mineral Inſtances of Regeneration in Nature, from the direct Principles themſelves without Addition; or whether this Action be not uſually performed by ſome certain Aſſiſtance within the Power of Art to procure; and particularly what is the Office of the Air, Water, and Fire, in bringing about this natural Operation *d*) in the way of *Fermentation*, *Putrefaction*, *Accretion*, *Nutrition*, and the general Principles of Motion or Life *e*); and whether

d) See *Exp.* I.
e) See *Lect.* VII. *paſſim.*

the

the common Elements do not contribute ſome Part of their Subſtance, as well as Energy, in the Change *. From ſuch an Enquiry, conducted in a regular Manner, it ſhould ſeem that ſome capital *Canons* might be derived for improving this grand Part of operative Philoſophy.

* See the preceding Lectures upon the Elements.

LECTURE X.

CONTAINING

The Curation of Vegetables; or the Means of preparing and fitting vegetable Subjects for various Uses, viz. Brewing, Diſtilling, Vinegar-Making, *&c.*

The Subject. 1. WE are now proceeding to examine into the Nature of Seminal Vegetation, and the Curation or Preſervation of Vegetables, with a View to the Improvement of Chemiſtry and the Arts thereon depending.

Its Extent. 2. The Subject is of large Extent, and if duly proſecuted, might tend to the Enrichment of the preſent Arts, or the Diſcovery of new ones. For on regulating the Growth, and on the Curation of Vegetable Productions, depends the Perfection of Corn, Wines, Malt, Bread, Sugar, Tobacco, Spice, Drugs, Simples, Dying-Stuffs, and the like. And new Diſcoveries either in Vegetation, or Curation, might eaſily introduce new Trades; as has been the Caſe in Sugar, Tobacco, Wines, Spirits, *&c.*

The Procedure. 3. By Experiments in Vegetation, we here propoſe to ſhew the Methods of regulating or conducting this natural Power for the Service of Arts; by directing it to anſwer particular Ends. Thus by ſtopping ſhort towards the Beginning of Vegetation in Barley, we procure Malt; and by permitting the Grapes to hang till they grow not only ripe, but almoſt dry, upon the Vine, we procure rich ſweet Wines. And thus we may

may ſtop Vegetation at any Period, or continue it longer than ordinary, according as the Occaſions of different Arts require.

4. By Experiments in *Curation* we would ſhew the Methods of collecting, preparing, and ſecuring vegetable Commodities; ſo as that they may long remain ſound, perfect, and fit for Service. And thus our preſent Lecture will conſiſt of two Parts; the one relating to the ways of *growing* Vegetables, according to the Uſes for which they are intended, and the other to the *gathering* and *preſerving* them, ſo as to have them conſtantly ready at hand, when they come to be required in Uſe. *Curation what.*

5. Our firſt Experiment therefore is calculated to ſhew the Method of ſtopping the natural Proceſs of Vegetation in the Seed; ſo as to prepare Grain, Pulſe, Nuts, Maſt, and Roots, for the making of Beer, Vinegar, and Spirits. Our ſecond is deſigned to ſhew the Method of curing both fermented and unfermented vegetable Juices, ſo as to make them keep ſound and good for ſeveral Years. Our third Experiment tends to ſhew the Method of curing vegetable Juices by Decoction, or Inſpiſſation, for the Service of Brewing and Diſtilling. And our fourth and laſt Experiment will ſhew the Method of curing Yeaſt, the Flowers of Wine, and Wine-Lees, for the Service of ſeveral Arts. Theſe Experiments now follow in order. *The Deſign of the Experiments.*

Experiment I.

The Method of ſtopping the Natural Proceſs of Vegetation, with a view to Malting; or the Preparation of Grain, Seeds, Pulſe, Nuts, Maſt, and Roots, for the making of Beers, Vinegars, and Spirits.

6. We

Malting. 6. We plucked up a Parcel of Garden-Beans, after they had been ſuffered to lie in the Ground about ſix Weeks in the Winter-Seaſon; and found each Bean beginning to ſplit, or ſeparate, into its two *Lobes*, whilſt the *Radicle* was ſhot out ſome Inches downwards, and had begun to take Root in the Ground; the *Plume* alſo, which becomes the Stalk of the Bean, being riſen to the height of two Inches. In this ſtate we dried a few of theſe over a clear Fire, and thus found them turned to a Kind of Bean-Malt, that taſted ſweetiſh, bit mealy betwixt the Teeth, and diſſolved freely in warm Water; ſo as to afford a Wort, fit for 'fermentig with Yeaſt into a Kind of Beer or Ale.

7. This Experiment inſtructs us in the ordinary Proceſs of Malting; which, in the Caſe of Barley, is conformable hereto, and in the Caſe of Malting *Indian Corn* is the Proceſs itſelf *.

The Proceſs of Malting. 8. In making Malt from Barley, the uſual Method is to ſteep the Grain in a ſufficient Quantity of Water, for two or three Days, till it ſwells, becomes plump, ſomewhat tender, and tinges the Water of a bright brown, or reddiſh Colour. Then this Water being drained away, the Barley is removed from the ſteeping Ciſtern to a Floor, where it is thrown into what they call the *Wet-Couch*; that is, an even Heap, riſing to the Height of about two Foot. In this *Wet-Couch* the capital Part of the Operation is performed; for here the Barley ſpontaneouſlly heats, and begins to grow, exactly in the ſame manner as in our preſent Example of Beans; ſhooting out firſt the *Radicle*, and then if ſuffered to continue, the *Plume*, *Spire*, or *Blade*. But the Proceſs is to be ſtopped ſhort at the Eruption of the Radicle,

* See below §. 10. See alſo ſome Experiments to this Purpoſe in the *Philoſophical Tranſactions*.

otherwiſe

otherwiſe the Malt would be ſpoiled. The way to ſtop it is, to ſpread this Wet-Couch thin over a large Floor, and keep it turning once in four or five hours, for the ſpace of two Days, laying it ſomewhat thicker each time. After this, the Malt is again thrown in a large Heap, and there ſuffered to grow ſenſibly hot to the Hand, as it uſually will in twenty or thirty Hours time; then being ſpread abroad again and cooled, it is thrown upon the Kiln, to be dried criſp without ſcorching.

9. And this is the general Proceſs of Malting, wherein almoſt every Maltſter has his ſecret or particular way of working. But to render the Operation perfect, the following Cautions muſt be obſerved: (1.) That the Barley be newly thraſhed, or at leaſt newly winnowed; (2.) That it be not mixed or made up of different Sorts; (3.) That it be not over ſteeped in the Ciſtern, or ly there ſo long as to make it ſoft; (4.) That it be well drained; (5.) That it be carefully looked after in the Wet-Couch, ſo as to ſtop the firſt Tendency of the Blade to ſhooting; (6.) To turn the Wet-Couch inſide outermoſt if the Barley *comes* (that is, ſhoots) more in the middle than on the ſides; (7.) To keep it duly turning after it is out of the Wet-Couch; (8.) To give it the proper heating in the dry Heap; (9.) To dry and criſp it thoroughly upon the Kiln, but without a fierce Fire, ſo as to be ſeveral Days in drying a Kiln of Pale Malt. If theſe Directions be carefully obſerved, the Malt will always be good. *How managed to beſt advantage.*

10. The Method of Malting *Indian-Corn*, or *Virginia Wheat*, is much leſs laborious. For if this Corn be buried two or three Inches deep in the Earth, and covered with the looſe Mould dug up to make room for it, in ten or twelve Days time the Corn will ſprout, and appear like

a green

a green Field ; at which time being taken up, and waſhed or fanned from its Dirt, it is immediately committed to the Kiln, and by this means it becomes good Malt, exactly as Beans ſo treated would do.

11. It is obſervable of this Corn, that both its Root and Blade muſt ſhoot to a conſiderable length, before it will make Malt. And perhaps this is the Caſe in all large-bodied Grain and Nuts *a)*.

Extended. 12. It might be of Service to transfer this eaſy Experiment to the making of Malt from Barley, Rice, and the other ſmall Grains and Seeds: but the Attempt may be attended with Difficulties; becauſe in the making of Malt, the Barley muſt be ſuffered to grow in its Root only, and not in the Blade; whence it would be difficult, at firſt, to hit the exact time for taking it out of the Ground. And, again, as the Grain is ſo ſmall, it might prove troubleſome to ſeparate it from the Earth or Mould. However, the thing may deſerve to be tried *b)*.

Its Effects, and End. 13. It is a Conſideration of a higher Nature to determine the phyſical Effect procured by Malting, and whether the End may not be obtained by cheaper and leſs laborious Means. The phyſical Difference betwixt malted and unmalted Corn appears to be the Production, or Extrication, of a ſweet ſaccharine Subſtance in the Malt, which is wanting under that form in the Corn. And it is the ſweet Subſtance alone, which we require

a) It may be worth trying, whether the ſame Proceſs is not, with due Care, applicable to the Malting of Turnips, Potatoes, Carrots, Parſnips, *&c.*

b) And poſſibly ſome Contrivance might be found, by the means of large Hair-Cloths, or otherwiſe, to incloſe the Grain, ſo that the looſe Earth ſhould not mix among it ; and at the ſame time an Opportunity be afforded, of commodiouſly examining how far the Barley is *come* at any time after lying.

in

in Malt for the making of Beer, Ale, Vinegar, and inflammable Spirits a). But even unmalted Corn, duly treated, may be made to afford Beer, Ale, Vinegar, and Spirits: This, therefore, may intimate to us a way of making ſuch Liquors, without the formal Extrication of any remarkably ſweet ſaccharine Subſtance. According to ſome Trials we have made, unmalted Corn affords half the Quantity of inflammable Spirit by Fermentation and Diſtillation, as the ſame Corn would do when malted. And ſuppoſe that unmalted Corn were to be made into a Kind of Dough, or Paſte fermented with Yeaſt, as is uſual for Bread, and then baked; would not this be a cheap Subſtitute for Malting b)? At leaſt, it deſerves to be tried, how much Beer, Ale, Vinegar, and Spirit, might be procured this way, compared with that other of Malting.

14. On the other hand, if only a ſweet ſaccharine Subſtance be required in Malt, are there not cheaper and eaſier ways of procuring it than by Malting? Do not many Trees afford ſuch a ſaccharine Juice, by Tapping in the Spring, without prejudicing the Trees? Is not young green Corn itſelf remarkably ſweet; and does not this ſweet Juice enter the Compoſition of the Ear, and there remain fixed, or almoſt loſt in a ſaccharine Form, till recovered by Malting? Here is a Door opened for explaining the Nature of Sweetneſs, and deducing the particular Hiſtory of Sugar. Such a Work, for its Uſefulneſs in Trades and ordinary Life, we wiſh were extant; and till ſome conſiderable Progreſs is made there-

a) See *Lect.* VII. *Exp.* I, II, IV.

b) They are ſaid to brew after this manner in ſome Countries.

in, the Art of Malting, and all thoſe that depend upon it muſt remain ſhort of perfection.

15. Thoſe, who are diſpoſed to go upon the Enquiry, may pleaſe to compare the Art of Starch-Making with that of Malting, and particularly try whether ſome conſiderable Uſes may not be made of the Refuſe Liquors produced in both Arts. The high-coloured Liquor drawn from the Barley in the ſteeping Ciſtern is a vegetable Tincture, that might, if not by itſelf, yet by being uſed inſtead of Water to ground Malt, be worth fermenting and diſtilling for Spirit; and the Starch-Makers refuſe Liquors have been obſerved to contain a Quantity of inflammable Spirit.

16. Our preſent Experiment may in this reſpect be made general, that it ſhews us there are different times of ſtopping, or preventing, the farther Growth of Vegetables, for the Service of Arts. And this Doctrine may be extended to the forming a Set of general Rules, for gathering the different Parts of Plants, at different Seaſons of the Year, for different Uſes.

Uſes. 17. Thus Roots, for inſtance, to be had perfect, ſhould be gathered and dried in the Spring, before the Leaves are formed; Leaves ſhould be gathered when they are fully opened, but before the Flowers appear; Flowers when they are not fully opened; and ſome, as red Roſes, in the Bud. Seeds are to be gathered when full ripe, and beginning to dry, before they fall ſpontaneouſly; and Trees are generally beſt felled and flawed for their Bark in the Beginning of the Spring. But all this is to be underſtood of the common Uſes of the Subjects; for there are many particular Occaſions, which require them immature. Thus Buckthorn-Berries, ſhould be ripe gathered for making

making the Syrup, but unripe, for making the Painter's Colour called *Sap-Green.*

EXPERIMENT II.

A Method of Curing both unfermented and fermented vegetable Juices.

18. (1.) We melted Brimſtone in an Iron Ladle, and dipping ſlips of coarſe linnen Cloth therein, made what the Wine-Coopers commonly call Match. (2.) We took a ſlip of this Match, and ſetting one end thereof on fire, put it into the Bung-Hole of a Caſk, which being at firſt looſely ſtopped, ſuffered the Match to burn nearly out. Then the Bung being driven in tight, we ſet the Caſk aſide for an hour or two, and found that this Operation communicated a violently pungent and ſuffocating Scent to the Caſk, with a conſiderable Degree of Acidity, which is the *Gas* and acid Spirit of the Sulphur. We now filled the Caſk with a very ſmall Wine, which had ſcarce finiſhed its Fermentation; and bunging it down tight, we put it in a proper place to clarify. *Matching or Fumigating with Brimſtone.*

19. This is the common Method of matching Caſk for Wines, but particularly for Stums. It is an uſeful Experiment; for poor Wines could ſcarce be kept potable a few Months wihout it; nor could Stums be prepared in large quantities by any other Method commonly known.

20. By Stum we underſtand the unfermented Juice of the Grape, ſeveral times racked and drawn from its Sediment, the Caſk being every time thus fumigated with Brimſtone, to prevent the Liquor from fermenting, as it would otherwiſe readily do and ſo become Wine. It is the Fume of the burning Sulphur which thus ſtops all Tendency to Fermentation, and continues the natural Juice of the Grape in a ſweet ſtate, fit to be readily *Stum what.*

dily mixed with Wines inſtead of Sugar; for which purpoſe it is very much uſed in *Holland*, and other Countries, as alſo for giving a new *Fret*, or Briſkneſs, to decayed Wines; ſo that very large Quantities of this Stum are annually imported to all Parts along with the Foreign Wines. And after the ſame manner a Stum is prepared in *England* from the Juice of Apples, which ſerves the ordinary purpoſes of the Wine-Cooper.

Inconveniences of Matching. 21. The principal Inconveniences in this Method of matching the Caſk are theſe; (1.) that it communicates a nauſeous ſulphureous Taſte and Smell to the Wine; and (2.) that it is not applicable to red Stums, or red Wines, without greatly impairing, or almoſt deſtroying their Colour; whence the Stums in common Uſe are always white, the Produce of white Grapes. And becauſe this Method of Matching does not ſuit with red Wines, hence it is, that all red Wines are uſually doſed with Brandy in order to preſerve them. And for Wines in general, it might very well ſuffice to burn a little Spirit of Wine in the Caſk; and if they want Strength, or Spirit, to preſerve them ſound, to add Brandy or Spirit of Wine, proportionably. By which means they may be preſerved without any nauſeous Smell, or Taſte, which always attend the Way of matching; tho' matched Wines loſe of their ſulphureous Taſte, and Odour by long keeping. But for Stums, there is no other Way commonly known and practiſed, to preſerve them, but by uſing the Fumes of Sulphur.

The Experiment extended. 22. The Experiment however is almoſt general, and may be applied to advantage in the caſe of all fermented Liquors, and again to unfermented vegetable Juices; ſuch as thoſe of Citrons, Quinces, Oranges, &c. which it prevents from running

ning into Fermentation or Putrefaction. And this Effect it seems to have, chiefly by stiffening the Air, or weakening its natural Elasticity *. For as all vinous Fermentation is found to generate Air, so the burning of Sulphur is found to stiffen or destroy Air. And hence it seems to be, that the Fume of burning Brimstone readily checks the Fermentation of Liquors; so that if a Cask, by fretting or fermenting, appears ready to burst its Hoops, a Dish of burning Brimstone held under it will soon quell the Motion: which is one known Method of checking or suppressing vinous Fermentation.

Experiment III.

The Method of curing vegetable Juices by Decoction, or Inspissation.

25. We made an Infusion of Malt, in the common Manner of Wort for Beer or Ale; then letting it stand to clarify, we decanted the clear Liquor, and boiled it over a soft Fire to the Consistence of Treacle: in which State it will long keep sound, or fit for making Beer, Vinegar, or inflammable Spirit. *Wort inspissated.*

24. This Experiment shews us a general Way of reducing fermentable Subjects to a small Compass, and of securing them against external Injuries. Thus a Kind of Treacle from Malt might be procured in cheap Years, for the Service of the Vinegar-maker, the Brewer, and the Distiller. The Method is likewise applicable to any other sweet or saccharine Juice; as that of Grapes, the Tappings of Trees, the fermentable Juices of Summer Fruits, and of certain sweet Roots, as Parsnips, &c. *The Experiment extended.*

25. These inspissated Juices, if not boiled too high or scorched in the Operation, are easily

* See Mr. *Hale*'s *Vegetable Staticks.*

brought back to a due Degree of Thinneſs with Water, and fermented in the ſame Manner, and for the ſame Purpoſes, as they might have been before they were boiled: So that Beer, Vinegar, or Spirits may be thus commodiouſly procured, at any Time, even in hot Climates; and it ſhould ſeem that Brewers and Diſtillers might alſo reap ſome Advantage from a prudent Uſe of this Expedient.

26. The Wine-Merchant might thus order the Juice of Grapes, or Stum, to be boiled down in Wine Countries, and ſo left fit to be reduced by Water and fermented into Wines in others. And for this Purpoſe the poorer Vintages might ſerve, as well as the rich; excepting only that the Rob, when reduced by Water, would not afford ſo much Wine as the thicker or richer Juices. But the Operation muſt be performed with conſiderable Exactneſs, to make it ſucceed ſo as to produce artificial Wines perfectly like the natural.

27. This Proceſs alſo ſeems applicable to Hops, which in cheap Years, may be thus made into a Kind of Extract, without any Loſs of their valuable Parts; whereby the numerous Contingencies attending that Commodity, might in good Meaſure be prevented. But there would here be Danger of Fraud; becauſe the Extracts of Gentian, Centaury, or other bitter, ſtomachic Vegetables might be mixed with the Extract of Hops, ſo as not to be eaſily diſcovered. Yet perhaps this Inconvenience would not be greater than that generally ſuffered already; for many, no doubt, are well aſſured by Experience, that the Extract of Gentian is a wholeſome Bitter, which might very well ſupply the Place of Hops in Brewing.

28. A Proceſs ſomewhat of this Kind is frequently practiſed in Wine-Countries; *viz.* either

by

by ſuffering the Grapes to grow almoſt dry upon the Vine; or elſe by boiling down their Juice, till it becomes ſufficiently thick to afford ſuch rich Wines as *Canary* or *Frontignac*; whoſe Strength may be readily imitated by adding a leſs Proportion of Water to the Rob, or inſpiſſated Juice of Grapes, in the Manner above explained *.

29. Before we quit this Proceſs we would recommend it to be tried, upon the Juice that may be eaſily expreſſed from a vegetable Subject commonly thrown away as uſeleſs: we mean the Shells of green Peaſe, which by being barely boiled in Water, communicate a ſaccharine Sweetneſs thereto; ſo that the Liquor has been made into tolerable Drink, and a good Spirit.

Experiment IV.

A Method of curing Yeaſt, the Flower of Wine, and alſo Wine-Lees, for the Service of Diſtilling, Wine-Making, Vinegar-Making, &c.

30. We took a Quantity of common Ale-Yeaſt, and putting it into a cloſe Canvas Bag, gently ſqueezed out the Moiſture in a Screw-Preſs, till the remaining Matter was left as hard as Clay; and in this State having packed it cloſe in a tight Caſk, and ſecured it well from the Air, it kept freſh and ſound for ſeveral Months; as has been often experienced by others. *Yeaſt cured and preſerved.*

31. This is an Experiment of conſiderable Uſe to Brewers and Diſtillers, who employ very large Quantities of Yeaſt, and yet ſeem in *England* to have no good Method of preſerving it, or raiſing Nurſeries thereof; for Want of which they ſuſtain a conſiderable Loſs. Whereas the Brewers in *Flanders* make a great Profit, by ſupplying the *Uſe.*

* §. 23—27.

Malt-Diſtillers of *Holland* with Yeaſt, which is rendered laſting and fit for Carriage, after the Manner of our preſent Experiment.

The Experiment extended.

32. The ſame Method is practicable to much greater Advantage in the Yeaſt of Wine, and in Wine-Lees, if they could be imported into *England*. For by this Means we might eaſily imitate the Wines and Brandies of foreign Growths; the Lees and Yeaſt of Wine readily affording an eſſential Oil, by Diſtillation, of which a ſmall Proportion will flavour a large one of Wine or Brandy. But a ſhorter and more perfect Way is to let any taſteleſs, or other proper Wine, fret or ſtand, for ſome Time, upon ſuch Lees, or Wine-Yeaſt, whereby it will to great Advantage acquire the natural Taſte and Flavour of the Wine, to which the Lee, or Yeaſt, belonged.

Perfect Curation what.

33. Thus we have given a few Examples of *Vegetable Curation*, on which the Improvement of ſeveral Arts depends. We cannot go through all the Species of it, for that would be an immenſe Labour; nor are Men hitherto arrived at the perfect Method of preſerving Vegetables in their natural Form, with their Colours, Odours, and other ſenſible Qualities, for any Number of Years. Yet ſomething conſiderable might be done in this Way, by proper Application. Fruits may long be preſerved freſh in Spirit of Wine, firſt well ſaturated with the Skins and tinging Parts of the Fruit. And many of them may be tolerably preſerved in perfectly fermented Liquors, which generate no more Air. The more ſolid Kinds of Subſtances may be commodiouſly cured, by gently drying them in the Sun, Shade, or other ſlack Heat. Thus Peaſe, or Beans, being dried young in a ſlack Oven, in their proper Seaſon, may be boiled green and tender, in the Winter, almoſt like thoſe new gathered. Certain Ways of pre-

preserving Fruits, and other vegetable Subjects, both in a dry and moist Form, with Sugar, are now generally known: But there are some extraordinary Means of curing several particular Kinds of Bodies reserved as Secrets by Artists; tho' even these might be exceeded, if we had a thorough Knowledge of the present Subject. The Design might also be extended to the animal Kingdom, under the Name of *Animal Curation*; the compleat Art whereof would prove highly useful at Sea.

AXIOMS *and* CANONS.

1. We learn from the preceding Enquiry, that Men have Power to stop the Course of Nature in Vegetation, so as to make this Principle answer their own particular Ends and Designs; whence Arts may receive considerable Improvements *a*).

2. That the Art of Malting is farther improveable by a general Acquaintance with the Nature of Vegetation, vegetable Juices, the Art of Fermentation, and the Art of Sugars *b*).

3. That the Labour and Expence attending the Art of Malting may, in some Measure, be saved, by procuring and separating the sweet Juices of Vegetables as Nature affords them; or by boiling them down to a Treacle or saccharine Substance *c*).

4. That there are different Seasons of the Year peculiarly fitted to the collecting or procuring of these Juices, and all other vegetable Matters, according as they are required ripe or immature *d*).

a) See *Exp.* I.
b) See *Exp.* I. II.
c) See *Exp.* I. III.
d) See *Exp.* I.

5. That the Fumes of burning Sulphur have a great anti-fermentative, anti-corruptive, or preservative Power upon vegetable Juices *a*); and this without rendering the Liquors unwholesome, tho' the Fume is disagreeable, and of itself suffocative.

6. That the Fumes of burning Sulphur have a Power of discharging the Colour of red Wines *a*); and on a like Account these Fumes are usually employed for the Blanching of Silks, Flannels, &c.

7. That *Vegetable Curation* depends chiefly upon the Exclusion of the Air and all superfluous Moisture; and this either singly or conjointly *b*)

8. That *Vegetable Curation* consists in keeping all the Principles of a vegetable Subject together undestroyed, in their natural Texture or Arrangement *b*).

9. That all sweet vegetable Juices may be preserved sound and serviceable, by inspissating them over a soft Fire; so as to throw off their superfluous aqueous Parts, and leave the sweet or saccharine Substance behind, in a state fit for Fermentation, upon the Addition of fresh Water *c*).

10. That several bitter vegetable Juices, capable of answering the End of Hops in Brewing, may be inspissated by the Fire, and preserved for that Purpose *c*).

11. That those extremely corruptible Substances, Yeast, the Flowers of Wine, and Wine-Lees, may be preserved sound, barely by freeing them from their superfluous Moisture, and securing them from the external Air and too great Heat *d*).

a) See *Exp* II.
b) *Exp* II, III, IV.
c) See *Exp*. III.
d) *Exp*. IV.

12. That

12. That the Business of *Vegetable Curation* may receive great Improvements by a proper chemical Enquiry, made with a direct View to this Subject; from whence many farther Advantages are derivable to Arts and Trades, particularly to the Sugar-Colonies abroad, to Brewers, Wine-Makers, and Distillers in hot Countries; and that the Enquiry likewise might be advantageously extended to *Animal Curation* *.

* See *Exp.* IV.

LECTURE XI.

CONTAINING

Ways of illustrating and improving the Arts depending upon Vegetable FERMENTATION; *particularly* Brewing, Diſtilling, Vinegar-Making, &c.

The Subject. 1. IN our laſt Lecture we endeavoured to ſhew the Method of procuring certain vegetable Commodities, and preſerving them uncorrupted, for the Service of Arts: In our preſent, we ſhall conſider ſome Uſes of theſe Commodities, when thus preſerved; or the Ways of employing them, ſo as to afford various Preparations for the commodious carrying on of Trade, and the Buſineſs of ordinary Life.

2. As our Conſideration is reſtrained to the vegetable Kingdom, the Arts that will chiefly come before us at preſent are, thoſe of Wines, Sweets, Malt-Liquors, Vinegars, and Brandies; in all which we have already made ſome Progreſs *. But there remains much behind for the Improvement of theſe Arts; which lie in a State far from that Simplicity, on which their Perfection ſeems to depend.

The Deſign of the Experiments. 3. Theſe Arts we ſhall here endeavour to improve by four direct Experiments. The *firſt* is capital, and calculated to ſhew the Method of reducing vegetable Juices, cured by Decoc-

* See *Lect.* X.

tion or Inſpiſſation *, back to a State fit for affording Vinegars, Wines, and Brandies by Fermentation; and at the ſame Time to exhibit a new Method of making an artificial *Muſt*, or *Stum*, as good as the natural, and equally fit for refermenting, fretting, improving, and making Wines, Vinegars, and Spirits, in all Countries.

4. The *ſecond* Experiment will exhibit the common Methods of forcing, or fining down, fermented vinous Liquors, ſo as to render them expeditiouſly bright or clear, and fit for Uſe.

5. The *third* Experiment will ſhew a Method of converting White Wines into Reds; and of recovering, or improving, the Colour of decayed red Wines.

6. The *fourth*, a Method of concentrating Wines, Vinegars, or Malt-Liquors, for Carriage, or Exportation.

7. The *fifth* will ſhew a Method of recovering prick'd Wines.

8. The *ſixth* and laſt will ſhew a more profitable Method, than that commonly uſed in *England*, of fermenting Malt for Diſtillation, or the Production of common inflammable Spirits.

Theſe Experiments now follow in their Order.

Experiment I.

To ſhew the Method of reducing vegetable Juices, cured by Inſpiſſation or Decoction, back to a State fit for affording Wines, Vinegars, and Brandies, by Fermentation; and at the ſame Time to exhibit a Method of making an artificial Muſt, or Stum, as good as the natural, and equally fit for refermenting, fretting, improving, or making Wines, Vinegars, and Spirits.

9. We took three Pounds of white Lump Sugar well cleanſed of its Treacle, and melting it *Artificial Muſt prepared.*

* See *Lect.* X. *Exp.* III.

in

in three Quarts of fair Water, added in the boiling half an Ounce of finely pulverized *Rhenish* Tartar; which diſſolved with a remarkable Ebullition, and gave a grateful Acidity to the Liquor. Then taking the Veſſel from the Fire, and ſuffering it to cool, we thus procured a *Muſt*, which in all reſpects reſembled the natural tart and ſweet Juice of a white flavourleſs Grape, when that Juice is well purified, and often racked from its Sediment, in order to make *Stum*. And if our artificial *Muſt* be ſtummed, that is matched, or well fumigated with burning Brimſtone, after the Manner ſhewed in our laſt Lecture *a)*, it thus becomes a perfect *Stum*; which may be made of any Flavour, at the Diſcretion of the Artiſt.

Uſes. 10. This Experiment is ſo pregnant, that it might deſerve to have its Uſes explained by an expreſs Treatiſe *b)*. It affords abundant Inſtruction for improving the Arts of Sweets, Stums, Wines, Vinegars, and Spirits; it likewiſe affords ſome uſeful Inſtructions about the Nature of ſweet and tart vegetable Juices, and the Ways of imitating them by Art. But theſe Particulars we can only juſt touch upon for the preſent.

The Experiment how deduced. 11. The Experiment itſelf was formed upon the Analyſis of the Juice of the Grape before Fermentation; which Juice, to the Senſes, appears no other than a ſaccharine Subſtance diſſolved in Water, with the Addition of a tartarous Acid: And this being fully confirmed by a chemical Reſolution, it was hence eaſy to expect, that if Tartar, which is the natural Salt of Wine, or of any ſweet vegetable Juice fermented, could be artificially diſſolved in a proper Mixture of Sugar and Water, it would give an exact Reſemblance

a) *Exp.* II.
b) See the Appendix to this Lecture.

of the thing. Accordingly it was found upon Trial that Tartar might be thus diſſolved, ſo as to communicate an agreeable Acidity to Sugar, and thus to imitate, in great Perfection, the natural ſweet Juices of Vegetables, without their particular Flavours: and hence our Experiment diſcovers to us the Nature, Uſe, and Perfection of the Art of *Sweets*

12 By a *Sweet* is underſtood any vegetable Juice, whether obtained by Means of Sugar, Raiſins, or other Foreign or Domeſtick Fruit, which is added to Wines in order to improve them. Whence we ſee that the Art of Sweet-Making might receive a high Degree of Improvement, by uſing pure Sugar as one general wholeſome Sweet, inſtead of thoſe infinite Mixtures of Honey, Raiſins, Syrups, Treacle, Stum, Cyder, *&c.* wherewith the Sweet-Makers ſupply the Wine-Coopers, to eke out or amend their Wines. For pure Sugar being added to any poor Wine will ferment therewith, improve it, and bring it to a proper Degree of Strength and Vinoſity. If the Wine to be thus amended is tart of itſelf, no Tartar ſhould be added to the Sugar; but if it be luſcious or too ſweet, then the Addition of Tartar is proper. *A Sweet what.*

13. The preſent Experiment adds no leſs Improvement to the Art of *Stums*, which may perhaps be hence brought to its Perfection. And here we deſire the Men of Buſineſs would duly reflect, that wherever Sugars go, there go in a ſolid form *Stums*, *Wines*, *Vinegars*, and *Brandies*; that is, the actual Matter out of which, by the bare Addition of Water, theſe ſeveral Commodities may be readily prepared. For it is by no Means neceſſary that Sugars ſhould be imported and exported in a liquid Form, for the making *Extended.*

of

of Stums, Wines, *&c.* because it is ſo eaſy to add the Tartar and Water in any Port they arrive at.

Farther Uſes in the Trade of Wines.

14. Our Experiment alſo points out the Way of perfecting the *Art of Wines*, by reducing the component Matter thereof to a ſmall Bulk, and occaſionally, in any Climate, bringing it back with Water into a Muſt; which Muſt may be tinged of any Colour, or impregnated with any Flavour, ſo as to be fermented into a Wine of any Species or Denomination. Thus if a few Drops of the eſſential Oil of Nutmeg, or Cinnamon, were to be rubbed with a little Sugar into a Kind of *Elæoſaccharum* *, and then mixed with our artificial Muſt, or Stum, the Wine made of it would have a very grateful Odour and Flavour. And ſo if an eſſential Oil were procured from the Lees of any particular Wine, and introduced into our artificial Stum, after the ſame Manner, the artificial Wine would thus have the Odour and Flavour of the natural Wine that afforded the Lees; bating for the Roughneſs, Hardneſs, or Dryneſs given by the Huſk and Stone. For our artificial Muſt has no Flavour or Colour of its own, but readily receives and becomes impregnated with either by Art. And how far this Experiment may be uſeful in teaching a Method of making a rich concentrated Wine, for the extemporaneous Improvement of the poorer Sorts, or for making a ſerviceable Kind of extemporaneous Wine, barely by mixing with Water, we recommend to the Trial of thoſe who have a Talent at this Kind of Experiments.

And Vinegars.

15. The Art of *Vinegar-Making* may alſo poſſibly receive a high Degree of Improvement by Means of the preſent Experiment, as it affords us a Method of diſſolving Tartar in Water, on which the whole Art of Vinegar-making ſeems to

* See hereafter, *Lect.* XIII. *Exp.* IV.

depend

depend. For there are many phyſical and chemical Reaſons and Experiments, to ſhew that Vinegar is no more than a particular Kind of *fluid Tartar*. And the Art of making Vinegar would then be perfect, when it could readily, or extemporaneouſly, prepare and concentrate the Commodity; ſo as to give it a Kind of ſolid or conſiſtent Form, which ſhould render it durable, bring it into a ſmall Bulk, and leave it fit to be reduced by Water into a fluid Form, for Uſe in all Climates.

16. We plainly ſee that the original component Matter of Vinegar, which is Sugar, lies in a ſmall Bulk, and may be readily converted by Water, Air, and Heat into Vinegar *. Sugar in the Act of *Acetification* ſeems wholly converted into a fluid Tartar; and if the aqueous Liquor be ſeparated from Vinegar, we find the Vinegar is thereby rendered the ſtronger: inſomuch that if Vinegar were to be highly concentrated by Congelation, it would become almoſt ſolid, or a Kind of actual Tartar. Whence the Rule is eaſy, that in order to make an almoſt ſolid Vinegar, we ſhould endeavour to diſſolve Tartar in an aqueous Liquor. Whence, for perfecting the Art of Vinegar-Making, we recommend the diſſolving of Tartar largely with Sugar, or Treacle, and the ſtrongeſt Vinegar, by repeated Imbibitions, Heat, and a proper Management.

In the Diſtillation of Spirits.

17. We proceed to ſhew ſome Uſe of our Experiment in the Art of Diſtillation; which Art likewiſe might poſſibly arrive at Perfection by its Means. It is generally known that a taſteleſs, flavourleſs, yet perfectly vinous and cheap Spirit, is the grand *Deſideratum* in the Art of Diſtilling: Now ſuch a Spirit ſeems eaſily procurable from our Stum, made highly acid by the Addition of

* See *Lect.* VI. *Exp.* II.

Tartar,

Tartar, and fermented till that Acidity prevails, as it ſoon will do, ſo as to prove a true Vinoſity. And thus a highly vinous, yet flavourleſs Spirit, may be obtained at a very reaſonable Charge, if a Man thoroughly underſtands the Art of Fermentation. And ſuch a Spirit might be readily flavoured and converted into French Brandy, Arrack, or any other Kind of Spirit, that commonly ſells for a much greater Price *a)*.

Farther Uſes.

18. Theſe Particulars, with ſeveral others that might be mentioned, hold of our Experiment in its perfect State: for to reduce ſweet vegetable Juices to a pure white Sugar, without any Participation of Treacle, is an extreamly *perfect Curation*, which coſt much Labour before it was diſcovered. But now the thing is common, we ſeem almoſt to neglect it; at leaſt do not enquire into the farther Uſes of ſo capital a Diſcovery, to the apparent Detriment of the Sugar-Trade, and the Colonies thereon depending.

19. Tho' Curation by bare Decoction, or Inſpiſſation, is of a lower Claſs, yet ſtill it has its Uſes *b)*; for even Treacle is an uſeful Subſtance: But the Rob of Malt, as we ſhewed in our laſt Lecture *b)*, may be employed for the making of Beer, Ale, Vinegar, and Spirit, in all Climates, after the ſame Manner as we here uſe Sugar. And the Perfection of this Curation would be, to reduce all ſuch Robs to an actual Sugar; as with ſkill might be done, we apprehend, to Advantage. Tho' as ſome Countries and Palates prefer Malt-Liquors and Corn-Spirits, to Wines and the fineſt foreign Brandies, this Art of Sugar-Making need not be univerſally extended to Malt and Grain.

a) See hereafter *Lect.* XII.
b) See *Lect.* X. *Exp.* III.

18. Many

20. Many other Uſes are derivable to Arts and natural Philoſophy from our preſent Experiment; but we have only Time to mention one more. We ſee that Stums, Wines, Vinegars, and inflammable Spirits of all Sorts, may be commodiouſly obtained by its Means; we now add, that the original Matter of them all may be reduced to a brown, thick, treacly, or other coloured Subſtance, whether red, yellow, or black, and exported under this diſguiſed Form to any trading Part of the World, for preparing theſe Commodities there. And thus the Country poſſeſſed of Sugar, might advantageouſly ſupply many others with Matter for exerciſing of ſeveral Arts; ſuch as the Production of Wines, Beers, Vinegars, and Brandies. And in the ſame Manner might Families be ſupplied with an artificial Muſt, Stum, or Rob of Grapes, for making any Sort of Wine at home, with much greater Eaſe than they now brew Beer: for the expert Artiſt will eaſily give the proper Flavour and Colour of any Wine *, to this artificial Muſt, or Rob; ſo that there ſhould be nothing more required at home, for the making it into Wine, than to add the Water and the proper Ferment in the Caſk.

Experiment II.

The common Method of Forcing or Fining down fermented vinous Liquors, ſo as to render them expeditiouſly bright or clear, and fit for Uſe.

21. We took an Ounce of fine Iſing-Glaſs beat with a Hammer into Shreds, and diſſolved it by boiling in a Pint of Water, ſo that it became a ſtiff Gelly when cold. Some of this Gelly we whiſked *Wine fined.*

*) See above, §. 12. and hereafter *Exp.* III.

up

up into a Froth, with a little of the Wine intended to be fined; then ſtirred it well among the reſt in the Caſk, and bunged it down tight. By this Means the Wine will uſually become bright in eight or ten Days.

Uſes. 22. This Method is beſt ſuited to white Wines: but for red ones, the Wine-Coopers commonly uſe the Whites of Eggs, beat up to a Froth, and mixed in the ſame Manner with the Wines. And theſe are the common Methods of Forcing at preſent uſed in the Wine-Buſineſs.

Rationale. 23. The phyſical Reaſon of the Experiment is this, that the Bodies here employed as the Forcing are viſcous or glutinous, ſo as to entangle themſelves among the flying Lee, or light Feculencies, that float in the Wine; and thus forming a Maſs ſpecifically heavier than the Wine, ſink thro' the Body thereof, like a Net, carrying down all the Foulneſs they meet with in their Way. But when the Wine is extremely rich, ſo that its ſpecific Gravity proves greater than that of the Maſs compounded of the *Forcing*, as it is called, and the Dregs or Lee, this Maſs riſes upwards, and floats on the Top of the Liquor, in which Caſe alſo the Wine will draw off fine.

Inconveniencies of the Method. 24. The principal Inconvenience of this Method of fining Wines is its Slowneſs, as not having its Effect in leſs than a Week, or ſometimes a Fortnight, according as the Weather proves favourable or unfavourable, cloudy or clear, windy or calm; which appears to be Matter of conſtant Obſervation. But the Wine-Merchant frequently requires a Method that ſhall with Certainty make his Wines fit for taſting in a few Hours. And a Method of this Kind there is, but kept as a valuable Secret in a few Hands. Perhaps it depends upon the prudent Uſe of a tartarized Spirit of Wine and the common Forcing, as Acceſſories, along

along with *Gypsum*, or calcined Alabaster, as the Principal; all which are to be well romaged, or stirred together in the Wine, for half an Hour, before it is suffered to rest.

Fining not always necessary. 25. Let it be here observed that all Wines, Malt-Liquors, and Vinegars, which are well made and perfect in their Kind, will grow fine of themselves barely by standing; so that if they do not thus grow fine in a reasonable Time, it is a Sign they labour under some Disease, that is, are either too aqueous, too acid, too alkaline, tend to Putrefaction, or the like. In all these Cases, which may be properly enough called the *Diseases of Wines*, suitable Remedies are required before the Wines will grow fine.

Diseases of Wine how cured. 26. To enquire particularly into the Diseases of fermented Liquors, with their respective Cures, is not the present Design *a*); only we must observe, that the most general Remedy hitherto known for all the Diseases of Wines, is a prudent Use of a tartarized Spirit of Wine, which not only enriches, but disposes all ordinary Wines to grow fine. But Wines well prepared from artificial Must, in the Method above-mentioned, are subject to no Diseases. And even those obtained in the common Way may be effectually secured, against all Diseases, by Congelation, which takes away their superfluous Water without Prejudice to their vinous Parts *b*).

The Use of Milk in Wines. 27. Skimmed Milk likewise is a proper Forcing for all white Wines, Arracks, and small Spirits; but improper for red Wines, because it discharges their Colour. Thus if a few Quarts of well skimmed Milk be put to a Hogshead of red Wine, it will soon precipitate the greatest Part

a) See the Appendix to this *Lecture*.

b) See below *Exp.* IV.

of the red Colour, and leave the Liquor much paler, or almoſt white. Whence this Experiment ſometimes becomes of Uſe in turning pricked red Wines into Whites, where a ſmall Degree of Acidity is not ſo much perceived. And on this Property of Milk depends that other, of Kin thereto, whereby it whitens Wines that have acquired a brown Colour from the Caſk, or by haſty Boiling before they were fermented: For in theſe Caſes, the Addition of a little ſkimmed Milk will alſo precipitate the brown Colour, and leave the Wines almoſt limpid, or of what they call a *Water Whiteneſs*; which is much coveted abroad in white Wines as well as in Brandies.

EXPERIMENT III.

A Method of converting White Wines into Reds; and of recovering the Colour of decayed red Wines.

White Wine coloured red.

28. We put four Ounces of what is commonly called *Turnſol Rags* into an earthen Veſſel, and poured upon them a Pint of boiling Water; then covering the Veſſel cloſe, and ſuffering it to cool, we ſtrained off the Liquor, which we found of a very deep red Colour, inclining to purple; ſo that a ſmall Proportion thereof would give a beautiful bright red, to a large one of white Wine mixed therewith.

The Experiment improved.

29. For keeping, this Tincture might be mixed with Brandy, or made into a Syrup with Sugar; but the uſual Way with the Wine-Coopers and Vintners is to infuſe the Rags cold in Wine, for a Night or more, and then wring them with their Hands. The Inconvenience of this Method is, that it gives the Wine a diſagreeable Taſte, or what is vulgarly called the *Taſte of the Rag*: whence

whence the Wines thus coloured uſually paſs among the Judges for *preſſed Wines*, that have got this Taſte from the Canvas Bags in which the Lees were preſſed.

30. The Way of infuſing the Rags in boiling Water is not attended with this Inconvenience; but then it loads the Tincture with Water, which may prove prejudicial to the Wine; or if made into a Syrup, or mixed with Brandy, the Colour is thus diluted, or weakened; ſo that a large Quantity of theſe additional Ingredients comes to be uſed with a ſmall one of the Colour, tho' that alone be the Thing required.

31. Hence the Buſineſs of colouring Wines red is attended with conſiderable Inconveniencies, in thoſe Countries that do not afford the *tinging Grape*, which yields a Blood-red Juice, and with which the Wines of *France* are often ſtained. In Defect thereof at *Oporto* they ſometimes uſe the Juice of Elder-Berries, and ſometimes Logwood, when their Wines are not naturally red enough; for this Colour, it ſeems, they muſt have, to make them ſaleable. *Inconveniencies.*

32. The Colour afforded by our preſent Experiment is not properly the *Port*, but the *Bourdeaux-Red*, which does not ſo well ſuit with *Port-Wines*: Whence the Foreign Coopers are often diſtreſſed for Want of a proper Colouring to their red Wines in bad Years. We would, therefore, recommend to them the Uſe of an Extract made by boiling *Stick Laque* in Water; which gives a rich Red, that comes tolerably cheap, and is, perhaps, the perfect red *Port*-Colour *. But if this proves unſatisfactory, let a Method be tried of making a Laque out of the Skins of the ting- *Remedied.*

*) See hereafter *Lect.* XIV. *Exp.* II.

ing Grape, or *Raiſin de Teinte.* Cochineal might likewiſe anſwer the Purpoſe, tho' it loſes of its Colour by mixing with all acid Wines. Elder-Berries give this Colour in a tolerable Degree, but not without communicating a nauſeous Flavour.

33. The Produce of our preſent Experiment might anſwer well, if the Colour could be had pure, or made up into Cakes, without being imbibed by Rags; for it is very eaſy to obſcure its too great Brightneſs, or vivid purple Briſkneſs, by the Addition of a little burnt Sugar, Rob of Sloes, Rob of Oak, Rob of Wine, or any other Colour bordering upon the Tawny, ſo as to make a true *Port*-Colour.

EXPERIMENT IV.

A Method of condenſing or concentrating Wines, Vinegars, and Malt-Liquors, for Exportation.

Wines and potable Liquors improved by Freezing.

34. We took a Quart of ordinary red Port-Wine, included in a *Florence* Flaſk, and placing the Flaſk in a Mixture of one Part common Salt and two Parts Snow, or beaten Ice, we found the more aqueous Part of the Wine was ſoon turned to Ice; from which, by a bare Inclination of the Glaſs, the thick, rich, or more vinous Part of the Wine, was eaſily drained.

The Experiment regulated.

35. This Experiment is here performed too quick, ſo that ſome of the thick and valuable Parts of the Wine are catched and detained in the Ice. To perform it in Perfection, the natural freezing Cold ſhould be employed; by which Means, Wines, Vinegars, and Malt-Liquors may be

be reduced to a fourth of their ordinary Bulk, without any conſiderable Loſs of their eſſential Parts; little more than the uſeleſs, or detrimental Water being thus ſeparated, ſo as to leave all the eſſential Parts of the Wine admirably cured, or capable of remaining perfect, for ſeveral Years, as has been found upon Trial. And by a prudent Uſe and Application of this Experiment, we conceive that great Improvements might be made in the Wine-Trade.

36. For by a proper Contrivance, and a little Dexterity, which may be eaſily gained by Experience, large Quantities of the pooreſt Wines might be thus, at little Expence, converted into rich ones, ſo as to increaſe their Value in Proportion to the Diminution of their Bulk. And thus alſo, by repeating the Operation, might extremely rich and generous Wines, or a true Quinteſſence, be procured, for the Amendment of the thinner and poorer Sorts. And in this View it ſhould be remembered, that mountainous Wine-Countries are often furniſhed with Snow, by means whereof artificial Freezing might be practiſed in the time of Vintage; the bare intimation of which may give a ſufficient Hint for introducing a new and uſeful Branch of Buſineſs, as Wines may be hence concentrated after Fermentation, no leſs commodiouſly than the Juice of the Grape before that Operation *a*). And if to this be added, that the *Art of Congelation* is alſo capable of Improvement from a proper Uſe of *Sal-Ammoniac* and Water *b*); for, as the *Sal-Ammoniac* remains eaſily recoverable, it ſhould ſeem that little more than a ſuitable Apparatus is required to bring this

a) See *Lect.* X. *Exp.* III.
b) See *Lect.* V. *Exp.* II.

Bufinefs to Perfection, with all defirable Advantage.

EXPERIMENT V.

A Method of recovering prick'd Wines.

Prick'd Wine recovered.

37. To a Bottle of prick'd red *Port*-Wine we added about half an Ounce of tartarized Spirit of Wine; then fhaking the Liquor well together, we fet it by for a few Days, expecting to find it remarkably altered for the better; as upon Trial it appeared indeed to be.

38. This Experiment depends upon the ufeful Doctrine of *Acids* and *Alkalies* a). All perfect Wines have naturally fome Acidity; but when this Acidity prevails too much, the Wine is faid to be *prick'd*, which is a State thereof tending to Vinegar b). But the prudent Introduction of a fine *alkaline Salt*, fuch as that imbibed by Spirit of Wine digefted upon Salt of Tartar, (for fo the tartarized Spirit of Wine is prepared) has a direct Power of taking off the Acidity; to which Effect the Spirit of Wine alfo contributes, and is in other Refpects a great Prefervative of fermented Liquors c). And if the Operation be dextroufly performed, prick'd Wines may be thus recovered, and made to remain found and faleable for fome Time. The fame Method is likewife applicable to *hard* Malt-Liquors, or fuch as are but juft turned four, and not near becoming Vinegar.

39. An Expedient of the fame Nature is frequently made ufe of to recover four Small-Beer, by

a) See thefe Terms explained in the *Gloffary* prefixed to our *Lectures*.

b) See *Lect.* VII. *Exp.* II.

c) See *Lect.* VII. *Exp.* IV. and the Appendix to the prefent *Lecture*.

by adding thereto a little Chalk or Powder of Oyſter-Shells; for Chalk and Oyſter-Shells being terreſtrial Alkalies, immediately take off the too great Acidity of the Liquor, and cauſing an Ebullition therewith, give it a conſiderable Briſkneſs, if drank before the Ebullition is entirely finiſhed. In order to continue it the longer, 'tis beſt to add the Chalk, or Oyſter-Shells, whole to the Liquor in the Caſk; but Care muſt be taken to drink it out ſoon, otherwiſe the Liquor will ſpoil *a)*.

Experiment VI.

A more profitable Method, than the common, of fermenting Malt for Diſtillation, in order to obtain from it a Brandy, or inflammable Spirit.

40. We took ten Pounds of Malt reduced to a fine Flour, and three Pounds of common Wheat-Meal; to theſe we added, firſt, two Gallons of cold Water, and ſtirred them very well together; then five Gallons of Water boiling hot, and ſtirred all very briſkly again. Letting them now ſtand for two Hours, we repeated the Stirring again, and when the whole was grown cold, we added to it two Ounces of ſolid Yeaſt, and ſet it by in a warmiſh Place, looſely covered, to ferment *a)*. *Brewing for Diſtillation.*

41. This Experiment exhibits the *Dutch* Method of preparing the *Waſh*, as it is called, for Malt-Spirit, whereby they ſave much Trouble, and procure a large Yield of Spirit; thus commodiouſly reducing the two Buſineſſes of Brew-

a) See *Lect.* VII. *paſſim.*

ing and Fermenting, to a single Operation. In *England* the Method is, to brew and mash for Spirit just as they ordinarily do for Beer; only instead of boiling the Wort, they pump it into large Coolers, and afterwards run it into their fermenting Backs, to be there work'd, or fermented with Yeast; thus bestowing twice as much Labour in the Operation, as is required; and at the same Time losing considerably of their Quantity of Spirit, by leaving the gross Bottoms out of the Still, for Fear of burning.

And Advantages.

42. In the Manner of our present Experiment, where the Malt is ground fine, we have all its fermentable Parts set loose, so as at once to mix with the Water. And we can thus put all the *Bottoms* into the Still, without Danger of burning; because being rendered so fine at first, they entirely lose their Clamminess in the Fermentation, so as to become light or buoyant, and thus increase the Yield of the Spirit.

Regulation.

43. The Meal of unmalted Corn is found necessary to be mixed along with the Malt, to prevent its over-fermenting, and throwing off the Matter of the Spirit. But as Dispatch is here particularly required, to avoid Expence and a large Apparatus of Vessels, a considerable Quantity of Yeast is added to quicken the Fermentation, so that it may be finished in two or three Days.

44. More Yeast should be added if the Weather be cold, and less if it be hot; the Converse is to be understood of Meal, more whereof is required in hot Weather to check, and less in cold, to hasten the Operation; which in the present Case is designed to be violent, contrary to what ought to be observed in the Fermentation for Wines, where the slower the Operation is performed, the better the Liquor will prove. Which

Rule

Rule may likewiſe obtain here in a leſs Degree: for it is poſſible to ferment the Waſh ſo violently, that it ſhall ſoon end in Putrefaction *a*). And thus by rightly conducting the ſeveral Parts of the Proceſs, we may, by Diſtillation, procure all the Spirit that Malt and Meal are capable of affording by Fermentation. The Method of procuring this Spirit will be ſhewn in our next Lecture *b*).

AXIOMS *and* CANONS.

1. We have ſeen in the preceding Enquiry, that excellent Stums, Sweets, Wines, Vinegars, and Brandies, may be prepared from Sugar, in any Climate, where Water and Tartar can be procured *c*).

2. That Malt-Liquors, and Malt-Vinegars, may be commodiouſly prepared in any hot Climate, from the *Rob* or Treacle of Malt; which is fit for Tranſportation, ſo as to convey the deſired Virtue of the Malt in a ſmall Bulk, and retain it perfect for ſeveral Years *d*).

3. That the Perfection of the *Art of Vinegar-Making* depends upon the Converſion of Sugar into a fluid Tartar; or a Method of permanently diſſolving a large Proportion of Tartar in Water *e*).

4. That it is poſſible to reduce both Wines and Vinegars to a thick Syrupy Form *f*): ſince the

a) See *Lect*. VII. *paſſim*.
b) See *Lect*. XII. *Exp*. I.
c) See *Exp*. I. See alſo *Lect* VII. *Exp*. I.
d) *Exp*. I. See alſo *Lect*. X. *Exp*. III.
e) See *Exp*. I. See alſo *Lect*. VII. *Exp*. II.
f) *Exp*. I, IV.

original

original Matter of them both, *viz.* Sugar, is ſolid, and ſince they both may be concentrated by Froſt to a high Degree of Richneſs and Thickneſs.

5. That a new Art may be introduced of ſupplying Foreign Countries with a proper, or rich, ſyrupy, or treacly Subſtance, which ſhall lie in a ſmall Compaſs, for the making of Wines, Beers, Vinegars, and Spirits, in all Climates, with conſiderable Advantage *a*): A Conſideration deſerving the Attention of the Sugar-Colonies, or their Mother-Kingdoms.

6. That the ſweet and tart Juices, as thoſe of Summer-Fruits, Cherries, Grapes, *&c.* conſiſt of a ſaccharine and tartareous Subſtance; or, to ſpeak explicitly, of an actual Sugar, and an actual fluid Tartar: which affords an uſeful Rule for improving theſe natural Juices in bad Years, and again for imitating them by Art; as alſo for producing Wines, Vinegars, and Brandies, without them, where Sugar and Tartar can be procured *b*).

7. That there is a great Affinity betwixt Sugar and Tartar, ſince they not only reſide together, and are intimately mixed in all ſweet and tart vegetable Juices, but alſo ſeem readily convertible into each other; for the acid and tart immature Juices of Plants become ſaccharine by Ripening; Wine made wholly of Sugar and Water ſhoots a large Quantity of Tartar; and Sugar is wholly convertible into Vinegar, which is a fluid Tartar. Whence much Light might be derived for explaining the Nature of Vegetation, Acidity, Sweetneſs, Immaturity, Ripeneſs, Vi-

a) *Exp.* I, IV. See alſo *Lect.* X. *Exp.* III.
b) *Exp.* I. See alſo *Lect.* VII. and X. *paſſim.*

nification,

nification, Acetification, and the Art of procuring Tartar *a*).

8. That the Improvement, or Perfection, of ſeveral Arts may depend upon a ſingle Experiment; as we remarkably ſee by our ſimple Experiment of diſſolving Tartar in Water and Sugar *b*); which has a direct Tendency to improve the ſeveral Arts of Sweets, Stums, Wines, Vinegars, and Spirits.

9. That a very large Proportion of Water enters the natural Compoſition of Stums, Wines, Vinegars, and Spirits *c*); as plainly appears from hence, that the eſſential Matter of them all is contained in dry Sugar, which being barely diſſolved in Water, and fermented, becomes Wine; or a Liquor that may, by Congelation, be reduced to a fourth, or a ſixth Part of its natural Bulk, without any conſiderable Loſs of its valuable Part, or of little more than its ſuperfluous Phlegm or Water *d*).

10. That the Diſeaſes of Stums, Wines, and Vinegars, are owing to an Over-Proportion of aqueous Parts; ſo that if their Water be taken away, without doing Violence to the eſſential Matter, thoſe ſeveral Commodities may be preſerved in a State of Perfection; as we ſee they actually are by Concentration, or Congelation, which thus advantageouſly ſeparates their aqueous Parts without hurting the reſt *d*).

11. That numberleſs new Sorts of Wines and Brandies are producible, barely by adding any well-ſcented Vegetables, or their eſſential Oils, or a

a) See *Lect.* VII. and X. See alſo the preſent *Lecture*, *Exp.* I.
b) *Exp.* I.
c) *Exp.* I. and IV.
d) See *Exp.* IV.

Mix-

Mixture of ſuch Oils, to a natural or artificial Muſt in the Fermentation *a*). And the ſame may be proportionably underſtood of the Colours of Wines; which might, by proper tinging Ingredients, be thus procured blue, green, yellow, or of other Colours, if it were neceſſary, as well as pale, or red *b*).

12. That the phyſical Agent in the Fining of Wines, and other fermented Liquors, is ſome proper viſcous Subſtance, which entangles the groſs Particles, and either ſinks with them to the Bottom, or riſes to the Top, ſo as to ſeparate and keep them ſeparate from the Body of the Liquor; and that, on this Foundation, better Methods of fining may be diſcovered, than thoſe hitherto commonly known and practiſed *c*).

13. That *tartarized Spirit of Wine* is a Remedy for acid Wines, and not only abates their Acidity, but alſo ſtrengthens, and diſpoſes them to grow fine, when they are thick and turbid *d*).

14. That Milk, deprived of its Cream, will diſcharge the Colour of red Wine, by precipitating the tinging Matter to the Bottom; and ſo likewiſe leſſen, and take off the brown Colour, wherewith white Wines are ſometimes accidentally tinged *e*).

15. That the Buſineſs of colouring red Wines artificially may be improved by a proper Uſe of an artificial Turnſol without Rags; ſuch as an Extract of Stick-Laque, *&c.* but particularly an artificial Tincture of the Huſk or Skin of the red Grape, or a particular Laque made from the *Raiſin de Teinte f*).

a) *Exp.* I. See alſo *Lect.* VII. *Exp.* I.
b) See *Exp.* III.
c) *Exp.* II.
d) *Exp.* V. See alſo the Appendix below.
e) *Exp.* II. *f*) *Exp.* III.

16. That

16. That it is in the Power of Art greatly to accelerate the Operation of vinous Fermentation, ſo as to finiſh the whole in a few Days Time: But that this ſhould be done only when a Spirit, and not a Wine, is intended; becauſe ſuch a haſty Fermentation ſubverts or deſtroys the Texture requiſite in vinous Liquors *a*).

APPENDIX to Lecture XI.

Sect. I.

The Theory of Vinous Fermentation.

1. The extenſive Doctrine of Vinous Fermentation being little regarded, in Proportion to its philoſophical and practical Uſes, it may be proper in this Place to lay down its *Theory*, after a conciſe axiomatical Manner (as we are the better enabled to do from the Labour which Dr. *Stahl* has beſtowed upon this Subject *b*) and ſubjoin a few Obſervations with regard to Practice.

2. *Vinous Fermentation* is an inteſtine Motion performed by the inſtrumental Efficacy of Water; ſo as to ſtrike aſunder, attenuate, tranſpoſe, and again collect and recompoſe, in a particular Manner, the Salt, Oil, and Earth of a fermentable Subject *c*).

3. Fermentable Subjects, therefore, are mixed Bodies; conſiſting of *Salt*, *Oil*, and a *Subtile Earth* *d*).

4. Theſe compound Particles of all fermentable Subjects are ſo ſmall, that when aſunder they become imperceptible to the Senſes; for

a) See Lect. VII. *paſſim*. See alſo the preſent, *Exp.* VI. and the following *Appendix*.

b) See his *Zymotechnia fundamentalis*.

c) Conſider all the *Inſtances*, or what ſeems equipollent to them all, Sugar and Water.

d) Into which all fermentable Subſtances are reſolved by a chemical Analyſis.

neither

neither the Touch nor the Sight diſtinguiſhes them: Whence being mixed with an aqueous Fluid, they leave it tranſparent. Neither have fermentable Bodies any conſiderable Smell or Taſte, beſides the Taſte of Sweetneſs.

5. Theſe *Principles* of Fermentation, *viz.* the Salt, Oil, and Earth, muſt of Neceſſity be in a compound State; for Separation preſuppoſes Connexion *a*). And by Compoſition is not here underſtood bare Juxta-poſition, but a very intimate Coheſion of the ſmall and different Particles: So that the Salt, Oil, and Earth, in each of theſe little and inſenſible Compounds, are in actual Coheſion, Connexion, and Union.

6. When, therefore, any one of theſe *Principles* abounds in an Over-Proportion for an intimate Union, the whole Efficacy of the Fermentation is either ſtopped and impaired, or elſe preſently determined. and limited to one certain Species.

7. And this is to be particularly remarked of the volatile or eſſential *Oil*; which being in an Over-Proportion for an intimate Union with the reſt, rather hinders than promotes vinous Fermentation, but greatly diſpoſes the Subject to Putrefaction *b*)

8. But if the *Salt* predominates, this does not ſo much prevent the Succeſs of the Fermentation, provided it be in ſome Kind of Connexion with the oily and earthy *Principles*: And if it be not thus connected, it is readily taken, by Solution in the Water, from the other duly mixed Portion, and thus, in ſome Meaſure, promotes and aſſiſts the Operation.

9. This equable Connexion of Salt, Oil, and Earth into a ſingle compound Particle, makes a

a) See above §. 2.

b) As in Mace, Cloves, Nutmeg, &c.

Corpuſcle

Corpuſcle ſoluble in Water; that is, this compound Corpuſcle is, by Means of its ſaline Particle, connected with the aqueous Corpuſcles, and moved up and down therewith; that is, it becomes diſſolved therein.

10. Where theſe compound Corpuſcles are not thus connected with the Water, many of them join together either into a groſs Matter *a*), or into a looſe, chaffy, or ſpungy one *b*).

11. When diluted with a little Moiſture, theſe compound Corpuſcles feel ſlippery, clammy, and unctuous to the Touch, and after the like Manner affect the Taſte with a ropy Sweetneſs or Inſipidity *c*).

12. When undiſturbed, and left to themſelves, they preſerve their mutual Coheſion, and their ſolid or dry Conſiſtence, without Alteration *d*).

13. But as ſoon as an aqueous Fluid is put to them, there preſently begins a Commotion, and afterwards a ſubtile Separation among them.

14. This Commotion and Separation firſt begins in the whole Subſtance *e*): for before Water is added, the Subject may remain in dry, ſolid, and large Pieces *f*); which being reduced to Powder, each Grain thereof is an Aggregate of many leſſer compound Corpuſcles; and theſe being put into Water, diſſolve and ſeparately float therein, till at Length they become ſo ſmall as to be inviſible, and thicken the Conſiſtence of the Liquor.

15. When the compound Particles are thus ſeparated from one another, they are next gra-

a) As in the Lees of Wine.

b) As the Grains in Brewing.

c) As appears in all Inſtances.

d) Conſider Malt, Raiſins, Sugar, and all the Inſtances.

e) As when Sugar diſſolves in Water.

f) As in Malt, Sugar, &c.

dually

dually ſeparated from their own different Parts, that is, the different Particles whereof they conſiſt, *viz.* the Salt, the Oil, and the Earth, are diſjoined from one another by the Interpoſition of the Particles of Water.

16. The firſt Commotion is no more than a bare Solution, when the Water lays hold of the ſaline Parts of the compound Corpuſcle, and thus carries them about with itſelf. For of theſe ſeveral *Principles* the ſaline one ſooneſt diſſolves in Water.

17. But the ſucceeding Separation, *viz.* the *fermentative Motion*, is a different Thing, and what diſentangles the oily and earthy Parts from the ſaline, partly by the Impulſe of the others in their Motion, and partly by the Force of the aqueous Particles that are now continually meeting and daſhing againſt them.

18. This Motion is performed by the Water, as a Fluid, or Aggregate of an infinite Number of Particles, in actual and perpetual Motion; their Smallneſs being proportionable to that of the fermenting Corpuſcles, and their Motion, or conſtant Suſceptibility of Motion, by Warmth and the Motion of the Air, diſpoſing them to move other ſubtile, moveable Corpuſcles alſo.

19. But more particularly, an aqueous Fluid gives this Commotion, by the certain Agreement of Figure and Size which its Particles have with thoſe of the *Salt* of the fermentable Subject: Whence they come to be readily and cloſely applied together, ſo as to move almoſt like one and the ſame compound Corpuſcle; whilſt the Water is no way diſpoſed to cohere immediately with the Oil or Earth. And thus an unequal Concuſſion is made in the compound Corpuſcles of the Subject; which Concuſſion at length

length ſtriking out the ſaline Particle, and looſening the others, brings on a Separation of the original Connexion of the Subject.

20. Thus if, inſtead of Water, an oily Fluid were poured upon any fermentable Subject, no vinous Fermentation would enſue; as the Oil can neither give a ſufficient Impulſe to the compound Corpuſcles, which are groſſer than its own conſtituent Particles, nor force away the oily or ſaline Particles of the Subject from the Connexion of the others, which detain, and as it were envelope or defend them, from its Action.

21. Hence an *aqueous Fluid* alone is the true *Inſtrument* for procuring a fermentable Motion to theſe mixed Corpuſcles of the Subject.

22. As the ſmall Parts of this aqueous Fluid are in a perpetual Motion, and by Means thereof affect the compound Corpuſcles of the Subject, a certain Degree of this Motion is required, which principally depends upon external Heat.

23. It is true, a conſiderable Degree of cold will not abſolutely prevent all Fermentation, though it will greatly retard it; and a boiling Heat will prevent it ſtill more. The due Heat therefore for promoting and quickening the Operation, is a tepid one, or the mean betwixt the two Extremes of Freezing and Boiling.

24. The Admiſſion of the Air alſo, though not of abſolute neceſſity, yet greatly promotes and quickens the Action, as being a capital *Inſtrument* in the Moving of oily Particles, and the true Analyſer of oily Subjects, in Concurrence with the Motion of Fire *.

25. But whilſt the Air thus contributes to haſten the Effect, it at the ſame Time, by its Activity,

* See *Lect.* II. *Exp.* III. IV.

Activity, causes some remarkable Alterations in the oily Part; as being capable not only of moving, but of absolutely dissolving and displacing it from its original Connexion, and thus carrying it off with itself from the whole Mass *a*).

26. And hence, though the Consideration of the Air does not in the general so properly belong to Fermentation, yet it does in particular; as having an accidental Power to alter every Species of this Operation: Whence its Agency ought to be well understood, in order either to procure desireable Alterations in the fermenting Mass, or to prevent and correct such as are not eligible.

27. The *oily Principle*, which the Air thus separates and dissolves, is also elastic, though it probably has that Property from its Intercourse with the Air itself, added to an extreme Subtility of Parts; so that a small Bulk thereof containing a large Number of individual Particles, may fill and satiate a large Bulk of Air *b*).

28. To proceed: When an *aqueous Fluid* is added to a fermentable Subject, exposed to a temperate Heat, and in some small Degree to the open Air, a fermentative Struggle immediately arises; the Water by its continual intestine Motion dissolving the saline Part of the compound Particles, and carrying them up and down with itself infinite Ways, amidst innumerable other Particles, as well merely aqueous as fermentable ones: Whence, by this Collision and Attrition, the oily and earthy Particles are at length sepa-

a) As may appear by the Loss of Spirit and Flavour in open Fermentation, where the Matter is exposed to too much Air.

b) As in the Atmospheres of odoriferous Vegetables; and again in Perfumes or strong-scented Drugs; as Musk, Ambergrease, Camphire, Assa-fœtida, &c.

rated

rated and disjoined from their Connexion with the ſaline.

29. The oily Particles, as being the moſt ſubtile, and moſt diſpoſed for *elaſtic Motion*, would thus be thrown up to the Surface of the Liquor, and carried off by the Air, if they were not long involved or enveloped in the earthy ones; which are not only undiſpoſed and unfit for Avolation, but alſo ſtrongly inclined to form larger Collections or Aggregations with other earthy ones, and ſo ſink with them to the Bottom *a*).

30. But before this can be fully brought about, that is, before many of the earthy Particles are gradually collected together by their frequent Occurſions, ſo as to form a Bulk that can be no longer moved about by the aqueous Fluid, it happens that, by theſe repeated Colliſions, ſome of the oily Particles (now disjoined from the ſaline ones, which are ſtrongly agitated by the aqueous Particles, and ſeparated from the earthy ones) are again, by Degrees, more intimately connected with the ſaline ones; whilſt, on the other Hand, theſe ſame ſaline Particles imbibe and take to themſelves ſome of the earthy ones, which being left ſingle, upon their Separation from the oily Particles, floated ſeparately about in the Fluid *b*).

31. And hence proceed the ſeveral different Conſequences of Fermentation; *viz.* (1) From the Extrication of the ſaline Particles of the Subject proceeds the tart, ſaline, or acid Taſte of

a) In the Form of Lees or Sediment.

b) Obſerve that this whole Doctrine is not delivered as hypothetical, but as derived from a careful Conſideration of all the *Inſtances*, both *à priori* and *à poſteriori*, in the Way of a juſt *Induction*.

the Liquor; which is more ſenſible at firſt, before the Liquor is duly compoſed and ſettled, or the new Arrangement and Connexion of the ſaline Particles with thoſe of the oily and earthy Kinds compleated: After which the Liquor proves milder, ſofter, or leſs pungent. (2) From the oily Particles being ſet at Liberty, proceeds the ſtrong Smell of the Liquor, and the Head or the ſhining Skin upon the Surface. (3) The earthy Particles collecting together in Cluſters, cauſe the Fluid firſt to appear turbid, and afterwards to precipitate a viſible earthy or clay-like Matter: And ſome of theſe earthy Parts in their Motion arriving at the Head or oily Skin on the Surface, cauſe it to thicken; and afterwards carrying it down along with them, thus conſtitute the *Lees* which abound in Oil. (4) From this Struggle or Colliſion, which is productive both of Solution and a new Connexion in the ſaline and earthy Corpuſcles, proceeds the *Ebullition* in Fermentation. And laſtly, by the ſame repeated Colliſion of the oily with the aqueous and ſaline Particles, the *inflammable Spirit* is produced *a*).

32. *Water* performs this whole Series of Changes, by becoming the Inſtrument and *Medium* of new Separations, Tranſpoſitions, and Combinations; as alſo preſerving theſe new Combinations after they are made, by a Kind of conſtant Interpoſition, or eſſential Concurrence *b*). For Wine cannot, without extreme Alteration, be deprived of all its Humidity; though it may be freed from the ſuperfluous Part thereof by Congelation, without the leaſt Prejudice *c*).

a) See *Lect.* VII. *Exp.* IV.
b) See *Lect.* XI. *Exp.* IV.
c) This appears to be true in Fact.

33. And

33. And although the aqueous Humidity were intirely taken away, yet the fermented Matters would ſtill retain and reſpectively ſhew the Alteration brought upon them; for the Spirit, with its eſſential Aquoſity, would appear in one Place, the acid Salt in another, and the dry Earth, or unctuous *Fæces*, in a third *a*): And in the two laſt the aqueous Part may be totally ſeparated, without any way altering the Places or State they were put into by the Act of Fermentation *b*).

Sect. II.

Practical Obſervations relating to vinous Fermentation.

1. According to the Doctrine above delivered, every fermentable Subject is in itſelf, or may be reduced to, a dry and ſolid Body, conſiſting of oily, ſaline, and earthy Parts, ſo put together as perfectly to diſſolve with Water into a tranſparent clammy Liquor: Whence Malt or other Grain, Grapes or other Fruit, are to have their proper fermentable Parts eſtimated by the Quantity of dry, pure, fermentable Matter, or Sugar, they would yield; all their other Parts being either chaffy or aqueous, and foreign to the real Purpoſe of Fermentation.

2. This teaches us a Rule for reducing all fermentable Matters to their leaſt Dimenſions, and preſerving them at all Times fit and perfect for Uſe; *viz.* by making them into pure dry *Sugars*: Which, though at preſent generally

a) As we ſee in Tartar, and dry Wine Lees.

b) See *Lect.* VII. *paſſim.*

practiſed upon the Sugar-Cane only, is performable to good Advantage upon other Subjects *a*).

3. The Perfection of Fermentation in general depends upon three Things; *viz.* (1.) the Goodneſs and Suitableneſs of the Subject; (2.) the Goodneſs and Proportion of the Water put to it; and (3.) the Regulation of the Operation.

4. The Goodneſs of the Subject in general is determined by its Purity and perfect Solubility in Water, without impairing the Tranſparency thereof, or changing its Colour. And this Character is excellently anſwered by the fineſt Sugar; though the uſual Manner of preparing and refining it, by a ſtrong Heat, ſomewhat indiſpoſes it for a ready Fermentation, which newly expreſſed and unboiled vegetable Juices are greatly diſpoſed to; whence their Fermentation is much ſooner finiſhed.

5. That Water is generally allowed beſt for Fermentation, which of itſelf contains moſt fermentable Parts; and ſuch is, (1.) the Water that naturally grows along with Fruits; (2.) Rain Water, which is impregnated with vegetable Matters; and (3.) River-Water, which alſo contains ſome vegetable Subſtances; but (4.) Spring Water is the pureſt and leaſt altered by foreign Mixture: Whence the trueſt Eſtimate may be made of a fermentable Subject by its Means, provided it have no Peculiarity contrary to the Nature of Fermentation *b*).

6. The Quantity or Proportion of the Water is limited by the Nature of the Thing. We ſee that dry fermentable Subjects will never of themſelves fall into Fermentation; too little Moiſture

a) See *Lect.* VII. *Exp.* I. and *Lect.* X. *Exp.* III.

b) See *Lect.* V. VII. and X.

diſpoſes

difpofes them rather to putrify than ferment * ; and too large a Proportion fcatters and diffufes them, fo that the Parts have not their Effect upon each other, and become in a Manner loft : So that there is a certain middle Proportion which is beft, and fuffers the Whole to ferment freely, and to obtain fuch a Body and Confiftence as will enable it to keep found and perfect ; and this Proportion is about two thirds or three fourths of Water to one of perfectly pure and dry fermentable Matter.

7. The Regulation of the Operation includes, (1) the Manner of putting the Subject to work ; and (2) the external Regimen during the Operation. The Subject may be fet to work either with or without Addition, and with or without Heating ; and this according to the Climate or Seafon of the Year. The recent expreffed Juice of Grapes feldom requires either ; but falls immediately to ferment of itfelf, and finifhes the Work in a few Days. But in cold Countries all fermentable Juices require to be quickened by artificial Warmth, and the Addition of a proper Ferment. The Heat fhould be barely tepid, and the Quantity of Ferment moderate ; fo as to begin the Operation fpeedily, before the Liquor receives any Damage from the external Air, or Change of Weather. The Ferment employed muft be of the fame Nature with the Liquor, or yielded by a fermenting Subftance of the fame Kind ; otherwife it will introduce and imprefs its own foreign Nature upon the Subject.

8. *Ferments* are thofe Subftances which added to a Liquor prepared for Fermentation, make it begin and end the Operation fooner than it would have done by itfelf. They confift of

* See *Lect.* VII.

the moſt ſubtile, moveable Parts of the fermenting Liquor, already ſeparated from the groſſer or more ſluggiſh; and are therefore thrown up to the Top of a fermenting Liquor: Whence being taken in their State of fermenting Motion, and added to a freſh Parcel of prepared Liquor, no wonder if they ſoon ſet it alſo in a fermenting Motion. But Care muſt be had not to uſe an Over-Proportion, leſt inſtead of quickening the Operation, it ſhould be perverted by too great a Confuſion and Diſorder; which if it ſhould happen, can not eaſily be ſtopped, nor its Inconveniences be eaſily remedied.

9. The external Regimen during the Operation regards the Admiſſion or Excluſion of the Air, and the Warmth of the Place. The free Admiſſion of the Air greatly promotes and quickens the Operation, but carries away ſome of the fine, volatile, unctuous Parts of the Subject, and conſequently impoveriſhes the Liquor: whence the moſt perfect Way is to exclude the Air, and to perform the Operation in a cloſe Caſk, if Expedition be not required. In this Caſe, a little Space ſhould be left unpoſſeſſed by the Liquor at the Top of the Veſſel, and then there will be no Danger of burſting it. Indeed this might otherwiſe be readily prevented, by the Uſe of a *Valve* to let out the foul Air, which is conſtantly generated in Fermentation, and if too long detained in the Caſk, is apt to be imbibed again by the Liquor, ſo as to give it a nauſeous Taſte and Odour. And if the Climate or Seaſon be cold, the Place of the Operation ſhould be kept moderately warm by Fire, or ſome proper Contrivance; otherwiſe the Fermentation may languiſh, or be checked, before the full Effect is procured.

10. Theſe Cautions being duly obſerved, the

the Operation will be performed to great Advantage. When it is fully ended, or rather a little before, the containing Veſſel muſt be cloſe ſtopped up, and kept well ſecured from the external Air, that the Liquor may, of itſelf, grow perfectly bright and fine; as it will do, if no Error has happened in the Management. And this is the moſt perfect Method of fermenting Wines, where the fermentable Liquor is prepared by Art *a*); but other Cautions and Rules are required, when Nature affords the Juice imperfect, or unduly mixed, as in bad Vintages, *&c.* *b*).

11. But this Method of fermenting cloſe is ſomewhat ſlow; and greater Expedition is often required in Practice, inſomuch as ſometimes to become the primary Conſideration. We ſhall therefore next take a View of the ſeveral artificial Means to be uſed for ſhortening the Operation, without any conſiderable Prejudice to the Liquor.

12. The Things that have a principal Tendency to haſten the Buſineſs of Fermentation, are, (1) the making of the Liquor ſufficiently dilute; (2) the Addition of a large Proportion of Ferment; (3) the keeping the Whole in a due Degree of Warmth; and (4) the free Admiſſion of the external Air.

13. 'Tis a common Obſervation, that thin Wines finiſh their Fermentation ſooner than ſuch as are rich; as if, for the Sake of Diſpatch, they ſhould be made a little thinner than uſual. The Defect may be afterwards ſupplied with Spirit of Wine, and richer Wine, according to the Practice in Wine-Countries when the Vintage proves poor and watery *c*).

a) See *Lect.* VII. *Exp.* I. & *Lect.* XI. *Exp.* I.
b) See *Lect.* VII. & XI. *paſſim.* *c*) See *Lect.* XI. *Exp.* IV.

14. A

14. A large Proportion of Ferment has a great Power to forward the Operation, and becomes neceſſary in making all the artificial Wines, where the vegetable Juice is not recent, or where it has felt the Force of the Fire; unleſs the Wine be purpoſely deſigned to ferment imperfectly, that it may retain its Sweetneſs, and appear the richer: but this is always with a Loſs of Strength or Spirit, which, however, may readily be ſupplied by the Help of Brandy.

14. Where the utmoſt Expedition is required, a due Temperature, or tepid Degree of external Warmth, muſt, by all Means, be kept up by Art, if the Climate or Country does not naturally afford it: For Heat has a peculiar Power of liquifying and thinning all Fermentable Juices, ſo as to make them work, without leſſening their Strength as diluting does; which indeed it rather increaſes, if it be not too violent, or too long continued.

16. We have already obſerved, that too free an Admiſſion of the external Air, though it greatly forwards the Operation, yet conſiderably prejudices the Liquor, by carrying off its finer and more ſpirituous Part. The free Air, therefore, is to be admitted prudently, and principally at firſt, in order to excite the fermentative Motion; and this ſpirituous Part may be afterwards detained, or kept from flying off, towards the End of the Operation, by covering the Veſſel cloſe, or giving it but little Vent. And when theſe ſeveral Means are prudently uſed together, the Operation may be performed with conſiderable Expedition and Advantage; provided the original fermentable Matter be rightly diſpoſed, or duly mixed of ſaline or acid, oily, and terreſtrial Parts.

17. The *Phænomena* of vinous Fermentation are various, and differ according to the Degree of

of the Operation; though the ultimate Effect is generally the ſame. Sometimes the Fermentation gives manifeſt Signs of itſelf; as by Frothing, Hiſſing, Exploſion, *&c.* and ſometimes again ſcarce any manifeſt Signs at all; whence we may conſider it as an *apparent* or *latent Operation.* The apparent is ſufficiently known by its Signs; but the latent has been leſs regarded.

18. When any fermentable Matter is ſufficiently diluted with Water, it has immediately a natural Tendency to Fermentation, and hath often actually fermented and produced a Wine, though a Spectator could neither ſee, nor well ſuſpect, any fermenting Motion in the Liquor. In this Caſe, where no Ferment has been uſed, and the Operation proceeds in its own natural, ſlow, and ſilent Manner, there may be commonly ſeen on the Surface a thin, ſhining Skin; which, inſtead of a large, frothy Head in the ſtronger Fermentation, keeps in the fine Parts, and prevents their Avolation and Eſcape. Sometimes alſo a Degree of Hoarineſs, Finew, or Mouldineſs, will appear on the Top, without mixing itſelf with the Body of the Liquor, or without communicating any ill Taſte thereto. And in this Manner a ſlow and ſilent Fermentation has been carried on for ſeveral Months, without any ſpirting up of Bubbles, or other common Signs of the Operation; though it has, at laſt, finiſhed its Courſe to greater Perfection.

19. And ſomething like this *ſilent Fermentation* remains for a long Time in the Liquor, after the common *tumultuary Fermentation* is finiſhed, which indeed leaves its Work but imperfect; ſo that the Liquor afterwards requires a conſiderable Time to grow fine, ripen, and become fit for Drinking: Whereas in the ſilent Method

thod, these Ends are all at once carrying on at the Time of the Operation. And here lies a great Part of the Advantage which the slow Way of fermenting close has over the common one.

20. It is observable, that though a small Quantity of Liquor finishes its Fermentation sooner than a large one, yet the larger proves the better; as a great Body of Liquor is not so liable to receive pernicious Alterations, from Heat, Cold, the Air, or other accidental Things. And even where nothing remarkable of this Kind has happened, it is surprizing to note the Difference betwixt a small Quantity and a large one, of the very same Liquor, fermented in the very same Manner, only the one in a small and the other in a large Vessel.

21. Small Wines may be brought to undergo a second Fermentation, by being mixed with proper fermentable Materials; and thus may be rendered stronger and richer, so as to be fit for Exportation, *&c.* Otherwise it is observed that Wines which finish their Fermentation in eight or ten Days, will not ordinarily endure the Sea.

22. It is a necessary Caution in all Fermentation, to prevent too great external Heat, for Fear of changing the Fermentation to Putrefaction *, and to remove the Wines to a cooler Place, when the Violence of the Operation is over; that they may purge and fine themselves by Degrees, without Danger of turning acid, as they are apt to do in a hot Place. Or if they cannot be kept cool, they ought to be early racked from their Lees; which tends to preserve them sound, and prevents their turning eager, ropy, and foul *a).*

*) See *Lect.* VII.

23. It

23. It is to be obſerved of all Liquors prepared by Fermentation, that the Interpoſition of *Water* keeps not only the ſaline, oily, and ſpirituous Parts, but alſo the mucilaginous and earthy ones, in their due Arrangement and ſome Degree of Connexion; from which if they are again diſturbed, there happens ſuch a Change as cannot well be prevented from proving pernicious, but the Liquor will ſucceſſively and haſtily proceed on to Corruption *a*). Thus if a fermented Liquor be agitated by a great boiling Heat, its proper Arrangement is thereby diſordered, and the Liquor not only becomes manifeſtly thick and turbid, but more ſaline and auſtere, through the Separation of the ſpirituous and oily Particles from the ſaline ones, wherewith, being before in ſome Meaſure connected, their Acrimony was ſheathed or abated.

24. Such Liquors tend ſo much the faſter to Alteration or Putrefaction, if they are not carefully looked after and preſerved; but eſpecially if, through any great Commotion by Heat, the more intimate Connexion of the ſpirituous Parts with the ſaline and mucilaginous, or even with the remaining aqueous ones, be diſturbed and broken: Whence either the whole Maſs turns to Vinegar, or to a ropy, corrupt, putrid Subſtance *a*). But if ſuch fermented Liquors are carefully preſerved at Reſt, and kept from Injuries, they will long remain in a ſound and uncorrupted State; as we continually ſee in Wines and Malt-Liquors.

25. And farther, all theſe fermented Liquors will be fitted to reſiſt the Alterations of the Weather or

a) See *Lect.* VII.

Seaſons

Seafons of the Year, with refpect to Heat, Cold, and a fermenting Humidity in the Air, (which is by fome efteemed the Caufe of Fretting in Wines) if their fuperfluous Water be artificially feparated from them, fo as that the Liquor itfelf may be concentrated; in which State it will remain for many Years unchangeable, through the Summer's Heat, and the Winter's Cold *.

26. When a chemical Analyfis is made of thefe Liquors, the firft Part that rifes is *inflammable Spirit*; the next, *Phlegm*, mixed with an Acid, and an effential Oil, leaving a thick Matter, or Rob of Wine, at the Bottom; which, when freed from its fuperfluous Moifture, is obferved to be very durable, and full of Tartar. But the bare Mixing of thefe feveral Parts together will not make the original Liquor again: Which fhews that they were all before connected in a certain particular Manner, which was diffolved and deftroyed in the Act of Separation; and again, that each of thefe Productions received a particular new Kind of Alteration from that Act of Separation, which will not fuffer them to reunite as before, without fome proper intermediate Subftance, or a new Fermentation.

27. Hence pure Wine confifts of much Water, a moderate Quantity of inflammable Spirit, a little effential Oil, a Proportion of acid Salt, and a certain mixed Subftance, or *Rob*, called by *Becher*, the *media Subftantia Vini*. And whilft thefe feveral Parts remain firmly united together in their due Proportion, the Wine is in its perfect State: But as their Connexion proves loofe, or any one of them becomes deficient, or abounds in an Over-Proportion, then the Wine is faulty,

* See *Lect.* XI. *Exp.* IV.

and

and expofed to Injuries and Alterations for the worfe: And this fhews us the true Foundation of what may be called the *Health* or *Difeafes* of *Wines*.

28. That a large Proportion of Water neceffarily enters the Compofition of Wine, appears plainly by its artificial Preparation *a*); and again from the Congelation of the natural *b*). But though this large Quantity of Water is requifite in the Fermentation, and ferves to carry it on the better; yet it is not afterwards effential to the Wine, but rather foreign and detrimental, expofing and fubjecting it to Changes, which it would not otherwife undergo: Whence the fovereign Remedy for all Wines, is to deprive them of their fuperfluous Water, in order to render them perfect and unchangeable, without fome uncommon and extraordinary Violence or Accident. And indeed this Remedy is fo effectual as to make all others unneceffary; infomuch that the pooreft and thinneft Wines may, by its Means, be rendered perfectly durable, and full bodied *b*).

29. But as there may be fome Difficulty in the particular Ufe of this grand Remedy (in the large Way of Bufinefs) the next Expedient is, to ufe highly rectified and pure Spirit of Wine, in fuch Proportion as to prevent all Change for the worfe, and preferve the effential Parts of the Wine, as it were by a Balfam. But when the Cafe is very bad, this Remedy of itfelf will fcarce prove fufficient, unlefs affifted by fomewhat to give a Body as that gives Strength. Whence it is highly convenient to have always at Hand a

a) See *Lect*. VII. *Exp*. I.

b) See *Lect*. XI. *Exp*. IV.

Quan-

Quantity of Wine made as rich as ever it will ferment; a ſuitable Proportion whereof being added along with the Spirit, will have a very good Effect; eſpecially if the Whole be quickened with a little *eſſential Oil of Wine*, which, in the Caſe of over-aqueous Wines, is generally deficient. And this being a capital Diſeaſe in Wines, or that to which moſt of the reſt are originally owing, it may be proper here to give a Form of a Remedy which has been found effectual for the Purpoſe.

30. Take an Ounce of fine eſſential Oil of Wine, mix and grind it with a Pound of dry Loaf-Sugar into an *Elæoſaccharum*; diſſolve this *Elæoſaccharum* in two Gallons of the richeſt Wine; and add to it two Gallons of the fineſt Spirit of Wine, ſo as that they may be well incorporated together. The Doſe of this Mixture muſt be proportioned to the Exigence; but in ordinary Caſes one half will ſuffice for a Pipe of Wine.

31. There is a Diſeaſe of Wines oppoſite to the former, and that is when too much of their aqueous Moiſture is drawn from them, whence they become dry and parched, as it were, for Want of it. This Caſe indeed cannot well happen, except by the Method of Condenſation; whereby Wines may have their eſſential Parts brought ſo cloſe together, as to become unfit for Drinking till ſet more aſunder, and diluted. But this muſt not be attempted with Water alone, for Fear of inducing a Flatneſs. The beſt Way is, to have a dilute or thin taſteleſs Wine ready at Hand for the

the Purpoſe *a*); whereby any Degree of Smallneſs may be given at Pleaſure.

32. But the artificial Method of preparing Wines renders all Remedies unneceſſary, as it intirely prevents their Diſeaſes; ſo that they need not be made either too aqueous, or too dry, but conſtantly of a perfect full Body, and therefore not ſubject either to Acidity, Ropineſs, or Foulneſs, when once well cleared of their groſs Lees, in the ordinary Way of Racking.

33. But in Caſe the Wine ſhould not ſoon grow fine of itſelf, the Addition of a little tartarized Spirit of Wine will haſten the Effect *b*): Or, to make at once a general Remedy for Wines that are too poor and aqueous, or will not thoroughly fine themſelves; let a pure, taſteleſs, and totally inflammable Spirit be made from Sugar; digeſt this Spirit upon a tenth Part of pure and dry Salt of Tartar for three Days; decant the Liquor, and put it to ten Times its own Quantity of a Wine made as rich as it poſſibly would ferment: Of this Preparation ſix or eight Quarts will at any Time mend, improve, and fine down a Pipe of ordinary Wine.

a) See *Lect.* VII. *Exp.* I.
b) See *Lect.* XI. *Exp.* II. IV.

LECTURE XII.

CONTAINING

Attempts to illustrate and improve the Arts depending upon DISTILLATION; *viz.* Malt-Stilling, Rectifying, and Compounding.

The Subject. 1. HAVING already gone through the Arts depending immediately upon *vegetable Fermentation*, we next proceed to consider the Ways of improving the Art of *Distillation*, which depends thereupon secondarily.

Distillation, what. 2. The Word *Distillation* is here used in the popular Sense, to signify the Art by which all inflammable Spirits, Brandies, Rums, Arracks, and the like, are procured from vegetable Subjects, by the Means of a previous Fermentation, and a subsequent Treatment of the fermented Liquor by the Alembic, or Hot-Still, with its proper Worm and Refrigeratory.

The Arts therein concerned. 3. The Arts therefore at present to be considered are those of Malt-Stilling, Rectifying, and

and Compounding, with the Buſineſs of the Brandy-Merchant, the Officers of Cuſtoms and Exciſe ſo far as relates to Spirits, and of the ſeveral Dealers in Brandies, Rums, Arracks, and Cordial Waters.

Deſign of the Experiments.

4. The Experiments we ſhall exhibit will ſhew, (1.) the Method of Diſtilling a Spirit from a fermented Malt-Wort, commonly called *Waſh*, in order to obtain *Aqua Vitæ*, or the ordinary Malt Spirit, of which many Cordial Waters are made by the Compounders, Apothecaries, and others: (2.) Our *ſecond* Experiment will exhibit the Method of purifying or rectifying this Spirit of the firſt Running, or, *Low-Wines*, as they are called, into a ſaleable Proof-Spirit, or what they emphatically call *Proof Goods*; that is, a certain ſtandard Spirit, uſually conſiſting of one half Water and the other half Alcohol: (3.) Our *third* Experiment will exhibit the Art of the rectifying Diſtiller, or the Method whereby the Proof Goods of the Malt-Stiller are made into a ſweeter or cleaner Spirit, for the finer Uſes of the Compounder and Apothecary: (4.) Our *fourth* Experiment will ſhew the true Method of examining Proof in Spirits, and diſcover the Invalidity of the common Methods of judging of the Purity, Genuineneſs, and Goodneſs of Brandies, Rums, and Arracks: And (5.) our *fifth* Experiment, will ſhew the Method of making Cordial or Compound Waters in Perfection.

EXPERIMENT I.

The Method of diſtilling Malt-Waſh, or a fermented Mixture of Meal and Malt, for Spirit.

The Diſtillation of Waſh. 5. We briſkly ſtirred together the Malt-Waſh prepared in the laſt Experiment of our laſt *Lecture*, and therewith filled two thirds of a Still, firſt made hot and dewy on the Inſide with boiling Water, and kept the whole Stirring till it almoſt begun to boil; then we immediately clapped on the Head, and luted it down. There now ſoon ran, in a ſlender Stream, from the Noſe of the Worm, a ſpirituous Liquor that was inflammable, or burnt in the Fire. We continued to work ſo long as the Liquor that came over would, when thrown upon the hot Still-Head, catch Flame from a lighted Candle applied to the riſing Fume.

Low Wines. 6. And thus we obtained what the Malt-Stillers call a *Malt Low-Wine*; that is, a ſpirituous Liquor from fermented Malt and Meal, ſo diluted with Phlegm or Water, as that the laſt Runnings of it would not burn upon the Still-Head. That which comes over after the Spirit falls off from being Proof, till it will no longer burn on the Still-Head, is called by the Name of *Faints*

The Experiment extended. 7. This Experiment may be rendered general, by a ſlight Variation of Circumſtances; that is, it may be made to ſerve as an Inſtance of all the Ways of procuring inflammable Spirits, whether Brandies, Rums, Arracks, Cyder-Spirit, or the like: For if any Wine, Beer, or fermented Liquor

Liquor from Sugar, Treacle, Roots, Fruits, *&c.* be treated in the ſame Manner, it will afford a Spirit differing only according to the Nature, or ſpecific Taſte and Odour, of the Subject.

8. But none of theſe Subjects will afford the leaſt drop of inflammable Spirit without a previous Fermentation *a*). Thus though the recent Juice of the Grape, or any other fermentable Juice, were diſtilled to Drineſs, yet no inflammable Spirit would be procured: Whence it appears that inflammable Spirit is a Thing produced by *Fermentation b*).

9. The Cautions required to render the Experiment ſucceſsful, and the Production perfect, are, (1.) That the Fermentation be well performed, and the Liquor become truly vinous, and of an acid Pungency *c*); (2.) that it be gently diſtilled, by Means of a ſoft, well regulated, Fire; (3.) that the groſſer Oil, apt to riſe along with the Spirit, be kept back by a proper Strainer, or thick doubled Flannel, laid under the Noſe of the Worm. If theſe Cautions be duly obſerved, the *Low-Wines* will prove conſiderably pure and vinous. *Cautions.*

10. When all the Spirit is thus obtained there remains behind in the Still what they commonly call *Bottoms*; that is, the groſs Parts of the fermented Meal and Malt mixed with Water. This groſs Matter is generally uſed for the Feeding of Hogs; whence the Malt-Stillers *Management.*

a) See *Lect.* VII. *Exp.* IV.
b) See *Lect.* XI. *paſſim.*
c) See *Lect.* VII. and XI.

of *England* are commonly large Dealers in Hogs: But in *Holland* that makes a ſeparate Buſineſs.

11. Thus we have gone through three of the principal Branches of Malt Stilling; *viz.* the Brewing, Fermenting, and firſt Diſtilling Parts; or the Making of the Wort, the Working it in the fermenting Back, and the diſtilling it from the Waſh *a*). There is but one Part more of this Art, *viz.* the Rectifying Part; or the Way of *making up their Goods*, as they call it, to ſaleable Proof: And how this is performed will be ſeen by the following Experiment.

EXPERIMENT II.

The Method of ſimple Rectification, or Diſtilling the Low-Wines, produced by the foregoing Experiment, into Proof-Spirit for Sale.

Proof-Spirit. 12. We took the Low-Wines produced in the preceding Experiment, and diſtilled them over-again *in Balneo Mariæ*, or barely by the Heat of boiling Water; and thus we obtained a purer and higher rectified Spirit than before, which being let down with fair Water to a certain Size or Standard called *Proof b*), is what the Malt-Stillers underſtand by Proof-Goods, or *their* rectified Malt-Spirit.

a) See *Lect.* XI. *Exp.* VI.

b) What this Proof is, ſee explained in the fourth Experiment of the preſent Lecture.

13. The

13. The common Malt-Stillers indeed do not thus rectify their Spirit *in Balneo Mariæ*, but barely rediſtill their Low-Wines in a ſmaller Still; ſo that their Spirit is not ſo clean as that of our preſent Proceſs. The Perfection therefore of the Art of Diſtilling from Malt ſeems to require a good Method of rectifying clean, as well as a careful Obſervance of the Cautions above laid down *a*).

14. Having thus regularly gone through the whole Art of the *Malt-Stiller*, as it is practiſed by the more intelligent Artiſts, we proceed to offer a Conſideration or two for its farther Improvement.

15. The Inconveniencies of this Art regard either the Subject, or the Work. The Subject, we ſee, is Malt; which being of a large Bulk, in Reſpect of its ſaccharine Part, and requiring a great Proportion of Water to extract this Part, hence many large Veſſels, ſuch as Maſh-Tuns, Coolers, Fermenting-Backs, Coarſe-Stills, and Fine-Stills, become neceſſary therein; whereby the Labour alſo is increaſed, and the Price of the Commodity enhanced. This Art, therefore, being far removed from Simplicity, is conſequently far removed from Perfection. *Inconveniencies.*

16. The Remedy here ſhould ſeem to depend upon the Introduction of a new Art, ſubſervient to the Art of the *Malt-Stiller*, and confining itſelf to the Boiling down of Malt-Wort to a Rob *b*), ſo as to ſupply the *Malt-Stiller* with his Subject, in the ſame Manner that the *Fine-Stiller* is now ſupplied by the Sugar-Baker *Remedied.*

a) See §. 9.
b) See *Lect.* X. *Exp.* III.

with Treacle: For thus the complex Bufinefs of the *Malt-Stiller* might be commodioufly reduced to a great Degree of Simplicity.

17. By the fame means the Spirit of the *Malt-Stiller* would alfo become much finer than at prefent; becaufe the Subject would come tolerably refined to his Hands, or purged of its grofs, mealy, and hufky Matter, which yields a difagreeable Oil in Diftillation; and is alfo apt to burn in the Still, and fpoil the Spirit. We therefore recommend it to thofe who are fkilled in this Branch of Diftillation, to try whether a Spirit fuperior to that of Treacle may not be procured from the *Rob of Malt*, prudently prepared and fermented

Fine-ftilling.

18. There needs no particular Experiment to fhew the bufinefs of the *Fine-Stiller*; that being no more than Working, in the Manner above explained, from a Wafh made by fermenting Treacle with Yeaft; though it is ufual to add a confiderable Proportion of Malt, and fometimes a little powdered *Jalap*, in the fermenting Back. The Malt accelerates the Fermentation, and makes the Spirit come out the cheaper; and the *Jalap* prevents the Rife of any crufty Head on the Surface of the fermenting Liquor, and fo leaves a greater Opportunity for the free Accefs of the Air; which alfo fhortens the Work, by turning the foamy into the more hiffing Kind of Fermentation.

EXPERI-

EXPERIMENT III.

The Art of the Rectifier; or the Method whereby the Proof-Goods of the Malt-Stiller are made into a cleaner Spirit, for the finer Uses of the Compounder and Apothecary.

19. To two Gallons of the common Proof-Spirit of the Malt-Stiller, procured after the Manner of our second Experiment, we added three Ounces of the Black Flux, or a Mixture of Tartar and Nitre calcined to Blackness *; and drew over all that would run in an uninterrupted Stream from the Nose of the Worm, by Means of the *Balneum Mariæ.* The Spirit which thus came over we made up Proof with fair Water. And the Spirit thus prepared is the common saleable *Proof Goods* of the rectifying Distiller, when he works to a Truth. *Rectification of Spirits.*

20. This is the Spirit we commonly meet with in Trade under the Name and Notion of *Malt-Spirit*, which is thus fitted for making the common Cordial or compound Waters; being cleared considerably of its fœtid Oil and nauseous Phlegm, by Rectification. If it be desired still cleaner one of the best Methods is, to dilute the strongest Part that comes over first, with a large Proportion of fair Water, draw off the Spirit gently again by the *Balneum Mariæ*, and then make it up proof with fine soft Water. *Malt Spirit.*

21. But this Method will not yet give us the Spirit without some nauseous and disagreeable Flavour; nor do the Rectifiers appear acquainted with any good Method for that Purpose. *Inconveniencies.*

* See *Lect.* II. *Exp.* II.

They

They have been groping after it, but generally in the dark, for want of a proper Knowledge of the Facts and Experiments neceffary in the Enquiry. Thus, for inftance, they feem little apprehenfive that it is the Oil of the Malt, refiding in the Spirit, which occafions all their trouble; or that it is the effential Oil of the Subject which gives to Malt-Spirits, Brandies, Rums, and Arracks their particular Flavours. For if the effential Oil could be totally feparated from Malt-Spirit, that Spirit might be rendered flavourlefs and taftelefs; and then any other Flavour might, by Means of other effential Oils, be introduced into it; fo that it might be made to refemble either *French* Brandy, Rum, or Arrack. And in the effecting of this, with Simplicity and Cheapnefs, the Perfection of the Art of Rectifying feems to confift.

Remedied. 22. For this purpofe we would recommend the Way of Working from a Spirit largely diluted with Water, into Water again; for thus the effential Oil would be doubly feparated at one Operation. But we have no great Hopes that any Direction of this Kind can prove ferviceable to them, while they remain unacquainted with chemical Operations, and the beft Contrivances for Diftilling in the large Way with Elegance and Simplicity.

23. The Chemifts, however, have helped them to a tolerable Expedient for covering the Imperfections of the Spirit which they cannot cleanfe; *viz.* by the Addition of what is called *Spiritus Nitri dulcis*; a fmall Proportion whereof will give an agreeable Vinofity to a Hogfhead of Spirit. Bnt this Expedient is attended with an Inconvenience; for the Flavour is very apt to fly off, or be loft, when the Spirit is kept in a Cafk: But the Succefs proves different, when the

the Spirit is kept and well ſtopped down in a Glaſs.

24. The Art of the *Rectifier* might be entirely ſet aſide as uſeleſs, if the original *Malt-Stiller* could make his Spirit perfect at a ſecond Operation, as we judge he might. But here again the *Malt Stillers* can ſcarce be brought to forſake the beaten Track. If they are diſpoſed to improve their Art, we would recommend to them, *firſt*, the Brewing in Perfection; and *ſecondly*, the Keeping of their Waſh, after the Manner of ſtale Beer, till it has entirely loſt its Malt Flavour, and acquired a pungent, acid, Vinoſity; and then, *thirdly*, leaving out the Lees, to diſtil with a well-regulated Fire. Thoſe who have not tried would ſcarce conceive what an agreeable Spirit may be thus procured from Malt, at the very firſt Diſtillation. The gainful Part of the Secret depends upon *an artificial Method of making Malt Liquors expeditiouſly ſtale, bright, and flavourleſs, but in other reſpects vinous* *. *Improvements.*

Experiment IV.

The Method of examining Proof in Spirits; and detecting the Invalidity of the common Ways of judging of the Purity, Genuineneſs, and Goodneſs of Brandies, Rums, and Arracks.

25. We took a long Phial, half filled with the common Proof-Spirit of the *Malt-Stiller*, and giving it a ſmart Stroak with its Bottom againſt the Palm of the Hand, there appeared on the Surface of the Liquor a Chaplet, or Crown of Bubbles, which went off, or diſappeared, in a certain ſtrong Manner; that is, it firſt *Proof taken of Spirits.*

*) See *Appendix* to *Lect.* XI. See alſo *Lect.* VII.

remained

remained a while, and then went off by Degrees, without breaking into ſmaller Bubbles, or riſing into larger. And when the Bubbles go off in this Manner, the Spirit is ſaid to be proof or merchantable *.

Erroneous. 26. And by this Kind of Proof all Diſtillers, Brandy-Merchants, Brokers, and the Officers of the Cuſtoms and Exciſe, judge of the Strength and Quality of Brandies and Spirits, in all the Brandy-Countries and Sea-Port Towns of *Europe*: whence it is alſo conveyed to other Parts of the World. It may therefore appear ſtrange to oppoſe the general Opinion and Practice, in a particular where the Intereſt of ſo many trading People, watchful againſt all Impoſition, is concerned: And yet we undertake to ſhew, that this Kind of Proof is a mere Fallacy and Deception; for if but a little vinous or ſaccharine Matter, as Treacle, Syrup, Muſt, the Rob of Fruits, &c. be added to a Quantity of highly rectified Spirit of Wine, this ſlight Addition will give a Brandy-Proof to that Spirit; which, therefore, by this Trial, may be made to paſs for Brandy; that is, for a Compoſition of half Water and half Alcohol, whereas in Reality it is almoſt totally Alcohol.

Detection. 27. The Fraud is eaſily detected; not in the common Way practiſed upon the *Keys*, but by burning a little of the Spirit in a Spoon; for thus it will leave the ſaccharine Matter behind in a dry Form.

Sophiſtication. 28. Whether there be any Method commonly known in *Europe*, of making a ſpirituous Liquor that contains much leſs than a half of Alcohol, to paſs current for Proof-Spirit, is not ſo certain: But doubtleſs this might be

* See *Lect.* VII. *Exp.* IV. § 36, 37.

eaſily

might be eaſily effected; for we ſee that Arrack is Proof, or affords a ſtrong Crown of Bubbles, upon ſhaking, as well as Brandy; yet Arrack contains not uſually above half the Quantity of Alcohol that Brandy does; and if but a Drop or two of its own or any other eſſential Oil be added to a Pint of Proof-Brandy, this is ſufficient to deſtroy its Proof, and make it appear much weaker than it is.

30. To prevent being impoſed upon in this Way, we might have Recourſe to the *Eſſay-Inſtrument*, or *Hydroſtatical Balance.* A Gallon of Alcohol is computed to weigh ſeven Pounds and a half, and a Gallon of Water, eight Pounds; whence the compound Gravity of an equal Mixture of the two may be aſſigned. But it is a more ſure and ready Method, to burn a little meaſured Quantity of the Brandy to be tried, in a cylindrical metalline Veſſel, plunged in cold Water to an equal Height with the Brandy, and when it ceaſes to burn, exactly meaſuring the Remainder, which is the Water: Where if the Spirit has loſt one half of its Meaſure by Burning, the Brandy may be allowed Proof; if more or leſs, it muſt be judged of accordingly *. *Diſcovery.*

31. But beſides the falſe Method of judging of the Strength of Brandies by what is called Proof, there is another no leſs fallacious one of judging of their Genuineneſs; tho' kept a great Secret in few Hands, as a Thing ſome Dealers imagine a certain Criterion for determining whether foreign Brandies are mixed with Corn Spirits. Theſe Dealers are provided with a certain *yellow Liquor*, a few Drops whereof being poured *Eſſay Liquors.* *Its Uſe.*

* See a Paper by M. *Geoffroy*, to this Purpoſe, in the *French* Memoirs.

into

into a Glafs of right *French* Brandy, gives it a beautiful blue Colour; by the Strength and Brightnefs of which Colour they judge of the Genuinenefs, or unmixed State of the Commodity, and buy upon this Kind of Proof: Whence they may come to be much deceived; for if an ordinary Malt Spirit was to be coloured with Oak, it would fuftain the prefent Method of Proof, and might therefore be purchafed by thefe Dealers for *French* Brandy.

How made. 32. This Proof-Tincture, or *Effay Liquor*, may be expeditioufly prepared, by diffolving a little green Vitriol (firft calcined to Rednefs) in a weak Spirit of Sea-Salt; which thus becomes a *yellow Liquor*, a fingle Drop or two whereof being added to a Glafs of any inflammable Spirit coloured yellow or brown with Oak, will inftantly turn it of a beautiful bright Blue: Whence it is evident that this Kind of Trial is no more than a Fallacy, and only fhews when Brandies are tinged with Oak, as they conftantly are by lying long in the Cafk. And that it is the Oak which thus caufes *French* Brandies to turn blue with the *Effay Liquor*, appears again from hence; That if the beft and oldeft *French* Brandy be re diftilled, and thus made colourlefs, it will not turn blue with the *Effay Liquor*; becaufe all the Tincture of the Oak, or tinging Matter of the Cafk, is left behind in the Still.

Its Fallacy detected. 33. One of the beft Methods to prevent being impofed upon by the Mixing of Malt-Spirit with a finer, is to acquire a Habit of judging by the Tafte and Smell; for Malt-Spirit is ufually fo ill rectified, by the Addition of fixed alkaline Salts, or certain flavouring Ingredients, that it may eafily be perceived by the Nofe or Palate; efpecially if the Brandy propofed for Examination be largely diluted with Water, to prevent

prevent its over-heating the Mouth; or elſe be burnt in a Spoon, ſo as to leave the Phlegm to be taſted and ſmelt by itſelf: For this Phlegm, if the Brandy were debaſed by a Corn Spirit, will taſte and ſmell exceedingly nauſeous, very different from the Phlegm of pure *French* Brandy.

Experiment V.

The beſt Method of making Cordial or Compound Waters.

54. We infuſed a Pound of freſh Citron-Peel in two Gallons of good Melaſſes Spirit, and committing the whole to the Still, drew off the Spirit gently, with Care to avoid the *Faints*; then *making up*, as they call it, with ſoft Water, ſo as to leave the Liquor Proof, we added half a Pound of fine Sugar, and thus procured a genuine *Citron Water*. *Citron Water prepared.*

35. This Experiment is general, and ſhews the uſual Methods of making all the Compound or Cordial Waters, by thoſe Diſtillers who are called Compounders, and alſo by Apothecaries; tho' Apothecaries ſeldom make diſtilled Waters ſo good as the Compounders. *The Experiment extended.*

36. The Perfection of this Branch of Diſtillation depends upon the Obſervance of a few Rules, which might be eaſily complied with: And theſe Rules we ſhall here lay down, as judging them of Conſequence to the Improvement not only of the Art of the Compounder, but alſo of a Branch of Pharmacy and Medicine. *Compound Diſtillation improved.*

37. The firſt Rule is, *To uſe a well-cleanſed Spirit, that is freed from its own eſſential Oil.* For as the Deſign of compound Diſtillation is to impregnate the Spirit employed with the eſſential *Rules.*

Oil

Oil of the Ingredients, it ought firſt to have depoſited its own.

38. The ſecond Rule is, *To ſuit the Time of previous Digeſtion to the Tenacity of the Ingredients, or the Ponderoſity of their Oil.* Thus Rhodium-Wood and Cinnamon require to be longer digeſted before they are diſtilled than *Calamus Aromaticus*, or Lemon Peel. Sometimes alſo *Cohobation* (that is, the pouring of the Spirit once drawn off, back upon the ſame Ingredients) proves neceſſary; as particularly in making the ſtrong Cinnamon Water, where the eſſential Oil is extremely ponderous, and hardly riſes along with the Spirit, without one Cohobation more.

39. The third Rule is, *To ſuit the Fire or Strength of the Diſtillation to the Ponderoſity of the Oil intended to be raiſed with the Spirit.* Thus ſtrong Cinnamon Water ſhould be diſtilled off briſker than the Spirit of Mint or Baulm.

40. The fourth Rule is, *That a due Proportion of only the finer eſſential Oil of the Ingredients be thoroughly united or incorporated with the Spirit, ſo as to keep out the groſſer and leſs fragrant Oil.* And this may be chiefly effected by leaving out the *Faints*, and making up to ſtrong Proof with fine ſoft Water in their Stead. And upon the Obſervance of theſe four eaſy Rules the Perfection of the Art of compound Diſtillation ſeems to depend.

41. The Addition of fine Sugar to Cordial Waters is a Thing of leſs Moment, and may be uſed or omitted occaſionally. And if theſe Directions be obſerved, there will be no need of fining down Cordial Waters with Allum, Whites of Eggs, Jſing-Glaſs, or the like; for they will be preſently bright, ſweet, and pleaſantly taſted, without any farther Trouble.

42. And

42. And thus we hope to have shewn the Way of perfecting the Art of compound Distillation, even by the common Alembic, or hot Still, without the Use of the *Balneum Mariæ*; for which there is here no Occasion, if the Artist be but expert in working by the Alembic.

AXIOMS *and* CANONS.

1. We learn from our present Enquiry, that inflammable Spirits are the Creatures of vinous Fermentation; or that they are actually produced, tho' not separated, in that Operation *a)*.

2. That the Action of Fermentation produces such a Change in the Wash, as to render it separable by the Fire into several Portions of Matter, besides the inflammable Spirit, specifically different from what the Liquor would have afforded by the same Treatment before Fermentation *b)*.

3. That at different Times of Distillation there come over Liquors of different Properties; and first of all, an extremely acrid, aromatic, and biting one; which goes off by Degrees, and ends in Acidity *c)*.

4. That the Art of *Malt-Stilling* may be considerably improved; (1.) by reducing the brewing and fermenting Parts to one Operation; (2.) by distilling slow; and (3.) by keeping back the gross Oil of the Subject.

5. That this Art may be farther improved, by fermenting a clear, well-brewed Wort, and keeping it to be stale, or till it has lost all Fla-

a) See *Exp.* I.
b) See *Lect.* VII. *Exp.* IV. See also *Appendix* to *Lect.* XI.
c) See *Exp.* I. and *Appendix* to *Lect.* XI.

vour of the Malt; as it will naturally do by long lying, or in a very ſhort Time by the Help of a certain artificial Treatment *a*).

6. That the Perfection of the Art of *Malt-Stilling* requires the Aſſiſtance of a new Art, to produce a Kind of Treacle from Malt, or the Reduction of the Art of the *Malt-Stiller* to the ſame Simplicity as that of the Fine Stiller *a*).

7. That the eſſential Oil of the vegetable Subject is the Thing which gives to all Spirits their particular Odours and Flavours *b*).

8. That the fineſt, moſt ſubtil and efficacious Part of this eſſential Oil always riſes firſt in Diſtillation *b*).

9. That the Purity and Perfection of Spirits, conſidered merely as Spirits, greatly depend upon their being cleanſed firſt of the eſſential Oil, eſpecially its groſſer Part, and next of the Phlegm *c*).

20. That Brandies are a Mixture of one half Water, and the other half Alcohol; that the Meaſure of the Strength of Brandies is the Quantity of Alcohol they contain; and therefore that their Water may be commodiouſly left behind upon Exportation or Carriage *d*).

11. That as Brandies hold ſome ſmall Proportion of eſſential Oil, they are in Strictneſs dilute *Quinteſſences c*); whence their Properties and Effects may be eaſily explained, in a chemical Manner.

a) See *Exp.* I. and III.

b) See *Exp.* I. III. V.

c) See *Exp.* I, II, III. V.

d) See *Exp.* I, II, III, IV.

12. That

12. That the Perfection of Rectifying Spirits depends upon finding out a simple Method of separating all the Oil and Water from a Spirit *a*).

13. That the great Affinity betwixt the essential Oil and Spirit is the physical Cause of the Difficulty found in the Rectification of Brandies *b*).

14. That the Perfection of the Art of *Malt-Stilling*, whereby a pure Spirit might be procured at the first Operation, would supersede the Art of Rectifying *a*).

15. That the Bubble Brandy-Proof may be artificially given to high rectified Spirit of Wine, and easily destroyed in Proof-Spirit, without weakening the Spirit *c*).

16. That the common Methods of trying and examining Brandies by the Bubble-Proof, and by their turning blue with a vitriolic Solution, are absolutely fallacious, and not to be trusted for the Purposes intended *d*).

17. That *physical Proof* in Brandies is the Property they have, upon shaking, to generate a Crown of moderately large Bubbles on their Surface, by Means of a certain Tenacity, arising from a stated Proportion of essential Oil dissolved in among them; which Tenacity may also be given by other Bodies *d*).

18. That a sure Method of determining the Strength of Brandies is by Deflagration, or burning away their Alcohol; then examining the remaining Phlegm by Weight or Measure, and

a) See *Exp.* III.
b) *Exp.* I, II, III. V.
c) *Exp.* III, IV.
d) *Exp.* IV.

comparing it with the Weight or Meaſure of the Alcohol *a*).

19. That erroneous Notions, or inaccurate and falſe Methods of Trial, may prevail, and become almoſt univerſal in Trade; ſo that even the prudent Merchant ſhall buy and ſell upon weak Trials, whilſt the Detection, Rectification, or Adjuſtment thereof, belongs to ſome other Branch of Knowledge *a*).

20. That the Way of perfecting the Art of compound Diſtillation is, (1) To procure a well-cleanſed Spirit; (2) To uſe proper Digeſtion; (3) To diſtil briſk, or ſlow, as the Subject requires; and (4) To keep back the Faints, and the groſs Part of the eſſential Oil of the Ingredients *b*).

a) *Exp.* IV.
b) *Exp.* V.

LEC-

LECTURE XIII.

CONTAINING

The Ways of procuring Vegetable Oils *and* Salts; *with their Uses in several* Arts *and* Trades.

I.

1. WE now proceed to illustrate and improve the common Methods of procuring and employing vegetable *Oils* and *Salts*; on which the Exercise of various Arts and Trades depends. *The Subject.*

2. The Parts of Vegetables that chiefly abound with Oil are, the Seed, the Leaves, the Fruit, and the Bark. Thus the Seeds of Mustard, and of the Sun-Flower, Almonds, Nuts, Beech-Mast, &c. afford a copious Oil by Expression; and the Leaves of Rosemary, Mint, Rue, Wormwood, Thyme, Sage, &c. the Berries of Juniper, Olives, *Indian* Cloves, Nutmeg, Mace, &c. the Bark of Cinnamon, Sassafras, &c. yield a considerable Proportion of essential Oil by Distillation *. *The oily Parts of Vegetables.*

3. And much in the same Manner is Oil or Fat contained in the Parts of Animals; being either interspersed among the muscular Flesh, collected into particular Bags or Cells, or lodged in the Cavities of the Bones, &c.

* See below, *Exp.* II.

The Design of the Experiments. 4. Our *first* Experiment will ſhew the Method of procuring Oils by Expreſſion, from Nuts, Seeds, Maſt, Olives, &c. The *ſecond* Experiment will exhibit the Method of procuring thoſe called the Eſſential Oils of Vegetables. The *third* Experiment will ſhew the Method of rectifying thoſe called the Empyreumatic Oils. Our *fourth* Experiment will ſhew the Method of refining Sugar. The *fifth* Experiment will ſhew the Way of refining *Tartar* : Our *ſixth* the Manner of refining *Nitre*, or Salt-Petre; and our *ſeventh* will ſhew the Method of making Pot-Aſh.

EXPERIMENT I.

The Method of procuring Oil by Expreſſion, from Nuts, Seeds, Maſt, &c.

Expreſſed Oil of Almonds. 5. We took two Pounds of Sweet Almonds, blanched, and beat them ſmall in a Stone Mortar; then wrapping the Maſs up in a Piece of ſtrong and thick Canvas, we committed it to a ſtrong Screw-Preſs; where being ſqueezed betwixt two cold Iron Cheeks, it gradually parted with a conſiderable Quantity of Oil.

The Experiment extended. 6. This Experiment holds of all thoſe vegetable Matters that contain a copious Oil, in a looſe Manner, or in certain Cavities or Receptacles; the Sides whereof being burſt by ſqueezing, makes them let go the Oil they contain. And thus the Zeſt, or Oil of Lemon-Peel, Orange-Peel, Citron-Peel, &c. may be readily obtained by Preſſure, without the Uſe of Fire; for the Rinds of thoſe Fruits being preſſed green, the oily Parts will ſeparate from the aqueous,

aqueous, and may be rendered pure by washing them in fair Water *.

7. How far this Method of obtaining Oils may be applied to Advantage, seems not hitherto considered. It has been commonly applied to Olives, Almonds, Lint-seed, Rape-seed, Beech-Mast, Ben-Nuts, Wallnuts, Bay-Berries, Mace, Nutmeg, *&c.* but not that we know of to Juniper-Berries, Cachou-Nuts, *Indian* Cloves, Pine-Apples, or Fir-Nuts, and many other Subjects that might be enumerated, both of foreign and domestic Growth. It has however been of late applied to Mustard-seed, with good Success; so as to extract a curious yellow, or golden-coloured Oil from that Seed, and at the same Time leave a Cake behind fit for making the common Table Mustard.

8. Certain dry Matters may, as well as moist ones, be made to afford Oils by Expression; for when they are not so moist as Almonds, or fit to be reduced to a Pulp in a Stone Mortar, they may be ground into a Meal, which, being suspended to receive the Vapour of boiling Water, will thus be moistened so as to afford an Oil, in the same Manner as Almonds; especially if the Iron Cheeks employed be first heated, by lying in boiling Water. And thus an Oil may be procured from Lint-seed, Hemp-seed, Lettuce-seed, White Poppy-seed, *&c.*

9. The Oils obtained by this Treatment, *Regulated.*
should be suffered to depurate themselves by standing in a moderately cool Place, to separate from their Water, and deposite their Fæces; from both which they ought to be carefully freed. And if in this Manner they are not

* See below, § 9.

rendered ſufficiently pure, they may be well waſhed and beat with freſh Water, and then thoroughly ſeparated from it again, by the Separating-Glaſs; by which Means they will be rendered bright and clean.

10. Particular Care muſt be taken to keep ſuch of theſe Oils cool as are deſigned for eating, or for any internal Uſe; becauſe they are apt in a few Days Time to turn rancid and corroſive with the Summer's Heat, ſo as to prove very unwholeſome. Hence the Phyſician and Apothecary ſhould be cautious that the Oils given in Pleuriſies, and other Diſtempers, be freſh drawn from ſound Subjects, no way tainted, or already turned rancid, as Almonds, Piſtachios, and other Nuts, are apt to be: And again, that theſe Oils have felt no conſiderable Heat, either in the Drawing, or by ſtanding long in a warm Place. And the ſame Caution ſhould likewiſe extend to animal Oils and Fats, intended either for internal or external Uſe; ſince theſe alſo become rancid, or change to a yellow, red, or grey Colour in hot Weather, and thus become exceedingly nauſeous and corroſive; as we ſee in Butter, Bacon, and other fat Bodies, which then prove fit only for the Tallow-Chandler, or other ignoble Uſes.

Applied to other Subjects.

11. Our preſent Experiment is likewiſe applicable to the procuring of Oils or Fats from certain animal Subjects; for the Membranes, the ſkinny, and ſtringy Parts of animal Bodies, which contain much Fat, being chopped ſmall, and ſet in a Pan over the Fire, become fit for the Canvas-Bag, and by Preſſure afford a large Quantity thereof; as we ſee in the Art of Chandlery, which thus extracts the oily Matter, leaving

leaving behind a hard Cake, or what they commonly call *Graves.*

12. These *Graves*, and all the Residuums of the present Process, after being squeezed ever so hard with the Press, will still afford a copious Oil by boiling in Water; so that it might perhaps be more profitable for the *Tallow Chandler* to boil his *Graves* for Oil, as Bones are usually boiled for it, than to dispose of them in the ordinary Manner. And it is surprizing to observe, what a large Proportion of Oil these dry, and to appearance almost exhausted Bodies, will yield, by repeated boiling in Water, but particularly by being committed to the *Digestor* *.

13. So likewise if the Almonds remaining in the Canvas, after the Expression of their Oil, be ground in a Mortar with warm Water, the Water will thus extract their remaining Oil, and turn therewith into a milky Liquor, or *Emulsion.* And if this Operation had been performed upon the Almonds at first, before we committed them to the Press, we might thus have got out all their Oil, and left only a dry, chaffy, or light, husky, and exhausted Matter behind. Whence we have a Method of dissolving Oils in Water, and thereby of making a Kind of artificial Milk; which, by standing, will afford a Cream, and turn sour, like the Milk of Animals, but not grow rancid with Heat, like Oil. Whence such Emulsions may, in some Cases, be medicinally used with greater Safety and Success than expressed Oils.

Farther Uses.

14. Any of these expressed Oils will receive particular Colours and Odours at the Discretion of the Artist. For Example: If a little

Oils coloured.

* See *Lect.* VI. *Exp.* VII.

Alkanet-

Alkanet-Root be barely infuſed in Oil-Olive, it gives a beautiful red Colour to that Oil, without altering its Taſte. So again; if a few Drops of the eſſential Oil of Cinnamon be added to a Pint of Sallad Oil, ſuch Sallad Oil may be rendered thereby agreeable to thoſe who admire the Flavour of Cinnamon. And thus may Oil, Butter, *&c.* be diverſified infinite Ways, by a proper Uſe of tinging Ingredients, and ſuitable chemical Oils.

Eſſences. 15. The ſame Contrivance has likewiſe its Uſes in making Eſſences for the Service of the *Perfumer*; not only where eſſential Oils are procurable, but alſo where theſe either cannot well be obtained, or but in ſmall Quantity. The eſſential Oil of Jaſmin Flowers, Honey-Suckles, Sweet Briar, Damaſk Roſes, Lilies of the Valley, *&c.* are either extremely dear, or ſcarcely obtainable by Diſtillation; and in ſome of them the odorous Matter is ſo ſubtil as to be almoſt loſt in the Operation. But if Jaſmin Flowers, Damaſk Roſes, Lilies of the Valley, *&c.* be barely infuſed in fine Oil of Nuts, or Oil of Ben, drawn without Heat, and kept in a cool Place, the ſubtil odorous Matter of the Flowers will thus paſs into the Oil, and richly impregnate it with their native odoriferous Spirit; which can ſcarce otherwiſe be procured, or ſeparated from the Flowers, without Loſs, or Debaſement. And theſe Eſſences may be rendered perfect by ſtraining off the Oil at firſt put on, letting it ſtand again, without Heat, upon freſh Flowers, and repeating the Operation twice or thrice.

What they are. 16. If we conſider the Thing attentively, we ſhall find that the Eſſences thus obtained are a Kind of *eſſential Oils*, not greatly differing from thoſe prepared by Diſtillation from the Flowers,

Seeds,

Seeds, or Barks of odoriferous Vegetables; for all ſuch *eſſential Oils* are found to be little more than the native odorous Spirits of the vegetable Subject, wrapped up, lodged, or entangled in an unctuous or direct oily Subſtance. This oily Subſtance indeed riſes, or becomes volatile, by the Heat of boiling Water; but ſo do not the Oils gained by Expreſſion *: Whence the principal Difference betwixt thoſe *natural*, and *artificial eſſential Oils*, as we may call them, ſeems to conſiſt in the different Tenacity, Volatility, or Fixedneſs of their unctuous or direct oily Parts, the *native Spirit* appearing the ſame in both; tho' indeed it is more delicate and unimpaired in the artificial Kind of eſſential Oils, as not having felt the Force of Fire. And hence perhaps ſome conſiderable Improvements might be made in the Art of the *Oilman*, *Perfumer*, and *Apothecary*; not to mention other œconomical Uſes, and the Art of the *Dairy*.

Experiment II.

The Method of procuring the eſſential Oils of Vegetables by Diſtillation with Water.

17. We took eight Pounds of Juniper Berries, and bruiſing them in a Stone Mortar, directly put them into a Still, together with four Gallons of River-Water; then working with a briſk Fire, we drew off a Gallon of Water, and obtained along with it a conſiderable Proportion of a fragrant eſſential Oil, which we *Eſſential Oil of Juniper diſtilled.*

* See *Exp.* II. hereafter.

ſepa-

ſeparated from the Water by a Separating-Glaſs.

The Experiment extended. 18. This Experiment is eaſily rendered general, or made applicable to the Diſtilling of the eſſential Oils from Flowers, Leaves, Barks, Roots, Woods, Gums, and Balſams, with a ſlight Alteration of Circumſtances; as by longer Digeſtion, briſker Diſtillation, &c. according to the Tenacity and Hardneſs of the Subject, the Ponderoſity of its Oil, &c. *a*).

Uſes. 19. If the Liquor that remains in the Still, after the preſent Operation, be ſtrained, and evaporated to the Conſiſtence of Honey, it makes the *Rob of Juniper-Berries*, which may perhaps defray the Charge of the Operation, it being eſteemed a valuable Medicine, and uſed as a Strengthener of the Stomach and Inteſtines, as a Preſervative from the Stone and Dropſy, and as a Cure for the Diſorders of the urinary Paſſages.

Eſſential Oils claſſed. 20. Eſſential Oils may be divided into two Claſſes, according to their different ſpecific Gravities; ſome floating upon Water, and others readily ſinking to the Bottom thereof. Thus the eſſential Oils of Cloves, Cinnamon, and Saſſafras readily ſink; but the Oils of Lavender, Marjoram, Mint, &c. ſwim in Water. The lighteſt of theſe eſſential Oils is, perhaps, the Oil of Citron-Peel, which floats even on Spirit of Wine; and the heavieſt ſeems to be the Oil of Saſſafras: But the ſpecific Gravities of the intermediate eſſential Oils are not hitherto adjuſted and *tabled*, as for the Service of Chemiſtry they ought to be *b*).

a) See *Lect.* XII. *Exp.* V.

b) See below, §. 29.

21. For

21. For obtaining the full Quantity of the more ponderous Oils from Cinnamon, Cloves, Saſſafras, &c. it is proper (1) to reduce the Subjects to fine Powder; (2) to digeſt this Powder for ſome Days in a warm Place, with thrice its Quantity of ſoft River Water, made very ſaline by the Addition of Sea-Salt, or ſharp with Oil of Vitriol; (3) to uſe the ſtrained Decoction, or Liquor left behind in the Still, inſtead of common Water, for a freſh Digeſtion; (4) to uſe for the ſame Purpoſe the Water of the ſecond Running, after being cleared of its Oil; (5) not to diſtil too large a Quantity of theſe Subjects at once; (6) to leave a conſiderable Part of the Still, or about one fourth, empty; (7) to uſe a briſk Fire, or a ſtrong boiling Heat, at the firſt, but to ſlacken it a little afterwards; (8) to have a low Still-Head, with a proper internal Ledge and Current leading to the Noſe of the Worm; and (9) to cohobate the Water, or pour back the Liquor of the ſecond Running upon the Matter in the Still, repeating this once or twice. *How obtained to Advantage.*

22. Theſe Cautions are all neceſſary, in order to diſtil the ponderous eſſential Oils to Profit and Perfection. The phyſical Reaſons whereon they depend may deſerve to be conſidered. (1) The Reduction of the Subject to Powder, expoſes all its Parts the better to the Action of the Water and Salt; whereby the Oil is the more mollified, attenuated, and rendered fitter to riſe along with the aqueous Vapour in Diſtillation. (2) The Digeſtion is requiſite, for the ſame Reaſon; as being no more than allowing Time for this Action to be performed, in a moderate Warmth. The Water ſhould rather be the ſoft Water of Rivers, than that of Rain, which is more corruptive or fermentative; or than *Reaſons of the Caution.*

than that of Springs, which is often hard, ſo as not to mollify the Oil, but rather defend it from the Action of the Salt, or Acid; which are added not only to prevent all Tendency to Fermentation or Corruption, that would abſolutely change or deſtroy the Oil, but more particularly, as having a known Property of attenuating, liquifying, diſſolving, and purifying groſs, viſcous, and tenacious Oils. Beſides which, it likewiſe increaſes the ſpecific Gravity of the Water; whereby the Subject is now buoyed up, ſo that it cannot readily touch the Bottom of the Still, or come in the way of the Fire to be ſcorched. At the ſame Time this Addition alſo increaſes the Heat of the Liquor, or makes it exceed that of mere boiling Water; whence the Aſcent of the Oil is likewiſe promoted. (3) The ſtrained Decoction is properly uſed inſtead of Water, as being already ſaturated with oily Particles, ſo that it cannot much rob the Subject. And (4) the ſame holds alſo of the Water of the ſecond Running, which neceſſarily contains ſome oily Particles. (5) If too large a Quantity of the Subject be diſtilled at once, the Heat will neceſſarily act unequally, or be ſtrong upon ſome Parts, and weak upon others; whence, as the Oil is ſo extremely ponderous, a large Part of it will be left behind in the Subject. (6) If too much empty Space be left in the Still, it will be difficult for the ponderous Oil to aſcend; and if too intenſe a Heat be uſed, it deſtroys the grateful Odour of the Oil, without raiſing any conſiderable Quantity; and if the Still be filled too full, the Matter will be apt to boil over, and foul the Oil. (7) The Fire is ordered to be briſk at firſt, to prevent the Oil, now in ſome Meaſure ſeparated by the Heat, from going back into the Subject: But

But after a Part is thus come over, if the Fire be not a little ſlackened, the Oil is apt to ſcorch, and come out at the Noſe of the Worm in the Form of a Smoke, that cannot be catched and condenſed; yet the whole Operation need not be continued long, or above two Hours, becauſe the valuable Part of the Oil ſoon comes over. (8.) If the Head of the Still be not low, the ponderous Oil will have too far to riſe; and unleſs the Oil be directed to the Worm by a proper Ledge and Current, a conſiderable Part will fall back into the Still, and ſo prolong the Operation, or leſſen the Yield. (9.) Laſtly, two or three Cohobations, or Returns of the Water upon the Subject in the Still, muſt needs bring over all the Oil that will any way riſe. And Water already ſomewhat impregnated with the Oil, is manifeſtly better for the Purpoſe than ſuch as has never been uſed before.

23. The Directions here laid down, for obtaining the ponderous eſſential Oils to Advantage, are eaſily transferred to the obtaining of the lighter: So that we need not dwell particularly upon them.

24. Many of theſe *eſſential Oils* being coſtly things, it is common to adulterate or debaſe them ſeveral Ways, ſo as to render them cheaper both to the Seller and Buyer. Theſe ſeveral Ways ſeem reducible to three general Kinds, each whereof has its Method of Detection; for as in *Logic* every Sophiſm has its Redargution, ſo in *Chemiſtry* every Fallacy may be diſcovered. *Eſſential Oils adulterated.*

25. Eſſential Oils are adulterated, *(1.)* with expreſſed Oils, *(2.)* with Alcohol, and *(3.)* with cheaper eſſential Oils.

26. *(1.)* If any eſſential Oil be adulterated with an expreſſed Oil, this is eaſily diſcovered, by adding a little Alcohol to a few Drops of the ſuſpected *The Fraud diſcoverable.*

ſuſpected eſſential Oil, and ſhaking them together: For the Alcohol will thus diſſolve all the Oil that is truly eſſential, or gained by Diſtillation, but leave the expreſſed Oil untouched; whereby the Compound of the two will be ſeparated, ſo as that their Quantities may be judged of, or the Proportion of the Debaſement found: And then by adding Water to the Alcohol, which had taken up the eſſential Oil, the Water will unite with the Alcohol, and leave the eſſential Oil ſeparable in its own Form.

27. *(2.)* If an eſſential Oil be adulterated with Alcohol, as it may be in any Proportion up to that of an equal Quantity, without being eaſily diſcoverable either by the Smell or Taſte: the Way of Detection is, to let a few Drops of the ſuſpected Oil fall into a Glaſs of fair Water; for if Alcohol be mixed with the Oil, the Water will immediately turn milky, which it would not do if the Oil were pure. And by continuing to ſhake the Glaſs, the whole Quantity of Alcohol employed in the Adulteration will unite with the Water, and leave the Oil undiſſolved behind.

28. *(3.)* The third Method above mentioned, of adulterating the richer chemical Oils, is by mixing them with the cheaper eſſential Kinds; ſuch in particular as the Oil of Pine-Wood, Oil of Turpentine, *&c.* And this is frequently practiſed, by putting Fir-Wood, Turpentine, or Oil of Turpentine, into the Still, along with the Herbs, ſuppoſe Roſemary, Lavender, Origanum, *&c.* in the ſame Manner as Diſtillers add common Malt Spirit in the Diſtilling of Wine Lees. And by this Means the Yield of an Oil may be conſiderably increaſed. But the Oils thus adulterated will diſcover themſelves in Time, by the want of their natural Flavour,

which

which is overpowered by that of the Turpentine, *&c.* But the quicker Detection is, to drench a Piece of Paper, or a Linen Rag, in the suspected Oil, and hold the Paper or Rag before a gentle Fire; for thus the grateful Odour of the Plant will soon fly off, and leave only the Smell of the Turpentine, *&c.*

29. But if this Way of adulterating essential Oils be practised in Perfection, it seems scarce discoverable, unless the *Table of the specific Gravities of essential Oils*, above recommended *, were ready at Hand. For it is known to some few that *Balsam Capivi* yields a large Proportion of essential Oil by Distillation with Water, even to the quantity of five or six Ounces from a Pound; and that this Oil is much sweeter than any of those before said to be used for Adulteration: Whence it is easy by distilling any of the aromatic Vegetables along with this Balsam, or by mixing their Oils with the Oil of *Balsam Capivi*, to debase them largely, without being greatly subject to Discovery, except by the more philosophical Chemists, who understand the uses of the *Hydrostatical Balance*. But it should be observed whether, by long keeping, the chemical Oils thus adulterated with the Oil of *Balsam Capivi*, will not discharge the Ink of the written Label, fastened to the containing Glass, as essential Oils adulterated with Oil of Turpentine, or other terebinthinaceous Oils, are found to do, on account of the acid Vapour that continually exhales from such adulterated Oils.

30. The Methods already laid down for detecting the Sophistications commonly practised in *essential Oils*, are general; besides which

* See §. 20.

ſome Oils require peculiar Methods. Thus the eſſential Oil of Camomile Flowers may be certainly known to be adulterated with Copper and Oil of Turpentine, &c. if it retains its original blue Colour above a Year. The eſſential Oil of Rue, if genuine, remains fluid in the Cold, and if adulterated, congeals. And every Fact of this Kind, of which there are many already known, ſhould be duly collected: For it is certainly of great Importance to Medicine, that the genuine eſſential Oils of Vegetables ſhould be well diſtinguiſhed from the adulterated, becauſe capable of producing extremely different Effects in the Body; a Conſequence little regarded by the fraudulent Adulterator.

EXPERIMENT III.

A Method of rectifying Empyreumatic Oils.

Empyreumatic Oil ſweetned.

31. It was obſervable in our dry Diſtillations of Wood *a)*, Wormwood *b*), and Bone *c)*, &c. that there always came over a groſs, fetid, empyreumatic Oil, of a nauſeous Smell, diſagreeable Colour, and abominable Taſte. To rectify this Oil, we took two Pounds thereof, and waſhed it well by the repeated Affuſion of hot Water, and ſtirring them well together, till at length the Water came away conſiderably pure; whereby the Oil was rendered leſs nauſeous both to the Smell and Taſte: Then ſetting it in an open Veſſel over the Fire, that it might diſcharge the Water lodged therein by the Waſhing, we afterwards put it into a Glaſs Retort, and drew it over in a Sand Heat; whereby it left behind a black,

a) See *Lect.* II. *Exp.* III.
b) See *Lect.* VIII. *Exp.* II.
c) See *Lect.* VIII. *Exp.* I.

feculent,

feculent, or burnt crufty Matter, and became more fluid, fweet, and mild.

32. If the Diftillation be repeated ten or twelve times, either in a frefh Retort every time, or in the fame, the Oil being conftantly returned upon its own *Fæces*, or *Caput mortuum*; thefe *Fæces* will every time increafe in Quantity, fo as to leave the Oil purer and thinner, till at length it becomes almoft as thin and fluid as Oil of Turpentine, or Spirit of Wine; being extremely volatile, tranfparent, and penetrating, but ftill of a hot, pungent Tafte, and a fomewhat faint and difagreeable Odour. *The Experiment carried farther.*

33. This Oil, obtained from an animal Subject, particularly from Blood, has been lately ufed in *England*, as a Remedy for the Epilepfy, Gout, and other obftinate Difeafes, under the Name of *Oleum animale*. It was many Years fince ufed for the fame Purpofes in *Germany* *. Yet doubtlefs it fhould not be given too freely as an Internal: But, as an external Medicine, it may be of Service in refolving hard Tumours, removing fixed Pains, &c. for it is extremely penetrating and difcutient. And on this Account it might, perhaps, be ufed to Advantage in feveral Arts that require a highly fubtilized Oil. *Ufes.*

34. But it being chargeable to bring the grofs empyreumatic Oils to this Degree of Purity and Subtilty, many chemical Operators continue to throw them away as ufelefs; and the rather, becaufe of that intolerably naufeous Smell and Tafte with which they affect all Things that they touch, or come in the Way of. But as large Quantities of thefe Oils are neceffarily obtained in the Diftillation of Harts-Horn, Blood, &c.

* See *Hoffman. Obfervat. Phyfico. Chym.* p. 58. 59.

it may be worth trying, whether they cannot be purified in a cheaper Manner than that above described: For Example; By drawing them over from Pot-Ash; or, what is still more profitable, by digesting them therewith, so as at length to turn the Mixture, by Sublimation, into a volatile, alkaline Salt, as good as that of Harts-Horn, Blood, putrefied Urine, *&c.*

And thus much for the Subject of vegetable Oils. We next proceed to vegetable Salts.

II.

EXPERIMENT IV.

The Method of refining Sugar; or bringing the sweet Juice of the Sugar-Cane into a white, dry, and solid Substance.

Sugar refined.

35. We took six Pounds of coarse or black Sugar, as it comes unrefined from the Sugar-Colonies, and dissolving it, over the Fire, in an equal Quantity of strong Lime-Water, we added the Whites of four Eggs, whisked up into a Froth, and stirred the Whole well together, in order to clarify the Sugar, after the same Manner as Syrups are usually clarified; we then boiled the Liquor to a higher Consistence than that of a Syrup, or till it would shoot grainy in the Cold. To make it do this the better, we continued to add Lime-Water at several times in the boiling. Having obtained this Point of Consistence, by the Sugar-Refiners called *Proof*, we poured the whole into a Sugar-Baker's Earthen Mould, stopping the Hole in the lower End, and setting the Mould in a moderately warm Place, the Sugar, after some Days, *set* hard, or hardened; then opening the lower Orifice

Orifice of the Mould, we inverted the ſharp End into a little Pot, or *Sugar-Baker's Receiver*, and applied to the wider End, or on the Top of the Sugar, a Mixture of Tobacco-Pipe Clay and Water, made into a Kind of thin Paſte, or pappy Subſtance. And thus the Water quitting the Clay, ſoaked through the Sugar, without diſſolving the grained Part, and carried down with it only the treacly Matter, lodged betwixt the Pores of the Sugar; which treacly Matter was catched by the Receiver underneath. And thus, by keeping the Clay frequently wetting, and ſometimes renewing it, all the Treacle was got out, and a pure Loaf of White Sugar left behind; which we afterwards dried in a warm Chamber, and kept it in a dry place.

36. The chemical Hiſtory of Sugar deſerves to be traced through all its Stages. The ripe Sugar Canes are ground down in a Mill betwixt Iron Rollers, kept continually feeding; ſo that the expreſſed Juice runs in a conſtant Stream, into its proper Receiver, from whence it is ſoon committed to the firſt boiling Pan, to prevent its turning eager: there it is boiled, ſcummed, and cleared of its groſſer and lighter Feculencies that float a-top, and alſo drawn from its heavier *Fæces* which fall to the Bottom. And thus the Juice is brought to a Kind of *Mellago*, or *Rob* *: For the Juice of the Sugar-Cane, when firſt boiled down, is like the Rob of Malt, Raiſins, the boiled Juice of the Birch or Sycamore-Tree, *&c.* and would never appear in the ſaline Form of Sugar, without ſome Contrivance to ſeparate its herbaceous, feculent Part, and a particular Addition to give it a conſiſtent Form. Both theſe Ends are anſwered by the Addition

The Proceſs and Rationale.

* See *Lect.* X. *Exp.* III.

of Lime-Water: For the Rob of the Sugar-Cane being of an acid and unctuous Nature, the Quicklime deftroys the prevalent Acidity, diffolves and feparates the groffer unctuous Matter, and at the fame time, combining along with the truly faccharine Part, gives a folid and dry Confiftence. And fomething of this Effect Lime-Water has in every frefh Boiling; fo that by a prudent Ufe hereof the Sugar may, after repeated Operations, or by boiling it over again with more or ftronger Lime-Water, be brought almoft to a cryftalline Form. And on the Strength, Goodnefs, and Quantity of the fine Part of the Lime, thus introduced into Sugar, depends the Hardnefs, Whitenefs, and fhining, rocky Refplendency of Loaf-Sugar. So that the Perfection of the Refiner's Art depends in a great Meafure upon the prudent Choice of his Lime, and the Management of his Lime-Water.

37. The treacly Matter feparated from the Sugar, is collected together and boiled, fcummed, and treated with Lime-Water again, to obtain from it all the Sugar that it will afford in a dry form. When no more can be procured from it by the Sugar-Baker, it is then called *Treacle*; being before ufually termed *Syrup*, which it perfectly refembles: Infomuch that a thorough Knowledge of the Art of preparing *Syrups*, with the Effects of their Different Confiftences, and their Difpofition to ferment, turn acid, or candy, and the beft Ways of clarifying them, *&c.* may contribute to improve the Art of Sugars; and accordingly it appears, that moft of the Improvements in the Refining of Sugars have been owing to Apothecaries and Chemifts.

38. Sugar,

38. Sugar, thus refined, and difcharged of its fuperfluous oily Parts, is thereby rendered dry, thirfty, or apt to imbibe aqueous Moifture or Oil; upon which Property depends that ufeful Invention of *Elæofaccharums*, occafionally mentioned above *, by means whereof we are furnifhed with a very advantageous Method of uniting Oils with Waters, Wines, Spirits, or all Manner of aqueous, vinous, or fpirituous Liquors; fo that fuch Liquors may be altered in their Flavours, and improved in their Virtues, at pleafure. For, by grinding a fmall Proportion of any effential Oil with dry Loaf-Sugar, the Oil is thus rendered mifcible with any of the above mentioned Liquors, and at the fame Time is no Way impaired, but rather improved in its Efficacy.

39. And thus we are taught an extemporaneous Method of making all thofe fimple and compound Waters, whofe Virtues depend upon the effential Oils they contain; which is the Cafe of moft fimple Waters, as thofe of Mint, Penyroyal, &c. Nay, fome fimple Waters may be procured in greater Perfection by this Means than by Diftillation, as it is commonly performed. Thus the fimple Water of Baulm, for Inftance, may be made better by means of the *Elæofaccharum of Baulm* and pure Water, than by fimple Diftillation, which in this Cafe brings over but little of the effential Oil.

40. And for compound Waters, they may be thus made to greater Perfection than we ufually meet with them. For if only the firft Part of the effential Oils that comes over be ground with Sugar, and introduced into a very clean Spirit, the Cordial Waters fo prepared will be

* See *L.ɑ.* XI. *Exp.* I.

no way inferior to thoſe diſtilled in the ordinary Manner. And thus Cinnamon-Water, Clove-Water, Nutmeg-Water, Citron-Water, *&c.* which depend upon the Uſe of but one Ingredient, may be readily made. And if compound Waters are required from ſeveral Ingredients, we need only have a compound *Elæoſaccharum* at Hand.

41. Theſe *Elæoſaccharums* alſo, as they are eaſily made, either ſimple or compound, in great Variety, might help to improve the Art of Cookery, as affording the Virtues of Aromatics in a commodious Form, for ſeveral œconomical Occaſions; and may thus be carried the longeſt Voyages without Danger of ſpoiling, or of having their Virtues impaired: an Inconvenience to which the natural Spices, though ever ſo well cured, are liable.

42. Again; A proper Set of theſe *Elæoſaccharums* might afford a Variety of ſerviceable Medicines, that ſhould have all the Qualities required in the beſt; that is, ſhould be at once ſimple, parable, efficacious, and pleaſant: For as eſſential Oils contain the ſpecific Virtues of the Subjects, or thoſe Qualities which conſtitute every Plant the Thing it is, they are of Conſequence ſome of the moſt concentrated, powerful, reſtorative, and reviving Medicines hitherto known.

EXPERIMENT V.

The Way of Refining Tartar.

Tartar refined. 43. We took two Pounds of common white Tartar reduced to Powder, and put to it five Gallons of fair Water, in an earthen Pan, and ſetting it over the Fire to boil, we in the mean Time beat up the Whites of two or three Eggs, and

and whiſked them in among the Liquor, which we afterwards ſkimmed and ſtrained; then ſet it to ſhoot in an earthen Veſſel, in a cool Place, for two Days, at the Expiration of which we found a Parcel of whitiſh Cryſtals ſticking to the Sides of the Veſſel.

44. This is a very troubleſome and imperfect Operation; for Tartar requiring twenty times its own Quantity of Water to diſſolve it, the Veſſels, the Fire, and the whole Apparatus, muſt of Neceſſity be large to refine a ſmall Quantity of this Salt; which yet is not ſufficiently refined at one Operation, though the Whites of the Eggs take up much dirty, and light earthy Matters, while the more ponderous ſink to the Bottom upon ſtanding. Hence the Operation muſt be ſeveral times repeated, before the Cryſtals will become perfectly white; which they will ſcarce ever do, if the Veſſel wherein the Operation is performed be metalline; and Veſſels of Earth, which this Salt does not corrode, being hard to procure ſo large as they are required for the Purpoſe, this adds to the Inconvenience. *Inconveniences.*

45. It is true, for moſt Uſes in Chemiſtry, unrefined Tartar will anſwer as well as the refined, but for the Service of certain Arts, particularly Dying, it is required thoroughly purified: So that a more commodious Method of refining it ſhould be endeavoured after, that we might at leaſt be able to refine it in *England*, as well as they do in *France*. *Remedied.*

46. Tartar is of a very particular Nature; being a ſolid and firm vegetable Salt, extremely hard to diſſolve in Water, as containing much earthy and unctuous Matters, which defend it from the Action of Water: Whence we are directed to ſoften the Body of this Salt, or looſen

its

its Texture, in order to its more commodious Refinement. And this End may be obtained by a prudent Uſe of Lime-Water, or a weak Lixivium of Pot-Aſh, or Salt of Tartar; as in the Making of *tartarized Tartar* *, where common Tartar is united with its own fixed Salt, and rendered eaſily ſoluble in a ſmall Proportion of Water. But there need not be ſo much Alkali uſed for this Purpoſe, as to deſtroy the Acidity of the Tartar; and if too much ſhould happen to be added, it may be mortified with Oil of Vitriol, ſo as not to prejudice the Salt.

The Experiment perfected. 47. But where an extremely pure and perfect Cream or Cryſtal of Tartar is required, we recommend the ordinary Cryſtals, or Cream of Tartar, to be diſſolved in Water, made highly acid with rectified Oil of Vitriol; for if the ſuperfluous Humidity be afterwards exhaled, the Tartar will thus ſhoot into perfectly tranſparent and beautiful Cryſtals, without at all participating of the Oil of Vitriol. And by the Help of theſe Directions common Tartar may be refined in great Perfection, and with no greater Trouble than the more ſoluble vegetable Salts.

Uſes. 48. When the Powdered Cryſtals of Tartar are mixed with half their Weight of Salt of Tartar, and diſſolved together in boiling Water, they make a very extraordinary neutral Liquor, or *Menſtruum*; and by Evaporation a neutral Salt of very uncommon Properties. This Salt eaſily runs in a moiſt Air; and will powerfully aſſiſt in extracting the reſinous or oleaginous Parts of Vegetables, by being boiled with them in Water. The aqueous Solution of this Salt will diſſolve the tough Bodies even of Myrrh, Gum-

* See below § 48.

Lac,

Lac, and is much better fitted than Salt of Tartar for many of the ſame Purpoſes where that Salt is commonly employed. This neutral Salt, or tartarized Tartar, is excellent in healing Wounds, and cleanſing Ulcers: It is an agreeable and ſucceſsful Purgative in hypochondriacal Caſes; and, diſſolved in Water, makes a pleaſant Kind of *Purging Water*. Its Virtues and Powers, both as a Menſtruum and a Medicine, ſeem not hitherto ſufficiently known; whence we recommend it to farther Experience.

Experiment VI.

The Method of Refining Nitre, or Salt-Petre.

49. We diſſolved four Pounds of rough Nitre, as it comes to us from the *Indies*, by boiling it in as much Water as would commodiouſly ſuffice for that Purpoſe; then ſet it to ſhoot for two or three Days in a covered Veſſel of Earth, with Sticks laid acroſs for the Cryſtals to adhere to. Theſe Cryſtals being afterwards taken out, were drained and dried in the open Air. *Nitre refined.*

50. This ſeems to be the beſt and ſimpleſt Method of purifying Nitre; for thus, by its own natural Property of cryſtallizing, it ſhoots pure from the Sea-Salt, or other Foulneſs that is apt to mix among it. However, if the Nitre prove unctuous, it may be proper to add a little lixivium of Pot-Aſh, Lime-Water, or Allum. And if by this Means it does not become ſufficiently pure for making the beſt Gun-powder, or *Aqua Fortis*, it muſt be diſſolved again, and re-cryſtallized, in the Manner of our preſent Experiment; which being repeated, with a larger Proportion of Water than before, evaporating ſlowly

ſlowly and ſuffering the Salt to ſhoot in a moderately warm Place, without the free Admiſſion of the external Air, the Nitre will be obtained in its utmoſt Purity and Perfection. It is judged to be pure, when being thrown upon live Wood Coals, it fulminates briſkly, and will then make perfect Gun-powder and *Aqua Fortis*.

Hiſtory of Nitre.

51. The chemical Hiſtory of Nitre is ſtill defective. This Hiſtory ſhould ſhew, by what Means Nitre is procurable from all animal and moſt vegetable Matters: For there are many Experiments and Obſervations which ſeem to prove, that Nitre originally proceeds from putrified Vegetables; that many uncorrupted vegetable Subjects contain it in a large Proportion; and that all animal Subjects contain a *ſemivolatile Nitre*; which may be rendered more fixed, or like the common, by the Addition of Pot-Aſh or Quicklime *a*).

52. To thoſe diſpoſed to enter upon this uſeful Enquiry, we recommed a full Knowledge of the Methods now in uſe for procuring Nitre from certain Earths that are dunged by Animals, and putrefied Vegetables; the ſhorteſt Ways of ſeparating the unctuous Matter from the Nitre, which occaſions all the Difficulty; and a due Compariſon of the Proceſs for procuring and refining of Nitre with that for procuring and refining of Sugar. There is Reaſon to believe, an Enquiry of this Kind might be attended with ſuch Succeſs, as to ſhew that Nitre is not peculiar to any one Country, but obtainable in Plenty, wherever animal and vegetable Subjects abound *b*).

a) See Mr. *Lemery*'s Papers upon this Subject in the *French* Memoirs. See alſo Dr. *Stub's Legends no Hiſtories.*

b) See *Glauber's Proſperity of Germany.*

EXPERI-

Experiment VII.

The Method of Making Pot-Ash.

53. Having burnt a Quantity of common Billet-Wood to grey Aſhes, we took ſeveral Pounds of thoſe Aſhes and boiled them in Water, ſo as to make a very ſtrong *Lixivium*, or *Lie*. This Lie we ſtrained thro' a coarſe Linen Cloth, to keep out any black Parts of the half-burnt Wood that might happen to remain in the Aſhes; then we directly evaporated this ſtrained Lie in an Iron-Pan over a quick Fire, almoſt to Drieneſs. We took out the Matter remaining at the Bottom, and putting it into an Iron-Crucible, ſet it in a ſtrong Fire till the Matter melted; and then immediately poured it out upon an Iron-Plate, where it ſoon cooled, and appeared in the Form of a ſolid Lump of Pot-Aſh. *Pot-Aſh prepared.*

54. And much after this Manner is Pot-Aſh made in the large Way of Buſineſs, for the Service of the Soap-Boiler, Glaſs-Maker, Fuller, *&c.* But according to the Difference of the Wood or combuſtible Matter employed, with the Manner of burning it, and conducting the Proceſs, different Kinds of Pot-Aſh are prepared. *Uſe.*

55. There are certain ſaline Plants that yield this Pot-Aſh to great Advantage, as particularly the Plant *Kali*; there are others that afford it in leſs Plenty, and of an inferior Quality, as Bean-Stalks, *&c.* But in general, all vegetable Subjects afford it of one Kind or other, and may moſt of them be made to yield it tolerably perfect, after the Manner of our preſent Experiment; even the Loppings, Roots, and refuſe *And application.*

refuse Parts of ordinary Trees, Vine prunings &c.

Difference. 56. But besides the Difference found in different Vegetables for producing this Salt, as some may naturally contain more or less of the saline, oily, or earthy Principle, than others *; another Difference will arise from the Manner of burning the Subject, according as that is done with a greater or less Degree of Fire, or Admission of the Air. If a vegetable Subject be burnt in a close, stifling Manner, to a grey, or somewhat blackish or brown Ash, these Ashes thus containing more of the Oil of the Subject, will afford a more unctuous Salt, that easily melts in the Fire, and is better fitted for the ready making of Soap. But if the Subject be burnt in the open Air, so that it have every Way free Access thereto, the Ashes will be white, or contain no Part of the Oil of the Subject; and thus the Salt will difficulty melt in the Fire, and prove fitter for the making of Glass (where no Oil is required) than of Soap.

57. A third Difference in Pot-Ash arises from the Length or Shortness of Time it is detained in the melting Fire; whereby it becomes either of a grey, white, bluish, or greenish Colour; grey or white if it be soon taken out; and bluish or greenish if long detained therein. And according to these Differences Pot-Ash is more or less sharp or strong; a longer Continuance in the Fire always consuming the more unctuous Parts, and leaving the saline ones more naked: provided no considerable Proportion of Earth remain mixed with the Salt, which in that Case would soon be vitrified, or turn to Glass, and have no saline Property at all.

* See *Lect.* VIII. *passim.*

58. The

58. The fixed Salts of all Vegetables, when reduced to abſolute Purity, or entirely ſeparated from the other Principles, appear to be one and the ſame Thing; at leaſt not manifeſtly to differ *. Whence it ſhould ſeem that, by a ſuitable Management, good ſaleable Pot-Aſh might be made in all Places where vegetable Matters abound: For if, by examining *Ruſſia* Pot aſh, for Example, we find, that its ſuperior Excellence depends upon its being clear of Earth, or upon its containing a large proportion of Oil, or fixed Salt; theſe Advantages may, by properly regulating the Operation, be given to *Engliſh* Pot-Aſhes, ſo as perhaps to render the latter as good as the former. But where the Pot-Aſh of any remarkably ſaline Vegetable is to be imitated, as that of *Kali* ſuppoſe, we would recommend a prudent Sprinkling of the Subject with Salt or Sea Water in the Burning. And by theſe Ways properly diverſified, any Principle that is naturally wanting in the Subject might be artificially introduced, ſo as to perfect the Art of Pot-Aſh, on which the Art of Soap-making depends. *Improvement.*

59. For to make Soap requires an intimate Union of the Salt of Pot-Aſh with Oil, or any vegetable or animal Fat. This Union in the preſent Method of Soap-makihg is procured by a tedious Operation, or by long Boiling a weak Lie of Pot-Aſh and Quicklime with the Fat; adding a ſtronger and a weaker Lie occaſionally by degrees, till the Point requiſite to the Perfection of the Soap is hit. *Uſes in the Art of Soap.*

60. It might greatly contribute to ſhorten this Operation and eaſe the Expence thereof, if a mechanical Motion or Engine were employed inſtead of Fire, to procure this intimate Union of *Improvement in that Art.*

* See *Lect.* VIII.

the

the Lie and Oil. And that ſomething of this Kind is practicable appears from hence, that if, for Example, half a Pint of the Soap-boiler's ſtrongeſt, or *Capital Lie*, as they call it, be briſkly ſhook in a Phial, with an Ounce or more of Oil-Olive, for half a Quarter of an Hour, and then the Phial be ſuffered to reſt, there will, in a ſhort Time after, be found a ſolid Cake of tolerable Soap at the Top of the Liquor; and may be eaſily preſerved in that Form by breaking the Phial, and rendered harder by being expoſed to the Air.

Hiſtory of Soap.

71. We could wiſh that the *Chemical Hiſtory* of Soap were extant; for it ſhould ſeem that many Advantages might be thence derived to particular Arts and Trades. This Hiſtory is a Thing of larger Extent than will be generally apprehended, as containing three large Branches; (1) the *Hiſtory of Pot-Aſh*; (2) the *Hiſtory of Oils and Fats*; and (3) the *ſeveral Ways of uniting them to advantage.*

62. (1) The *Hiſtory of Pot-Aſh* would ſhew wherein the Superiority of the foreign Aſhes, particularly thoſe of *Marſeilles*, *Caſtile*, *Venice*, and *Joppa*, conſiſts; why the Soaps at preſent made in *England* fall ſhort of Perfection; and poſſibly inform us of the Ways whereby even *Joppa* Soap might be equalled in *England*. For ſuch a Hiſtory would trace out the real phyſical Differences betwixt one Sort of Pot-Aſh and another, and the Ways of converting any one of them into the reſt *, ſo as to fit them for the Soap-boiler, Glaſs maker, &c. reſpectively; it would ſhew how the mildeſt Pot-Aſh is obtainable, for the more curious Soaps, and eſpecially for thoſe intended to be uſed medicinally, &c.

* See above, § 62—65.

And,

And, by the Way, there is Room to ſuſpect that a thorough Enquiry into this Subject would ſhew the Matter of all Pot-Aſh to be the Matter of Nitre; or that all the Vegetables which yield Pot-Aſh by *Calcination*, might be brought to afford Nitre by *Putrefaction*; or that Pot-Aſh is nearly the ſame Thing, both in Nature and Subſtance, with *fixed Nitre* *.

63. (2) The *Hiſtory of Oils and Fats* would alſo ſhew how one Sort might be converted into another, or hard animal Fats into liquid Oils, and liquid Oils into ſolid Fats, by digeſting Oils with certain coagulating Acids, &c. how all the foreign ſolid Oil-Soaps might be imitated in *England*; and how a great Variety of *liquid Soaps* might be prepared for many different Purpoſes; the Foundation of the Thing entirely depending upon the Uſe of a highly ſubtilized, and thin *vegetable Oil*.

64. (3) The *Hiſtory of uniting fixed vegetable Salts with Oil*, might deſcribe ſeveral Machines for the Purpoſe; whereby many Tuns of Soap ſhould be readily made by Means of Mills, wrought by the Wind or Water; and this either with or without Fire. It might alſo inform us of ſeveral *Menſtruums*, or *connecting Mediums*, which ſhould, either alone, or with little Aſſiſtance, procure an intimate Union. And that ſomething of this Kind is practicable, we are aſſured by particular Experiments.

AXIOMS and CANONS.

1. We learn from the foregoing Enquiries, that large Quantities of Oil may lie concealed

* See *Glauber*'s *Proſperity of* Germany; and M. *Lemery*'s Papers upon *Nitre* in the *French* Memoirs.

in Bodies apparently dry; where neither the Eye, nor any of the Senſes, can perceive the ordinary Signs of Oil *a*).

2. That Oils gained by Expreſſion are apt to turn rancid, and become unwholſome, by Heat: Whence they ſhould always be kept cool, and not be drawn by the Means of Fire, if intended for curious or internal Uſes *a*).

3. That much Oil may be ſeparated by boiling Water from Subjects that have already felt the utmoſt Force of the Preſs: Whence an Eye ſhould be had upon the Cakes of Lint-ſeed, Muſtard-ſeed, *&c.* for obtaining a farther Oil, after they have been once ſqueezed *a*).

4. That the oily Subſtance of Nuts, Almonds, and the like vegetable Subjects, is ſoluble in Water, by bare Triture, into a vegetable Milk, having a great Affinity with the Milk of Animals *a*).

5. That *expreſſed Oils* may be readily changed, or improved, in their Colours, Taſtes, and Odours; ſo as that any one of them may afford a great Variety of apparently different Kinds *a*).

6. That aromatic Vegetables yield an *eſſential Oil* by Diſtillation with Water; which Oil contains the eſſential or ſpecific Taſte, Smell and Virtues of the Subject *b*).

7. That the *native Spirits*, or fine odoriferous Parts of Vegetables, are readily imbibed, and long preſerved, by expreſſed vegetable Oils *a*).

8. That the Difference betwixt the *artificial* and *natural eſſential Oils of Vegetables*, depends upon the different Fixedneſs or Volatility of their direct unctuous Parts *b*): Whence we are directed to a Way of introducing the *native Spirits* of

a) *Exp.* I.
b) *Exp.* II.

Plants

Plants into finer or lighter Oils than the common expreſſed Kinds; ſo as perfectly to imitate, or exceed, the natural eſſential Oils.

9. That there are ſure Methods of diſcovering ſeveral fraudulent and abuſive Kinds of Adulteration in *eſſential Oils*; but that a more curious Adulteration is practicable, ſo as to elude the common Trials *a*).

10. That every *eſſential Oil* has its determinate ſpecific Gravity: Whence, if a Table of their ſpecific Gravities were formed, from a known genuine Set, ſuch a Table might be of Service in detecting the Frauds or Debaſements frequently practiſed in theſe Oils *a*).

11. That ſeveral Cautions are required to extract the *eſſential Oils* of aromatic *Indian* Vegetables to Advantage; which Cautions being duly obſerved, ſuch Oils may be obtained in *England*, perhaps as perfect as in the *Indies* *a*).

12. That a highly attenuated Oil is, by repeated Rectifications, obtainable from the groſs, fetid, and empyreumatic Oil of vegetable and animal Subjects *b*).

13. That the groſs, empyreumatic, *animal Oils* may, by Digeſtion with fixed Alkalies, afford volatile Salts *b*).

14. That the Matter of *Sugar* is, originally, a vegetable Juice, apt to grow ſour with Heat, and not reducible by bare Boiling to ſolid Sugar, but only to a mellaginous or treacly Subſtance *c*).

15. That many other vegetable Juices, as particularly thoſe of the Birch and Sycamore Trees, the Rob of Malt, of Raiſins, *&c.* are convertible into good Sugars, by the ſame Means that are uſed in the ordinary Sugar-making *c*).

a) *Exp.* II.
b) *Exp.* III.
c) *Exp.* IV.

16. That the Art of refining Sugar, ſo as to make it rocky, perfectly white, ſpangly and reſplendent, principally depends upon a prudent Choice and Uſe of Lime-Water *a*).

17. That refined Sugar renders *eſſential Oils* inſtantaneouſly miſcible with Wines, Water, and Spirits; ſo as to afford a ready Means of improving ſeveral Arts *a*): Or that the proper Introduction, Uſe, and Application of *Elæoſaccharums*, may improve the Art of Diſtilling, Pharmacy, Wines, Cookery, and Medicine *a*).

18. That the troubleſome Art of *refining Tartar* may be ſhortened and improved by the Uſe of Alkalies and Oil of Vitriol *b*).

19. That Tartar is convertible into a very different Salt, by being united with its own fixed Salt; ſo as hence to become a powerful Menſtruum, and a valuable Medicine *b*).

20. That Cryſtallization, once or twice repeated, is a ſure Method of refining Nitre, or *Salt-Petre* *c*).

21. That Nitre is not originally a foſſil, but a vegetable Salt; and thence to be found in animal Subjects *d*).

22. That a full Enquiry into practicable Methods of procuring Nitre directly from vegetable and animal Subjects, may be attended with Succeſs *d*).

23. That ſerviceable Pot-Aſh may be made in any Place that abounds with vegetable Subjects *e*),

24. That the Art of making Pot-Aſh is improveable by chemical Knowledge, to the Advantage of the ſeveral Arts thereon depending *e*).

a) *Exp.* IV. *b*) *Exp.* V. *c*) *Exp.* VI. *d*) *Exp.* VI. and VII. *e*) *Exp.* VII.

25. That

25. That in particular, the Art of Soap-making may be brought to much greater Perfection in *England*, by Means of a mixt chemical and mechanical Enquiry *a*).

LECTURE XIV.

CONTAINING

Attempts to illuſtrate and improve the Buſineſs of Colours, Dyes, *and* Stains.

1. OUR preſent Buſineſs is to diſcover the Means of producing, varying, changing, and deſtroying the Colours of Bodies; with a View to improve the ſeveral Arts that depend upon the Uſe of Colours, Dyes, and Stains *b*). *The Subject.*

2. This we ſhall endeavour to perform by Means of Experiments, firſt upon Light, and then upon ſelected Subjects of the vegetable, animal, and mineral Kingdoms; in order to find out the phyſical Cauſes of the Effects produced. *The Means.*

3. The *firſt* Experiment therefore will ſhew, that common Light is ſeparable into ſeveral Colours: The *ſecond* will be collective, or afford a Variety of Inſtances to prove that the Colours of Bodies depend upon a certain Diſpoſition of Parts, fitting them to reflect the differently *The Heads of the Experiments.*

a) *Exp.* VII.

b) The preſent *Lecture* was not publickly read, as the reſt were; a clear ſun-ſhiny Day, which the Experiments require, not happening at the Time.

coloured Rays of Light: The *third* principal Experiment will exhibit the Method of obtaining thoſe *vegetable Colours* commonly called *Laques:* The *fourth* will teach the Way of preparing a certain animal Colour called *Pruſſian Blue:* and the *fifth* will ſhew the Way of preparing a metalline Colour, for tinging Glaſs red, &c.

EXPERIMENT I.

That the Rays of Light are compounded, and ſeparable into ſeven diſtinct Kinds or Orders of Light, on which all Colours depend.

A leading Experiment, with the Prism.

4. (1) Having darkened a Room, by ſhutting up all the Windows, and bored a ſmall Hole in a Shutter oppoſite to the Sun; if a Glaſs Priſm be now properly placed againſt this Hole, we find that an oblong and variouſly coloured Image of Light will be thrown upon the Cieling, or farther Wall of the Room. (2) If this Image of Light be carefully examined, it will appear to conſiſt of ſeven diſtinct Colours, or different vivid Lights, which are conſtantly found in the ſame Order; *viz.* Red in the firſt Place, Orange in the ſecond, Yellow in the third, Green in the fourth, Blue in the fifth, Violet in the ſixth, and Indigo in the ſeventh: But a ſlight View diſtinguiſhes only five principal Colours; *viz.* Red, Yellow, Green, Blue, and Violet. (3) If theſe ſeveral coloured Lights be ſeparately received upon another Priſm, in the ſame Manner as the Sun's Rays are by the firſt, they ſuffer no farther Diviſion, or Reſolution, but remain invariably the ſame: And this they do whatever figured Glaſs, Cryſtal, or Diamond be made uſe of. (4) But if the whole Number of

The Priſmatic Colours.

Not farther reſolvable.

of theſe differently coloured Rays be received, from the firſt Priſm, upon a *Lens*, or double convex Glaſs, in the Room, they are thus blended together again, and may be thrown upon Paper, or any other Body, placed at a due Diſtance, ſo as to form a Spot of white and bright Light in the Focus of the convex Glaſs. (5.) If the red Rays be ſeparately received by an opake white Body, that Body appears to be red; if the yellow Rays be ſeparately received in the ſame Manner, by an opake white Body, the Body appears to be yellow; and ſo of the other Colours reſpectively: A red Body appears more vivid, or intenſely red, in the red Light; a blue Body more vivid, or intenſely blue, in the blue Light, *&c.* But all coloured Bodies appear more dead or languid in Lights of different Colours from their own; as a red Body in a blue Light, *&c.*

Compound white Light.

Objects aſſume the Colour of the Light.

5. This general Experiment is the Foundation of Sir *Iſaac Newton*'s Doctrine of Light and Colours *; and may ſhew, (1.) that the Sun's Light is not a ſimple Thing, but compounded of ſeven different Orders of coloured Rays; all which being exquiſitely blended together, conſtitute a perfectly white Light: (2.) That theſe ſeven Orders of Rays are differently refrangible; that is, differently diſpoſed to be turned out of their Way, in paſſing from one tranſparent Body into another; the red Rays leaſt, the Violet moſt, and the reſt in their Order as mentioned above: Which is the phyſical Reaſon of the Diviſion of Light into theſe ſeven Orders of Rays, and that there are no more than ſeven original Colours of Light: (3.) That Bodies appear of the ſame Colour with the

Light a Compound

Of ſeven Colours.

* See his *Optics, paſſim.*

The Colours of Bodies from Light. White and Black no Colours.

Order of Rays they reflect, or turn back, into the ſame Medium from whence they were received: (4.) That White and Black are no true Colours; but White an equal Reflection of all the original Colours, and Black the Abſorption of them all; for if they were returned, either mixed or unmixed, Whiteneſs, or ſome of the ſeven original Colours of Light, and not Blackneſs, would appear: (5.) That the Variety of Colours in natural Bodies proceeds from their differently reflecting or refracting the Rays of one, two, or ſeveral Orders, more than the reſt. Thus the Bodies denominated red chiefly reflect the red Order of Rays; thoſe denominated blue Bodies chiefly reflect the blue Rays of Light; and are thence ſaid to be red, blue, &c. And all the mixed Colours of natural Bodies ariſe from their reflecting two or more Orders of Rays together, and abſorbing or ſtifling the Reſt.

Colours of Bodies whence.

EXPERIMENT II.

Or, collective Inſtances to ſhew that Tranſparency, Whiteneſs, Blackneſs, and Colours, as conſidered in Bodies, depend upon certain particular Structures, Textures, or Arrangements of the Parts of Bodies; differently diſpoſing them to tranſmit, reflect, refract, or abſorb the Rays of Light.

The Texture of Bodies changed by Triture.

6. (1.) Glaſs, Cryſtal, Diamonds, Nitre, Borax, and other tranſparent ſolid Bodies, loſe their Tranſparency, and appear white, upon their being reduced to Powder; that is, by a bare Alteration of their groſs Texture, or a ſimple Reduction to ſmaller Parts, ſo as to make them reflect many of the Rays of Light which they before tranſmitted. And the ſame holds of the Whites of Eggs whiſked up to a Froth, frothy Water, &c.

7. Black

7. Black Talc, by being made red hot in the Fire, is turned of a Gold Colour; Syrup of Violets, by a boiling Heat, loſes its beautiful Violet Colour, ſo as at length to become pale, or colourleſs; white Loaf-Sugar, being barely melted over the Fire, without Water, immediately changes its Whiteneſs, and becomes brown, or, by a longer Continuance, black; ſo that a ſingle Grain of this black Subſtance will tinge a Pint or a Quart of fair Water, or colourleſs Brandy, of a beautiful yellow, brown, or ſtraw Colour; for which Purpoſe it is uſed by Diſtillers, and others a). *By Fire.*

8. All the finer coloured Flowers, as Violets, Carnations, Roſes, &c. loſe their Colours barely by being expoſed to the open Air for any long Time; ſo as at laſt to appear perfectly diſcharged, or white; as if they had been expoſed to that particular Diſcharger of Colours, the Fume of burning Brimſtone. And the ſame is remarkable of the finer or lighter Kinds of Colours in Silks, or the light Blues, Yellows, and Reds, particularly the light grain-coloured Silks; all which Colours are gradually changed, diſcharged, or aboliſhed, in wearing, or by the Silks being long expoſed to the Action of the Air b). But the Scarlet Colour is more fixed and durable. And, in general, the deeper any Colours are, the more fixed and durable they prove; as being thus not Shades, as the Pinks, light Blues, &c. are, but true Colours, correſponding to the original Colours of Light. Add to this, that Dyers conſtantly find their Colours prove brighteſt, or ſtrike to the beſt Advantage, when the Air is clear b). Laſtly, the blue eſſen- *By the Air.*

a) See *Lect.* II. and XII.
b) See *Lect.* III. *paſſim.*

tial Oil of Camomile-Flowers loses its Colour, and changes to a dirty Green, by being exposed to the Air.

By Water. 9. Different Waters strike different Colours with the same tinging Ingredients. Thus irony Waters turn black, or inky, with Galls, Green Tea, &c. And Dyers find some certain Waters more proper for their Purposes than others. And, in general, the purest and lightest Waters strike the best Colours with Dying-Stuffs. And hence it is that such Waters as have, by long standing, putrified, or fermented, and purged themselves, or been filtred thro' the common Filtring-Stone, or Sand, are found to extract and communicate Colours to the greatest Advantage *.

By Salts. 10. Salts having a Power to alter the Textures of Vegetables, do consequently produce Changes of Colours therein Thus most Flowers, whether blue or red, as Violets, Roses, &c. turn green with *Alkalies*; but Violets turn red, and red Roses have their native Redness greatly hightened by *Acids*. So again, the yellow Roots of Rhubarb, Turmeric, &c. are hightened, or made redder, by *alkaline Salts*.

The Texture of Metals less alterable. 11. As Metals have a strong Texture in their metalline Form, so they preserve their natural Colours durably, unless corroded or dissolved by their particular Menstruums; after which, their Solutions strike particular durable Colours, or afford the strongest *Stains*.

Iron. 12. Iron dissolved in stale Small-Beer gives the beautiful Yellow used in Callico-Printing; when sublimed with *Sal-Armoniac* it also affords a Yellow. And the common Iron-Moulds made by Ink, are owing to the Iron dissolved in the

* See *Lect.* V. *passim.*

Copperas,

Copperas, whereof the common Black Writing-Ink is made.

13. Copper melted with Zink appears of a Gold Colour; dissolved in *Aqua-Fortis* it affords a beautiful Green; and in any urinous Spirit, a beautiful Blue; and the Solutions may be reduced to dry Colours, by Crystallization, or Evaporation. The same Metal precipitated with common Salt, out of *Aqua-Fortis*, gives the Turquoise Colour to white Glass, when melted therewith. *Copper.*

14. Tin, a white, or colourless Metal, affords a light blue Colour, by being fluxed with Antimony and Nitre. The same Metal is necessary in striking the Scarlet-Dye, with *Aqua-Fortis* and Cochineal. Its Calx turns, by strong Fusion, to a Glass of the opal Colour. *Tin.*

15. Lead, being corroded by the Fumes of Vinegar, makes the fine White called *Ceruse*, and the white Fucus called *Magistery of Lead*; being calcined in a strong naked Fire, it becomes Minium, or Red Lead; and this melted into Glass with Sand, is the Foundation of the Art of imitating all the coloured Gems: For this Glass itself will resemble the Hyacinth, and by the Addition of prepared Gold and Tin, the Ruby *a*); the Sapphire with Cobalt, the Emerald with Iron and Copper, the Amethyst with Gold, and the Granat with Iron, *&c. b*). *Lead.*

16. Silver, another white, or colourless Metal, being dissolved in *Aqua-Fortis*, if Chalk is put to the Solution, turns of a beautiful Purple, or Amethyst Colour: And its own Solution, tho' pale as Water, durably stains the Nails, the Skin, the Hair, and other animal Substances, brown or black. *Silver*

a) See below *Exp.* V. *b*) See *Neri's Art of Glass*; and Mr. *Boyle's Philosophical Works, passim.*

17. Quick-

Quick-silver. 17. Quickſilver mixed with Brimſtone makes a black Maſs; and this, by Sublimation, affords the beautiful red Pigment called *Cinnabar*, or Vermillion: and the Solution of Quickſilver, being precipitated with common Salt, yields a ſnow white Powder; which alſo turns black, by being mixed with Sulphur.

Gold. 18. *Gold*, diſſolved in *Aqua Regia*, affords a fine yellow Liquor; which ſtains animal Subſtances beautifully purple: And if the Solution be ſufficiently weakened with Water, and mixed with a Solution of Tin, a fine red or purple Powder may be thus obtained for ſtaining Glaſs moſt beautifully red *a*).

Minerals. 19. Many mineral Subjects are natural Pigments; as native Cinnabar, Ochre, Black Lead, *&c.* but particularly the yellow Earth called *Light Ochre*, found in *Shottover* Hills, which is uſed native as a light Yellow, and by Calcination makes a light Red. This Colour *England* ſupplies *Italy* with; and *Le Gar* would frequently ſay he had been no Painter without it *b*).

Experimental Inſtances of Colours produced, deſtroyed, and regenerated upon ſimple Mixture.

A colourleſs Liquor affording Colours by Mixture. 20. (1) Put dry red Roſe-Leaves into Spirit of Wine, and, by ſtanding a little therein, the Roſe-Leaves will loſe their red Colour, without manifeſtly tinging or altering the Liquor; then add a little Oil, or Spirit, of Vitriol thereto, and the Liquor will appear of a red Colour. But if a little alkaline or urinous Spirit be poured to the Mixture, the red Colour preſently changes to a Green; which, by the Addition of a

a) See hereafter, *Exp.* V.
b) See below, *Exp.* V. § 67.

little

little more Spirit of Vitriol, turns to a red Colour again.

21. (2.) Make a ſlight Infuſion of bruiſed Galls in Water, ſo as not to diſcolour the Water; filtre the Infuſion; make alſo a weak Solution of Green Vitriol in Water, and filtre the Liquor, ſo that they may both appear pellucid: Theſe Liquors being now mixed together, an inky Blackneſs will immediately ariſe; but if a little Oil of Vitriol be added to the Mixture, the Blackneſs will, by Degrees, totally vaniſh, and the Liquor appear pellucid again; tho' the Blackneſs may be recalled by the Addition of a little Salt of Tartar. *Colourleſs Liquors producing Blackneſs.*

22. (3.) If a little bruiſed Camphire, which is a very white Subſtance, be put into pellucid Oil of Vitriol, and the containing Glaſs be ſhook for ſome Time, the Camphire will diſſolve, and gradually change the Mixture to a Brown, and at length to a full Black. But upon the Addition of fair Water, the Blackneſs entirely vaniſhes, and the Camphire riſes to the Top in its priſtine Form, and native Whiteneſs *. *A white ſolid, and pellucid Fluid, turned into Blackneſs.*

23. (4.) If the Shavings of *Lignum Nephriticum* be infuſed for ſome Time in cold Water, and the clear Liquor be decanted into a clean Glaſs, and viewed from the Light, the Liquor will appear of a beautiful Blue; but if viewed towards the Light, of a Yellow. If a little Spirit of Nitre be put to this Liquor, it loſes its Power of reflecting the blue Rays; but the Addition of a little Oil of Tartar, *per deliquium*, recovers that Power again. *A Liquor differently coloured as differently viewed.* *Its Colour deſtroyed and recovered by Mixture.*

24. (5.) If Logwood be infuſed in Water, it gives a red Colour; which, upon the Addition *Red changed into Purple by Mixture.*

* It is remarkable, in this Experiment, that the ſtrong Scent of the Camphire is abſolutely wanting in the black Solution; but recovered upon the Addition of the Water.

of

of a little Spirit of Urine, turns to a fine Purple: But this may be changed to a dilute Red, by dropping in a little Spirit of common Salt.

Red Colours hightened and lowered by Mixture.

25. (6.) An Infusion of *Brazil* Wood, or Cochineal, in Water, is much hightened in its red Colour, by the Addition of Spirit of Urine; and lowered or turned paler by the Spirit of Salt.

A pellucid Liquor made blue by a white Body.

26. (7.) If Spirit of Wine be digested upon recent Camomile-Flowers, and distilled over from them in a Glass Retort, the Spirit will thus acquire a beautiful blue Colour, which may be made deeper by being drawn over again from fresh Flowers.

A blue Colour destroyed by Mixture.

27. (8.) A beautiful blue Tincture being made by digesting Spirit of Urine upon Filings of Copper, the Addition of a little Oil of Vitriol entirely destroys the blue Colour; as a little Spirit of Salt turns it to a Green.

Pellucid Liquors made red by Mixture.

28. (9.) Pellucid Oil of Vitriol being mixed with pellucid Oil of Turpentine, or the essential Oil of Aniseeds, or more particularly with Oil of Cloves, they turn thereupon into a thick, red Balsam. And so again, if a pellucid common Oil be, by Means of a little Wax and continued Triture, gradually mixed with fair Water, they unite into a very thick, white Substance, Balsam, or cold Cream.

A white Powder made yellow by Mixture.

29. (10.) Oil of Vitriol being distilled over from Quicksilver, leaves a white Powder behind; to which if Water be poured, the Powder presently becomes of a beautiful Yellow.

The same Solution affording differently coloured Precipitates.

30. (11.) To a Solution of Quicksilver in Spirit of Nitre, add Spirit of Urine; and a white Powder will be precipitated: To another Parcel of the same Solution add Oil of Tartar *per deliquium*, and a yellow Powder will fall to the Bottom: To a third Parcel of the same Solution add

add Spirit of Urine, and the Precipitate obtained will be of a Fleſh-Colour.

Limpid Ink appearing red.

31. (12) If a clean new Pen be dipped in Spirit of Vitriol, and the common deep Blue Paper be wrote upon therewith, the Letters appear of a very bright and beautiful Red: And, in the ſame Manner, pellucid Spirit of Salt ſtains a black Hat red.

Inviſible Ink.

32. (13) A pellucid Solution of *Saccharum Saturni* in Water, being wrote with, becomes inviſible upon the Paper, when dried: But the bare Fumes of another tranſparent Liquor, *viz.* an Infuſion of Quicklime and Orpiment in Water, will ſoon render the inviſible Writing black and legible. And thus thoſe commonly called Inviſible or Sympathetic Inks are made.

A white and green Body makes Purple.

33. (14) The volatile Salt of Sal-Ammoniac, a white Body, and the Cryſtals of Copper, a green one, will, by Mixture, become Purple.

A Green and White, red on the Surface.

34. (15) Salt of Steel, a green Body, and Sugar of Lead, a white one, being mixed together, the Surface of the mixt Powder will appear red; whilſt the internal Parts are of a dirty White.

35. (16) That original, and ſimple, as well as compound, Colours, are producible by Mixture, appears from many Experiments.

A Green from Light paſſing thro' blue and yellow Glaſs.

36. (17) If the Sun's Rays paſs thro' two Pieces of differently coloured Glaſs, for Inſtance, a blue and a yellow Piece, laid upon each other, and theſe Rays be received from the Glaſſes upon white Paper, they then appear of a beautiful Green.

Greens dyed from blue and yellow.

37. (18) It is common with the Dyers, to dye the Cloth firſt Blue with Woad, and turn that Blue into a Green by the Yellow called *Dyer's Weed*, or *Luteola*.

Green from a blue and yellow Liquor.

38. (19) To a fine yellow Solution of pure Gold, in *Aqua Regia*, add a deep blue Solution of Copper in Spirit of Urine; and the Mixture will appear green.

From blue and yellow Ammel.

39. (20) Blue and yellow Ammel, being melted together, conftitute a green one.

Many Painter's Colours by Mixture.

40. (21) The Painters make a great Variety of compound Colours, by mixing two, three, or more different Colours together, either on their *Pallat*, or on the Canvas.

Mixed Colours may make White.

41. (22) A Mixture of the feven original Colours, or even five of them, will make a White; and the more perfectly, the finer and more perfect the coloured Bodies are. Thus, if a large Top be painted on its upper Surface, one Part red, another yellow, another green, another blue, and another violet; this Surface, whilft the Top is fpinning brifkly (fo that the Motion fhall confound the feveral Colours, or make them appear mixed to the Eye) will exhibit a dirty Kind of Whitenefs. And in like Manner, by mixing together Powders of different Colours, as Vermillion, Orpiment, Indigo, Verdigreafe, &c. in proper Proportions, the compound Powder will, in a ftrong Light, appear to be white. And if differently coloured Flames could be brought to mix, this Experiment might be made in greater Perfection.

Flames of different Colours.

42. (23) Flames are of different Colours, according to the Bodies that produce them. Thus the Flame of burning Camphire is white, like the Focus of a Burning-Glafs; the Flames of Spirit of Wine, and of Sulphur, are blue; the Flame of white Wax is white, inclining to blue; that of Tallow, white, but rather inclining to yellow, &c. Whence proceeds the Difference of the Colours of Bodies, as viewed by Day-light, Candle light, Fire-light, fulphureous Light, &c.

&c. And, for making Experiments to this Purpose, Oil might be impregnated with certain Metals, as particularly Copper and Iron, by Triture, and Digestion, so as to exhibit their particular Flames.

The Prismatic Colours imitated.

43. (24) The Prismatic, or original Colours may be imitated to considerable Perfection in Liquors, where the Parts of the tinging Substances are rendered extremely minute or fine. Thus a Solution of Cochineal in Spirit of Urine, viewed in a strong Light, affords a most vivid and beautiful Red; a Solution of Copper in Spirit of Urine, yields a glorious Blue; a Solution of Verdigrease in distilled Vinegar, is an excellent Green; a Solution of Gold in *Aqua Regia*, makes a fine Yellow; an Infusion of Violets in hot Water, affords an excellent Violet Colour, &c. And from a thorough Acquaintance with these Liquors, and the Methods of varying, mixing, and heightening their Colours, many Improvements in the Arts depending upon Colours, Dyes, and Stains, might be rationally expected.

Result of the Experiments.

44. (25) The foregoing Set of Experiments not only confirms the former leading Experiment made with the Prism, but also Sir *Isaac Newton*'s general *Doctrine of Colours*: For it is hence manifest, that slight mechanical Alterations in Bodies, produce, alter, or abolish all Kinds of Colours therein; or that all the Colours of Bodies are only original Colours of Light, differently reflected, either in a simple or variously compounded State, according to the particular Disposition, Texture, Mixture, or Arrangement of the small Parts of the reflecting Body, so as to afford that infinite Variety of Colours we meet with in natural and artificial Things.

EXPERIMENT III.

The Method of preparing the vegetable Colours called Laques.

The Laque of Turmeric. 45. Take a Pound of Turmeric-Root, reduced to fine Powder, three Pints of fair Water, and an Ounce of Salt of Tartar; put them into a glazed earthen Veſſel, and let them boil together, gently, over a clear Fire, till the Water appears richly impregnated with the Turmeric, or will ſtain a Piece of white Paper beautifully yellow; then filtre the Liquor, and gradually add to it a ſtrong aqueous Solution of Roch-Allum, till the yellow Matter is all curdled together, or precipitated: After this, pour the Whole into a Filtre of Paper; where the aqueous Part will run off, and leave a yellow Matter behind; which being edulcorated, or waſhed in the Filtre, by the repeated Affuſion of freſh Water, till the Water comes away inſipid, and afterwards dried, becomes the *Laque of Turmeric*, or a beautiful yellow Colour for Painting.

The general Way of obtaining Laques. 46. This Experiment ſhews a general Method of obtaining a Laque from all the vegetable Subjects fitted to afford it: For in the ſame Manner may a red Laque be made from Madder, Brazil, and many other dying Woods, or tinging Vegetables. But where the Colour of the Subject depends upon a very ſubtil Texture, Mixture, or Arrangement of the Parts, this Method deſtroys, or at leaſt impairs, the Colour; as particularly in Violets, Red Roſes, Carnations, *&c.* So that it ſeems applicable only to the tinging Vegetables of a ſomewhat ſtrong and firm Texture.

47. In

47. In some Cases also a simpler Process is sufficient to obtain rich *Laques* particularly that beautiful red one emphatically called *Laque*; and from which the Name seems to be derived to the rest. This red *Laque* is obtained barely by boiling *Stick-Lac* in Water; then filtring the Decoction, and evaporating the superfluous Humidity: For the beautiful red Colour adheres to the Outsides of the Sticks broke off the Trees, along with the *Gum-Lac*; and readily communicates itself to boiling Water *. As some of this tinging Matter likewise sticks to the Gum itself, it is proper to boil them both together: For the Gum does not prejudice the Colour, nor dissolve in boiling Water: So that after the Operation the Gum is as fit for the making of Sealing-Wax, or other Uses that do not require the Colour, as it was before. *The particular Laque of Stick-Lac.*

48. And much after the same Manner is that extremely rich and beautiful red Colour called *Carmine* prepared from Cochineal and a Solution of Tin; for Carmine may be conceived as no more than the Scarlet, or Bow-Dye Liquor, concentrated, or reduced to what the Painters call a *Body*. *Carmine.*

49. How far our present Experiment may be applicable to other Parts of the *Materia tinctoria*, seems not hitherto well considered. Doubtless it might afford a great Variety of *new Colours*, by a proper Extension and Diversification in the *Menstruum* and *Method*. For Example: If *Red Saunders* be digested warm in Spirit of Wine, *Extension of the Experiment.*

* The tinging Matter adhering to the Sticks and Gum is perhaps not a vegetable, but animal Substance; somewhat of the Nature of Cochineal, and deposited in Form of an Excrement, by a certain Kind of Bees, in the *Indies*. See a Paper upon this Subject in the *French* Memoirs; see also Mr. *Boyle* upon human Blood. *Abridgm.* Vol. II. p. 481.

A red Rosin from red Saunders. the Menstruum acquires a deep red Colour; and if drawn off by Distillation, leaves behind it a red, tasteless, and inodorous *Rosin*, that affords no Smell even upon burning, nor dissolves in any expressed or essential Oil; yet, even in a small Proportion, tinges Spirit of Wine of a full red Colour, so as to render it useful for anatomical Injections, *&c.*

Another from Red Wine Lees. 50. In like Manner may a particular gummy, red Substance, or Pigment, be obtained, by Spirit of Wine, from dried red Wine Lees; and whether the tinging Parts of the more cumbersome dying Woods and Stuffs could not be advantageously extracted, at the Places of their Growth, so as to leave their ponderous Bulk behind, and bring away only their concentrated, essential Colours, might deserve the Consideration of the Merchant, the Dry-Salter, the Dyer, the Callico-Printer, *&c.* It might be tried in Log-Wood, Campeche, or Brazil; in Madder, Safflore, and many other dying Woods and Stuffs, whose Names we seldom meet with but in the *Bills of Entry.*

EXPERIMENT IV.

The Way of preparing an animal Colour called Prussian Blue.

The Process for making Prussian Blue. 51. Take of crude Tartar and Nitre, each four Ounces; pulverize, and mix them together; and, by Deflagration, bring them to a fixed Salt; which being powdered hot, add to it four Ounces of thoroughly dried Ox-Blood, reduced to fine Powder: Calcine the Mixture in a covered Crucible, whereof it may fill two thirds: Then lightly grind the Matter in a Mortar, and throw it hot into two Quarts of

 boiling

boiling Water; boil them together for half an Hour; afterwards ſtrain off the Liquor, waſh the black remaining Subſtance with freſh Water, and ſtrain as before; continuing to do thus till the Water poured off becomes inſipid. Put the ſeveral Liquors together, and evaporate them to two Quarts. Now diſſolve an Ounce of green Vitriol, firſt calcined to Whiteneſs, in ſix Ounces of Rain-Water, and filtre the Solution. Diſſolve alſo half a Pound of crude Allum in two Quarts of boiling Water; and add this to the Solution of Vitriol, taken hot from the Fire; pouring to them likewiſe the firſt Lixivium, whilſt thoroughly hot, in a large Veſſel: A great Ebullition and a green Colour will immediately enſue. Whilſt this Ebullition continues, pour the Mixture out of one Veſſel into another, and afterwards let it reſt; then ſtrain the Liquor thro' a Linen Cloth, and let the Matter, or Pigment, remain in the Strainer; from whence put it, with a wooden Spatula, into a ſmall new Pot; pour upon it two or three Ounces of Spirit of Salt; and a beautiful blue Colour will immediately appear. Let the Matter be now well ſtirred; then ſuffered to reſt for a Night; afterwards thoroughly edulcorate it by repeated Affuſions of Rain-Water; allowing a proper Time for the Precipitate to ſubſide: And thus, at length, it will become exquiſitely blue. Laſtly, let it drain upon a Linen Strainer, and dry it gently: By all which Means it becomes the Pigment that goes by the Name of the *Pruſſian Blue.*

The Cautions required in it.

52. The Succeſs of the Experiment depends greatly upon the Calcination. The Crucible is firſt to be ſurrounded with Coals, at ſome Diſtance; that it may grow gradually hot, and the Matter leiſurely flame and glow. Let this

Degree of Heat be continued till the Flame and Glowing decreaſe; then raiſe the Fire that the Matter may glow with an exceeding white Heat, and but little Flame appear above the Crucible. The Lixiviums ſhould be very hot, and mixed together with the utmoſt Expedition*.

Its Nature. 53. The Method of making this *Pruſſian Blue* in Perfection, has been held and purchaſed as a very valuable Secret, both in *England*, *Germany*, and elſewhere; but it is now got into ſeveral Hands. Its Proceſs is very extraordinary, and could ſcarce be deduced *a priori*, from any reaſoning about the Nature of Colours. It is allowed an excellent blue Pigment, and by ſome preferred to *Ultramarine*; tho' its Durability might have been ſuſpected, from the vegetable and animal Matters uſed in its Preparation, if the Colour did not ſeem wonderfully fixed by the Operation.

Many animal Matters uſed in Colours, 54. A great Variety of Colours are prepared by the Means of animal Matters; and more particularly by the Means of Urine; which, when it has ſtood to ferment, or putrify, ſerves to extract, change, or fix the natural Colours of ſome Bodies; and to heighten the Colours of others. *Particularly Urine.* Thus it is uſed in the preparation of the ordinary Blue called *Archil*; which chiefly comes to us from *Holland*: It is alſo uſed in the changing or fixing of *Turnſol*; ſo as to make a moſt elegant Red from the Sun-Flower: It is alſo a principal Ingredient, along with *Indigo*, in making that noble, fixed, and durable Blue, very lately diſcovered in *England*, for the ſtaining of Callico; a Colour that firſt appears Green,

* See *Philoſophical Tranſactions*, N° 381.

but

but by washing with Soap changes, and fixes into a lovely Blue.

55. Certain chemical Preparations from animal Subjects are likewise employed for extracting, changing, or heightening the Colours of various Bodies. Thus the alkaline, or volatile, Spirit of Urine, Blood, Bones, *&c.* extracts a fine Blue from Copper, changes a green Solution of Copper to a Purple, and heightens the Red of Cochineal. And doubtless the present Stock of Colours might be considerably enlarged, or improved, by a prudent Choice of *animal Menstruums.* *The Spirit of Urine, &c.*

56. By animal Menstruums we mean both the natural and artificial Kind: The natural are such as Blood, Serum, Gall, Urine, *Saliva,* Rennet, Whey, Butter-milk, *&c.* most of which being properly employed, will either discharge or produce Colours. Thus recent Urine discharges the common Ink out of Linen; the *Saliva* discharges Red Ink; Butter-milk takes Stains and Mildews out of Linen, *&c.* Blood, we see by our present Experiment, affords a rich and beautiful Blue; and Gall is a natural Yellow; which may deserve to be treated as Blood, in making the *Prussian Blue.* *Animal Menstruums, natural.*

57. These natural animal Menstruums, or other animal Substances, being chemically treated, may afford a great Variety both of simple and compound Liquors, or new artificial Menstruums, for farther improving the Business of Colours, Dyes, and Stains. Thus, as putrified Urine affords an alkaline Spirit, by Distillation, that serves to produce, alter, or destroy a great Number of Colours; so likewise might the Liquors obtained, by Distillation, from recent, or fermented Whey, Butter-milk, *&c.* And by variously compounding these several Substances, *And artificial.*

or Liquors, even by random Trials, or chance Experiments, ſome new Diſcoveries in Colours might be made; as in the preſent Example of the *Pruſſian Blue:* Tho' we have a much greater Dependence upon Experiments conducted in a rational Manner; or in the Way of an Art, formed upon a competent Knowledge of chemical Operations, with their Productions and Effects; which will enable the Enquirer to reaſon, by Analogy, from one Experiment to another; and thus lead, in a ſure and guarded Manner, to new Inventions and Diſcoveries.

The Experiment extended. 58. Thus, for Inſtance, the chemical Operator having found that common Bones, burnt only to Blackneſs, afford the Bone-black; it is eaſy to transfer the Experiment to Ivory, whereby a better Black is produced. And thus, upon finding that dried Ox-Blood has ſo great an Effect in making the *Pruſſian Bule*, we are naturally led to try the ſame Experiment with the Blood of different animals; or other concreted animal Juices, as Gall, Feathers, Fleſh, Leather, *&c.* or the entire Bodies of certain Inſects, Fiſh, Birds, *&c.* And this ſhould be done with proper Diverſifications of the Ingredients, and their Proportions; all along carefully noting the ſeveral Phænomena and Events; which will conſtantly afford Light and Inſtruction to the Mind, for the better regulating and conducting of the Enquiry, till it ends in a full Diſcovery.

EXPERIMENT V.

The Way of preparing a metalline Colour, from Gold and Tin, for tinging Glaſs of a beautiful Red.

59. Diſſolve Gold in *Aqua Regia*, and dilute the fine yellow Solution with a large Proportion of

of fair Water; to the Mixture add, by Degrees, a sufficient Quantity of a saturated Solution of Tin, made also in *Aqua Regia*; and a most beautiful red, or purple-coloured Powder will soon fall to the Bottom of the containing Glass. Decant the Liquor, and dry the Powder; a few Grains whereof being melted along with crystalline Glass, will tinge it throughout of an extremely fine purple or ruby Colour *a*). *The Ruby of Gold.*

60. By Means of this Experiment the ancient Art of Staining Glass red, long supposed to be lost, seems at present restored. All the Colours are easily given to Glass, as we mentioned above *b*): But this seems to have been kept as a Secret in very few Hands, till lately; and may be considerably diversified, so as to introduce a grateful Variety of beautiful red and purple Colours in Glass *c*). *Its Uses, in the Art of Glass.*

61. It should also seem that the Art of Callico-Printing, which now wants a Red, equally perfect with the Blue it has lately obtained, might hence be furnished with such a Red; tho' there is Reason to suspect it might come out too dear for ordinary Use. But as the Perfection of this Art consists in discovering fixed, bright, and permanent Colours, not subject to change for the worse in the open Air; such Colours should rather be expected from mineral or metallic Matters, than from those of the vegetable and animal Kingdoms; which usually afford Subjects of too lax and alterable a Texture for permanent Colours, unless they could be some way substantially fixed. *In Callico-Printing.*

a) See *Cassius de Auro*, p. 105.
b) See *Exp.* II. § 15.
c) See Mr. *Boyle*'s Philosophical Works. *Abridgm.* Vol. I. p. 457—459.

The Indian *Colours how made.* 62. It appears highly probable that the *Indians*, for making the fine, bright, and durable Colours wherewith their Callicoes and Chintzes are ſtained, uſe metalline Solutions; for ſome ſtained Callicoes having been kept for forty or fifty Years, the bright Colours have been obſerved to eat out the Cloth, exactly in the ſame Manner as the corroſive, acid Spirits, which diſſolve Metals, are found to do: Whence, to imitate their richeſt and nobleſt Colours, we are directed to uſe proper metalline Solutions, made after the Manner of our preſent Experiment.

The higheſt Improvement of Colours. 63. But it would be a farther Step towards Perfection, not only in this Art, but alſo in the Art of Painting, to prepare the fineſt Colours without employing either acid or alkaline Salts; which uſually ſubject Colours to change, or elſe are apt to prey upon the Cloth, or Canvas, as we ſee in Verdigreaſe, the blue and green Cryſtals of Copper, &c. Whence we are directed, (1) to ſearch for Menſtruums that are neither acid, alkaline, or ſaline; (2) for ſuch metalline *Calxes*, Precipitates, or Powders, as will not loſe their Colours by being well waſhed, to get out their Salts; (3) to prepare certain metalline Matters by Calcination, or the bare Aſſiſtance of the Fire; and (4) to look out for *native Colours*, wherein no ſaline Matter abounds.

Variation and Extenſion of the Experiment, by Triture. 64. (1) It may be worth the trying, whether certain Metals are not ſoluble by Triture, with the pureſt Oils employed in Painting, and ſuch as contain neither acid nor alkaline Salts; or whether mere Water, the Whites of Eggs, Saliva, Gum-Water, &c. may not, by the ſame Means, be made to diſſolve them; ſo as that the metalline Particles may be left behind upon Callicoes, Cloths, &c. when the aqueous or mucilaginous Matter is dried, or waſhed away from them.

them. But no great Effect can be rationally expected in ſuch Attempts, unleſs the Triture be long continued, and Mills, or other well adapted Engines, be uſed for the Purpoſe: For we find, in all Inſtances, that Metals muſt be reduced to very fine Particles before they will tinge or colour.

65. (2) The Pigments or Colours obtained by Cryſtallization, ſuch as the blue and green Vitriols, or Cryſtals of Copper, &c. cannot be deprived of their aqueous or ſaline Parts by a dry Air, or by Waſhing, without ſuffering extreme Alterations, or being left in the Form of a groſs, terreſtrial Matter, differently coloured from what they were at firſt. Thus the fine green Cryſtals of Iron, by being expoſed to the Air, become white; and when well waſhed in Water, loſe their Greenneſs, and turn to a reddiſh or yellow-coloured Ochre, or Earth: And if deprived of their ſaline and aqueous Parts, by a ſtrong Diſtillation, they leave behind a brown or red *Caput mortuum*; which being waſhed in Water, affords not a green, but a dark-coloured Pigment, or Kind of *Spaniſh Brown*. And as this holds proportionably of other Colours obtained by Cryſtallization, there are little Hopes of procuring durable Pigments by that Operation, which ſhall be of the ſame Colours with the Cryſtals themſelves; tho', after being well waſhed, different Colours may be thus procured. *By Cryſtallization, Lotion, and Diſtillation.*

66. (3) Metalline and mineral Matters are reducible to a conſiderable Degree of Subtilty or Smallneſs of Parts, by Fire, or dry Calcination; ſo as to leave them durably poſſeſſed of their native or adventitious Colours. Thus *Lapis Lazuli*, by being calcined, becomes the fine, durable, rich Blue, called *Ultramarine*: *Light Ochre*, by *Dry Calcination.*

by the ſame Treatment, becomes a *light Red*; or the moſt uſeful Fleſh-Colour in Painting. *a*) Lead, by Calcination, becomes durably red; and Iron, durably brown. But a proper Method ſeems wanting for the dry Calcination of the nobler Metals, Gold and Silver: Though, for the Uſes of Gilding, *&c.* theſe nobler Metals are eaſily calcined by dipping linen Rags into their reſpective Solutions; then drying the Rags, and ſetting them on Fire, ſo as that they may burn to Aſhes; whereby a dry and fine metalline Powder is readily obtained.

New and durable mineral Pigments diſcoverable. 67. (4) Many native mineral Pigments, or durably tinging Subſtances, are already diſcovered, that do not abound with Salts; ſuch as Ochre, both yellow and red, Cinnabar, or Vermillion, Zaffora, Manganeſe, *&c.* and doubtleſs many others might be found in Countries that are ſtored with Mines, or where a proper Search is made after new mineral Subſtances *b*).

Ores tried by the ſtaining of Glaſs. 68. Our preſent Experiment likewiſe affords an uſeful Method of examining Ores, or diſcovering a ſmall Proportion of a metallic Subſtance in a large Proportion of Earth, *&c.* for a Quantity of pulverized cryſtalline Glaſs being ready at Hand, it is but mixing a little of the Ore, or mineral Matter, therewith, and melting them together; whereby the Glaſs will be deeply or lightly tinged of a certain Colour, according to the Nature and Quantity of the Metal contained in the mineral Matter. Thus a little Silver tinges white Glaſs yellow, Copper green, *&c.* Putty, or a Mixture of calcined Tin and Lead, turns it white, *&c.* tho' theſe Colours will ſomewhat vary, according to the Mixture of the metalline Matters with others, the Regulation of the Fire,

a) See above *Exp.* II. §. 20. *b*) See ib.

and

and other Circumſtances: So that a Sett of particular Experiments are required, to bring this Affair to greater Certainty, and reduce the whole to a regular *Table*. But this Method, if ſufficiently verified, might be commodiouſly uſed, when the Quantity of Ore, or mineral Matter, is ſmall, or contains but a very minute Proportion of Metal; for a little metalline Matter will thus tinge a large Proportion of Glaſs.

69. The Art of Enamelling in Glaſs alſo depends upon a prudent Uſe of mineral Pigments; or a Mixture of Miniature-Painting and Annealing: For the Method here is, to lay the Colours upon Glaſs, as the Painter does upon Canvas; and afterwards to ſoften the Glaſs, by a proper Degree of Heat, in the Annealing-Furnace, under a Muffle, till the Colours ſink into the Glaſs. And in this Manner alſo is Glaſs frequently coloured, on its more ſuperficial Parts, without being tinged throughout; as we ſee in the coloured Glaſs of certain Church-Windows, and ancient Buildings. *The Art of Enamelling.*

AXIOMS and CANONS.

1. The preceding Enquiry ſhews, That the *phyſical Cauſe* of the Generation, Variation, and Deſtruction of Colours in Bodies, is the different Refrangibility and Reflexibility of the different Orders of the Rays of Light *a*).

2. That Colours therefore are not inherent in the Bodies ſaid to be coloured; but rather in the Rays of Light which fall upon them; and are thence reflected to the Eye, ſo as to cauſe the *Senſation of Colour* *b*).

a) *Exp.* I. II. *b*) Ib.

3. That

3, That Colours, ſo far as they may be conſidered as in the Bodies ſaid to be coloured, depend upon a certain mechanical Texture, or Mixture of the ſmall Parts of Bodies; which Texture, or Mixture, being altered, or deſtroyed, the Colours alſo are altered, or aboliſhed *a*).

4. That Whiteneſs in Light is an intimate Mixture of the ſeveral Orders of Rays; and Whiteneſs in Bodies, the actual Reflection of their Rays in their natural, mixed, or unſeparated State *b*).

5. That Darkneſs is the Abſence of the Rays of Light; and Blackneſs in Bodies, not a Colour, but the Want of thoſe Rays being reflected from the Surface of the Bodies ſaid to be black; or, in other Words, that Blackneſs is produced by the Rays of Light being abſorbed, ſtifled, or drank in, by the Bodies denominated black *c*).

6. That *Tranſparency* in bodies is their Tranſmitting the Rays of Light; and *Opacity* their not Tranſmitting, but reflecting theſe rays *d*).

7. That common Light is compounded of ſeven different original orders of Rays; *viz.* Red, Orange, Yellow, Green, Blue, Indigo, and Violet; and that according as Bodies reflect more or leſs of theſe Rays, ſuch Bodies appear of different ſimple or compound Colours *e*).

8. That great Alterations of Colours are producible by a bare Alteration of the Arrangement, Texture, or Mixture of the ſmall Parts of Bodies; or by the Interpoſition of different Parts, upon bare Triture, and ſimple Mixture *f*).

9. That vegetable and animal Colours are, in general, leſs durable, or more ſubject to change,

a) *Exp.* I. II. *b*) ib. *c*) ib. *d*) ib. *e*) ib. *f*) *Exp.* II. III. IV. V.

than

than the mineral Kind; on Account of the loofer, or more porous Nature and Texture of the two former, and the ftronger and clofer of the latter *a*).

10. That the Arts of Enamelling, and Imitating Precious Stones, in Glafs, depend upon the Addition of metalline *Calxes* to the Glafs of Lead, or pure cryftalline Glafs, in Fufion; and that an infinite Variety of the moft durable and beautiful Colours are obtainable by this Means *b*).

11. That many new Colours may be reafonably expected from a proper Enquiry into, and a chemical Treatment of, various Subjects of the vegetable and animal Kingdoms *c*); and that there are four principal Ways of obtaining new, fixed, or durable mineral and metalline Colours; *viz.* (1) by difcovering new *Menftruums*; (2) by finding fuch metalline Powders as will bear to be wafhed from their adhering Salts; (3) by properly applying dry Calcination; and (4) by enquiring after native mineral Colours that are not faline *d*).

12. That a great Variety of new and fixed Colours may be prepared from Metals, and their Menftruums, or certain Mixtures of metalline and mineral Matters, for the farther Service and Improvement of the feveral Arts that depend upon Colours, Dyes, and Stains *e*).

a) *Exp.* II. III. IV. V. *b*) *Exp.* II. V. *c*) *Exp.* III. IV. *d*) *Exp.* V. *e*) *Exp.* II. III. IV. V.

LECTURE

LECTURE XV.

CONTAINING

Attempts to illustrate and improve the common Ways of preparing Remedies.

The Subject. 1. THE Business we are now entering upon is Pharmacy; a Subject which has almost engrossed Chemistry to itself: Whence many understand by Chemistry little more than the Preparation of Medicines. This Notion is countenanced by the Books of Chemistry generally published; which seldom contain more than Directions for the Making of Medicines: So likewise the Courses of Chemistry usually given, turn chiefly upon the Application of Chemistry to Pharmacy.

2. That Chemistry is applicable to the Illustration and Improvement of many other Arts, hath we hope been shewn in the preceding Lectures. But as the Application of it to Pharmacy is a Thing of Importance to Life and Health; and as Men generally think that this is the principal Office and Use of Chemistry; we judge it proper to bestow two Lectures upon the Subject: In the first whereof we propose to consider the present State of Pharmacy, with the Means to improve it, upon the footing it now stands; and in the second we will endeavour to shew how it may be reduced to a greater Degree of Simplicity; and thus be brought nearer to Perfection: The one we may call the *copious*, and the other the *concise* Method of Pharmacy.

3. We

3. We define *Pharmaceutical Chemiſtry*, the Art of directing and performing the ſeveral Proceſſes or Ways of Working, whereby natural Subſtances are reducible to uſeful Medicines. *Pharmaceutical Chemiſtry.*

4. And thus the whole Art conſiſts of two Parts, a *Theory*, and a *Practice*: The Theory is claimed by the Phyſician, and the Practice is turned over to the Apothecary.

5. Moſt of the natural Bodies being ſome Way or other employed as Subjects of Pharmacy, the *Materia medica* is extremely large, and its Operations various. Its Materials in the earlieſt Ages indeed were few, and the Ways of managing them ſimple: Subjects afterwards multiplied, Operations increaſed, and at preſent we ſeem abundantly ſtocked with both ſimple and compound Medicines. *Hiſtory of Pharmacy.*

6. But the Hiſtory of Pharmacy may deſerve to be more particularly traced, in order to ſee by what Means it arrived at its preſent State, and how it may be farther advanced.

7. Diſeaſes muſt have begun very early, if the firſt Inhabitants of the World experienced the ſame Changes of Seaſons, breathed the ſame Kind of Air, and uſed a like Diet and Regimen of Life with ourſelves. But ſoon after a Diſeaſe afflicts, the Patient ſeeks for a Remedy: Whence we may reaſonably ſuppoſe that this was the Foundation of Pharmacy in various Parts of the World.

8. Experiments being thus multiplied, and the Event gradually introducing better Methods of preparing the Simples, Pharmacy would begin to appear in the form of an Art: Yet when *Hippocrates* came to compile a Kind of Syſtem of Phyſic from the Obſervations of Antiquity, he deſcribed but few Preparations, and thoſe were generally ſimple.

9. Succeeding Phyſicians enlarged the *Materia medica*: *Galen* conſiderably ſwelled the Catalogue, which received many Additions from the *Arabians*.

10. And when Learning began to revive in *Europe*, the *Materia medica* was again enlarged, and great Changes wrought upon it by Chemiſtry: Whence Chemiſtry at length was generally received, and acknowledged to be of uſe in Pharmacy.

11. Both the Galenic and Chemical Part of this Art are now extremely copious. Neceſſity gave the Occaſion; Nature ſupplied the Materials; and Art and Obſervation diſcovered their Preparations, Virtues, and Uſes.

12. Thus we at preſent ſeem provided with a Competency of ſtanding Medicines; and have, by Degrees, acquired a Method of preſcribing in *extemporaneous Forms*.

13. The Art of Pharmacy may be conſidered as under the Management of Phyſicians, Apothecaries, trading Chemiſts, and Druggiſts.

14. It is the Office of the Phyſician to direct the Medicines, or give Rules for extracting, compounding, and managing the Simples. If the Phyſician therefore ſhould be defective in this Part, let the Apothecary, the trading Chemiſt, and the Druggiſt, be ever ſo juſt, or ever ſo knowing, the Art of Pharmacy muſt fall ſhort of Perfection.

15. To the Apothecary belongs the Reduction of the *Materia medica* into certain Forms of Medicines, according to the Direction of the Phyſician.

16. But there are two Kinds of Apothecaries, vulgarly known by the Names of *wholeſale* and *retail* Apothecaries. It is the latter alone we are here concerned with: Theſe act by Rule,

generally follow their Standard, and compound with Art and Care; tho' they will ſometimes ſubſtitute a *quid pro quo*, and now and then venture to reverſe an Order. In Proportion to their Skill and Care they are more or leſs liable to be impoſed on by the Druggiſt and the trading Chemiſt; all of them uſually ſelling what they buy. But if the Apothecary be often deceived by them, how ſtands it with the Patient and Phyſician? or what is the State of Pharmacy?

17. The retail Apothecaries, however, deal more in *Subſtitution* than in *Sophiſtication*. The prudent Phyſician therefore preſcribes what is uſually kept, and proper to keep, in the Shops, or what is otherwiſe eaſily obtainable. If there are other Abuſes committed in this Part of Pharmacy, they may perhaps be chiefly attributed to ſome Want of Skill or Conduct in the Phyſician.

18. The Deſign of the trading Chemiſts and Druggiſts is to furniſh medicinal Matters to the Apothecary, who cannot always detect an artful Counterfeit, or a dexterous Sophiſtication: And perhaps many Remedies, well deſigned by the Phyſician, have failed, or had miſchievous Effects, upon this Account.

19. This is propoſed as a ſhort Intimation of the preſent State of Pharmacy in *England*. If the Art be found more perfect in other Nations, it may perhaps be chiefly owing to this, That their Phyſicians are well acquainted not only with the Theory, but alſo with the Practice thereof; two Things which ſhould never be ſeparated, as being in Reality but one effective Thing conſiſting of two Parts; *viz.* previous Notion, and Execution.

20. What uſeful Addition or Reformation the *Materia medica* is capable of receiving, no one

at preſent can ſay. If a ſtrict Enquiry were made, perhaps it might be found proper to throw out of our preſent Collection a conſiderable Number of Materials, to make Room for others of greater Efficacy. But this is no Work for private Perſons. Our preſent Buſineſs is to ſee whether any Improvements may be made in the Ways of preparing the common Medicines of the Shops.

Deſign of Pharmacy. 21. And for the better regulating of our Enquiry it may be of ſome Service to lay down two larger Obſervations; *viz.* (1) That the Deſign of Pharmacy is to ſeparate from Bodies the more medicinal Parts with which they are naturally endowed; and, upon Occaſion, to mix ſuch of them together as will beſt anſwer the curative Intentions. All in the Power of Art is only to ſeparate and mix, or differently modify; it is Nature alone that is able to produce. Pharmacy therefore conſiſts in *Analyſis* and *Syntheſis* *.

Rules. 22. (2) As it is the Perfection of Art to copy Nature juſtly, ſo by reſolving Bodies into their Principles we obtain a general Rule for Compoſition, and ſee the ſeveral Steps we ought to take in it. Nature ſhews us that in all mixed Bodies there is a Baſis or *Subſtratum*; ſomething to ſupport and envelope the other Ingredients. Thus natural Salts are the diluted with Water; the Oils with both; and all together compoſe one uniform and elegant Whole. To preſcribe juſtly, therefore, we ſhould imitate Nature: If we compound without Regard to this Rule, the Ingredients will appear huddled together, as if it were by Chance; and,

* See *Lect.* VIII. and IX.

instead

inſtead of preſerving and aſſiſting, they will often clog, encumber, and deſtroy each other.

The Intent of the Experiments.

23. We now proceed to our Experiments, by which we propoſe to illuſtrate and improve (1) the common Method of diſtilling Simple-Waters; (2) the common Method of preparing Tinctures; (3) the Method of preparing Syrups; (4) the Method of making Electuaries; and (5) the Method of making compound Oils, Unguents, and Plaiſters: Thus propoſing to touch upon the chief Articles of the preſent *Galenical Pharmacy*, as it is vulgarly called; tho' in Reality it be no leſs *chemical* than the other.

EXPERIMENT I.

The beſt Way of diſtilling Simple-Waters.

Simple Waters, how diſtilled.

24. We took as much dried Mint, cut ſmall, as filled two thirds of our Still; then adding a Quantity of Rain-Water ſufficient to make the Plant float commodiouſly, yet leaving a fourth of the Still empty, we digeſted a while with a gentle Heat; then worked the Still, drawing off only ſo long as the Water appeared thick or milky, and taſted rich and grateful; whereby we obtained a *Simple Mint-Water* in tolerable Perfection.

The Experiment extended.

25. This Experiment, with a few occaſional Alterations, may ſhew a general Method of obtaining Simple Waters in their greateſt Perfection. The Subjects beſt fitted for it are thoſe of the odorous, aromatic, and oily Kind; tho' ſome others alſo may perhaps communicate particular Virtues to the Water: Among the fitteſt may, however, be reckoned, *Angelica*, *Anniſeed*, *Baulm*, *Calamint*, *Cinnamon*, *Cloves*, *Fennel*, *Hyſop*, *Roſemary*, *Tanſey*, *Wormwood*, &c. but parti-

cularly Pepper-Mint, which affords an extremely aromatic, pungent, and agreeable Water, good againſt the Cholic, and many other Diſorders of the Stomach and Bowels; though its Uſe is, perhaps, too little known.

Cautions. 26. It is a principal Caution, in this Operation, to remove the Receiver before the more pellucid, acid, faint, and dead Water comes over, as it ſoon will do; and if ſuffered to mix among the reſt it is apt to ſpoil the whole, by giving it a vappid or faint Taſte, and ſometimes a Degree of Acidity, or vitriolic Stypticity, and an emetic Quality; for Part of the eſſential Salt of the Plant, which now begins to riſe, uſually corrodes the Copper Head of the Still, and carries over with it ſome Particles of the Metal. Hence theſe Waters ſhould be diſtilled either with a Glaſs Head, or one of Pewter, or well tinned Copper; or elſe the Operation ſhould be carefully watched, that the ſecond Running may not mix with the firſt. The greater Care ſhould be taken, becauſe ſome Patients, more particularly Children and thoſe of a tender Habit, have ſuffered thro' a Neglect herein; and been vomited, purged, and griped by the Uſe of a Simple Water, contrary to the Intention.

Regulation. 27. The Simple Waters diſtilled after the Manner of our preſent Experiment may in many Caſes prove too ſtrong to be uſed alone; but then it is eaſy to let them down to the proper Strength with common diſtilled Water: And this is, beyond all Compariſon, better than to mix ſuch Waters with their own Faints, or Liquor of the ſecond Running.

Improvements. 28. Two Improvements might be made in this Method of obtaining Simple Waters: The firſt, by means of Cohobation and Digeſtion; the other, by means of a previous

vious Fermentation of the Plant. With regard to the firſt; If the Liquor remaining in the Still be expreſſed from the Herb, and returned, along with all the Water that came over, upon a freſh Quantity of the ſame Subject, and they be digeſted together in a gentle Heat for two Days, and then diſtilled as before, the Water thus obtained will be much richer and more efficacious than the former: And if the ſame Proceſs be repeated two or three Times, thoſe who have not tried would ſcarce imagine how rich a Simple Water may be thus procured. This Method we would particularly recommend for making the Simple Water of Baulm, Elder-Flowers, Roſes, Camomile, and ſuch Subjects as are but ſparingly furniſhed with eſſential Oils; for otherwiſe they make but indifferent Waters.

29. The other Means of improving Simple Waters is by uſing a previous, imperfect Fermentation: This is performed by adding to the Plant and Water, put together as in our preſent Experiment, a tenth or twelfth Part of Sugar or Honey, or elſe a fortieth Part of Yeaſt; then ſetting the whole in a warm Place to ferment for two or three Days only, ſo that the Herb may not fall to the Bottom, nor the Fermentation be above half finiſhed: thewhole being afterwards committed to the Still, a Water may, at one Operation, be obtained extremely rich, or impregnated with the full Virtue of the Plant. And thus may Simple Waters be made fit for long keeping without ſpoiling; the ſmall Proportion of inflammable Spirit generated in the Fermentation ſerving excellently to preſerve them. And theſe two Methods ſeem applicable to the Improvement of all thoſe Simple Waters commonly found in the Shops.

 30. We

30. We ſhould next proceed to ſhew the Method of perfecting or improving Compound Waters, if we had not already endeavoured to do it in our *Lecture* upon Diſtillation by an Example in *Citron-Water* *.

EXPERIMENT II.

The beſt Way of making light Tinctures, and Infuſions.

Light Tinctures prepared. 31. We took half an Ounce of the Rind of *Seville* Orange ſhaved thin, half a Dram of Gentian-Root thin ſliced, a Scruple of the Tops of *Roman* Wormwood, half a Dram of Cardamums, and half a Dram of Cochineal, each of them lightly bruiſed: Theſe Ingredients we put to ſteep for a night in a Pint of *French* Brandy, and filtred the Liquor the next morning.

Regulation. 32. This Experiment is general, and not performed for its own Sake, but to ſhew the Method of making all Kinds of the lighter and finer Tinctures and Infuſions without Fire, which would here prove prejudicial. The Preparation itſelf is, however, a good Stomachic Bitter, of the ſame general Nature with thoſe commonly ſold under the name of *Stoughton's Elixir*. The Excellence of theſe Preparations depends not more upon the Choice and Goodneſs of the Ingredients, than upon the Manner of their being infuſed; For if ſuffered to remain too long in the Menſtruum, or if Heat be uſed in extracting the Tincture, the groſs, terreſtrial, and nauſeous Parts of the Ingredients will be fetched out, and the Tincture thus be loaded with a heavy

* See *Lect.* XIII. *Exp.* V.

inert

inert Matter, of little Virtue. But if the Infuſion be made in the Cold, and the Liquor ſtrained off ſoon, only the finer and more ſpirituous Parts of the Ingredients will be imbibed by the Menſtruum; whence the Preparation will not only taſte and ſmell more brisk and agreeable, but alſo have a much greater Virtue and Efficacy. But if, thro' the Shortneſs of their Continuance in Infuſion, the Ingredients ſhould not have ſufficiently impregnated the Liquor, the beſt Method is to pour it again upon freſh Ingredients, and again to ſtrain it off, without letting it ſtay too long upon them, or applying the Heat of the Fire. And thus, by repeated Affuſions of the ſame impregnated Menſtruum upon freſh Ingredients, an Infuſion or Tincture may be obtained, of almoſt any Degree of Strength or Richneſs, without containing the groſſer or more inactive Parts of the Ingredients, but only what may be called their finer Spirit or Quinteſſence. And this is no inconſiderable Secret both in Chemiſtry and Pharmacy; and may deſerve Regard of thoſe who deſire to procure the full Virtues of the Simples, unaltered in their Nature, yet exalted or concentrated to ſuch a Degree, that a few Spoonfuls of the Liquor ſhall contain the Spirit or Quinteſſence of a Pound of a Plant. And this is an Effect not to be expected from the Fire, which almoſt conſtantly alters the Nature of Things committed to it; nor can a valuable Eſſence of Violets, Jaſmin, Lilies, Borage-Flowers, or any Flower or Plant of an extremely fine odoriferous Spirit, be procured by Heat, tho' it readily may by ſteeping theſe Flowers in cold Water, cold Vinegar, cold Wine, or the like; and frequently pouring the Tincture upon

freſh

fresh Flowers, till the Liquor becomes strongly impregnated.

33. Apothecaries usually commit the same Error in preparing the finer Tinctures, that they do in making their Cordial Waters; in both Cases saturating the Liquor with the grosser, more useless, and less spirituous Parts of the Ingredients; whence the Cordial Waters of the Shops too often abound with a gross, heavy, disagreeable Oil; and the Tinctures of the Shops with a gross, heavy Earth, or Kind of bituminous Matter, instead of a brisk, lively, and invigorating Spirit; which alone is the Thing required in both Cases.

34. This Doctrine of Tinctures and Infusions should be reduced to Rule for the Improvement of Chemistry, which will never be perfected till it can extract, separate, and concentrate, the Virtues of Things unimpaired, or unaltered in their Nature. And doubtless it would prove a very serviceable Thing in Chemistry, Medicine, and Natural Philosophy, to know the best and easiest Ways of concentrating the Virtues of Bodies unaltered: And this may, in some Measure, be effected by our present Method, and the Use of well a dapted Menstruums: For, in general, (1) a quick and cold Infusion extracts the Spirit of Vegetables; but a long and hot one confounds, impairs, or destroys it. (2) To repeat quickly thecold Infusion of a fresh Subject in the same impregnated Menstruum, seems greatly to collect and concentrate the Spirit, that is, the finer and more essential Part of Bodies. (3) The proper Menstruums for this Purpose seem to be such as pure Rain-Water, Vinegar, Wine, Water mixed with a little fine Alcohol, Water and a little Sugar; and for certain Uses, the common atmospherical Air, which

which an excellent Menſtruum to extract the Spirit or Effluvia of Plants, as we remarkably find in ſpicy Groves Gardens, and may be uſed with good Effect.

35. But to obtain the ſaturated Tinctures of hard, reſinous, or gummy Bodies, requires a different Treatment, as in the following Experiment.

Solution of Gum Lac.

36. We took two Ounces of that hard *Indian* Roſin called *Gum Lac*, and reducing it into a fine Powder, made it into a Kind of ſtiff Paſte with Oil of Tartar *per deliquium*; we ſet this Paſte in an open Glaſs to dry by a gentle Heat; then removed it to the open Air, that it might relent or grow ſoft; and after this we dried it again as before: By repeating the Proceſs once or twice the hard Body of the Roſin was at length reſolved into a purple coloured Liquor; which being now gently dried, and reduced to Powder, afforded an excellent Tincture, by being boiled for two or three Hours in a tall Glaſs with Alcohol.

The Experiment extended.

57. This Proceſs is almoſt general, or may be advantageouſly uſed for making the Tinctures of *Myrrh*, *Gum Juniper*, *Dragons-Blood*, *Amber*, and other hard, gummy Subſtances, which will ſcarce otherwiſe yield a Tincture in Spirit of Wine. Any Improvement in the extracting Tinctures with Alcohol may tend conſiderably to improve the Art of Pharmacy; becauſe ſuch Tinctures are generally found powerful Medicines, the Spirit of Wine appearing greatly to increaſe the Virtue of the Subjects. Thus, tho' the Tincture of Amber prepared in this Manner appears to be only a bare Solution of the Subſtance of the Amber, yet it is found to have ſuch Effects as are no Way equalled by any fine Powder of Amber: And what ſeems remarkable,

able, tho' ſo large a Quantity of fixed Alkali be uſed in the Preparation of theſe Tinctures, yet they give no manifeſt Signs of containing an Alkali; which is therefore changed in the Operation, either by the Acid naturally contained in theſe reſinous and gummy Bodies, or by being expoſed to the Air, or by both.

Varied. 38. There are other Methods of extracting the Tinctures of theſe hard, gummy Bodies, but that delivered appears to be the beſt; tho' it might perhaps be ſhortened, by uſing ſome proper intermediate Subſtance to divide the Particles of the Subject, ſo as that the alkaline Salt, the Air, and the ſpirituous Menſtruum might all come into fuller contact therewith and act more forcibly thereon. And for this Purpoſe we would recommend pure virgin Earth, ſuch as is commonly uſed for the making of Teſts or Cupels; by Means whereof Spirit of Wine will extract a tolerable Tincture from *Myrrh*, without the Addition of any fixed Alkali.

39. But when Tinctures not ſpirituous, or only aqueous Solutions of theſe hard, gummy Bodies are required, we recommend the Uſe of the ſoluble Tartar, or *Tartarum Tartarizatum*; for a Solution of this Salt will readily diſſolve Myrrh, even in the Cold; as Water diſſolves Gum-Arabic *.

EXPERIMENT III.

The beſt Method of making Syrups.

40. We took three Ounces of the yellow external Rind of freſh Oranges, and infuſed them in a cloſe Veſſel, with a gentle Heat *in Balneo*

* See *Lect.* XIII. *Exp.* V. §. 47.

Mariæ,

Mariæ, for ſix Hours, along with a Pint and a half of pure Water; then ſuffering the Infuſion to cool we filtred the Liquor; and, adding to it twice its own Weight of hard double-refined Sugar, made it into a Syrup, in a cloſe Veſſel ſet *in Balneo Mariæ*. *Syrup of Oranges made.*

41. We could not contrive a general Example to fit all Syrups, becauſe they differ greatly in Reſpect of the Liquors of which they are made; or according as theſe Liquors are Infuſions, Decoctions, natural Juices, Wines, or Vinegars. We choſe to give an Inſtance in a Syrup made of a Liquor by the Infuſion of an aromatic Subſtance, whoſe Virtue would be almoſt intirely loſt if the Syrup were to be prepared by long Boiling, as it is ſometimes directed, with leſs than an equal Weight of Sugar. Diſpenſatory-Writers have perhaps no where erred more remarkably than in directing the Making of Syrups; which ſeems the more ſtrange, becauſe this Part of Pharmacy is extremely facile. The Misfortune ſeems to have lain here, that great Men cannot ſubmit to conſider common and ordinary Things: nevertheleſs the Credit of a Phyſician may ſink in the Eſteem of thoſe who by their Employment are led to a Knowledge of theſe ordinary Things. *Uſes.*

42. We judge that the Whole of this Buſineſs may be reduced to a few eaſy Rules, which we ſhall here endeavour to lay down for improving this Branch of Pharmacy. And (1) It is Matter of Experience that aqueous Infuſions, Decoctions, or other aqueous Liquors, require twice their own Weight of dry Sugar-Candy to make them into a Syrup of a juſt Conſiſtence for keeping, without candying or fermenting. This Rule, by directing the Uſe of *Sugar-Candy*, ſeems to fix the Conſiſtence of Syrups with Exactneſs; *Rules.*

neſs; becauſe all Salts acquire a determinate Proportion of Water in cryſtallizing; ſo that Sugar in the Form of Candy conſiſts of one certain Proportion of Water, whilſt different Kinds may hold more or leſs aqueous Matter, according to the Manner of refining, the Accidents of Weather, &c. Hence therefore all ſuch Infuſions for Syrups as are of a delicate or deſtructible Colour, which is impaired by boiling (for Example, Violets, Clove July-Flowers, &c.) and all ſuch Infuſions as contain any volatile Parts, which would evaporate by a boiling Heat, (for Example, thoſe of Nutmeg, Cinnamon, Orange-Peel, Citron-Peel, &c.) ſhould have twice their own Weight of Sugar added to them, and be kept cloſe covered in the gentle Heat of a *Balneum Mariæ*, till the Sugar is diſſolved; to haſten which the Sugar ſhould befirſt reduced to fine Powder.

43. (2) The Decoctions of ſuch vegetable Subſtances as loſe no valuable Parts by boiling, may be boiled down to the Form of a Syrup along with their own Weight of Sugar; the two being firſt clarified together with Whites of Eggs in the ordinary Way: But if the Ingredients here contain any unctuous or balſamic Parts on which their medicinal Virtues depend, let the Sugar be added from the firſt, and boiled along with the Ingredients; afterwards ſtraining and clarifying the Decoction, before it is boiled to near the full Conſiſtence of a Syrup. This Rule is founded upon that remarkable Property which Sugar has to diſſolve Oils, or the finer reſinous Subſtances, ſo as to make them intimately mix with Water. Whence it may deſerve to be conſidered whether the *Syrup* of *Myrtles*, *Comfrey*, and *Diacodium* ſhould not be thus prepared. It muſt alſo be obſerved that

by

by boiling the Sugar ſo long with the Decoction the aqueous Part exhales, and leaves the Syrup much ſtronger than it could have been made without this boiling.

44. (3) All vegetable Juices are to be thoroughly purified before they are made into Syrups. Thus the Juices of Citrons, Lemons, and Oranges are to paſs the Filtre, and then be made into Syrups, without boiling, according to the firſt Rule; obſerving to uſe no metalline Veſſel about them. But the Juices of Fruits, as particularly Mulberries, Rasberries, *&c.* will not clarify without a beginning Fermentation; but by ſtanding for a Day or two they will begin to ferment and liquify, and may then be commodiouſly ſtrained thro' Flannel; after which theſe alſo are to be made into Syrups with about an eighth Part leſs than twice their own Quantity of Sugar, or with two Pounds and twelve Ounces of Sugar to a Pint of Juice, on account of their being ſomewhat ſaccharine themſelves. And this holds alſo of Wines and Vinegars, when they come to be made into Syrups; for Wine contains an inflammable Spirit which does not incorporate with Sugar; and alſo a thick ſyrupy Subſtance, which is found in Vinegar likewiſe. By a due Application of theſe Rules we apprehend the Buſineſs of making Syrups may be brought to tolerable Perfection.

Experiment IV.

The beſt Method of making Electuaries, by an Example in the Saſſafras-Electuary.

45. We took two Ounces of the beſt Saſſafras newly raſped, and half an Ounce of Cinnamon finely powdered; theſe Ingredients we boiled in a tall *The Saſſafras Electuary made*

a tall Glaſs in a Sand-Heat, with ten Ounces of Water and fourteen Ounces of Sugar, ſo as that nothing might evaporate, for two Hours; then ſtraining and preſſing out the Syrup, we added to it an Ounce of freſh raſped Saſſafras, a Dram of Cinnamon, and ten Grains of Nutmeg, both reduced to fine Powder; and made the Whole into an Electuary.

Regulation. 46. In the common Method of making this Electuary the Saſſafras and Cinnamon are boiled in the Water, whereby a great Part of their Virtue is loſt or not extracted: Whence the Medicine comes to be defrauded of its Due. But here, by boiling the Ingredients in a tall Glaſs, with a due Proportion of Sugar and Water, to make a Syrup (allowing an extraordinary Proportion of Water for what the Saſſafras will drink up) we obtain the fine aromatic Virtues of the Ingredients to Advantage, without any conſiderable Loſs.

Rules. 47. To make Electuaries in Perfection where a Syrup is employed as their Baſis, (1) the Syrup ſhould be prepared in the Manner above delivered *, ſo as that the Virtues of the Ingredients may be preſerved; (2) the Powders, or Species employed, ſhould be freſh and fine ground; (3) the Gums, where any are uſed, muſt be well cleanſed, and diſſolved in their proper Menſtruums; and (4) the Whole muſt be mixed, or thoroughly united, into a ſmooth, uniform Subſtance, of a due Conſiſtence for keeping, without either candying or running into Fermentation.

48. (1) Where Syrups are uſed in the making of Electuaries, care is not only required that the Virtues of the Ingredients of the Syrups be

* *Exp.* III.

pre-

preſerved as much as the Form will allow of, but alſo that its Conſiſtence be not too high; for this would diſpoſe it to candy in the Electuary, and render the Medicine unduly mixed, or knotty; the Sugar concreting together in Lumps, or ſhooting away from the Species. Again; If the Syrup be made too thin or aqueous, ſo as not to ſuſpend and hold the Powders together by a binding Conſiſtence, it will of Neceſſity ferment in hot Weather, and become firſt ſomewhat vinous, afterwards ſour or acetous, and at length corruptive *a*); ſo as to change, invert, or deſtroy the Nature of the Medicine: For purgative Ingredients, by Fermenting, loſe their purgative Virtues; and all other Ingredients, by Corrupting, are reduced to an inert Kind of Fæces or *Caput mortuum*, very different from the Thing intended *b*). And hence Electuaries that have thus fermented, or changed their Nature, may ſometimes prove pernicious, inſtead of ſalutary.

49. The Electuaries made with the Pulp of Fruits are leſs diſpoſed to keep, for any conſiderable Time, perfect, on account of the greater Tendency which ſuch pulpy Subſtances have to Fermentation and Putrefaction. Thus, tho' the *Lenitive Electuary* were made ever ſo artificially, it will ſcarce keep many Months without altering its Nature; but eſpecially if the Conſiſtence was originally too thin: Whence ſuch Electuaries ſhould be made in ſmall Quantities, or freſh as they come to be wanted.

50. But this does not equally hold of the *capital Electuaries*, ſuch as *Venice-Treacle*, or *Mithridate*; which require to lie for ſome Time, that the Ingredients may digeſt, or ripen, as it were,

a) See *Lect.* X. *paſſim.* *b*) See *Lect.* VII.

and grow mellow together; for the Gums and Spices that enter these Compositions preserve the Medicines from Alterations for the worse, and the Mixture becomes more perfect by Time; provided the Honey used in their Composition do not candy, or the Whole become too dry. To keep the Honey from candying, some Artists mix the Spices and Gums with it unclarified; only taking Care to separate the foul Parts that lodge either at the Top or Bottom. And if the Medicines prove too dry, it is usual at any Time to soften, or beat them up in a Mortar, with *Canary*: And thus these Capitals of the Shops are supposed to improve by keeping. But *Diascordium*, having few of the warm Gums in its Composition, is more apt to alter, and lose of its astringent or styptic Quality by keeping: For which Reason it seems an Alteration here for the better, to use a Quantity of *Saccharum rosatum* instead of Honey, or *Diascordium*; as this not only gives a greater Compactness to the Medicine, but also contributes to preserve its Colour and Virtues.

51. (2) The Powders, or Species, that enter the Composition of Electuaries, should be fresh, because they lose of their Virtue by keeping; and they should also be fine ground, because they would not otherwise intimately mix with the Honey or Syrup, nor so readily part with their Virtues in the Stomach, nor render the Medicine so agreeable to the Eye. The common Method of reducing these Powders to a sufficient Degree of Fineness, by the Mortar and Searce, is faulty; because this Method exposes them too long to the Action of the open Air; whereby their more volatile and grateful Parts are carried off, whilst only the grosser are left behind: it might therefore be proper to have a close Engine

Engine contrived for the Purpoſe, ſo as to prevent this ill Effect.

52. Some Artiſts grind their Powders for Electuaries by Means of a Horſe-Mill; but the Mill-Stones here wear off, and communicate a gritty or ſtony Matter to the Ingredients, ſo as to prove diſagreeable in the Mouth, and ſomewhat increaſe the Bulk of the Medicine, without adding to its Virtues. Nor is this Method, by the Mill, free from the Inconvenience of the Mortar; for the finer or more ſpirituous Parts of the Ingredients alſo fly off; as is ſenſibly found by the whole Neighbourhood where any large Quantity of the Ingredients for *Venice-Treacle*, *&c.* is ground by the common Horſe-Mill. *Improvements.*

53. (3) The better Way doubtleſs is, by the Means of Iron Rollers, moving oppoſite to each other in a cloſe Box, to grind all the Ingredients, *viz.* the purified Gums, the Roots, Herbs, Flowers, *&c.* along with the Honey and Wine, after the Manner of the new invented *Chocolate-Engine*; for thus the fine, volatile, and aromatic Parts of the Ingredients may, as well as the groſſer, been tangled with the Honey and Gums, and all at once be mixed uniformly together into a ſmooth Maſs of a due Conſiſtence.

54. (4) But perhaps a much better, though more troubleſome, Method would be, to get out the full Virtues of the Ingredients, without any of their groſſer Parts, in the Form of Extracts, eſſential Oils, *&c.* and to mix theſe Oils, Extracts, Gums, Roſins, *&c.* together, with a ſuitable Proportion of Honey, *&c.* ſo as at once to perfect and concentrate the Medicine; which might therefore be given in Doſes of an agreeable Smallneſs, with all the Advantages that can well be expected. And the ſame Method ſeems alſo applicable to the making of *Pills* and *Troches*.

EXPERIMENT V.

The best Methods of making the compound Oils, Unguents, Cerates, and Plaisters.

Oils, or Liquid Balsams. 55. We took twelve Ounces of fine Sallad-Oil, half a Pint of *Canary*-Wine, and half an Ounce of Dragons-Blood reduced to fine Powder; these we boiled together, over a gentle Fire, till the Wine was exhaled; and thus obtained a fine red Oil, or liquid Balsam. *Consistent Balsams.* (2) To one Half of this Oil we added four Ounces of yellow Bees-Wax, six Ounces of *Venice* Turpentine, and dissolved them together over the Fire; then removing the Vessel into the Cold, we added half an Ounce of Balsam *Peru*; and thus made a red Ungent, or better Sort of *Lucatellus*'s Balsam. *Cerates.* (3) To the other Half of the red Oil we added a due Proportion of Wax; so as when cold to give it the Consistence of a Cerate, or soft Plaister: *Plaisters.* And (4) By adding more Wax, and a Proportion of Rosin, we made the Cerate into a Plaister of a hard Consistence.

The Experiment extended. 56. This Experiment at once shews us the Method of preparing the compound Oils, Unguents, Cerates, and Plaisters. The making of compound Oils, in general, depends upon boiling certain Ingredients, as particularly recent Herbs well bruised, or else their Juices, in Oil, till the aqueous Moisture is exhaled (as the Wine was in the present Experiment) and the Plant become almost crisp; at which Time the Vessel must be removed from the Fire, and the Oil squeezed from the Herb by Means of a Screw-Press.

And applied. 57. This Oil is now to be set over the Fire again, that its remaining aqueous Moisture may exhale,

exhale, and the groſſer Parts of the Whole ſubſide; whereby the Oil will become not only more beautiful in Colour, but alſo more durable, or keep the better from turning mouldy. If the Pan be not removed from the Fire before the Herb is grown criſp, the Oil will be in Danger of turning black, or being burnt; which both ſpoils the Colour, and gives a diſagreeable Odour. If theſe Cautions are duly obſerved, the common compound Oils, by Decoction, may be obtained in their intended Perfection; as Oil of Camomile, Elder, Roſes, Earth-Worms, *&c.* And after the ſame Manner are ſeveral compound Ointments made, by boiling Herbs along with Lard, or Suet; as the Ointment of Elder, Populeon, Nerve-Ointment, Melilot-Suet, *&c.*

58. The red Oil, obtained in the firſt Step of our preſent Experiment, ſhews how liquid compound Balſams are procurable by diſſolving reſinous Gums in Oil, over the Fire. And in this Manner a fine Balſam may be made with *Gum Elemi*, and tinged beautifully red with Dragons-Blood, or an Infuſion of Alkanet-Root in Oil. And upon the ſame Foundation might ſeveral excellent liquid Balſams be prepared for chirurgical Uſes.

59. Powder of Red Saunders has been commonly uſed, inſtead of Dragons-Blood, in the making of *Lucatellus*'s Balſam; but doubtleſs Dragons-Blood is much better ſuited to the Intention of a Balſamic, a Healer, and Detergent; and alſo improves the Colour of the Medicine: Tho' Red Saunders may be made to give a very good red Colour to the Balſam, by infuſing the Powder cold for two or three Days in White Wine; which opens the Body thereof, exalts the Colour, and renders it communicable with Advantage to the unctuous Ingredients.

But this End may be more expeditiously answered by infusing a little Alkanet-Root in the Oil.

60. The Consistence of an Unguent is given either by using animal Fats, as Lard and Suet, or by the Addition of Wax, Rosin, Pitch, dry Powders, metalline *Calces*, *&c.* and by adding a smaller or larger Proportion of these solid or dry Ingredients, we obtain the Consistence of a Cerate, or Plaister, respectively. When hard animal Fats are used, the Process differs not from that for making the compound Oils*; and where Wax, Rosin, *&c.* are employed, the Management is the same as in the present Experiment, where the Consistence of the Oil is thickened into that of a Balsam by Wax.

61. When dry Powders, or metalline *Calces*, are used in the making of Ointments, the Powders should be fresh and fine ground, and the metalline *Calces* made more subtile by Triture; after which the Whole may be mixed smooth together, or beat up in a Mortar: And thus the *Unguentum album*, *Desiccativum rubrum*, *Diapompholygos*, &c. are readily prepared.

62. The Plaisters made with metalline *Calces*, such as *Diachylon*, and *de Minio*, require no Wax or Rosin to give them an emplastic Consistence; the bare Solution of the metalline *Calces*, or the Litharge, and Red Lead, by boiling in the Oil, being sufficient for the Purpose. Thus, if half a Pound of Red Lead, half a Pint of Vinegar or Water, and twelve Ounces of Oil, be boiled together over a gentle Fire, with continual Stirring, till the aqueous Moisture be consumed, and the Red Lead entirely dissolved; the Matter, when cold, will be of a hard, emplastic Consistence, and differently coloured, or red,

* See above §. 55.

brown,

brown, or black, according as it was more or leſs boiled.

63. In the making of Plaiſters with metalline Powders and Oils, it is always proper to add Water or other aqueous Liquor, to keep the Mixture from burning, or turning black, before the due Conſiſtence is gained, or the requiſite Diſſolution made. But here great Care muſt be had, not to throw in cold Water, if that added at firſt be exhaled before the Operation is finiſhed; for this would be dangerous, by cauſing the Matter to crackle, fly about, and boil over with great Violence: But if the Water be added in the State of boiling, it occaſions no Tumult; and may be thus uſed with Safety.

64. When aromatic Species, native Balſams, or eſſential Oils, are ordered in Unguents or Plaiſters, Care muſt be taken to add ſuch Ingredients towards the End of the Operation, when the Veſſel is removed from the Fire; becauſe the Heat of boiling Oil, *&c.* would cauſe the fine aromatic or odoriferous Parts of the Ingredients to exhale, and be loſt to the Unguent or Plaiſter. The ſame Caution ſhould be likewiſe extended to the *Cantharides* uſed in the *Paſta epiſpaſtica*, &c. and to other Bodies of a delicate Texture, whoſe more efficacious Parts are exhaled by Heat. And by the due Obſervation of theſe few Rules and Cautions, the common compound Oils, Unguents, Cerates, and Plaiſters, may be made in conſiderable Perfection.

AXIOMS *and* CANONS.

1. We learn from the preceding Enquiry, That ſome Part of the Salts of Plants, as well as their Oils, will riſe by Diſtillation with Water, and give an acid or alkaline Nature to the

ſimple Waters thus prepared, according to the Nature of the Plant *a*).

2. That no Simple Waters ſhould be diſtilled ſo low, as to bring over any remarkable acid or alkaline Liquor from the Plant; for fear of miſchievous Effects, or making ſuch Waters prove emetic or purgative, contrary to the Intention *b*).

3. That the Virtues of Simple Waters chiefly depend upon their containing the eſſential Oil of the Plant *c*).

4. That there are two Methods of perfecting Simple Waters; *viz.* Cohobation, and Fermentation *d*).

5. That all Tinctures and Infuſions of Ingredients, whoſe principal Virtues depend upon their lighter, or more ſubtile and ſpirituous, Parts, ſhould not be made with Heat, but in the Cold *e*).

6. That if ſuch Tinctures or Infuſions be required rich and ſtrong, they are to be made ſo, not by ſuffering the Menſtruum to remain long upon the Ingredients, or by the Uſe of Heat; but by adding freſh Ingredients ſeveral Times to the ſame Liquor; infuſing them quick, and each Time keeping out the Ingredients that have once been uſed *f*).

7. That the Fire is apt to exhale, alter, or conſume the more ſubtile and ſpirituous Parts of Vegetables; and therefore unfit to be uſed where theſe more delicate Parts are required *g*).

8. That the Buſineſs of Infuſions and Tinctures may be greatly improved by extracting the efficacious, or more ſpirituous Parts of Vegetables, unaltered in their Nature; yet con-

a) *Exp.* I. *b*) ib. *c*) ib. *d*) ib. *e*) *Exp.* II. *f*) ib. *g*) ib.

centrated,

centrated, or brought together into a moderate compaſs.

9. That rich Tinctures may be extracted, with Spirit of Wine, from the hardeſt reſinous and gummy Bodies hitherto known, by Means of fixed Alkali properly applied *a*).

10. That even aqueous Solutions may be made of the ſame Kind of Bodies, by Means of the *Tartarum tartarizatum*, or ſoluble Tartar *b*).

11. That the Ways in common Uſe for the making of Syrups, Electuaries, compound Oils, and Plaiſters, are improveable by the Obſervance of a few eaſy Rules *c*).

12. That, therefore, there are grounds to expect ſome Improvement of the common Pharmacy, upon the footing it now ſtands, barely by perfecting the Methods of preparing the Shop-Medicines in Uſe, without either retrenching their Number, or introducing new ones; that is, by reducing the Art to a greater Simplicity.

a) *Exp.* II. *b*) ib. *c*) *Exp.* III. IV. V.

LECTURE XVI.

CONTAINING

Attempts for reducing PHARMACY *to a greater degree of Simplicity and Efficacy.*

The Subject. WE now proceed to consider how Pharmacy may be reduced to Simplicity; which in Arts appears to include Perfection.

The Simplicity of Pharmacy. 2. The Simplicity of Pharmacy seems to consist in supplying a few powerful, parable, safe, and agreeable Medicines, for the Cure of Diseases.

The Fate of Medicines. 3. Those versed in the History of Physic observe that Remedies have their Run, or Revolutions of Fate and Fortune; many of them being highly esteemed or magnified for a Season, and afterwards thrown aside and neglected.

4. Not to mention the Medicines celebrated by the Ancients, there are Numbers of others which have had their Revolutions almost within our own Memory. The *Elixir Proprietatis* of *Paracelsus*, the *Liquid Laudanum* of *Helmont*, the *Sal volatile oleosum* of *Sylvius*, the *Aperitive Tincture* of *Mœbius* *, the *Antihectic* of *Poterius*, the *Aqua benedicta*, or *Vinum emeticum*, of *Rulandus*, the *Bezoardic Powder* of *Sennertus*, Ceruse of Antimony, and many more, have been extrava-

* That is, Spirit of common Salt neutralized with Salt of Tartar, and tinged with Red Roses.

gantly

gantly valued in their Time; but are now ſunk in the Eſteem of Phyſicians. And thus perhaps our preſent Opiates, our Salt of Vipers, our Pearls, our Bezoar, our *Aurum fulminans*, &c. may loſe their Credit hereafter, or give Way to others of no greater Efficacy.

5. If we enquire into the Cauſe of this Inſtability in Pharmacy, it does not appear owing to the Medicines themſelves, but rather to the Inattention, Levity, and Raſhneſs of Men: Inattention, in not ſufficiently regarding and diſtinguiſhing between the Kinds and Differences of Diſtempers and Conſtitutions; Levity, in preſently changing one Medicine for another, if the expected Effect is not ſoon procured; and Raſhneſs, in uſing ſuch Medicines as come recommended by incompetent Judges, or unfair Repreſenters. *Cauſe of their Fate.*

6. If the Cauſe were owing to any Changes in the Medicines themſelves, we could have little Hopes of redreſſing the Evil; but as it is owing to ourſelves, we are hence encouraged to look out for a Remedy.

7. The Art of forming a ſound Judgment of the Succeſs and Virtues of Medicines is ſo little known, that the Mind uſually fluctuates therein, as being deſtitute of a ſecure Foundation; and conſequently is led by Rumour, Opinion, and Example, inſtead of the true Light ariſing from careful Obſervation, and well digeſted Experience. Whence it frequently happens that unlucky Events are attributed to uſeful Medicines; whilſt ſuch Events were really owing to ſome other Cauſe. *Regulation.*

8. This Inattention is ſucceeded by Levity and Raſhneſs: For when a Medicine thus fails to anſwer the Expectation conceived of it, it is uſual to reject it with Contempt, and immediately to ſeize

ſeize, in its Stead, the firſt new one that comes ſtrongly and vehemently recommended; which again, after Trial, is frequently rejected in the ſame Manner as the former. And thus the Lives of Phyſicians are often ſpent in flying from one Medicine to another, without fixing upon thoſe that are ſtable, or ſuch whoſe Virtues are duly determined and aſcertained.

9. This perverſe Temper or ill Habit of the Mind muſt therefore be cured; or elſe Phyſicians will continue to fluctuate, and never bring Pharmacy to a State of Perfection.

10. The Way of rectifying this ill Habit, we apprehend, is to acquire a Competency of ſound and fundamental medicinal Knowledge, by keeping ſteady to the Uſe of a few ſimple Medicines; which are eaſily prepared, no way hazardous, and yet powerful in their Effects: And to ſhew the Way of procuring a few ſuch Medicines, is the Deſign of our preſent Lecture.

11. We judge that all Medicines are commodiouſly reducible to four general Claſſes; *viz.* *Evacuants*, *Alterants*, *Strengtheners*, and *Quieters*: For as all the Cauſes of Diſeaſes muſt regard either *Quantity*, *Quality*, or *Motion*, the Medicines adapted to theſe Cauſes will be either *Evacuants*, *Alterants*, *Augmenters*, or *Appeaſers* of Motion in the Body.

12. It muſt, however, be obſerved, that under each of theſe general Tribes of Medicines there are ſome better adapted than others to the Diſeaſes of particular Parts. Thus it is Matter of Obſervation, that Mercury particularly affects the ſalival Glands, Cantharides the Bladder, &c. all which Remedies are to be collected, as ſo many particular Inſtances, under our reſpective general Heads of Medicines. And by duly proceeding in this Manner, it ſhould ſeem that

we

we might eaſily fix upon a ſmall Collection of Remedies, able, with a proper Regimen, to cure the ordinary Diſeaſes.

13. At leaſt, by throwing out of our preſent Collection ſuch as are certainly found to be of ſmall Efficacy, or certainly dangerous, we might greatly retrench the preſent Set of *Officinals*, and bring the more ſerviceable of them within the Compaſs of a *portable Cheſt*. And with this View we ſhall endeavour to point out ſome of the more efficacious, parable, ſafe, and agreeable Evacuants, Alterants, Strengtheners, and Quieters; all along fixing a Mark upon thoſe which we take to be either unſafe or inſignificant.

14. Our firſt Experiment will ſhew a Method of procuring a ſafe Emetic; the ſecond will ſhew how to prepare a ſafe Purgative; the third how to prepare a ſafe Perſpirative; the fourth how to prepare a ſafe Alterant; the fifth how to prepare an innocent Strengthener; and the ſixth how to obtain a powerful Quieter, or Anodyne.

EXPERIMENT I.

An eaſy and ſimple Method of obtaining a ſafe and gentle Emetic.

15. Two Drams of the common white Ipecacuanha being reduced to fine Powder, and infuſed for two or three Days in half a Pint of white *Lisbon* Wine, in the Cold; if the clear Liquor be decanted, freſh Wine may be added to the remaining Powder, ſo as to extract all the Virtue, which it will thus yield to Wine in the Cold. *An Emetic prepared.*

16. This Infuſion of Ipecacuanha in Wine appears to be the moſt ſafe, gentle, and agreeable Emetic hitherto known: Whence it may in moſt Caſes be properly ſubſtituted for the *Vinum benedictum* *Uſes.*

dictum, the *Tartarum emeticum*, and the other antimonial Emetics; which are all attended with ſome Degree of Virulency and Uncertainty in their Operation.

Ipecacuanha analyſed 17. The Ipecacuanha Root, upon a proper Analyſis by Means of Water and Spirit of Wine, is found to contain a direct ſaline and reſinous Part, whereof the ſaline is the larger; whence even an aqueous Infuſion of the Root will largely extract its Virtues: So that a ſtrong White Wine ſeems a Menſtruum well adapted to the Extraction both of its ſaline and reſinous Parts, on account of the large Proportion of Water, and a leſs of inflammable Spirit, that it contains. Add to this, that Emetics, as well as Purgatives, are found to act the freer, eaſier, and quicker, when joined with Wine, or other ſtrengthening ſpirituous Vehicle. However, after both Water and Spirit of Wine have ſucceſſively acted upon this Powder, it ſtill retains ſome Virtue; ſo that its Power is greateſt when given in Subſtance: Whence our preſent Method of extracting a Tincture from it with Wine only abates its Violence, and, in ſome Meaſure, moderates its Operation; ſo as to fit it for weak Conſtitutions, or render it almoſt univerſally ſafe.

Not improved by Chemiſtry. 18. This Root may, therefore, paſs for one of thoſe Simples which are little or nothing improved by a chemical Treatment; Nature ſupplying it almoſt ready prepared to our Hands, ſo as to require no more than drying and Reduction to Powder, at moſt no more than a bare Infuſion in Wine, to render it a ſafe Emetic.

Farther Uſes. 19. Now, being once poſſeſſed of ſuch an Emetic as this, which ſeems to include the Excellencies of all thoſe of the ſame Tribe, it is doubtleſs proper to practiſe the *Method of Rejec-*

tion

tion upon the rest; or at least to examine whether any of them deserve to be retained and kept in the Shops.

20. We observed above *, that the common antimonial Emetics, of which there is a great Variety, are virulent, or in some Degree poisonous; and therefore not to be trusted, when safer can be procured to answer the End. 'Tis true, some Practitioners have ventured to give Arsenic itself, in the Quantity of a few Grains, as an Emetic; and thus it sometimes operates violently, after the Manner of the emetic Preparations of Antimony, which are nearly allied thereto. But as we certainly know, by many fatal Instances, that Arsenic is a virulent Poison, even in a small Dose; it may seem a Kind of Madness to use it as an Emetic, when Ipecacuanha is at Hand. And the same is to be understood, tho' in a less Degree, of the *Mercurius Vitæ*, Glass of Antimony, Antimonial Cups, the Perpetual Pills, the Sulphurs of Antimony, and indeed all other drastic Emetics; which have a direct virulent Virtue, and, if given in too large a Dose, produce poisonous Effects. And here we do not except *emetic Tartar* itself; which, unless prudently diluted with Wine or some Cordial Water, is apt to prove not only uncertain and churlish in its Operation, but sometimes virulent or poisonous; especially when exhibited in a dry Form, as in that of Pills, Powder, or Bolus: For all antimonial or other metalline Emetics, coming in a dry Form into the Stomach, seem to lodge in its membranous Coats, and stimulate and corrode them; so as to occasion Spasms, Convulsions, &c. after the Manner of Poisons. *Poisonous Emetics.*

* §. 16.

21. And

Regulation. 21. And tho' Solutions of Vitriol, Verdigreaſe, and various Preparations of Copper, have been, and ſtill continue to be, uſed as Emetics, and generally operate quick; yet we cannot judge ſuch Preparations ſafe, or any way comparable to Ipecacuanha for Safety. And even theſe cupreous Emetics, when given in a large Doſe, have a corroſive Effect upon the membranous Parts of the Stomach; ſo as to prove, in a leſs Degree, poiſonous. And thus, if the whole Tribe of Emetics were carefully examined, and their Effects noted from competent Experience, we judge they would moſt of them be found unſafe or dangerous; and conſequently deſerve to be baniſhed the Shops, as Emetics, whilſt their Place may be ſo well ſupplied by Ipecacuanha. And this Method of Examination and Rejection being duly practiſed, might, as we apprehend, thin our Shops, and reduce the Bulk of our Pharmacopœias, to the great Advantage of Pharmacy and Medicine.

EXPERIMENT II.

An eaſy Method of procuring a ſafe and effectual Purgative.

A Cathartic prepared. 22. If in a Quart of *Dulwich*-Water we diſſolve an Ounce of fine Manna, and half an Ounce of black Tamarinds, then ſtrain off the Liquor clear, we ſhall obtain an agreeable purging Ptiſan, or cathartic Liquor, in a Doſe ſufficient for a full-grown Perſon of an ordinary Conſtitution; the Whole being drank at ſeveral Draughts, in the Space of about an Hour and half, or two Hours.

23. It appears to be Matter of Obſervation, that the common purging mineral Waters operate with

with more Ease, Gentleness, and Safety, than almost any Cathartics of the Shops; and only require to be concentrated by boiling, or quickened, in some Cases, to prevent the Trouble of taking two or three Quarts for a Dose. Our present Experiment, therefore, shews the Method of quickening these Waters, by the Addition of innocent Purgatives; such as are *Manna*, *Tamarinds*, *Epsom-Salt*, *Tartarum tartarizatum*, *Tartarum vitriolatum*, &c. *The mild Cathartic preferred.*

24. The Shops and common Dispensatories abound with purgative Medicines, many of them drastic, or violent, and some of them virulent, or almost poisonous; of which Kinds we reckon *Rosin of Jalap*, *Elaterium*, *Scammony*, *Gamboge*, *Coloquintida*, *Asarum*, &c. all which are of a caustic Nature, when given crude and alone, so as to prove mortal in a large Dose: Whence we apprehend that the crude and separate Use of all such Purgatives should be banished; especially as there are numerous Instances of their deleterious and poisonous Effects, and as we are abundantly provided of safer and more gentle Kinds; for Example, *Rhubarb*, *Manna*, *Tamarinds*, *Cassia*, *Cremor Tartari*, *Epsom-Salt*; and particularly the purging *mineral Waters*. Or if the Use of the more violent purging Simples be still retained, let them at least be boiled in Water; which is a certain way of rendering them milder, and discharging a great Part of their Malignity. And for the purgative Rosins, particularly those of Jalap and Scammony, we would recommend them to be ground fine, and beat into a Paste, with twice or thrice their Quantity of blanched Almonds; which, by their oily Matter, dissolve the Texture of these Rosins, and render them more safe and innocent *. *The violent to be rejected.* *Or rendered milder.*

* See below *Exp.* III.

25. But we do not apprehend that the Art of Medicine has any Occafion for thofe violent Purgatives. Certainly violent Purgatives are feldom proper, and generally prejudicial. If the ftronger be ever required, we would, inftead of the former virulent Kind, recommend the fimple Powder of Jalap-Root; which is found to operate much more mildly, and with greater Certainty and Effect, than its Rofin, Tincture, or other chemical Preparations of the Root; which is alfo the Cafe of *Mechoacan* and *Rhubarb*.

26. We defire it may be remembered, that the deleterious or poifonous Nature of the violent Purgatives above mentioned is much greater in the Body than that of the poifonous Emetics; doubtlefs becaufe fome Part of thefe Emetics is foon thrown up again by the Stomach; whereas the Purgatives defcend to the Inteftines, and mix with the Juices of the Body: Whence we have a ftronger Reafon for rejecting the Ufe of thefe virulent Purgatives, than the Ufe of the virulent Emetics.

Regulation.

27. And thus we conceive the Matter of Purgatives may be reduced to a tolerable Degree of Simplicity; yet fo as to leave Variety enough for fuiting the different Difeafes and Conftitutions where Purging is required. The Nature of our Defign will only permit us to indicate, as we go along, the Heads of this general Enquiry into the Means of reducing Pharmacy to an elegant and ufeful Simplicity; the Introduction whereof is not to be expected from private Hands.

EXPERI-

Experiment III.

A facile and simple Method of preparing a safe and effectual Sudorific.

28. If an Ounce of refined Camphire be beat, and ground, in a Marble Mortar, with two Ounces of blanched Almonds; the Camphire will be thus subtilly divided, and brought into an uniform Mass, fit for the forming of Pills, Boluses, *&c.* so as to be commodiously taken in the Way of a Sudorific, Discutient, or Perspirative Remedy; the Dose whereof may be assigned betwixt the Limits of three Grains and forty. *A Sudorific prepared.*

29. Sudorific, Perspirative, and Alexipharmic Medicines, make a large Part of the common Dispensatories: We judge that their Places may be advantageously supplied by a few powerful ones of approved Virtues; among which we esteem this of Camphire as a principal one, or at least superior to *Gascoign*'s Powder, *Lapis Contrayervæ*, *Bezoar*, &c. whose Virtues at best appear to be small. *Uses.*

30. We are sensible that the Qualities of Camphire are not universally agreed on by Physicians; some esteeming it hot, and others cold; some of great, and others of little Efficacy. However, the Case is not to be decided by Authorities, but Experience; which seems to declare that Camphire is one of the most powerful, most immediate, and most innocent Perspiratives, Sudorifics, and Alexipharmics hitherto known: For a large Dose of it, suppose a Scruple or more, being dissolved in Spirit of Wine, and given to a healthy Person, does not increase the Pulse, or excite a præternatural Heat; but rather causes a remarkable

Coolneſs and Compoſure, with a gentle Sweating, or Increaſe of Perſpiration. So little have the Virtues of this Medicine been underſtood; or ſo little can the Virtues of Medicines be deduced from their apparent Properties, or from reaſoning a *priori*!

31. The natural and medicinal Hiſtory of this Drug well deſerves to be traced: It appears to be an eſſential Oil, of peculiar Properties; tho' ſome would have it a Roſin, and others a Gum. Certainly it ſtands alone, as a Thing *ſui generis*; or a Body wherein the Nature of Roſins, Gums, and eſſential Oils, all meet in ſome Degree. It is perhaps one of the moſt diſcutient and ſubtile Remedies hitherto diſcovered: Whence it proves highly anodyne, perſpirative, and preſervatory. And we judge, from certain Obſervations and Experiments, that if the full Virtues of this Concrete, both internal and external, were ſufficiently known, it might ſupply the Place of numerous other Drugs and Preparations, to the Eaſe and Advantage of Pharmacy.

Farther Uſes.

32. In particular, we would recommend this Medicine to be uſed inſtead of the common ſudorific Decoctions of the Woods, in Caſes both of the recent and inveterate *Lues Venerea*: It may alſo be advantageouſly mixed along with the Balſams, or fine Turpentines, commonly uſed at the cloſe of that Diſtemper. In ſhort, we recommend it in all inflammatory, putrid, peſtilential, and even maniacal, Diſeaſes. And whoever has the Secret of prudently joining this ſimple Medicine along with Nitre, may, as we apprehend, perform Cures ſcarce to be expected from other Medicines frequently uſed for the ſame Purpoſes.

EXPERI-

Experiment IV.

An easy and simple Method of procuring a safe and powerful Alterant.

33. If an Ounce of well purified Nitre, and two Scruples of Cochineal in Powder, be boiled in five or six Ounces of Water; and the Solution be filtred, and afterwards evaporated to Driness, keeping the Matter stirring as it thickens; a fine red or purple Powder will be left behind; that is, the Nitre will be thus disguised, aud reduced to a Form fit for taking in the Way of Bolus, Powder, or Solution, with any convenient Vehicle. *An Alterant from Nitre.*

34. Nitre thus prepared, in order to conceal so common a Thing, we judge to be an extremely safe and useful Alterant, capable of producing considerable Effects in the Body, without causing any disturbance, or sensible Evacuation, unless in the Way of a Diuretic; in which Respect it operates as an Evacuant. *Uses.*

35. It is remarkable of Nitre, that it may with Safety be injected into the Blood. *Malpighi* injected six Ounces of its Solution into the Jugular Vein of a Dog, without observing any other Effect than its proving diuretic. It is farther observable of it that it heightens the florid Colour of extravasated Blood, and excellently preserves it from Putrefaction; yet does not liquify fresh and warm Blood, as has been imagined, but somewhat thickens it, almost in the Manner of a Mucilage: Which may give us the physical Reason of many of its Effects in the Body; as particularly its allaying Inflammations and Fevers, its stopping Hæmorrhages, curing the Spitting of Blood, &c. *Virtues.*

36 If the medicinal Virtues of this ſimple Medicine were to be enumerated, as they ſtand confirmed by competent Experience, perhaps they would prove more numerous than thoſe of almoſt any Medicine hitherto known. It has been found ſerviceable in the Stone, and Stoppages of Urine; in Deliriums, in malignant Fevers, in Diarrhoeas attending the confluent Small Pox, *&c.* ſo as to prove a Kind of general Remedy. And as all theſe Excellencies of the Medicine are joined with that deſirable Property of being innocent, or ſcarce any Way prejudicial to the Body; it may ſeem ſtrange that it ſhould be ſo little uſed, or that Medicines no Way comparable to it ſhould be preferred before it.

Whence diſeſteemed 37. Poſſibly the mixing of Nitre with other Medicines may have occaſioned its Virtues to be leſs known, or obſerved; perhaps that Humour of changing Medicines, almoſt every Day, may not have given it the Opportunity of ſhewing itſelf; but chiefly that ſtrange Method of jumbling many Simples together in one Medicine, ſeems to have prevented the due noting of the Effects of this and other ſimple Remedies. We, therefore, wiſh that the *Medicinal Hiſtory of Nitre* were drawn up, with Care and Judgment; as being perſuaded, that both Pharmacy and Medicine might, by means thereof, be brought much nearer to Simplicity and Perfection than they are at preſent.

EXPERIMENT V.

An artificial Method of preparing a powerful and innocent Strengthener.

38. We put half a Pound of the beſt *Peruvian* Bark, reduced to fine Powder, into a proper Glaſs, and poured upon it two Quarts of Spirit of

of Wine; then shaking them well together, set them to digest in a Sand-heat for two or three Days, till the Spirit of Wine appeared of a deep red Colour, inclining to Purple. We now strained the Tincture through a close Linen, and committed the Fæces at last to the Press. Then returning the Pressings, or remaining Powder, into the same Glass, we poured thereto two Quarts of strong White Wine, and again set the Matter to digest for two or three Days; then strained as before. After this we put the two Liquors into a Glass-Body, and distilled off a large Part of the Spirit of Wine; then evaporated the Remainder in a glazed Vessel, taking Care to keep the Matter stirring, and washing down, with some of the Spirit of Wine, the resinous Parts that adhered to the Sides of the Vessel. When the Matter began to grow thick, we added to it three Ounces of the Syrup of Orange-Peel; and thus brought the Whole to the Consistence of an Extract.

An essential Extract of the Bark.

39. This Method of extracting the Virtues of the Bark is the Invention of M. *Charas*; who experienced its Success in a large Practice for fifteen Years, wherein he never found it fail him, for the Cure of all Sorts of Intermittents. We have ourselves also had a competent Experience of its Success; and found it answer better than any other Preparation of the Bark we have seen: Whence we judge it the best Manner hitherto known of preparing an Extract from the Bark, so as to render it more innocent and effectual.

Its History

40. The Process was formed upon this Supposition, That the Bark contained a Rosin and a Salt for its principal component Parts; to the Extraction whereof the two Menstruums are well adapted. And, in Effect, we find that Spirit of Wine does extract a Kind of Rosin from the

Rationale.

Bark; and Wine ſuch a Part as renders it able to cure ſome Kinds of Intermittents in certain Conſtitutions: Whence theſe two Menſtruums, doubtleſs, take up the more medicinal Parts of this Subſtance, leaving its more woody or fibrous Part behind; which probably occaſions that Stoppage and troubleſome Weight at the Stomach we often hear complained of after taking large Quantities of the Bark in Subſtance.

41. The two finer and more medicinal Parts of the Bark being thus extracted, they are commodiouſly joined together again by the Interpoſition of the Sugar contained in the Syrup; ſo as to form an elegant Whole, that may be aromatized at Pleaſure with the eſſential Oil of Mint, Cinnamon, or Cloves.

Regimen. 42. The Doſe, and Method of exhibiting this Preparation of the Bark, are the ſame as the common; and though a much larger Doſe ſhould be given, it has not been found to produce any ill Effect. The Uſe of this Medicine is alſo attended with a quicker Recovery of the natural Complexion, Vigour, and Freſhneſs, than the Uſe of the crude Bark. And as the Medicine appears to be thus rendered ſo powerful and innocent, perhaps it may be proper to try it alſo in ſome other weakening Diſtempers, beſides Intermitting Fevers.

Elæoſaccharums recommended. 43. There are many other powerful and innocent Strengtheners, beſides this Preparation of the Bark; among the principal whereof come the capital Aromatics, Cinnamon, Cloves, Nutmeg; or rather their eſſential Oils; which being made into *Elæoſaccharums*, afford as potent Cordial Medicines, in a commodious Form, as can well be expected. But if more compounded Medicines are required, we would recommend the Uſe of a *compound Elæoſaccharum*, conſiſting

of

of a few select aromatic Oils, and the richest Gums and Balsams, as one general Cordial, or compound Strengthener. And thus a Medicine might be easily contrived, that should collect in itself, or concentrate, the Cordial Virtues dispersed in several capital Ingredients. Thus for Example, Camphire, Balsam *Peru*, Balm of *Gilead*, the essential Oils of Cinnamon, *Lignum Aloes*, Myrrh, *&c.* are all homogeneous, and capable of being united either alone, or with Spirit of Wine, or Sugar; so as to be given with all desirable Advantage and Convenience.

Experiment VI.

A ready Method of procuring a safe Quieter, or Anodyne.

44. We took half an Ounce of Opium, and dissolved it with a gentle Heat in five or six times its own Quantity of fair Water; then straining the Solution, and exhaling away the superfluous Moisture, in a temperate Sand-heat, we reduced the Matter to a dry Substance; which being ground in a Glass-Mortar, with twice its own Weight of hard Loaf-Sugar, seems to afford us one of the best or mildest Preparations of Opium; and may be given from one Grain to three or four for a Dose. *Opium prepared.*

45. By dissolving the Opium in Water, we get rid of its more gross and resinous Parts, which are found much more pernicious than the rest; and by dividing its Parts afterwards, with Sugar, we render the Medicine more uniform, resoluble, and miscible with the animal Fluids; and can thus the better adjust its Dose. But still this Medicine is not without some pernicious Property; nor is there any way known *Uses.*

known to render the Uſe of Opium perfectly ſafe and innocent in all Conſtitutions: For if a large Doſe of it be given, it is apt to diſturb or cloud the Head, cauſe a Vertigo, Delirium, or Convulſions; in particular, it proves prejudicial to the Stomach and Inteſtines, which it is apt to inflame and ſphacelate; thus acting, in ſome Degree, as a Poiſon: Whence a better Method of correcting it ſhould be endeavoured after, or a more innocent Remedy be uſed in its Stead. A Mixture of Nitre and Camphire, we apprehend, may ſupply its Place on many Occaſions, without any Fear of Danger or Inconvenience.

Regulation of Pharmacy. 46. Thus we have endeavoured to give an Inſtance of a ſimple and ſafe Preparation in each of the four general Tribes under which we conceive all Medicines may be commodiouſly ranged; *viz.* Evacuants, Alterants, Strengtheners, and Quieters. If the Method we have here obſerved were purſued to its due Length, it might, doubtleſs, terminate in the certain Diſcovery of a few ſimple, elegant, innocent, and powerful Remedies; at leaſt it would enable us to throw out, as dangerous, noxious, or poiſonous, a large Part of our preſent *Materia medica*, and pharmaceutical Preparations; and a conſiderable Part thereof, as almoſt uſeleſs, or inſignificant: Whence ſome tolerable Degree of Perfection in Pharmacy might be obtained.

47. Thus all the Medicines that have Lead in their Compoſition are ſcarce to be truſted for internal Uſe. We have various Inſtances of the poiſonous Nature of this Metal; as particularly among the Workmen at the White-Lead Houſes, the Colourmen, or Grinders of Ceruſe, and thoſe who any way work in Lead. And it were ſufficient to baniſh the frequent internal Uſe of

Saccha-

Saccharum Saturni, the *Tinctura antiphtheſica*, &c. to read, in the *Miſcellanea curioſa* *, how many Men were poiſoned by drinking acid Wine rendered ſweet with Litharge.

48. But Metals do not act in the Body till they are once diſſolved: Whence crude Mercury, ſwallowed in large Quantities, proves harmleſs, through the Want of a Menſtruum in the Stomach, &c. to diſſolve it. But when crude Mercury is diſſolved by its proper Menſtruum, as in the Preparation of Mercury-Sublimate, we ſee it becomes one of the ſtrongeſt Poiſons. Lead, Iron, and Copper, being much more eaſily diſſolved than Quickſilver, are ſeldom taken without ſome remarkable Effect; which muſt neceſſarily prove the greater, the more of an acid, or, in the Caſe of Copper, even alkaline Humour, is lodged in the Stomach or Inteſtines: Whence we derive a phyſical Reaſon why theſe Metals often produce different Effects in different Conſtitutions. The internal Uſe of the *Cryſtals of Silver*, though ſometimes ſucceſsfully given in dropſical Caſes, ſhould hardly be truſted, on account of their corroſive Acrimony; which has ſometimes occaſioned bloody Stools, and extreme Weakneſs. The common Tinctures of Copper, and Solutions of blue Vitriol, can ſcarce be taken internally with Safety; as being not only emetic, but in ſome Degree corroſive and poiſonous. Even the *Aurum fulminans*, though highly eſteemed by ſome as an internal Medicine, cannot be ſafely given, unleſs it has been firſt well waſhed from its Salts, and does not meet with a ſuitable acid Solvent in the Stomach: For in both theſe Caſes it may have dire Effects; of which there have

* Decad. III. Obſ. 30.

been

been remarkable Inftances: Iron and Tin have not been found fo pernicious to the Body, but rather beneficial; efpecially Iron, when prudently prepared and ufed. Indeed, of all the Metals, Iron feems to be the moft innocent, and fufficiently powerful, tho' diffolved in fo weak a Menftruum as Wine. And as this is the Refult of our Method of Rejection applied to Metals and metalline Preparations, fo we apprehend that if the fame Method were applied to the whole *Materia medica*, there would thence refult the difcovery of fafe and powerful Medicines for the Cure of all ordinary Difeafes: Whence we would recommend this Kind of Procedure to thofe who regard the Improvement of Pharmacy and Phyfic.

AXIOMS and CANONS.

1. We learn from the preceding Enquiry, That certain Simples are naturally better prepared for medicinal Ufe, than by the common chemical Treatment; fuch in particular are Ipecacuanha, Jalap, Rhubarb, Mechoacan, *&c.* Tables, or Catalogues, of which Kind of Simples ought to be formed, in order to abridge and perfect Pharmacy *a*).

2. That moft of the Emetics in common Ufe, efpecially the antimonial Kind, are virulent and fomewhat poifonous, compared to that milder one of Ipecacuanha *b*.)

3. That many of the common violent Purgatives are of an actually poifonous Nature, and therefore fhould be artificially corrected, or elfe make room for more innocent Kinds to be ufed in their Stead; particularly the purging *mineral Waters*, Manna, Rhubarb, *&c.*

a) *Exp.* I. *b*) *Exp.* II.

4. That

4. That the more violent and poiſonous Purgatives, ſuch as Elaterium, Coloquintida, Scammony, Hellebore, *&c.* may have their poiſonous Quality mitigated, or taken away, by boiling in Water and other Expedients *a*).

5. That the Effects of the poiſonous Purgatives are conſiderably greater in the Body than the Effects of the poiſonous Emetics *b*).

6. That the two principal Tribes of Evacuants, *viz.* Purgatives and Emetics, are reducible to a few ſimple and eaſy Preparations *c*).

7. That Camphire has conſiderable Virtues, as a Perſpirative, Sudorific, and Reſolver; being capable of uniting with oily Subſtances, and bearing a Relation to eſſential Oils, Roſins, Gums, and Balſams *d*).

8. That purified Nitre has many medicinal Virtues; ſo as advantageouſly to ſupply the Place of numerous other Medicines *e*).

9. That this purified Nitre has a great Power of preſerving the Blood uncorrupted, freſh, and florid *f*).

10. That many of the medicinal Virtues of Nitre do not depend upon its liquifying, but rather upon its jellying the Blood *g*).

11. That the Perfection of Phyſic and Pharmacy may have a conſiderable Dependence upon the medicinal Hiſtory of Nitre *h*).

12. That the *Peruvian* Bark may be rendered more innocent and effectual than when given in Subſtance, for the Cure of Intermittents, *&c.* by Means of a proper Treatment, or by extracting and uniting its ſaline and reſinous Parts with a ſuitable intermediate Subſtance *i*).

13. That this Bark appears to contain three very different Parts in a looſe Texture; *viz.* a roſin, a ſalt, and a woody Subſtance *k*).

a) *Exp.* II. *b*) ib. *c*) *Exp.* I. III. *d*) *Exp.* III. *e*) *Exp.* IV. *f*) ib. *g*) ib. *h*) ib. *i*) *Exp.* V. *k*) ib.

14. That

14. That poſſibly the reſinous and ſaline Extracts of the Bark may be ſerviceable in curing more Diſeaſes beſides Intermitting Fevers; and that probably the frequent Failure of the common Infuſions and Extracts of this Drug are owing to their containing much of its reſinous Part without the ſaline one, or the ſaline Part without much of the reſinous; and not a due Mixture and full Proportion of the two, as they are naturally found in the Bark itſelf: Whence the Subſtance has generally proved more effectual than any of thoſe imperfect Extracts, Tinctures, or Infuſions *a*).

15. That powerful Strengtheners, or Cordials, are obtainable from a Mixture of the richeſt Balſams, and eſſential vegetable Oils *b*).

16. That Opium may be ſo prepared as to become more innocent than in the common Methods of treating it *c*).

17. That a leſs noxious Quieter is wanted than Opium, and may, in ſome Meaſure, be ſupplied by Nitre and Camphire *d*).

18. That no Preparation of Lead can be long or freely uſed internally, without conſiderable Hazard *e*).

19. That the common Solutions and Preparations of Copper, Silver, Gold, and Mercury, are hardly proper for internal Uſe; nor even Tin and Iron, unleſs prudently prepared with gentle Menſtruums, and cautiouſly given *f*).

20. That there are rational Grounds to expect ſome conſiderable Improvements in the preſent State of Pharmacy and Medicine, by a due Enquiry, and a proper Uſe of the Means conducive to this End *g*).

LECTURE

LECTURE XVII.

CONTAINING

MINERALOGY; *or the Art of Mining: With the previous Operations to* Metallurgy; viz. *Roasting, Stamping, Washing, and the Business of Fluxes.*

1. WE are now entering upon a large, and extremely useful Branch of Chemistry; the Business of *Mineralogy* and *Metallurgy*. *The Subject.*

2. By *Mineralogy* we understand that previous Part of Metallurgy, which teaches the Ways of finding, judging, and digging Mines; with the Uses of Salts and Earths for making Fluxes, in order to the assaying and smelting of Ores for their Metals. *Mineralogy, what.*

3. By *Metallurgy* we understand the Performance of those several Operations required to separate Metals from their Ores, for the Uses of Life. And according to this Distinction we shall bestow one Lecture upon *Mineralogy*, and another upon *Metallurgy*, in the Sense we have here explained them. *Metallurgy, what.*

4. *Mineralogy* is an Art that requires a considerable Compass of Knowledge, before it can be practised to Advantage: For as this Art includes the Discovery, Sinking, and Working of Mines; it requires a competent Skill in the Nature, Effluvia, and Effects of mineral Matters, whether Earths, Salts, Sulphurs, Stones, Ores, Bitumens, *Requisites to Mineralogy.*

mens, Gems, or Metals. It likewife requires a Knowledge of the internal Structure of the Earth, and its various *Strata*; with a competent Skill in fubterraneous Architecture, Menfuration, Hydraulics, Levelling, and Mechanics; without which we can never judge what Mountain, Plain, or Valley, is proper to be dug; in what Manner to dig it; how to difcharge the Water that may flow in upon the Works; how the Beds of Ore and Stone will dip, or run; how the various Kinds of Earths, Marble, and other mineral or metallic Matters, are to be cut through, or broken; or how the general Procefs of Mining fhould be conducted, in order to procure, with the leaft Expence, or bring to open Day, the principal Matter or Ore required.

Qualifications of a Metallift. 5. And even when all thefe Difficulties are conquered, no more than half the Work is effected; and ftill the End can never be obtained without a tolerably exact Knowledge of feveral chemical Operations; *viz.* Trituration, Torrefaction, Lotion, Calcination, Cementation, Fufion, Amalgamation, Vitrification, Sublimation, Diftillation, and the like: Whence it might be laid down as a Rule, That every directing Metallift fhould not only be tolerably verfed in the feveral Parts of Natural Philofophy, but particularly be well acquainted with *Chemiftry*.

6. And perhaps it may not be improper to intimate, that many metallurgical Attempts have mifcarried, merely for Want of a competent Skill to conduct them. The under Workmen in this Way are generally a head-ftrong, ignorant People, that cannot be managed without the Ufe of fome good political Rules, and a Knowledge much fuperior to their own. Yet how little foever the Art of Mineralogy may have been under-

understood, History affords us numerous Examples of plentiful Fortunes and immense Treasures raised from Mines, as well by private Persons, as by particular States and Kingdoms. But the Vulgar, and even Philosophers unversed in Trade, generally reckon the Business of Mining unprosperous, and at best precarious and uncertain; especially when compared with Agriculture, or other Arts exercised more in the open Day. *The Success of Mining.*

7. The Truth is, Mines are liable to many Contingencies; being sometimes poor, sometimes soon exhaustible, sometimes subject to be drowned, especially when deep, and sometimes hard to trace. Yet there are many Instances of Mines proving highly advantageous for hundreds of Years. The Mines of *Potosi* are, to this Day, worked with nearly the same Success as at first; the Gold Mines of *Cremnitz* have been worked almost these thousand Years; and our *Cornish* Tin-Mines are extremely ancient. In general, the Profit of Mines, compared with that of Agriculture, is immensely greater in the same Time, so as to compensate largely for its Uncertainty. Even Lead-Mines generally yield twice or thrice the Returns of the richest Soils, cultivated in the ordinary Manner, either by Nature or Art. What then shall we say of the Mines that are rich in the nobler Metals? The neat Profit of the Silver alone, dug in the *Misnian* Silver-Mines of *Saxony*, in the Space of eighty Years, is computed at an amazing Sum *. *The Profit of Mines.*

8. Many Mines have been discovered by Accident. A Torrent first laid open a rich Vein of the Silver-Mine at *Friberg* in *Germany*. Some- *Accidental Discoveries of Mines.*

* See *Petr. Albin. in Chronic. Misn. Miner. German.*

times a violent Wind, by blowing up Trees, or overturning Rocks, has diſcovered a Mine. The ſame has happened by violent Showers, Earthquakes, Thunder, the firing of Woods, or even the Stroke of a Plough-Share, or a Horſe's Hoof.

The Art of Mining. 9. The Art of Mining does not wait for theſe favourable Accidents; but directly goes upon the Search and Diſcovery of ſuch mineral Veins, Ores, or Sands, as may be worth the working for Metal.

How to be practiſed. 10. The artificial Inveſtigation and Diſcovery of Mines depends upon a particular Sagacity, or an acquired Habit of judging, from particular Signs, that metallic Matters are contained in certain Parts of the Earth, not far below its Surface.

Signs of a Mine. 11. The principal Signs of a latent metallic Vein ſeem reducible to general Heads; ſuch as (1) the appearance of certain mineral Waters; (2) the Diſcolouration of the Trees or Graſs; (3) Pieces of Ore on the Surface of the Ground; (4) the Riſe of warm Exhalations; (5) metallic Sands, and the like: All which are ſo many Encouragements for making a ſtricter Search near the Places where any Thing of this Kind appears. Whence Rules of Practice might be formed for reducing this Art to a greater Certainty.

The Art of Boring. 12. But when no evident Signs of a Mine appear, the ſkilful Mineraliſt uſually bores the Earth in ſuch Places as, from ſome Analogy of Knowledge, gained by Experience (or by obſerving the Situation, Courſe, or Nature of other Mines) he judges may contain Metal.

13. This Method of Boring conſiſts in the Uſe of a Set of Scooping Irons, made with Joints, ſo as to be lengthened at Pleaſure, and thruſt down to a conſiderable Depth below the Surface of the Earth,

Earth; ſo as when drawn out again to bring back Samples of the Earth, or mineral Matter, from the Depth to which the Iron deſcended; much after the Manner that Samples of Sugar are taken out of the Hogſhead by the Inſtrument called a *Reſt*.

14. After a Mine is found, the next Thing to be conſidered is, whether it may be dug to Advantage. In order to determine this, we are duly to weigh the Nature of the Place, and its Situation, as to Wood, Water, Carriage, Healthineſs, and the like; and compare the Reſult with the Richneſs of the Ore, the Charge of Digging, Stamping, Waſhing, and Smelting. This is a Matter of common, civil, or œconomical Prudence. *When Mines may be dug to advantage.*

15. Particularly the Form and Situation of the Spot ſhould be well conſidered. A Mine muſt happen either (1) in a Mountain, (2) in a Hill, (3) in a Valley, or (4) in a Flat. But Mountains and Hills are dug with much the greateſt Eaſe and Convenience; chiefly becauſe the *Drains* and *Burrows*, as the Miners call them, that is, the *Adits*, or *Avenues*, may be therein readily cut, ſo as both to drain off the Water, and to form Gangways for bringing out the Load, or Ore, &c.

16. In all theſe four Caſes *, we are to look out for the Veins, which the Rains or other Accidents may have laid bare; and if ſuch a Vein be found, it may often be proper to open the Mine in that Place, eſpecially if the Vein proves tolerably large and rich: Otherwiſe the moſt commodious Place, for Situation, is to be choſen for the Purpoſe; *viz.* neither on a Flat, nor on the Top of a Mountain, but on its Sides: For the Mineraliſt is always to exerciſe his Judgment *Mines, where to be opened.*

* See §. 15.

in the due Choice of a Place to begin the Work.

The best Situation of a Mine. 17. The best Situation for a Mine is a mountainous, woody, wholesome Spot, of a safe, easy Ascent, and bordering upon a navigable River. Such a Place therefore being the Standard of Goodness, all others may be judged of as they approach to, or recede from it.

Requires Wood. 18. Wood is indispensably necessary for makeing the necessary Instruments, Engines, and Huts; as also for fencing the Pits, or Avenues, and supporting the Rock, where large Caverns are made by digging away the Ore: And again, for supplying Fewel to the melting Works; unless where Pit-Coal will serve the turn. But though no Wood or Coal should grow upon the Spot, it may often be supplied by Means of a navigable River, or cheap Carriage. And thus there are some rich Mines, in the hotter Climates, without so much as a Shrub growing near them.

Water. 19. Plenty of Water should never be wanting, and is best supplied by a River, from which it may be commodiously derived, by Pipes, into the Lavaderos, Smelting-Huts, &c. or even brought into the Burrows themselves, and made to work the subterraneous Machines. These are Conveniencies not to be expected from casual Rains, or the Torrents of the Mountains.

Good Roads. 20. The Roads and Conveniencies of Carriage, to and from the adjacent Parts, must be likewise regarded; as well for the Sale of the Metal produced, as the Conveyance of Goods and the Necessaries of Life to the Workmen: For it rarely happens that Provisions are afforded by the Spot where Metals are found.

21. The Places abounding with Mines are generally healthy; as standing high, and every way

Way expoſed to the Air: Yet ſome Places where Mines are found prove poiſonous, and can by no means be dug, though ever ſo rich. The Way of examining a ſuſpected Place of this Kind is, to make Experiments upon Brutes, by expoſing them to the Effluvia or Exhalations, in order to find the Effects thereof. *And wholſome Air.*

22. But a conſiderable Advantage may ſometimes be made, without the Labour and Expence of Digging: For as Springs and Rivulets are frequently the Outlets of Mines, it may happen that the Sand of ſuch Waters ſhall be worth the waſhing for Metal; in which Manner large Quantities of Gold Duſt are often procured. And hence it appears to be, that the Sands of many rapid Rivers, and even the Sands of the Sea in ſome Places, contain Gold; though the latter in ſo ſmall a Proportion as ſeldom to be worth the Waſhing. But the Sand of ſuch Rivers wherein ſtamped Ores are continually waſhed may frequently deſerve to be aſſayed. *Metals obtainable without Mining.*

23. The Veins of a Mine differ greatly from each other, in Depth, Length, and Breadth. Some ſtretch obliquely from the Surface towards the central Parts of the Earth; and theſe are called *deep Veins*: Others lie ſhallow and circular, ſo as to encompaſs a large Space; theſe are termed *ſpreading Veins*: Others poſſeſs a great deal of Space, both in Length and Breadth; and theſe are called *accumulated Veins*; being no more than a Space poſſeſſed by a Group of Foſſils of one certain Kind. But to give the Hiſtory of Veins, and Fibres, which are ſmaller Veins, their Differences, their Directions, their Interſections, their different Goodneſs, their Diſcontinuations, their Riſing, Falling, &c. would be a large Work. Let it, however, be obſerved, that theſe Things ſeem to proceed in a certain *The different Veins.*

 order,

order, though the Laws thereof have not been ſo well obſerved as to afford us ſure Rules of Practice: Whence it ſometimes happens, that after a Vein has been ſucceſsfully traced for ſome time, it dips, breaks off, or takes a different Courſe, leaving the Workmen as it were at Fault.

How to be traced. 24. When a Vein of Ore is found, and all Things prepared for the Work, if the Vein be of the deep Kind * it is firſt to be laid bare, and a Pit to be ſunk upon it; at the Mouth whereof a Shed is to be raiſed, and a Crane, or Barrel and Winch, fixed, for drawing up the Ore. The Pit is to be ſunk either perpendicular or oblique, according as the Vein happens to run.

And dug. 25. It is alſo uſual, in this Caſe, to cut a Burrow, or Adit into the Side of the Hill. This Burrow is uſually cut twice as high as wide, that the Workmen may commodiouſly paſs along it with their Barrows and Burdens; being for that Purpoſe uſually about ſeven Foot and a half high, and almoſt four Foot wide. If this *The Burrows, how made.* Side Pit reaches to the ſunk Pit, it becomes a true Burrow, open at both Ends; and thus renders the Work more facile and commodious, as the Ore may be now wheeled out in Barrows, inſtead of being craned up to the upper mouth of the Pit. After the ſame Manner it is uſual to dig many Caverns into the Sides of the Mountain, in order to ſcoop out the Ore: So that ſometimes there are thus ſeveral Burrows made, to the Eaſe and Advantage of the Work.

The Digging various. By the Spade. 26 The Art of Digging the Veins varies according to the Nature of the Vein, or according as it is ſoft or hard. The ſoft Vein is generally dug with the Spade, and turned out into

* See above, §. 23.

wooden

wooden Trays, placed underneath to receive it: But the hard Veins are knocked out with a Gad, or Kind of Chizzel, and Hammer. But if the Ore is ſo hard as to be incapable of breaking in this Manner, they uſually ſoften it with Fire; which has the Power of rendering the hardeſt and moſt flinty Stones brittle and friable. But a ſtill more expeditious Method is the working with Gunpowder; by Means whereof much of the hardeſt Rock may be ſhivered and ſplit in a very little Time; a ſmall Parcel of Powder being laid in a long Hollow cut for the Purpoſe, after the Nature of a Gun-Barrel, and fired as it were at a Touch-hole; a ſmall Vent, where the Quick-match is applied, being left for the Purpoſe, and the reſt of the Orifice being hard ſtopped up with Clay.

By the Gad.

By Fire.

By Blaſting.

27. The Manner of purſuing and digging all Sorts of Veins, the Ways of under-propping, and diſcharging the Water from the Works, the ſinking of Air-ſhafts, curing of Damps, and the like, we have no time to deſcribe *; our more immediate Buſineſs being the Treatment of the Ore, after it is dug and brought to open Day. For this Purpoſe there are certain previous Operations required, of which we propoſe to exhibit Examples. Our *firſt* Experiment, therefore, will ſhew the Method of Roaſting ſulphureous or arſenical Ores; the *ſecond* will ſhew the Method of Stamping and Waſhing of Ores; and the *third*, the Method of preparing Fluxes.

The Deſign of the following Experiments.

* See *Agricola de re metallica.*

EXPERIMENT I.

The Method of Roasting Ores.

Mundic roasted.

28. We took a Pound of the common *Cornish* Mundic, and breaking it into small Lumps, exposed it upon the Grate of a Furnace, whilst the Fire was made below; and thus at first we gently heated and torrified the Mundic, but afterwards by Degrees increased the Fire, so as to make the Lumps glow, or appear red hot; in which State we kept them for half an Hour, or till no more sulphureous Vapour or Stench rose from them.

The Experiment explained.

29. This Experiment shews the common Method of Roasting Ores, in order to discharge their sulphureous, arsenical, or antimonial Parts, that might otherwise hinder their Fusion, or else carry off a considerable Proportion of the truly metallic Matter in melting. For fear this metallic Matter should fly off, we made the Fire gentle at first; but increased it, by Degrees, till the Lumps became red hot, because otherwise the Sulphur would not quit its hold; for Sulphur requires a naked Fire and the Assistance of the open Air, before it will burn, or go entirely off *.

And applied, to the kindly Ores.

30. The richer and more tractable Ores have no Occasion to undergo this previous Operation of Roasting, but are usually committed to Fusion soon after being dug up, and separated from their Stone, or Mine. However, if they contain any considerable Quantity of Sulphur, or Arsenic, it is usual to roast even these a little.

* See *Lect.* II. *passim.*

31. But

31. But some Copper Ores are so stubborn and refractory, or hold their Sulphur so tenaciously, as to require many Roastings before they will let it go: being either stamped or melted after every Operation, so that all the Parts may, at several Times, be equally exposed to the Fire, and have their Sulphur discharged. *To the more stubborn Ores.*

32. In the large Way of Business this Operation is usually performed in a Trench cut somewhat aslope in the Ground, that the Air may have the freer Access at the Bottom: they first place a Layer of Billet-Wood in this Trench, and upon that a Layer of the Ore, in little Lumps, and so continue, interposing a Layer of Wood and a Layer of Ore, for three or four Stories; when the Pile being compleated, they set Fire thereto, and make it continue to burn slowly for several Days together, during which Time there rises a large Quantity of sulphureous Vapour, that may be perceived to a considerable Distance. *In the large Way.*

33. But when the Ore, by repeated Roasting, Stamping, and Fusing, is become tolerably pure, they now finish the Operation by throwing it into a particular Furnace, having a Funnel to increase the Draught; so as to make the Fire the stronger, and discharge the sulphureous Fumes in greater Plenty. And this Furnace is so contrived, that the open Flame of the Wood may play directly upon the Ore; whence all its volatile Part is separated, and the Remainder left fit for the last Stamping and Washing.

34. When the Ores contain a large Quantity of Sulphur, this usually sweats out and runs down into Cavities made on Purpose to receive it; whence it may be ladled out, and cast into Moulds. But perhaps the most frugal Method of roasting Ores, so as to save, or collect, all the *The Sulphur, how collected.*

the Sulphur, or Arſenic, they contain, is not generally known and practiſed: For in the common Way, a large Proportion is loſt, which might be collected by Means of a proper Hood, in the Form of Flowers; and alſo the riſing Fume might, by a particular Structure of the Furnace, be made to paſs into a large Veſſel of cold Water, and there be condenſed; as we ſee in certain chemical Diſtillations and Sublimations.

Vitriol obtainable in the waſhing.

35. After the poorer and more ſtubborn Sorts of Copper-Ore have been thus ſucceſſively roaſted, and come to be quenched in Water, or waſhed, they often impregnate the Water with a vitriolic Matter; ſo that ſometimes profit may be made by evaporating theſe Waters, and ſuffering the Vitriol to ſhoot: For the acid Part of the Sulphur, here ſeparated by the Fire, is greatly diſpoſed to enter the metallic Part of the Ore, and diſſolve it; ſo as to form an actual blue Vitriol, or Vitriol of Copper, which ſells for a conſiderable Price.

Roaſting generally profitable.

36. And here it ſhould be remembered, that Ores rarely yield the leſs Metal for Roaſting; unleſs the Fire were made too ſtrong, eſpecially at the firſt: For when the Yield proves ſmall, the general complaint of the Smelters is, That the Ore, when ſent to their Furnace, was too little roaſted; though indeed the fault is often their own, in neglecting to make their Fire ſufficiently briſk and ſtrong from the firſt; which is a very conſiderable Secret for increaſing the Yield of an Ore.

Tho' not always in imperfect Ores.

37. There are, however, ſome Reaſons to believe, that many imperfect Ores loſe conſiderably of their Metal by Roaſting, eſpecially when they are mixed with arſenical, or antimonial, Matters, which have a known Property of volatilizing the impurer Metals, and carrying them

off

off in Fume: Whence, doubtleſs, it is that ſome poor Ores and Mundics are commonly treated with little Succeſs.

38. The Remedy in this Caſe we apprehend to be the due Uſe and Application of ſome *fixing Subſtances*, whether of an abſorbent, alkaline, or neutral Nature; ſuch as Quicklime, Kelp, or Pot-Aſh, dry River-Mud, Clay, Iron-Filings, or the like, mixed or ſtratified along with the Ore. And by certain Additions of this Kind, we doubt not but the Yield of ſome poorer Ores might be conſiderably increaſed. *This Inconvenience remedied.*

39. The Buſineſs of Roaſting Ores may be improved, and reduced to a few eaſy Rules. (1) We ſee it is of two Kinds, or ſimple and compound; that is, either with or without Addition. No Addition is wanted when the Ore proves rich, or in itſelf nearly of a metallic Nature, as ſome Ores are found to be. But Additions are principally required, when arſenical, antimonial, or ſulphureous Matters are naturally mixed with the Ores *. *Roaſting reduced to Rule, with regard to Additions.*

40. (2) The Fire is to be ſo regulated, from the firſt, that only the lighter, or more volatile, ſulphureous, or arſenical Fumes may go off; otherwiſe the more metallic Part alſo would fly away, and, without ſome proper Contrivance to catch it, be loſt. Yet the Ore muſt feel the force of an open Flame at laſt; otherwiſe all the Sulphur, Arſenic, Antimony, and other immature mineral Subſtances, will not be diſlodged. *The Fire.*

41. (3) The more theſe immature Subſtances abound in the Ore, the gentler the Fire ſhould be at firſt; and when the greater Part of them is thus exhaled, the Fire is to be quickened by a freer Admiſſion of the external Air.

* See §. 38.

42. (4)

And Washing. 42. (4) Laftly; Where fuch fixing Additions are ufed as are not metalline, for Example, Lime, Mud, &c. the unmetallick Parts ought again to be feparated by Stamping and Wafhing, before Fufion, which would otherwife be hindered, or ufelefsly encumbered.

EXPERIMENT II.

The Method of Stamping and Wafhing of Ores.

Mundic ftamped and wafhed. 43. We took the Mundic roafted in our former Experiment, beat it fine in a metalline Mortar, and fearced it; then putting it into a Buddling-Difh, we wafhed it in feveral Waters, taking care to feparate the heavier Portion from the lighter, and drying this heavier Part, which is always the more metallic.

Wafhing and Stamping not always neceffary. 44. Thefe Operations of Stamping and Wafhing are not neceffary in the richer Sorts of Ores, but are often abfolutely required in the poorer and more flinty Kinds. If a large Quantity of mere ftony Matter adheres to the Ore, it is fometimes knocked off with Hammers; fo as to leave the more metallic Part free from this barren or fuperfluous Subftance.

Hard Ores, how foftened. 45. If the Ore ftill proves hard and flinty, it is fometimes foftened by lying, for feveral months, expofed to the open Air, which thus renders it fit for the Stampers; though it fometimes alfo requires to be heated, or ignited, and quenched in Water, to fit it for that Purpofe. Thus a large Heap of hard, and otherwife untractable, Ore may be heated red hot, by interfperfing it with Billets, and fetting them on fire; after which it may readily be quenched, and rendered friable, by throwing cold Water upon it, or by paffing a fmall Stream of Water through it, derived from fome adjacent River. And fometimes this Operation

muft

muſt be repeated, before the Ore will grow ſoft and tractable.

46. It is uſual to ſtamp moſt Ores in a State of Moiſture or Wetneſs, to prevent the Avolation of their Duſt or Powder; but eſpecially ſuch as require much waſhing to ſeparate their barren and lighter earthy Parts, which would otherwiſe uſeleſsly encumber the melting Furnace. To perform this Stamping the more commodiouſly, a Stream of Water is made to paſs under the Stampers; ſo as to make various windings and turnings, and, in Part, run into certain Cavities, made on Purpoſe to catch and detain the heavier Matter, whilſt the lighter is waſhed away to a greater Diſtance by the Current. *Ores how beſt ſtamped in the large Way.*

47. But the Method of waſhing the Ores of the nobler Metals is more exact and curious; as in waſhing of Sand for Gold, on the Banks of the *Rhine* and *Danube*, where Gold is frequently found, eſpecially in ſuch Places where the Sand is raiſed into large Heaps, or a Kind of Mountains, by the Rapidity of the Stream. *The Ores of the nobler Metals how waſhed.*

48. Theſe Sands are uſually waſhedby the Hand, in a long Trough, made for the Purpoſe, with a Deſcent or Current, and lined at the Bottom with Flannel; for thus the Sand being artificially agitated with the Hand, the lighter and larger ſtony Matter riſes uppermoſt, whilſt the heavier deſcends, and is catched in the Pores of the woolly Cloth at the Bottom; in the mean Time the lighter Matters are waſhed farther off by a Stream running down the Declivity. When the Flannel has thus collected a conſiderable Quantity of the richer metallic Matter, the whole Cloth may be eaſily taken off, and rinſed in a proper Veſſel of Water, where all *Fine Gold Sand how waſhed.*

all the metallic Matter, before adhering to it, readily falls off, and ſinks to the Bottom of the Veſſel; and then, the Water being decanted, the Metal may be collected alone and dried. And this is the Method of procuring the Gold where the Sand is fine, or extremely ſmall.

The coarſer how treated. 49. In the larger Works, or where the Gold is mixed with big Sand, Gravel, or Stones, they make Uſe of Wire-Sieves, whoſe Meaſh is always of one certain Size; ſo as readily to tranſmit the fine Sand, or Gold Duſt, and retain the larger Gravel and Stones behind: For it is extremely rare to meet with a Grain of Gold, in the Sands of Rivers, ſo large as a Barley-Corn. Whence this Method by the Sieve is highly ſerviceable, and conducive to the former Operation: For though a large Quantity of fine Sand thus paſſes the Sieve, it may be readily ſeparated in the Trough, after the Method already deſcribed *.

The End of Stamping and Waſhing. 50. And this may ſuffice to ſhew the general and particular Methods of Stamping and Waſhing Ores. We ſee the End of theſe two previous Operations is to get rid of the Matters which are not metalline; that ſo the Furnace may not be uſeleſsly employed upon ſuch Subſtances as will themſelves yield no Metal in the Fire, and only hinder the metallic Parts of the Ore from coming together, and affording a Yield anſwerable to the Expence and Trouble of the Fuſion.

* § 48.

EXPERI-

Experiment III.

Ways of preparing the strongest Fluxes.

51. We took four Ounces of red Lead, an Ounce of White Sand in Powder, and two Ounces of dry decrepitated Salt, and mixed them all well together in a Mortar; this Mixture we put in a clean *Hessian* Crucible, fitted with a Cover, and fused it in a Wind-Furnace for a Quarter of an Hour; then taking it out, and letting it cool, we broke the Crucible, and found the Salt at top, and a pure Glass of Lead at the Bottom: This Glass we carefully separated and kept apart, as a powerful Flux. *Glass of Lead prepared as a Flux.*

52. The Salt is of no other Use in this Operation, than to serve as a Flux to the Sand, and make it more readily unite with the Red Lead; so as to form a Glass without any great Violence of Fire, or the Necessity of detaining it long therein. So that by this Means a Glass of Lead may be readily prepared for the Purpose of artificial Gems *, or other Uses. *Salt, why used therein.*

53. This Glass of Lead is an extremely useful Flux in the Business of assaying; and when kept long in Fusion, passes through the Pores of any common Crucible, almost like Water through a Sieve; so as, upon the Test, readily to vitrify, and carry off, all Sorts of metalline and mineral Matters, except Gold and Silver: On which Property, therefore, the Art of Cupelling depends. *The Use of this Glass.*

54. Fluxes seem reducible to two general Kinds; *viz.* the *vitreous* and the *saline*. By the *Fluxes of two Kinds;*

* See *Lect.* XIV. *Exp.* II. and V.

vitreous

viz. the vitreous. *vitreous* we underſtand all thoſe which either have of themſelves, or readily aſſume, a glaſſy Form in the Fire; among the Principal whereof we reckon the Glaſs of Lead, the Glaſs of Antimony, and Borax.

and ſaline. 55. By the *ſaline* Kind of Fluxes we underſtand all thoſe that are compoſed of Salts, whether Tartar, Nitre, fixed Alkali, or the like. And among the Principal of this Kind we reckon the Black Flux, which we formerly ſhewed how to prepare *; alſo Sandiver, Kelp, &c.

Their different Uſes. 56. The vitreous Kind ſeem more immediately deſtined to act upon the ſtony or vitreſcible Matter, wherewith ſtubborn Ores are frequently mixed; and the ſaline Kind, to act more immediately upon the Ore itſelf, for the due Excluſion or Separation of the Metal.

Some Ores require no Flux. 57. The more kindly Ores require no Flux to make them run thin, or to afford all the Metal they contain. And ſometimes Ores are ſo kindly as to contain their own Fluxes within themſelves. Thus we have met with Copper-Ores, which being barely ground to Powder, and melted, without any Addition, in a common Wind Furnace, have yielded as much, or even more pure Metal at the firſt Operation, than we could obtain from them by Means of the uſual Fluxes. Whence we ſee that artificial Fluxes are not always neceſſary; or that the principal Uſe of them is for the ſtubborn or leſs tractable Ores. *Metallurgy improveable by diſcovering cheap Fluxes.* And theſe are ſometimes ſo exceedingly hard to fuſe, and bring to a metalline Form, that it requires the utmoſt Power of Art to treat them advantageouſly in the larger Way of Buſineſs, where no conſiderable Expence can uſually be allowed for Fluxes.

* See *Lect.* I. *Exp.* II.

58. On

58. On this account it is that many Mines remain unwrought, as being intractable without great Charges. Whence the Improvement of the Business of Fluxes, so as to render them cheap and effectual, might greatly contribute to the Improvement of Metallurgy. We would therefore recommend to farther Enquiry what Matter it is, in the more soft and tractable Ores, which renders them so fusible, and easy to part from their Metal. Certain Experiments which we have made with this View seem to shew, that in Copper-Ores it is a Kind of bituminous Substance, capable of melting, by a strong Heat, into a soft and black kind of Glass. *Metallurgy.*

59. Some of the most powerful and cheap simple Fluxes hitherto known are dried Wine-Lees, dried Cow-dung and Horse-dung, dried River-Mud, Fuller's Earth, Iron Filings, common Salt, Glass, Kelp, Pot-Ash, Sandiver, *&c.* which may be used in the larger Work; as Nitre, Tartar, Borax, Sal-Ammoniac, Mercury-Sublimate, *&c.* may in the smaller, or for the making of Assays. *The cheap simple Fluxes.*

60. As for compound Fluxes, they are numerous; almost every Operator having his favourite one. And certainly some Fluxes are better adapted than others to certain Ores. But perhaps a few general ones might be fixed upon, which should serve instead of all those hitherto commonly known and used. We will here recommend three, which are powerful, almost general, and not expensive. *Cheap compound Fluxes.*

61. (1) Take of Nitre, prepared by long boiling it in Lime-Water, of Sea-Salt melted in the Fire, Sandiver, and dry Wine-Lees, each one part; Glass of Lead, three Parts; and powdered Glass, eight parts: mix them all well together.

This Flux added, in an equal Weight, will fuse a very ſtubborn Ore.

62. (2) For a ſtill ſtronger, take equal Parts of white Tartar, common Salt, and Nitre, prepared as above; calcine them to a white Powder, and mix therewith its own Weight of Glaſs of Lead; and of this Flux add two Parts to one of the ſtubborneſt Ore.

63 (3) For a powerful ſaline Flux take of the ſtrongeſt Soapboiler's Lees four Pounds, white Tartar and common Salt, melted in the Fire, each one Pound; boil them together with five Gallons of human Urine, to a dry Salt. This Flux is particularly proper where Sulphur and Cobalt abound, and render the Ore very refractory.

The Improvement of Fluxes. 64. But the great Secret in the making and adapting of Fluxes, is not only to ſeparate the Metal already ripened in the Ore, but even to mature and ripen the crude or immature Part of the Ore in the Fire. Something of this Kind, we apprehend, may be effected; as having reaſon to believe, that certain Fluxes, will obtain a larger Yield of Metal from certain Ores, than other Fluxes in common Uſe, though eſteemed of the beſt, and though they are perhaps of the deareſt Kind. Thus clean Iron Filings will often do more than Borax. But as the Scales and Crocus, or Ruſt, of Iron have been commonly uſed, inſtead of pure and perfect Iron itſelf, for a Flux, few Operators appear acquainted with the Excellence of perfect Iron employed for this Purpoſe. Many Advantages alſo are now commonly reaped by a prudent Mixing of one Ore with another of the ſame Denomination, and with the Slags or Recrements of Metals, in the Way of a Flux.

AXIOMS

Axioms and Canons.

1. We learn from the preceding Enquiry, that to practiſe Mineralogy and Metallurgy to advantage, a conſiderable Knowledge in Natural Philoſophy and the Operations of Chemiſtry is required *a*).

2. That many Miſcarriages in mineral Attempts have been owing to the Want of a competent Skill in Mechanics, Hydraulics, and Chemiſtry *a*).

3. That the Profit attending the ſcientifical Working of Mines is generally greater, and upon the whole more conſiderable, than that of Agriculture, or Merchandize *b*).

4. That there are two Ways of diſcovering Mines; *viz.* by Accident, and by Art: The latter whereof belongs to the intelligent Mineraliſt *c*).

5. That the Art of diſcovering Mines depends upon a certain Sagacity, which may be acquired by Uſe and Practice; or upon the Obſervation of particular Signs that generally denote a Mine; and again upon the Method of Boring, according to ſome Analogy of Knowledge, gained by being converſant with the common Appearances, Situations, and other Phænomena of Mines *c*).

6. That the Art of diſcovering Mines is reducible to Rule, ſo as not to be mere Conjecture, or Gueſs-work *c*).

7. That in general, Mines are to be firſt opened where a Vein is laid bare by accident or otherwiſe, eſpecially if it prove large or rich: But where no ſuch Encouragement appears, the

a) § 4—6. and Exp. I. II. III.
b) § 4—6.
c) § 8——13.

ſides of Hills are preferably to be choſen for an opening *a*).

8. That a deliberate Conſideration, and a competency of oeconomical Prudence, are uſually required to determine before-hand, whether a Mine, after it is diſcovered, may be wrought to Profit *b*).

9. That the moſt perfect Situation of a Mine is to be mountainous, woody, eaſy of Aſcent, healthy, bordering upon a navigable River, and good Roads *b*).

19. That Metals may be ſometimes obtained to Advantage without Digging; or barely by waſhing the Sands of certain Springs and Rivers *c*).

11. That mineral Veins differ greatly from each other, and accordingly require different Methods of Digging, which may be reduced to ſtandard Rules of Practice *d*).

12. That the Buſineſs of Mining is improveable by diſcovering better Methods of preventing or curing Damps in Mines, rendering poiſonous Mines wholeſome, or defending the Bodies of the Workmen againſt their ill Effects; as alſo by diſcovering better Methods of raiſing or diſcharging the Waters, following the Veins, breaking the Rock, bringing up the Ore, *&c.* *d*).

13. That the End of Roaſting Ores is to diſcharge their ſulphureous, arſenical, antimonial, or other rapacious Matters; which would otherwiſe carry off the purer Metal in the melting Furnace, and defraud the Account *e*).

14. That the richer Ores require neither Roaſting, Stamping, nor Waſhing; but may be di-

a) § 14—16. *b*) § 14—21. *c*) § 22, 47—49.
d) § 23—26. *e*) Exp. I.

rectly

rectly committed to the Smelting-Furnace, without Flux or Addition *a*).

15. That in order to roast Ores in Perfection *per se*, the Fire should be gentle at first, and afterwards increased to a Degree of Ignition in the Ore *b*).

16. That some Ores, joined with rapacious mineral Matters, may be advantageously mixed, or stratified, in Roasting, with proper fixing Ingredients *b*).

17. That Ores are seldom rendered the poorer, but generally the richer, for Roasting; unless the Fire at first be made too strong *b*).

18. That the Business of Roasting Ores is improveable, and reducible to a few easy Rules, with a View to render the Ore more pulverable, and discharge its volatile, sulphureous, and arsenical Parts; which, if retained, would, in strong Fusion, partly prevent the Separation of the purer Metal, and partly carry it off into the Air *b*).

19. That Metals, in their Ores are not those fixed Bodies they appear to be in the Bars or Ingots, into which they are brought by metallurgical Operations *a*).

20. That the Operations of Stamping and Washing are required only in the hard, flinty, and poorer Ores; the Design of these Operations being merely to separate the useless terrestrial, or flinty and stony Parts, which would otherwise encumber the Furnace and lessen the Yield.

21. That some hard Ores, may be softened, or rendered fitter for Stamping and Washing, barely by lying exposed to the open Air, which seems to turn some Parts of the Ore into a saline

a) Exp. I. II. III.
b) Exp. I.

matter, or Vitriol; whence a Kind of Friability or Softneſs is communicated to the Reſt *a*).

22. That the hardeſt or ſtubborneſt Ores may be ſoftened, and rendered fitter for the Stampers, by being firſt ignited, and then quenched in Water; eſpecially if this Operation be ſeveral Times repeated *b*).

23 That the two Operations of Stamping and Waſhing are, in good Meaſure, reducible to one, in the ordinary Ores; the Courſe of the Water being ſo directed under the Stampers, as immediately to carry off the lighter ſtony Matters, and leave the heavier or more metallic Parts behind *b*).

24. That the Sands of certain Rivers may, by a ſlight manual Operation, be ſometimes waſhed for their Gold to conſiderable Profit *c*).

25. That the waſhing of Sand for Gold may be conſiderably expedited, by a proper Uſe of the Sieve *b*).

26. That Glaſs of Lead is a powerful Flux; ſo as to be capable of vitrifying, and carrying away with itſelf upon the Teſt, all the metallic or mineral Matters that are not either Gold or Silver *d*).

27. That the vitreſcible Claſs of Fluxes are more adapted to operate upon the ſtony Parts of Ores, and the ſaline Claſs upon the Ores themſelves, ſo as to ſeparate their Metal *d*).

28. That the Buſineſs of Aſſaying and Refining Gold and Silver, depends upon that Property which Lead and the Glaſs thereof have of vitrifying, and carrying off upon the Teſt, all the known Matters, except the two nobler Metals *d*).

a) *Exp.* II. See alſo *Lect.* III.
b) *Exp.* II.
c) § 22, and *Exp.* II.
d) *Exp.* III.

29. Tha

29. That ſome Ores naturally contain their own Fluxes, and are therefore beſt aſſayed and ſmelted *per ſe* *a*).

30. That the Buſineſs of Metallurgy might be conſiderably improved, by diſcovering a cheap and general Set of powerful Fluxes *a*).

31 That an Enquiry into the Nature of the fuſible Matter, naturally contained in the more kindly Ores, might lead to a Diſcovery of ſome cheap and powerful Fluxes *a*).

32. That the large Number of compound Fluxes might be reduced to a few general Kinds, capable of performing as much as all of them ſeverally *a*).

33. That the greateſt Improvement of Fluxes depends upon making and uſing them ſo as to maturate the Ore, or otherwiſe cauſe a larger Yield than can be procured by the common Fluxes *a*).

34. That ſuch maturating Fluxes may be, in ſome Degree, obtained by a farther Knowledge of the Properties, Affinities, or Relations betwixt Metals and Metals, Metals and Minerals, Ores and Ores, or Minerals and Minerals *a*).

a) *Exp.* III.

LECTURE XVIII.

CONTAINING

METALLURGY; *or the Art of* Assaying, *and working Metals from their Ores.*

The Subject. HAVING already considered the several Parts of *Mineralogy* *, as previous to the Art of *Metallurgy*, we now come to Enquire into the Operations of Metallurgy itself.

Metallurgical Operations of two kinds. 2. These Operations are of two kinds, or smaller and larger; with regard to which the whole of Metallurgy may be divided into two Parts; *viz* *Assaying*, and *Smelting*.

Assaying. 3. By Assaying we understand the Method of determining by Trial, in Miniature, what will be the Yield of an Ore in pure Metal when it comes to be wrought in the larger Furnace.

And Smelting. 4. And by Smelting we understand the several Ways of reducing Ores to pure Metal in the large Way of Business, so as to fit the Produce for the civil, mechanical, and oeconomical Uses.

Design of the Experiments. 5. We shall here enquire into both these Parts of Metallurgy, or consider as well the Smelting as the Assaying of Ores. Thus the *first* Experiment will shew the Method of Assaying and Smelting Gold and Silver; the *second* will shew the Method of separating Gold from Silver; the *third* will shew the Method of Assaying and Smelt-

* See *Lect.* XVII.

ing

ing Copper, Tin, Lead, and Iron; the *fourth* will ſhew the Method of making Braſs and Princes Metal; and the *fifth* will exhibit the Method of making Steel.

Experiment I.

The Method of Aſſaying and Smelting Gold and Silver Ores.

6. (1) We took a Penny-weight of Silver-Ore reduced to fine Powder; and having put it together with half an Ounce of Lead cleared of its Silver, into a little flat Eſſay-Crucible, under a Muffle, in the Teſting Furnace, we continued to Uſe a gentle Heat till the Lead had imbibed the powdered Ore at leaſt its metallic Part, and ſeparated the more ſtony Matter in form of a glaſſy *Scoria* at the Top. (2) We now took out the Lump of Lead, impregnated with the Silver of the Ore, and placed it upon a *Teſt*, which had been heating, or nealing, all this while under the ſame Muffle; and working with a proper Degree of Heat, till all the Lead was either evaporated, vitrified, or ſunk into the Teſt, we found a little Bead, or Grain, of Silver left behind; which Grain, or Bead, being exactly weighed, and compared with the original Weight of the Ore, gives the proportion of Silver contained in the Ore, that is, determines its Richneſs: And the ſame Method is equally applicable to Gold-Ores, Sand, or any other Matters containing Gold, Silver, or a Mixture of both. *Silver Ore aſſayed by Teſting.*

7. This Operation is uſually called Teſting, or Cupelling; and exhibits almoſt the whole Art of the Aſſay Maſter and Refiner. We ſee the Proceſs conſiſts of two Parts; *viz. Imbibition*, and *Separation*: For the Lead is firſt made to drink *The Operation explained.*

drink in all the Silver from the Ore; and then the ſame Lead is entirely ſeparated from the Silver. And in this Manner alſo are Eſſays taken of Silver Coin, or any Mixtures of the nobler with the ignobler Metals: For when the Operation is exactly performed, no other Metals, beſides Gold and Silver, will be left upon the Teſt.

Its Rationale.

8. The phyſical Reaſon of the preſent Proceſs deſerves to be enquired into. The Laws or Principles on which it depends are theſe: (1) When the imperfect Metals, or other Minerals, are added to melted Lead, ſome of them will not enter into it, but remain floating on its ſurface, in form of a hard *Scoria*; which is the Caſe with Iron: (2) Others enter it, but gradually emerge again; as Tin: (3) Others totally exhale; as Regulus of Antimony, and Arſenic: (4) Others again burn to Aſhes, or run into Glaſs, along with the Lead; as does Copper: But (5) neither Silver nor Gold is capable of flying off, burning to Aſhes, or turning to Glaſs, by being detained in melted Lead: Whence theſe two Metals, of courſe, remain pure and ſeparated from all the Reſt, at the End of the Operation. And thus we find, that the Gold and Silver remaining all the Time mixed among the Lead, without going into Glaſs, continually ſink down from the ſhelving ſides of the Teſt, towards the Bottom of the Hollow, along with the Lead; which being at length totally conſumed, and the Fire unable to keep Silver or Gold melted without ſome Addition of Lead, they neceſſarily grow rigid, and fix in a ſmall Bead at the Centre of the Teſt.

Gold and Silver Ores, how treated in the large Way.

9. In the large Way of Buſineſs, Silver or Gold Ores are treated either by Amalgamation with Mercury, or by Smelting and refining them with Lead. The Method by Amalgamation is uſed

used only where the Ore is exceeding rich; particularly at the Silver Mines of *Potosi*: For by grinding such rich Ores with Mercury, the nobler Metals will be drunk up by it, and may be readily separated from it again by Distillation, which carries over the Quicksilver, and leaves the nobler Metals behind. Lead is used along with the poorer Ores, in order to drink up the nobler Metals they may contain; which it does much after the same Manner by Fusion, as Quicksilver does without it; so as to separate many heterogeneous Parts, by keeping them floating, and afterwards restoring the nobler Metals, by Cupellation. *By Amalgamation.*

10. The large Way of Smelting Gold and Silver Ores is analogous to the small one of Assaying; all things being proportionably larger, the Fire animated with Bellows, and the Blast directed upon the Surface of the melted Metal; so as to blow off the Lead in the Form of Litharge, before it is fully vitrified. But here the Silver is not perfectly refined at one Operation; some Proportion of Lead still remaining mixed among it, that requires to be burnt out, after the same Manner, in a stronger Fire: And even thus it is with great Difficulty that Silver can be obtained pure, or totally separated, either from Lead or Copper. This large Way of working might perhaps be improved in respect of the Vessel or Test employed, and the Management of the Fire; so as to work by the Means of Flame, without the Assistance of Bellows. *And Fusion.*

11. With regard to the Test, we are to observe that Bone-Ashes, though ever so well washed and sifted, are not, perhaps, the fittest matter to make Tests of; the Tests so made being apt to crack in the Fire, unless dried very gently for many Days before they are used. But there is *The larger Operation improveable in the Test.*

is a particular Kind of Talc, or unvitrifiable Spath-Stone, that being calcined to fine Powder, as it readily may, and made up with a ſmall Solution of Vitriol in Water, affords ſuch Teſts as may be immediately uſed without Danger of cracking.

And the Fire. 12. Again; the Flame of a Wind-Furnace may be made to play upon the Surface of the melted Metal; ſo as readily to perform this Operation, without the Uſe of Bellows, which violently tear away the Silver along with the Lead, in the Form of Litharge. And this farther Convenience may be obtained, that not only ſmaller and cheaper Wood, but even Pit-Coal ſhall here ſerve for the Fewel; provided the Structure of the Furnace be contrived for the Purpoſe. And in ſome Places they have of late advantageouſly uſed common Pit-Coal for Teſting in the large Way; and the ſame Improvements might alſo be made in the ſmall Way of Aſſaying.

Aſſaying imperfect. 13. But how improveable ſoever the Buſineſs of Aſſaying may be, it is ſcarce worth while to intimate in what Particulars it might be improved; becauſe the Aſſay-Maſters in all Countries are obliged to make their Aſſays in the Manner peculiar to each Country: Whence we ſee one Reaſon of the Diſagreements, ſo frequently complained of by Merchants, in the Aſſays made upon the ſame Kinds of Ore, in *Holland*, *Germany*, *England*, *France*, &c. The Methods employed for this Purpoſe all over *Europe* are, however, in moſt Reſpects the ſame; but ſhould never be truſted, unleſs two or three Experiments at leaſt, made at the ſame Time, by the ſame Perſon, agree in the ſame Report.

14. And

14. And perhaps in all Natural Philoſophy, Chemiſtry, and Metallurgy, there are no Experiments which require greater Skill, Accuracy, and Truth of Work, than thoſe in the Art of Aſſaying, to make them fit to be depended upon: Nor indeed can ſuch Preciſion as is here required be well expected, but from thoſe who are acquainted with the rapacious Nature of many volatile mineral Fumes, and the Methods of fixing them, or preventing their carrying off the nobler Metals upon the Teſt. To aſſay in Perfection alſo requires a Knowledge of the Relation and Differences of all the Metals with regard to each other; and particularly to Lead and Antimony. As this Art therefore requires ſo much Knowledge, and ſo much Accuracy, in order to practiſe it with Succeſs; hence, doubtleſs, proceeds the Difficulty we find in procuring a true Eſſay to be made upon any uncommon Ore: For the Art of Aſſaying is extremely backward in admitting of Improvements; as if it were to deſcend unaltered from one Generation to another. *Its Difficulty.*

Experiment II.

The Method of ſeparating Gold from Silver, by Quartation.

15. We took a mixed Maſs of Gold and Silver, and melting it along with three or four times its own Weight of pure Silver, we beat the whole Lump, when cold, into a thin Plate; which we put into a Glaſs of Proof *Aqua fortis* *, ſet in warm Sand; whereby the Silver was ſoon diſſolved, and the Gold let fall in a black Powder *Gold ſeparated from Silver by* Aqua fortis.

* See *Lect.* VI. *Exp.* VI.

to

to the Bottom. The Solution of Silver we now carefully poured off, and adding a little fresh *Aqua fortis* to the Gold, we used a somewhat stronger Heat than before, in order to dissolve any remains of Silver from amongst the Gold-Powder. Then the *Aqua fortis* being again decanted, we washed the Gold well, in several Parcels of fair Water. And now the Gold-Powder was put into a little Say-Cup, and placed under the Muffle in the Testing-Furnace till it became yellow. It might otherwise have been melted with Borax; which brings it to its true Colour and Form. We afterwards weighed the Gold, to determine the Proportion it bore to the Silver. Lastly, we precipitated the Silver out of the *Aqua fortis*, by suspending a Copper-Plate therein; then washed the Calx, and reduced it to its metalline Form in the same Manner.

Ratio-nale. 16. The Reason for adding three or four Times the Quantity of Silver, in Proportion to the mixed Mass, is, for fear the Mass should contain too much Gold to be fit for the Operation; or to spread the Gold contained in the Mass, and diffuse it so thinly, that it may not defend the Silver, as it otherwise would do, from the action of the *Aqua fortis*. And from the proportion of this Addition it seems to be that the Operation is called *Quartation*.

The Trouble and Expence of the Operation. 17. This Method of separating Gold and Silver was unknown to the Ancients; who therefore separated Silver from Gold by Calcination; and so lost all the Silver that was mixed with the Gold. And indeed the Method by *Quartation* is expensive and laborious; so as not to be very advantageously practised in the large Way of Business; though the whole has been divided into such a Number of Hands, as to make the several Parts come cheap: some Operators being wholly

wholly employed in making the *Aqua fortis*; others in purifying it, or bringing it to *Proof*; others in laminating the Silver, and diſſolving it; others in ſeparating and reducing the Calx of the Gold; others in precipitating the Silver with Copper; and others again in ſeparating the Copper from the *Aqua fortis*. And thus the whole Operation has been found to anſwer, ſo long as about a Dram of Gold could be recovered from a Pound of Silver.

The Operation improved, or ſuperſeded.

18. But there are certain Workmen of late, who have a Method of ſeparating Gold from Silver to much greater Profit, without the Uſe of *Aqua fortis*, or *Aqua regia*; and that barely by a dexterous Application or Management of the Fire; at leaſt without any coſtly Additions. This Method is kept as a Secret, but may, perhaps, be no other than that publiſhed by M. *Homberg a)*; which conſiſts in fluxing the mixed Maſs of Gold and Silver with equal Parts of rough Nitre and decrepitated Salt, placed at the Bottom, of the Melting-Pot. By this means the Operation, in the large Way, may be finiſhed in a Quarter of an Hour, the Gold falling to the Bottom, and leaving the Silver ſuſpended or detained in the Salts. Another Way of effecting this Separation may depend upon a dexterous Uſe of Sulphur, which has the Power of making Silver melt away from a metalline Mixture almoſt as eaſy as Lead *b)*.

Gold, how to be obtained pure

19. But to obtain either Gold or Silver in abſolute Purity is no eaſy Taſk. For the common Uſes, indeed, the Methods above delivered may ſerve; but for the more curious chemical and philoſophical Purpoſes, better Ways than

a) In the *French* Memoirs.
b) See below § 20.

are

are commonly known and practiſed ſhould be diſcovered. To refine Gold by melting and teſting it with Antimony, or Glaſs of Antimony, is generally, and even by the metallurgical Chemiſts, thought a perfect Way; but M. *Homberg* * has ſhewn, that even this Criterion, as alſo Quartation, Cupelling with Lead, Fluxing with Borax, &c. may fail, in Caſe the Gold be mixed with *Emery*, or poſſibly ſome other things. When Gold is *eager*, as the Workmen call it, that is, brittle, they hold it as a Secret to melt it with Mercury-Sublimate. But perhaps no Gold can be proved to be perfectly pure, till it has gone through all the trials hitherto known; or even ſome of a more curious Nature; particularly melting with crude Antimony, and afterwards cupelling the Regulus with Lead; and at laſt, fuſing it with Borax. Which Proceſs we recommend to thoſe who require Gold in abſolute Purity for any Standard, or very curious Operation.

Silver, how.

20. The Methods of obtaining Silver in Purity are various, and differ according to the Metal wherewith the Silver is mixed or alloyed. If Copper be the Alloy, the beſt and cheapeſt Way to purify the Silver is, to calcine it with half its Weight of common Sulphur; then melt the whole together; and throw into the Pot, at ſeveral Times a due Quantity of clean and new Filings of Iron, which will immediately draw the Sulphur from the Silver, and Form a *Scoria* at top, leaving the Silver free from Copper, Iron, or Sulphur at the Bottom.

* See the *French* Memoirs.

EXPERI-

EXPERIMENT III.

The general Method of Aſſaying and Smelting the impurer Metals; Copper, Tin, Lead, and Iron.

21. We took four Ounces of Lead-Ore reduced to Powder, and mixing it with an Ounce of the clean Filings of pure Iron, and half an Ounce of the Black Flux *, we melted them all together in a new Crucible ſet in a Wind-Furnace. By this Means we found the Lead clearly ſeparated, in a Lump, at the Bottom of the Crucible, after it was taken out of the Fire and ſuffered to cool. *Lead-Ore aſſayed.*

22. The Method of thus working in Crucibles, and by the Help of Fluxes, is not only too ſmall, but alſo too chargeable, to anſwer in the large Way of Buſineſs: Nor is there any Occaſion for being confined to this Method; ſince Fuſion in a naked Fire, or in Contact with the burning Fewel, is found to act as a powerful Flux, and get the Metal out of its Ore with Advantage. Hence we every where find that Metals are ſmelted in open Furnaces with a naked Fire. And though this hath long been a general Practice, the phyſical Reaſon of it ſeems little known; inſomuch that nothing is found more wanting in Philoſophical Metallurgy, than the particular *Hiſtory of common Fuſion.* *How ſmelted in the open Fire.*

23. The Ores of Lead, Tin, Copper, and Iron, are all commonly fuſed in Contact with the Fewel of the Furnace; the prepared Ore being at firſt ſtratified, or intermixed with the Wood or Coals: Nor could theſe Ores be any other Way fuſed in a large Quantity, ſo as *The Rationale.*

* See *Lect.* I. *Exp.* II.

to acquire a metalline Form, though urged with ever ſo ſtrong a Flame, or beat ever ſo violently upon by the Fire, while kept from touching the Coals, by being included in a large Crucible, or Melting Pot, after the Manner that Glaſs is made; or without adding ſome Flux-Powder, of an oily or inflammable Nature *a*). Even if the Ore thus treated were rich, or naturally contained ſome viſible Grains of pure Metal, this Metal would only remain in almoſt the ſame State as it was, without enlarging its bulk from the Reſt of the Ore: Whereas if a little powdered Charcoal be thrown in, or the Ores be committed to a naked Wood-Fire, they preſently reſolve into Metal.

The metallic Nature how preſerved, or recovered.

24. We might obſerve in our Experiment of Cupellation *b*), how extremely apt theſe imperfect Metals are to receive a deſtructive Alteration in the Fire, or to be burnt and reduced to Aſhes, or Glaſs, along with the Lead; on which Diſpoſition of theirs the Art of Cupelling depends. But by contriving to melt theſe Metals in Contact with the Coals, their metallic Form is greatly preſerved; eſpecially as the ſtony, vitrifiable Matter, wherewith ſuch Ores are uſually mixed, occaſions them, by their clinging Nature, to unite more intimately with the glowing Coals.

Metalline Calces reduced.

25. This Doctrine receives a remarkable Confirmation from the uſual Method of recovering Metals burnt to Aſhes at the Smelting-Furnace: For if the Litharge, blown off in teſting, or even the Glaſs of Lead, or the Aſhes of any other of the imperfect Metals, be barely melted in Contact with Charcoal, they preſently recover their metalline Form. And the ſame Thing

a) See *Lect.* II. *paſſim.* *b*) See *Exp.* I.

is

is likewiſe effected by the Addition of any unctuous or inflammable Matter; whence it ſeems to be the unctuous or inflammable Matter of the Coals, which thus inſinuating into the metalline Calces, reſtores their metallic Nature. And we have ſeveral Times, in the Courſe of theſe Lectures, had Occaſion to obſerve the great Affinity there is betwixt Oils and Metals *; inſomuch that their true metallic Form, or their Softneſs and Ductility, ſeems entirely owing thereto.

26. There are three Things, therefore, to be principally regarded in the Smelting of Ores; *viz.* (1) the Fuſibility of the Metal; (2) the Fuſibility of the *Scoria*; and (3) the Contact or Mixture of the metallic Matter with the inflammable Part of the Coals. *Three things to be regarded in Fuſion;*

27. (1) Different Metals run in different Manners from their Ores. Thus Lead, though extremely fuſible in the Metal, yet runs with Difficulty from the Ore; ſo as to require a conſiderable Violence of Fire. This Stubbornneſs, not belonging to the Metal, muſt be attributed to the ſtony, ſulphureous, or other mineral Matter, wherewith the Ore is mixed; which Matter ſeems to require a Degree of Heat capable of vitrifying the Lead, before the Metal will run: But then the Lead thus vitrified recovers a metallic Form again, by coming in Contact with the Coals. viz *The Fuſibility of the Metal: Inſtanced in Lead.*

28. In the Caſe of our preſent Experiment, the Iron-Filings laying hold of the ſulphureous Parts of the Ore, leave the Lead at Liberty to run much ſooner, and freer, from the Stone: Where alſo the great Degree of Heat communicated by the Iron-Filings, and their inflammable Nature, muſt have a conſiderable Effect, at the

* See *Lect.* VI. *Exp.* II. & *alibi paſſim.*

ſame Time that they will not incorporate with Lead, but float on its Surface in Fuſion.

Tin, Copper, and Iron. 29. Tin runs from its Ore with greater Eaſe than Lead; and is therefore ſmelted in much leſs Furnaces: But Copper requires an intenſe Heat, or a Blaſt-Furnace; and Iron, the greateſt Heat that can be given in a Furnace: and both Iron and Copper abſolutely require immediate Contact with the Fewel employed. Hence it appears, that each Metal muſt have its determinate Degree of Heat, to run it with Advantage from the Ore or Stone.

The Fuſibility of the Slag. 30. (2) In order, likewiſe, to obtain the Metal from the Ore to beſt Advantage, the *Scoria*, or Slag, muſt be neceſſarily made to run thin and fluid; otherwiſe it entangles or inviſcates the Metal, and will not let it ſeparate fully. And hence we frequently obſerve, in the Aſſaying of Copper Ores, ſmall grains of Metal interſperſed, here and there, among the *Scoria*, that require to be ſeparated by ſtamping and waſhing the whole Maſs; which Labour might have been prevented, by uſing a ſuitable Flux, and a proper Degree of Heat, capable of procuring a thin Fuſion; ſo as to have made all the Metal fall to the Bottom of the Crucible, which it conſtantly does when the Operation is well performed.

31. To promote a thin Fuſion of the Slag, in the larger Furnace, it is often proper to uſe the more ſoft and fuſible Sands as a Flux; and ſometimes that Loamy Sand, which the Smiths employ for the Welding of Iron; this Sand readily vitrifying, and adhering to the Metal in the Fire: And where it will anſwer the Charge, even Litharge, or Droſs of Lead, might be uſed for this Purpoſe, in the larger Furnaces; for ſcarce any Thing procures ſo thin a Fuſion of the Slag.

 32. In

32. In the large Work, Sulphur is found to adhere tenaciously to Copper; which Metal, therefore, seldom comes out pure in the Furnace, without repeated Fusions. The best Method of separating this Sulphur is, to use a violent Heat, no additional Flux at all, and the greatest Draught of Air that can any Way be procured; so that all Things may conspire to burn out, or carry off, the Sulphur, and introduce, in its Stead, a Thing of a different Nature; *viz.* the inflammable Matter of the Coals; on which, as we before observed, Ductility seems to depend. But where Iron is mixed with Copper, no better Addition is found than Sulphur, and the more sulphureous Marcasites; or what at the Smelting Huts they call *Marcasite Blocks*: For the Sulphur which these contain causes the Copper readily to run away from the Iron, and leave it behind in the Furnace. And here the Power which Sulphur has upon the several Metals is very remarkable. We before observed, that it renders Silver almost as fusible as Lead *: It also greatly increases the Fusibility of Iron, and Regulus of Antimony; but renders Tin much less fusible than it is of itself; and Lead, even refractory in the Fire: Whence certain Rules might be formed, for the Use and Application of Sulphur to Metals, for the Improvement of Metallurgy. And thus the whole Art of Smelting seems to depend upon knowing the Degree of Heat required by every Ore; so as to make the Slag, as well as the Metal, run thin, and evaporate or discharge the sulphureous Parts; and, lastly, to introduce the proper

Sulphur how separated from Copper.

* *Exp.* II. §. 18.

metallic, ductile Form, by Means of an unctuous or inflammable Matter.

Consequences of inartificial Fusions and Separations.

33. It seems principally owing to a Defect in the Knowledge of Fusion, that so many Recrements, or Slags, of Metals, anciently thrown, as useless, from the Furnace, have been wrought to considerable Profit of late, by more skilful Workmen; at least it seems more rational to attribute the Success to this Cause, than to any supposed Growth of Metals in such Slags: So likewise it is currently believed, that Lead grows rich in Silver, by lying exposed to the open Air, or by long covering Churches, or other Buildings; whilst perhaps it is rather owing to the Unskilfulness of the former Workmen, who were not able to separate all the Silver naturally contained in Lead. And thus it appears certain, that the ancient Metallurgists were unacquainted with any Way of extracting, to profit, a small Quantity of Silver out of Copper; which is now commonly done by an ingenious Contrivance *: Whence the ancient Copper found upon Temples, or other Buildings, frequently contains Silver. So likewise in the *Forest of Dean* they at this Day work the Slag of their old Iron-Works over again to Profit.

Metals to be carefully cooled.

34. All Moisture, as well as too sudden Cooling, proves prejudicial to the more ignoble Metals after Fusion; and sometimes dangerous to the Operator. A little Water falling upon melted Iron or Copper makes them expand with prodigious Violence, and discharge themselves abroad with a Force like that of a Canon: And even sudden cooling will often occasion the Surface of the Metal to crack, and force the more internal Part, not yet set or fixed, to issue out to

* See below, §. 35.

a cona confiderable Diftance; whence either Lofs of the Metal or Mifchief may enfue. But to prevent thefe ill Effects, after Cupellation, it is ufual for the Operator to throw a Quantity of Water, all at once, upon the Lump of Silver, as it lies in the Teft, at the Moment that it begins to grow rigid; for thus the Water, by its Coldnefs, fuddenly makes fo thick a Cover upon the Surface of the Silver, that the hotter infide Parts cannot break through the upper: Whence that fpringing, or fpouting out, of the Silver, which we fometimes fee in the fmaller Way of affaying upon the Teft, when the Metal fpontaneoufly cools, is entirely prevented.

35. We have already confidered how Gold and Silver are to be feparated when mixed *a*); we fhould alfo know how the lefs noble Metals may be feparated from one another: This is done either by Means of Fire alone, or by Means of Lead. Thus Copper, being more fufible than Iron, will, in a proper Furnace, melt, and run entirely from it; whilft the Iron is not made to flow with the fame Degree of Heat as melts the Copper, or elfe fticks behind in the Slag. After the fame Manner Lead, being more fufible than Copper, readily runs away from it, in a Furnace kept of a due Heat for the Purpofe. A Mixture of Iron and Lead is feparated in the fame Manner; the Iron floating upon the Surface of the Lead. Copper, Tin, Iron, Antimony, &c. we before obferved might be feparated from Gold or Silver, by tefting with Lead *b*); but then the ignobler Metals are loft. And where only a fmall Proportion of Silver is mixed with a large one of Copper, this Method would prove ufelefs, or prejudicial:

The ignobler Metals how feparated from each other; viz. Iron from Copper.

Lead from Copper.

Iron from Lead.

a) See *Exp.* II. *b*) *Exp.* I.

 Nor

Silver from Copper. Nor can a ſmall Proportion of Silver be well ſeparated from Copper, by any Method hitherto known; ſo as to preſerve the Copper pure, or eaſily recoverable: Whence at the Smelting-Huts the Method is, to get the Silver out of imperfect Copper, whilſt it ſtill remains mixed with its own Sulphur, under the Form of what they call *Black Copper*. This they melt, and make to run among a large Proportion of melted Lead; then caſting the Mixture out into large Blocks, theſe are carried to a particular Furnace, and there ſet upright, ſo as that the Fire, being lighted at top, may commodiouſly play between them. And thus the Lead melts away from the Blocks, carrying with it the Silver before contained in the Copper; the Blocks of which Metal are now left hollow, porous, ſpungy, and wrinkled. Theſe exhauſted Blocks are then removed to a hotter Furnace, in order to be farther drained of their Lead. The laſt Remains are now, in another Furnace, reduced to perfect Copper; and the whole Parcel of Lead, thus enriched, committed to the Teſt, in order to ſeparate the Silver.

Copper Ore teſted. 36. In the ſame Manner may Copper Ores be aſſayed, by teſting them with a ſmaller Proportion of Lead than is uſed to Silver Ores; tho' this Operation requires a great Degree of Care and Exactneſs, to prevent the Copper from being carried off with the Lead, or vitrified. So likewiſe when Copper happens to be mixed with Iron, the beſt Method of ſeparating them, in the Way of Eſſay, is to melt them with Lead; which readily imbibes the Copper, but throws the Iron to the Surface; where being entangled with the vitrified *Scoria* of the Lead, it may be taken off, and the Copper thus brought to a great Degree of Purity; though indeed it is apt

to

to lose a little of its Ductility, on Account of some very minute Proportion of Lead, or its Fumes, remaining therein.

37. We have not here confined ourselves to the Consideration of one Metal more than another; but endeavoured, under the present Experiment, to shew the Ways of treating all the ignobler Kinds, or working them, in the best Manner, from their Ores. It is easy to apply this general Doctrine, occasionally, to the Treatment either of Lead, Tin, Copper, or Iron. *The Doctrine general.*

EXPERIMENT IV.

The Method of making Prince's Metal.

38. We took six Ounces of Copper, and melting it in a Wind-Furnace, added to it an Ounce of Zink; then stirring the whole well together, we immediately poured out the Metal. The Copper and the Zink may be put into the Crucible together, if first covered over with the Black Flux; which prevents the Avolation of the Zink, or preserves its metalline Form. *A mixed Metal of Copper and Zink.*

39. This is an expeditious Method of making a fine Kind of Brass; whereas the common Method with *Lapis Calaminaris* requires a considerable Length of Time, and a violent Fire: For this Purpose they calcine and powder the Calamy; then mix it with a little Charcoal-dust; and to seven Pounds of this Mixture add five of Copper-Plates; then giving eleven or twelve Hours Fire, the Copper imbibes about one third of its Weight of the Calamy. *Brass how made.*

40. It is here remarkable that the Calamy, though no compleat metallic Body, nor malleable, should yet concrete along with the Copper, so as not only to increase its Weight, but also to extend *The Nature of Calamy.*

extend with it under the Hammer; which Zink, in making the Prince's Metal, does not do, though it appear in all Refpects of a more metallic Nature than Calamy.

And Zink. 41. The Agreements and Difagreements of thefe two Bodies, Zink and *Lapis Calaminaris*, may deferve to be farther enquired into, by particular Experiments. The Inflammability of Zink is very remarkable; for it burns durably of a bluifh white Flame in the Fire; and thus refolves into a white Calx.

Imitations of Gold. 42. Many curious Phænomena, and unexpected Refults, happen upon mixing metallic and mineral Bodies in the Fire; all which deferve to be tried, and noted, as Facts that might at leaft direct to the difcovery of feveral new and ufeful Mixtures, or Compofitions of Metals. We might be encouraged to profecute this Enquiry, by thofe pretty Imitations of Gold, lately introduced for the making of Watches, Buckles, Caneheads, Snuff-boxes, &c. But perhaps a better Imitation of Gold, for thefe and many other Purpofes, may be obtained by M. *Homberg*'s Method of treating Copper with Quickfilver: For if an Amalgam be made of one Part pure Copper, and three Parts Quickfilver; and the Amalgam be boiled in River-Water for two Hours; then the Quickfilver diftilled off, and cohobated once; the remaining Copper, being now fufed, will be found of a beautiful Gold Colour, and more ductile than common Copper; fo as to become well fitted for Watchwork, Gilding, and the finer Machines and Utenfils.

Homberg's Metal.

EXPERI-

Experiment V.

The Method of converting Iron into Steel.

43. We took a few Pieces of ſoft Iron-Wire, and burying them in a cloſe Crucible, full of powdered Charcoal, ſet the whole in a Wind-Furnace, for two or three Hours; then taking out the Pieces of Wire we found them changed to Steel. *Steelmade.*

44. The Method of making Steel has been uſually kept as a Secret, and at preſent there are but very few Steel-makers in *England*: The ancient Method was, to keep ſlender Bars of Iron ignited, for ſeveral Hours, in a melted Mixture of Iron and vitreſcible Sand; then taking out the Bars, forging them, and immediately plunging them, whilſt hot, into cold Water; afterwards forging them again, till they would eaſily ſnap, and appear white, and of a cloſe Texture, or Steel-Grain, when broke. *The ancient Method.*

45. The preſent Method is, to ſtratify a large Number of ſlender Iron Bars with powdered Charcoal; to fill a Furnace with them, in the Form of a long Cheſt; and then to keep up a ſtrong Fire, but ſo as not to melt the Iron, for two or three Days together. And thus at length, when the Furnace is cold, the Bars are taken out unaltered in their external Form: But they may be bliſtered according to the Pleaſure of the Operator, by uſing Quicklime along with the powdered Charcoal. *The modern Method.*

46. The whole Secret of making Steel ſeems to depend upon excluding the Air from the Iron to be wrought upon. Accordingly if a large Ball of Iron be kept ſo hot, for ſome Time, that its external Surface ſhall melt, and run like Water, *On what the Operation depends.*

Water, the internal Part of the Ball will, at the ſame Time, be converted into true Steel. And hence appears the Reaſon why certain Knots, or Spindles, of Iron are ſometimes found in the Middle of Caſt-Work, ſo hard that no Tool will touch them.

Caſe-hardening. 47. The Art of Caſe-hardening is a leſſer Degree of Steel-making; and is practiſed by baking Raſors, Files, Knife-Blades, *&c.* in a Kind of Oven, ſtratified with powdered Charcoal, Hoofs, Horns, and the like, ſo as to exclude the Air; and thus, by baking, to give a Coat of Steel to Inſtruments, ſome Depth below their Surface.

The beſt Steel, how made. 48. But the Making of the beſt Steel depends upon the Nature of the Iron employed, or its Ore; and uſually requires a proper Mixture of ſeveral Kinds together, as well as Perfection in the Art of Tempering; which, according as it is managed, ſuits the Steel for different Uſes. Thus Gravers are of one Temper, Drills of another, Watch-Springs of another, Razors of another, *&c.* Which Tempers are given them by being quenched with different Heats in Tallow, Water, or certain Liquors, Juices, or the like.

AXIOMS *and* CANONS.

1. We learn from the foregoing Enquiry, That different mineral and metallic Matters bear different Relations to melted Lead in Fuſion: Whence ſome of them will not mix therewith, but float on its Surface; others evaporate, and others vitrify with it; whilſt Silver and Gold remain unaltered by it, and unimpaired *.

2. That the nobler Metals have nearly the ſame Relation to Quickſilver, as they have to

* *Exp.* I.

melted

melted Lead; being readily drunk up by them both, and thus ſeparated from other heterogeneous Matters *a*).

3. That Teſting, in the large Way, is improveable by finding a properer Matter than Bone-Aſhes for the making of Teſts; by working without Bellows; and again by uſing Pit-Coal, and a well contrived Furnace *a*).

4. That the Art of Aſſaying is hitherto imperfect; but capable of receiving conſiderable Improvements from chemical and mechanical Knowledge *a*).

5. That the troubleſome and expenſive Method of ſeparating Gold from Silver by *Quartation*, may be advantageouſly ſuperſeded, or ſet aſide, by Means of Fuſion, or a dexterous Management of the Fire *b*).

6. That Gold and Silver are rarely rendered abſolutely pure, or ſeparated from all other Kinds of metallic or mineral Matters; and that to purify them to ſuch a Degree requires the Uſe of better Methods than thoſe commonly employed: though the Thing is ſtill performable by Art, and a ſuitable Proceſs *b*).

7. That the particular *Hiſtory of common metallic Fuſion* is wanting, for the Improvement of Metallurgy *c*).

8 That when the Ore of an imperfect Metal is in immediate Contact with the Fire or Fewel, it yields more and better Metal, than when contained in a Crucible, or kept from touching the Coals *c*).

9. That a languid Fire leſſens the Yield of an Ore; but a briſk one, if not too long continued, increaſes it *d*).

a) *Exp.* I. *b*) *Exp.* II. *c*) *Exp.* III. *d*) Ibid. See alſo *Lect.* XVII.

10. That

10. That the Businefs of Smelting in Perfection depends (1) upon ufing a Degree of Fire fuited to the Ore; (2) procuring a quick and thin Fufion of the *Scoria*; and (3) a clofe Contact of the Metal with the Fewel, or Coals, employed *a*).

11. That Sulphur has different Effects upon the different Metals; which Effects being well noted, Rules of Practice might be thence derived, for the farther Improvement of Metallurgy *a*).

12. That metalline Recrements, or the Slags of Metals once fmelted, have been wrought over again to profit, on Account of the imperfect Manner wherein the Ores were originally treated for their Metals *a*).

13. That the ignobler Metals are feparable from each other by the Application of proper Degrees of Heat; fo as to make the more fufible melt away from the lefs fufible; at leaft with the Affiftance of Lead *a*).

14. That all Metals are reducible, by burning, or Calcination, to terreftrial Powders, or *Calces*; which, by being melted with any inflammable Matter, affume their metalline Form again *a*).

15 That the great Enemies to Ductility, or the true metallic Nature, are Sulphur, Cobalt, and Things compounded thereof *b*); but that all unctuous or inflammable Bodies are friendly to Metals, and promote or reftore their Ductility, when melted therewith *c*).

16. That Copper may be made to approach the Colour of Gold, and at the fame Time not lofe, but increafe, its Ductility, by being amalgamated with, and diftilled from, Quickfilver;

a) *Exp.* III. *b*) *Exp.* III. See alfo *Lect.* XVII. *c*) *Exp.* III.

and

and that probably many artificial or compound Metals are discoverable, by mixing various metalline and mineral Bodies together; so as greatly to enrich and improve the Art of Metallurgy *a*).

17. That Steel is made by a proper Application of Fire to Iron, in a close Place, so as to prevent the open Air from communicating freely with the Iron *b*).

18. That Metals receive particular Alterations in their Texture or Consistence, according to the Nature of the solid Substance or Liquor, wherein they are quenched or cooled *b*).

19. That, in general, Ores are no more than a natural, loose Mixture of metallic Matters, along with earthy and sulphureous ones: Whence artificial Ores may be readily made, by calcining a Metal with Sulphur, and mixing it with Earth; so as, with Heat, to form solid Lumps of Ore, resembling those Dug out of Mines *c*).

20. That numerous Experiments remain to be made, Facts of Nature, or Observations, to be registered, and Relations of Bodies to be found, before this useful Subject of Metallurgy can be brought to Perfection *d*).

a) *Exp.* IV. *b*) *Exp.* V. *c*) See *Lect.* XVII. and XVIII. *passim.* *d*) *Exp.* I. II. III. IV. V.

LEC-

LECTURE XIX.

CONTAINING

Pyrotechny; *or Experiments relating to* Gunpowder, Explosions, *and* Phosphori.

The Design. 1. THE present Design is to enquire into the Nature of Gunpowder, Explosions, and *Phosphori*; and to try if any useful Doctrine or Discoveries may be thence derived, for the Improvement of Chemistry and Natural Philosophy. We therefore propose (1) to examine into the Nature and Composition of Gunpowder, with the Ways of trying and improving it; (2) to shew some of the more remarkable Kinds of Explosions; (3) to examine some of the more eminent *Phosphori*; and (4) to deliver the Doctrine pointed out by this Kind of Experiments.

The Intent of the Experiments. 2. Our *first* Experiment, therefore, will shew the Method of making Gunpowder; our *second* the Method of making the *Pulvis* and *Aurum fulminans*; our *third*, a Method of producing Heat and Fire by the Mixture of Sulphur and Iron Filings; our *fourth*, a Method of producing Coruscations with Oil of Vitriol and Iron Filings; our *fifth*, a Method of producing Fire and Flame by the Mixture of two cold Liquors; and our *sixth* Experiment will shew the Method of making the liquid Phosphorus of Urine.

Experi-

EXPERIMENT I.

The Method of making Gunpowder.

1. We took four Ounces of refined Salt-Petre, an Ounce of Brimſtone, and ſix Drams of Small-Coal; theſe we reduced to fine Powder, and continued beating them, for ſome Time, in a Stone-Mortar, with a Wooden Peſtle; wetting the Mixture, between whiles, with Water, ſo as to bring the whole into an uniform Paſte; which we then reduced to Grains, by paſſing it through a Wire-Sieve fit for the Purpoſe: And in this Form, being carefully dried, it became the common Gunpowder. *Gunpowder made.*

2. We formerly ſhewed the Way of refining Salt-Petre for the making of Gunpowder *. In order to reduce this Salt to Powder, they diſſolve a large Quantity of it in as ſmall a Proportion of Water as poſſible; then keeping it continually ſtirring over the Fire, till the Water exhales, a white dry Powder is left behind. *Nitre how pulverized readily.*

3. In order to purify the Brimſtone employed, they diſſolve it with a very gentle Heat; then ſcum and paſs it through a double Strainer. If the Brimſtone ſhould happen to take Fire in the melting, they have an Iron-Cover that fits on cloſe to the melting Veſſel, and damps the Flame. The Brimſtone is judged to be ſufficiently refined, if being put between two hot Iron Plates, it melts into a Kind of red Subſtance, without yielding any fetid Odour. *The Sulphur purified.*

4. The Coal for the making of Gunpowder, is either of Willow or Hazel, well charred in the uſual Manner, and reduced to Powder: And thus the Ingredients are prepared for mak- *The Coal prepared.*

* See *Lect.* XIII.

The Stamping. ing this Commodity. But as theſe Ingredients require to be intimately mixed, and as there would be Danger of their firing if beat in a dry Form, the Method is to keep them continually moiſt, either with Water, Urine, or a Solution of Sal-Ammoniac, and to continue thus ſtamping them together for 24 Hours; after which the Maſs is fit for corning, and drying in the Sun or otherwiſe, ſo as ſeduloully to prevent its firing.

Rationale *of Gunpowder.* 5. The exploſive Force of Gunpowder is now a thing commonly known; but the phyſical Reaſon thereof may not, perhaps, be hitherto ſufficiently underſtood. In order to explain it, let us obſerve (1) that Salt-Petre, of itſelf, is not inflammable; and though it melts in the Fire, and grows red hot, yet it does not explode, unleſs it comes in immediate Contact with the Coals; (2) that Brimſtone eaſily melts at the Fire, and than readily catches Flame; (3) that powdered Charcoal readily takes Fire, even from the Sparks yielded by a Flint and Steel; (4) that if Nitre be mixed with powdered Charcoal, and brought in Contact with the Fire, it burns and flames; (5) that if Sulphur be mixed with powdered Charcoal, and Fire applied to it, part of the Sulphur burns ſlowly away, but not much of the Charcoal; and (6) that if a lighted Coal be applied to a Mixture of Nitre and Sulphur, the Sulphur preſently takes Fire, with ſome Degree of Exploſion, leaving a Part of the Nitre behind; as we ſee in making the *Sal Prunellæ* and *Sal Polychreſtum.*

6. Theſe Experiments duly conſidered may give us the chemical Cauſe of the ſtrange exploſive Force of Gunpowder: For each Grain of this Powder conſiſting of a certain Proportion of Sulphur, Nitre, and Coal, the Coal preſently-

ly

ly takes Fire, upon Contact of the ſmalleſt Spark; whereupon both the Sulphur and the Nitre immediately melt, by Means of the Coal interpoſed between them, and burſt into Flame; which, ſpreading from Grain to Grain, propagates the ſame Effect almoſt inſtantaneouſly; ſo that the whole Maſs of Powder comes to be fired: And as Nitre contains a large Proportion both of Air and Water, which are now violently rarefied by the Heat, a Kind of fiery exploſive Blaſt is thus produced; wherein the Nitre ſeems, by its aqueous and aerial Parts, to act as Bellows to the other inflammable Bodies, Sulphur and Coal, blow them into a Flame, and carry off their whole Subſtance in Smoak and Vapour.

7. The Diſcovery of this Compoſition was accidental, and perhaps owing to that common Operation of fulminating Nitre with Sulphur, for the making of *Sal Prunellæ*. It appears to have been known long before the Time of *Schwartz*, as being particularly mentioned by Friar *Bacon*. *Its Diſcovery.*

8. The three Ingredients of Gunpowder are mixed in various Proportions, according as the Powder is intended for Muſquets, Great Guns, or Mortars: Though theſe Proportions ſeem not to be hitherto perfectly adjuſted, or ſettled by competent Experience. *The Ingredients differently proportioned.*

9. There are two general Methods of examining Gunpowder; one with regard to its Purity, the other with regard to its Strength. Its Purity is known, by laying two or three little Heaps near each other upon white Paper, and firing one of them; for if this takes Fire readily, and the Smoke riſes upright, without leaving any Droſs or feculent Matter behind, and without burning the Paper, or firing the other Heaps, it is eſteemed a Sign that the Sulphur and Nitre *How tried as to purity.*

were well purified; that the Coal was good; and all the three Ingredients were thoroughly incorporated together. But if the other Heaps alſo take Fire at the ſame Time, it is preſumed that either common Salt was mixed with the Nitre, or that the Coal was not well ground, or the whole Maſs not well beat and mixed together; and if the Nitre or Sulphur was not well purified, the Paper will be black or ſpotted.

How as to Strength. 10. In order to try the Strength of Gunpowder, there are two Kinds of Inſtruments in Uſe; but neither of them appear more exact than the common Method of trying to what Diſtance a certain Weight of Powder will throw a Ball from a Muſquet.

How ſtrengthened. 11. To increaſe the Strength of Powder, it ſeems proper to make the Grains conſiderably large, and to have it well ſifted from the ſmall Duſt. We ſee that Gunpowder reduced to Duſt has little exploſive Force; but when the Grains are large, the Flame of one Grain has a ready Paſſage to another, ſo that the whole Parcel may thus take Fire nearly at the ſame Time; otherwiſe much Force may be loſt, or many of the Grains go away, as Shot, unfired.

12. It ſhould alſo ſeem, that there are other Ways of increaſing the Strength of Powder; particularly by the Mixture of Salt of Tartar: But perhaps it may be improper to divulge any Thing of this Kind, as Gunpowder ſeems already ſufficiently deſtructive.

White Powder. 13. There has been much talk of a *white Powder*; which, if it anſwered the Character given it, might be a dangerous Thing: For 'tis pretended that this white Powder will throw a Ball as far as the Black, yet without making any Report. But none of the white Powder which we have

have ſeen anſwers this Character; being, as we apprehend, commonly made either with Touch-wood or Camphire, inſtead of Coal. The moſt dangerous white Powder, if it may be ſo called, is condenſed Air; which, though able to diſcharge a Ball, with great Force, to a conſiderable Diſtance, makes not a loud Report; eſpecially when not violently condenſed, as it need not be to have pernicious Effects.

14. And how far Wind-Guns are improveable, has not, perhaps, been well conſidered. Some of them we have ſeen diſcharge a great Number of Bullets ſucceſſively; even the laſt whereof would go through an Inch-Plank, at the Diſtance of ſeveral Yards: So that this Machine might anſwer the ſame End as a Muſquet. But whether it be practicable to make great Guns in the ſame Manner, is another Conſideration; and chiefly depends upon finding a Spring ſufficiently ſtrong to reſiſt the violent Force wherewith Air might be condenſed by the Uſe of a Winch, &c. *Wind-Guns.*

Experiment II.

The Pulvis *and* Aurum fulminans *prepared.*

15. We took three Ounces of purified Nitre, two Ounces of Salt of Tartar, and one Ounce of Brimſtone, and ground them well together in a Mortar; then putting a ſmall Quantity, as about half a Dram, of this Powder upon an Iron Plate, and placing it over a gentle Fire, as ſoon as the Powder juſt began to melt, it made a ſmart and loud Exploſion. Pulvis fulminans *prepared.*

16. The moſt philoſophical Way of accounting for this Effect of the *Pulvis fulminans*, is by ſuppoſing that the acid Spirits of the Nitre and *Its Effect accounted for.*

Sulphur, being loosened by the Heat, rush towards one another, and towards the Salt of Tartar, with so great a Violence, as, by the Shock, at once to turn the whole into Vapour and Fume.

Aurum fulminans *prepared.* 17. We dissolved a few Grains of fine Gold in *Aqua-Regia*, precipitated the Solution with Salt of Tartar, and thus obtained a Powder, which we dried with a very gentle Heat. A single Grain of this Powder being laid upon the point of a Knife, and held over a lighted Candle, presently went off, with a very brisk and loud Report.

Its odd Properties. 18. This *Aurum fulminans* has other remarkable Properties; for (1) it does not, like the *Pulvis fulminans* and Gunpowder, require the Application of actual Fire to make it explode; but though prepared with two of the most fixed Bodies, Gold and Salt of Tartar, yet is so volatile as to fly off, and give this loud Report, with a less Degree of Heat than suffices to kindle any of the most inflammable Bodies; or even by being strongly rubbed in a Mortar, or dried on a hot Furnace: (2) It exerts its explosive Force *in vacuo*, as well as in the open Air; and when made to explode in the exhausted Receiver, a fine Gold Dust has been found sticking to the Sides of the Glass. (3) The Addition of a little Brimstone to this Powder takes away its fulminating Property; so that after having been melted therewith, the Gold is set loose, and may be easily recovered, in its native form, by fluxing it with Borax.

The Rationale. 19. Hence it should seem that the Body of the Gold in this Powder is subtilely divided by the Action and Interposition of the Parts of the compound Menstruum; which Menstruum being of an an aqueous and aerial Nature, and its Parts closely wedged in betwixt the fine ponderous Parts of the Gold in the *Aurum fulminans*, when this Powder comes, any way, to feel such a Degree of Heat as suffices strongly to rarify and expand the aqueous and aerial Particles, they burst with Violence from their Prisons, and scatter the dusty Particles of the Gold around.

EXPERIMENT III.

The Production of Heat and Fire, by the Mixture of Sulphur and Iron-Filings.

20. We took two Pounds of clean Iron-Filings, and as much common Brimstone, and beating them together for some Time, in a Mortar, with the Addition of Water, we brought the whole to a Kind of Paste; which being close prest into an earthen Pot, and set in a Chimney, it in a short Time begun to grow hot, and at Length took fire. *The firing Mixture of Iron and Sulphur explained.*

21. This Mixture never fails to take Fire, if the Quantity be large; but if it be small, the Paste only heats and cracks, in several Places, so that hot Vapours issue out thereat. But if the Heat continues sufficiently long, the whole Mass will be changed into one uniform Substance; which, being ground and boiled in Water, affords good Vitriol of Iron *: Whence it is manifest, that the Acid naturally contained in the Brimstone enters the Body of the Iron, and dissolves it. This Action may therefore be the Cause of the Effect; especially if we consider that Sulphur consists of an unctuous or inflam-

* See below §. 26.

mable, as well as an acid Part: For this inflammable Part of the Sulphur, doubtless, takes Fire in the violent Conflict betwixt the Iron and the Acid of the Sulphur.

And applied. 22. This Experiment, if duly attended to and applied, may, in the usual Way of Philosophers, account for several Phænomena of Nature; such as burning Mountains, subterraneous Fires, Earthquakes, hot Baths, &c. Thus, for instance, as there are large Quantities of Iron-Stone, and Sulphur, found in the Bowels of the Earth; as also Marcasites, which are a Mixture of the two; when these come to be wet, as they may, on many Occasions, with Water, 'tis easy to conceive, that they must heat, swell, ferment, explode, and yield a hot Steam or Vapour, which forcing its Way through certain Caverns of the Earth, shall produce Earthquakes, or violent Strugglings, of longer or shorter Duration, till the Force finds vent, or expires through some Cranny into the Atmosphere. Sulphureous Vapours certainly abound in the Bowels of the Earth, and ferment, and conflict with Minerals, so as to take Fire, and make sudden Coruscations, or Explosions; and if confined in the Caverns of the Earth, sometimes burst and shudder those Caverns to Pieces. At which Time the hot Vapours, generated by the Explosion, and expiring through the Pores of the Earth, may raise Tempests and Hurricanes, or make the Ground sink into Chasms, or the Sea boil up in certain Places. These sulphureous Vapours at other Times ascending into the Atmosphere, may there ferment along with other Matters, take Fire, and thus Occasion Thunder, Lightning, the *Aurora Borealis*, and other fiery Meteors: At least this seems one probable

probable Cause of ſuch Effects, and has a Foundation in Nature *.

Experiment IV.

Coruſcations produced by means of Oil of Vitriol and Iron.

23. We took a cut Body, capable of holding two or three Quarts; and put into it three Ounces of Oil of Vitriol, and twelve of common Water; then warming the Mixture a little, we threw in, at ſeveral Times, two Ounces, or more, of clean Iron-Filings; upon which an Ebullition, and white Vapours, aroſe; then preſenting a lighted Candle to the Mouth of the Body, the Vapour took Fire, and at the ſame Time afforded a bright Fulmination, or Flaſh like Lightning. The Candle being ſeveral Times applied, in the ſame Manner, afforded the like Coruſcation; during which we ſometimes found the Glaſs filled with a Flame that reached, and circulated, to the Bottom of the Liquor; and ſometimes the Flame only roſe into the Neck of the Glaſs. *Artificial Coruſcations.*

24. This Experiment will not ſucceed, unleſs the Oil of Vitriol be largely diluted with Water, to make the Menſtruum fit for diſſolving the Metal. 'Tis alſo requiſite to heat the Liquor a little, in order to promote the Solution, that the Vapour may aſcend the freer: But if the Liquor be too hot, the Vapour will riſe too faſt; and ſo, when the Candle is applied, only take fire in the Neck of the Glaſs, without making any remarkable Fulmination. *Cautions.*

* See Sir *Iſaac Newton's Queries*, at the End of his *Optics*; and M. *Lemery*'s Paper upon the Subject, in the *French Memoirs*.

25. This

Rationale. 25. This Experiment appears to have a great Affinity with the preceding, and to depend upon nearly the ſame Principle; the Oil of Vitriol being a very powerful Acid, correſponding to that of Brimſtone; and Iron, in itſelf, containing ſomething that is properly ſulphureous, or inflammable. It ſhould ſeem, however, that it is not the Sulphur of the Iron alone, but that ſome ſulphureous Part of the Oil of Vitriol alſo contributes to the Effect; for Spirit of Nitre, or *Aqua fortis*, being uſed in this Caſe, produce no Fulmination: But the Spirits of Salt, of Sulphur, and of Allum, which are all ſulphureous, have here the ſame Effect as Oil of Vitriol.

Diſcovery and Uſe. 26. The Experiment ſeems to have been accidentally diſcovered, by inadvertently approaching a Candle near the Mouth of the Glaſs, whilſt Iron was diſſolving in diluted Oil of Vitriol, in order to make the common Vitriol of Iron; for if what remains in the Glaſs after the Fulmination is over, be boiled, filtred, evaporated, and cryſtallized, it affords this Vitriol in great Perfection, like what we before obſerved of the Mixture of Iron-Filings and Sulphur *a*).

27. We would recommend it to the curious in Chemiſtry, to endeavour to collect, and, if poſſible, to condenſe, a Quantity of the ſulphureous Vapour generated in the preſent Experiment: For this Vapour has not the fetid Smell of Brimſtone; but is, perhaps, ſomewhat like that volatile, aerial Spirit, which gives Virtue to certain mineral Waters *b*).

a) See above, §. 22.
b) See *Hoffman* of Mineral Waters.

EXPERI-

Experiment V.

Fire and Flame produced by the Mixture of two cold Liquors.

28. We took two Drams of ſtrong and freſh Spirit of Nitre, prepared with Oil of Vitriol, and putting it into a clean and dry four Ounce Gally-Pot, we ſet it under a Chimney; then immediately, and at once, poured to it a Dram of the true eſſential Oil of *Indian* Cloves; and there was inſtantly produced a loud Noiſe, a violent Conflict and Ebullition, with a conſiderable Flame; which being extinguiſhed, a reſinous Subſtance, or actual Roſin, was found at the Bottom of the Gally-Pot. *Oil of Cloves and Spirit of Nitre mixed.*

29. To render this Experiment ſafe, (1) it ought to be performed under a Chimney that may carry up the offenſive Vapour; (2) the Oil ſhould be poured from a Phial fixed at the end of a Stick, to prevent any of the fiery Matter from flying upon the Operator: And to render it ſucceſsful, (1) the Spirit of Nitre ſhould be ſtrong, and freſh drawn; (2) the Oil ſhould be genuine; (3) the Veſſel wherein the Mixture is made ſhould be perfectly clean, dry, and large enough to give the Matter room to ſwell; (4) the Oil ſhould be poured in at once, to make the more expeditious Mixture. *Cautions.*

30. This Experiment is neither confined to one certain Oil, nor to one certain Acid; the diſtilled Oil of Saſſafras, Guajacum, Box, *Jamaica* Pepper, Cinnamon, or even the empyreumatic Oils of Hartſhorn, Blood, *&c.* will ſerve the Purpoſe; or, in general, any thin, eſſential Oil, thickened with Balſam of Sulphur, *&c.* For *Extended.*

ſome

ſome Degree of Thickneſs or Tenacity in the Oil ſeems a primary requiſite, to make it explode with Spirit of Nitre; and for acid Spirits, Oil of Vitriol, and moſt of the other acid Spirits highly rectified, will produce Flame with the aromatic *Indian* Oils, if unadulterated.

31. The Experiment is made to give the greater Surprize when Gunpowder is fired by pouring a cold Liquor upon it; for if Gunpowder were put to the Oil, this alſo would be fired, upon pouring in the Spirit of Nitre. Hence it may ſeem ſtrange that Camphire, which is an exceeding inflammable Subſtance, ſhould not take Fire when added to the Oil, and treated as the Gunpowder. The Reaſon ſeems to be, that Camphire contains an Acid; and therefore when diſſolved in the Oil, ſomewhat anticipates or leſſens the Force of the Spirit of Nitre that is afterwards applied; ſo that the Shock betwixt the two is not now great enough to produce Flame: For in the Shock, or violent Conflict betwixt a ſtrong Acid and a thick Oil, diveſted of Acid, the Fire and Flame in the Experiment appear to be produced.

And accounted for

Its Force in vacuo.

32. Nor is the Effect leſſened when the Experiment is performed *in vacuo*; where half a Dram of Oil of Carraway-Seeds, and a Dram of Spirit of Nitre, have made a Flaſh like Gunpowder, and burſt the exhauſted Receiver, a Glaſs ſix Inches wide, and eight deep *. This is a very extraordinary Effect; as differing from moſt other flaming Bodies, which rather deſtroy than generate Air: But here muſt be a large Quantity of Air, or ſomething of equal Force, generated by the exploding Mixture, in order to balance and over-power the external Preſſure;

* See Sir *Iſaac Newton*'s *Queries* at the End of his *Optics*.

which

which in this Caſe was ſeveral hundred Weight. Hence it ſhould ſeem that the Force of our exploſive Mixture is much greater than that of Gunpowder; which will not explode *in vacuo*, nor, even with the Aſſiſtance of the Air, produce any thing like ſuch an Effect. It may therefore be worth conſidering, whether ſo great a Power could not be applied to ſome uſeful Purpoſe. The Mixture might be made cheap, by uſing any of the groſs and ponderous empyreumatic Oils, inſtead of the eſſential Kind.

Experiment VI.

The liquid Phoſphorus *of Urine.*

Solid Phoſphorus made harmleſs.

33. We took half a Dram of Camphire, and ground it in a Glaſs Mortar, with three Grains of the ſolid *Phoſphorus* of Urine; then added as much eſſential Oil of Cloves as ſerved to reduce the whole to a fluid Form. The Mixture thus made may be rubbed upon the Cloaths, the Hair, or the Hands, without Danger of burning *a*).

Hiſtory of Phoſphorus.

34. Chemiſtry hath ſcarce afforded any Thing more ſurprizing than the common *Phoſphorus*. To ſee Letters traced with this Matter become luminous in the dark, Images and the Bodies of Men to blaze with Light, and Abundance of the like Experiments performed by Means of *Phoſphorus*, made many Perſons curious to know how it was made *b*). The Preparation indeed ſeems even to this Day kept as a gainful Secret in few Hands, and the Matter is ſold at a very great Price; Whence we apprehend it would be of

a) See below under § 43. No. 11.
b) See M. *Homberg*'s Papers on the Subject.

ſingular

ſingular Service to Chemiſtry, to render this Commodity cheaper, and diſcover its farther Uſes.

35. With this view we ſhall here touch a little upon the Hiſtory of this *Phoſphorus*, commonly called *Kunckell*'s *Phoſphorus*, or the *Phoſphorus* of Urine. It was diſcovered by accident: One *Brand*, an obſcure Chemiſt of *Hamburgh*, ſtumbled upon it as he was ſearching after the Philoſophers Stone, which he firmly believed lay concealed in Urine. This Subject therefore he tortured a thouſand Ways; and at length, after a violent Diſtillation, found a ſhining Matter, ſince called *Phoſphorus*, in his Receiver. This Matter was ſhewn to Dr. *Kunckell*; but the Proceſs was concealed from him. Soon after this *Brand* died; and *Kunckell* reflecting that *Brand* worked wholly upon Urine, he continued to work upon the ſame Subject himſelf for four years together; and at length, in the year 1679, found the Thing he ſought after. Doctor *Kraft* has uſually paſt for the Inventor of this *Phoſphorus*, he being the firſt that carried it abroad: but he only diſtributed it for Dr. *Kunckell*, being at that Time unacquainted with the Preparation.

The ſolid Phoſphorus, how made.

36. The ſucceſsful Method of making it is this: Evaporate any Quantity of freſh Urine over a gentle Fire, to a black, and almoſt dry, Subſtance; then with two Pounds thereof thoroughly mix twice its Weight of fine Sand; put the Mixture into a ſtrong coated Retort of Stone; and, having poured a Quart or two of clear Water into a large Receiver with a long Neck, join it to the Retort, and work in a naked Fire; let the Heat be ſmall for the two firſt Hours; then increaſe it gradually to the utmoſt Violence: and thus continue for three or four

Hours

Hours ſucceſſively. At the Expiration of that time there will paſs into the Receiver a little Phlegm and volatile Salt, much black fetid Oil, and laſtly the Matter of the *Phoſphorus* in Form of white Clouds, which will either ſtick to the Sides of the Receiver like a fine yellow Skin, or fall to the Bottom in Form of a ſmall Sand. Now let the Fire go out; but take not away the Receiver before it is cold, for fear of ſetting the *Phoſphorus* on fire, by admitting the Air. To reduce theſe ſmall Grains into one Piece, put them into a little Tin Ingot-Mould, along with ſome Water; heat the Ingot, to make the Grains melt together; then add cold Water, till the Matter is congealed into one ſolid Stick, like Bees-Wax; which being cut into little Pieces fit to enter the Mouth of a Phial, may be preſerved by Water, and by keeping the Glaſs cloſe ſtopped. If the Glaſs be not kept ſtopped, the *Phoſphorus* will turn black on its Surface, and at length be ſpoiled.

37. The Cautions required to make the Proceſs ſucceed are, (1) to evaporate the Urine, while it is recent; (2) to prevent its boiling over, and ſo loſing the moſt unctuous Part; (3) to let the Matter afterwards Ferment in the cold: (4) to mix the black Matter with Sand, to prevent its melting and running together; (5) to uſe a Stone Retort, thoſe of Earth being too porous, and ſuffering the *Phoſphorus* to tranſude ſooner than paſs into the Receiver; (6) to have the Receiver very large, and with a very long neck, to prevent its breaking and overheating, which would either evaporate the white Vapour wherein the *Phoſphorus* conſiſts, or elſe prevent its coagulating; (7) to put Water into the Receiver, for keeping it cool, and quenching the *Phoſphorus*, as it falls to the Bottom; *Cautions.*

(8) to

(8) to make the Fire ſmall at firſt, that the Retort may be preſerved, and the black Matter gradually dried, which would otherwiſe ſwell, and come over in a black Froth; *Laſtly*, it is found neceſſary, that the Urine for the Operation be of ſuch as uſe Malt-Liquors, rather than Wine. All theſe Circumſtances being required for obtaining the *Phoſphorus* to advantage, no wonder if ſo many have miſcarried in their Attempts to make it.

The Proceſs ſhortened. 38. This Operation may be greatly ſhortened, by freezing and concentrating freſh Urine, afterwards evaporating it with care, and then digeſting it *per ſe* in the Manner above mentioned. When thoroughly digeſted, commit the Matter, in a large Quantity, to an Iron Pot, with an earthen Head, as the Chemiſts uſually do for making Spirits of Hartſhorn, or the Spirit and Salt of Urine. When all the Salt and Oil are thus obtained, let the *Caput mortuum* be taken out, and mixed with twice its own Weight of Alum. This Matter may now be put into a well coated Long-Neck, and worked with care in a Reverberatory Furnace, into very large Receivers, filled with Water, and connected to the Long-Necks by Adopters; the lower Ends whereof ſhould enter the Water, as in diſtilling Quickſilver, and the Operation be continued for eight or ten Hours. And this we apprehend to be the beſt Way hitherto known of procuring *Phoſphorus* to Advantage. Dr. *Wall* informs us that Mr. *Boyle*, concerned to find how ſmall a Proportion of *Phoſphorus* was afforded by Urine, deſired him to look out for another Subject that might afford it in greater Plenty. The Doctor afterwards cauſing a Piece of dry Matter to be dug up in the Fields where Night-men emptied their Carts, he obſerved a great Number

ber of ſmall Particles of *Phoſphorus* therein. This Matter the Doctor immediately carried to Mr. *Boyle*, who ſet *Bilgar* the Chemiſt to work upon it: But he could obtain very little *Phoſphorus* from it, till another Material was added thereto in Diſtillation; and then he procured *Phoſphorus* in ſuch plenty that, ſelling large Quantities at ſix Guineas the Ounce, he ſoon became rich and left *England* *. The Matter which thus fixes and increaſes the *Phoſphorus*, we apprehend to be Alum; which is itſelf not only in ſome Meaſure prepared from Urine, but appears to afford the ſame Kind of Acid that *Phoſphorus* yields by burning. For upon its Analyſis, *Phoſphorus* appears to be a Compoſition of a ſtrong Acid and an inflammable Matter united, exactly in the Manner of common Brimſtone; whence it may not improperly be called an *animal Sulphur:* And accordingly, like common Brimſtone, it will burn under a Glaſs Bell, and afford Flowers which, by attracting the moiſture of the Air, become an acid Liquor like *Oleum Sulphuris per Campanam.*

39. And in this Manner it has been uſed, ſo as to produce extraordinary Changes upon Metals, eſpecially in the philoſophical View; the Acid itſelf, even without Heat, proving a Menſtruum to perhaps all the Metals. But when this Acid is driven into the Pores of the Metal, by the Action of the Flame in burning the *Phoſphorus*, it ſeems productive of much greater Effects; as is known to thoſe acquainted with the ſublimer Metallurgy. And it is principally with a View of promoting this Kind of Experiments, that we have beſtowed ſo much of our Lecture upon facilitating the Method, and eaſing the Expence, *Farther Uſes.*

* See the *Philoſophical Tranſactions.*

of preparing this *Phoſphorus*; which of all the Kinds hitherto diſcovered ſeems the moſt uſeful.

Other kinds of Phoſphori. 40. This *Phoſphorus* has been ſeveral Ways diſguiſed, ſo as to make it appear under various Forms; ſometimes as a Solid, ſometimes as a Liquid, ſometimes as an Ointment, ſometimes as a running Mercury. There are alſo others of different Kinds; of which we ſhall only mention two, both diſcovered by M. *Homberg*. The

The black Phoſphorus. firſt is that uſually called the *Black Phoſphorus*, now commonly prepared with Alum and Wheat Flower, by taking four or five Parts of Alum to one of Wheat Flower, and calcining them together to a brown or blackiſh Maſs; which being powdered, is put into a Phial, looſely ſtopped with Paper, and ſet in a Sand-Heat, ſo as to continue glowing hot for ſome time; then the whole is removed from the Fire, ſuffered to cool gradually, and at laſt the Bottle is ſtopped cloſe. A little of this Powder being poured out of the Bottle, and expoſed to the open Air, immediately takes Fire, and appears like a glowing Coal. But the Powder muſt be freſh made, to have a ſtrong Effect; for the Sun's Rays, or the Moiſture of the Air, being gradually admitted to it, deſtroy its Virtue: whence it ought to be kept in a dark and dry Place. 'Tis remarkable of this *Phoſphorus*, that it may be made from almoſt any animal or vegetable Subſtance, inſtead of Wheat Flower; but that no Salt whatever can be ſubſtituted inſtead of Alum.

The Phoſphorus of Sal-Ammoniac and Lime. 41. M. *Homberg*'s other *Phoſphorus* is made of one Part Sal-Ammoniac, and two Parts Lime ſlaked in the Air; theſe being mixed well together, a Crucible is to be filled with them, and ſet in a ſmall Fire of Fuſion; where, as ſoon as the Crucible becomes red hot, the Mixture will melt, and ſhould be ſtirred with an Iron-Rod,

to

to prevent its running over. When the Matter is entirely fuſed, it may be poured into a Braſs Mortar; and when cold it will appear of a grey Colour, and almoſt as if it were vitrified. If now it be ſtruck with any hard Body, it appears as on Fire in the whole Extent of the Stroke; but the Matter being brittle, it may be proper for the Experiment's ſake, to dip little Bars of Iron, or Copper, into the melted Matter in the Crucible; for thus they will be enamelled, as it were, with the Matter; and theſe Bars may be ſtruck upon, ſo as commodiouſly to repeat the Experiment ſeveral Times before the Matter falls off. The Bars are to be kept in a dry Place, to prevent the *Phoſphorus* upon them from running by the Moiſture of the Air.

42. Both theſe *Phoſphori*, were diſcovered by Accident: The firſt was obtained by ſearching for a limpid Oil, from the common ſtercoraceous Matter, that ſhould fix Quickſilver; and the ſecond, by endeavouring to calcine Sal-Ammoniac with Lime, ſo as to render it fuſible like Wax; which end was obtained, but not the other. *Diſcovery of* Phoſphori *accidental.*

43. There have been no very conſiderable Uſes of theſe two *Phoſphori* hitherto diſcovered; but the *Phoſphorus* of Urine has been employed for making many curious Experiments; a few whereof we ſhall here exhibit.

(1) The Light of this *Phoſphorus* appears greater *in vacuo* than in the open Air. *Experiments with the Phoſphorus of Urine.*

(2) In hot weather it is obſerved to dart Flaſhes of Light through the Water wherein it is contained, ſo as exactly to reſemble Lightning; which thus darts unextinguiſhed through watery Clouds and Vapours.

(3) These Flashes of Light are not apt to kindle or burn any combustible Matter, in which they resemble the harmless Kind of Lightning; but in a condensed State this *Phosphorus* burns very furiously, and with a most penetrating Fire, so as to melt and dissolve Metals: In which respect it again resembles the more destructive Kinds of Lightning, which are found to have the same Effects.

(4) If a little Piece of this *Phosphorus* be viewed through a Microscope, the internal Parts appear in a constant Ebullition.

(5) A little Piece of it being put into a Silver Spoon, and held over the Fire, it bursts out into a shining Flame, leaving a red spot in the Spoon of a corrosive, acid taste; which being diluted with Water, the Mixture makes a conflict with Oil of Tartar *per deliquium.*

(6) If a little of it be ground in a Glass Mortar, with twenty times its own Weight of Nitre, it does not take Flame, but only disperse a shining Property through the Body of the Nitre; but if ground in the same Manner with Iron-Filings, reduced to Powder, a bright Flame immediately ensues.

(7) Though this *Phosphorus* appears to be a Kind of Sulphur; yet it does not dissolve in high rectified Spirit of Wine, but communicates some sulphureous Parts thereto: For if this Spirit be poured to Water in the dark, it yields a faint Degree of Light.

(8) The Nature of this *Phosphorus* is considerably changed, by being long digested with Alcohol: For thus it becomes a Kind of white transparent Oil, that does not coagulate without an extreme Degree of cold, nor afford any Manner of Light; and when fresh Spirit of Wine

Wine is poured thereon, it does not like other Oils, mix therewith, nor diſſolve therein.

(9) If this *Phoſphorus* be ſeparated from the Spirit of Wine wherewith it was digeſted, and be afterwards well waſhed in common Water, it, by Degrees, recovers its former Conſiſtence, and coagulates into a tranſparent Matter, whiter than before; but neither affords ſo much Light, nor recovers its primitive ſhining Virtue, nor its yellow Colour.

(10) The Spirit of Wine ſo ſeparated becomes yellowiſh, and ſmells ſtrong of the *Phoſphorus*; though it ſhines not, except when poured upon Water.

(11) This *Phoſphorus* being mixed with a large Quantity of Pomatum, makes, as well as with Camphire and the Oil of Cloves, a ſhining Unguent, that may be rubbed on the Hands and Face, without Danger of burning, ſo as to render them luminous in the Dark.

(12) If a Piece of Paper, or Linen, be dipt at one End in Spirit of Wine, and a Bit of *Phoſphorus* be cruſhed on the other End that remains dry, the Spirit will be fired by the *Phoſphorus*, without immediate Contact: But the ſame Thing will not happen, if the Paper were dipt in Oil of Turpentine, nor if a Bit of *Phoſphorus* were rubbed upon the End dipt in the Spirit of Wine; only when the Spirit is entirely evaporated the *Phoſphorus* will burn, though with Difficulty, and ſlowly.

44. There are many of theſe odd Kind of Experiments that might be made with *Phoſphorus*; which is a Subſtance that ſeems, in Chemiſtry, to be much ſuch a Thing as the Loadſtone in Natural Philoſophy; and its effects are almoſt as odd and difficult to explain, for want of knowing the latent Properties of Bodies.

AXIOMS *and* CANONS.

1. We learn from the preceding Experiments, That Gunpowder, and the Arts thereon depending, are capable of farther Improvement; and that more forcible and deſtructive Inventions, than thoſe at preſent in Uſe, are diſcoverable, if required *a)*.

2. That, in particular, great Uſe may be made of compreſſed Air in this Way, the Mixture of Iron-Filings and Brimſtone, in large quantities; the *Pulvis* and *Aurum fulminans*; Salt of Tartar; the Mixture of certain cheap Oils and acid Spirits, for producing extremely powerful and deſtructive Effects *b)*.

3. That many natural Phænomena, ſuch as Earthquakes, Thunder, Lightning, Vulcanos, the *Aurora Borealis*, Hot Baths, *&c.* are imitable and explicable by chemical Experiments, particular Mixtures, and exploſive Powers *c)*.

4. That Fire and Flame are producible by the ſimple Mixture of appropriated Bodies, if made with ſufficient Violence: or that Oils freed of their acid Part, and ſuddenly joined with ſtrong acid Spirits, are inſtantaneouſly productive of Fire and Flame *d)*.

5. That by this Action, or the intimate and ſtrong Union of acid Spirits with Oils, Roſins are producible *d)*.

6. That very violent Fxploſions may be made *in vacuo*, as well as in the open Air *d)*.

7. That the *Phoſphorus* of Urine is applicable to many extraordinary Purpoſes; particularly to the introducing of uncommon Changes in metalline Bodies *e)*.

a) See *Exp.* I. II. and V. *b) Exp.* I. II. III. V. *c) Exp.* III. IV. V. VI. *d) Exp.* V. *e) Exp.* VI.

8. That

8. That as moſt Diſcoveries of chemical Exploſions and *Phoſphori* were accidental, greater Things may be expected from a ſagacious Experience, conducted by Reaſon, and by a farther Diſcovery of Cauſes and Axioms *a*).

9. That the *Phoſphorus* of Urine may be made in large Quantities, and with ſmall Expence; ſo as to afford deſirable Opportunities for the farther Improvement of Chemiſtry and Metallurgy *b*).

10. That there may be many latent Properties in Bodies, remaining unknown to us, for Want of making the proper Experiments; which alone can diſcover, and bring thoſe Properties to light *a*).

b) *Exp.* VI.

LECTURE XX.

CONTAINING

Ways of applying Chemiſtry *to the farther Service and Improvement of* Natural Philoſophy, Arts, Trades, *and* Buſineſs.

I.

Deſign. 1. OUR preſent Lecture is intended to ſhew ſome particular Ways of extending and applying Chemiſtry to the farther Improvement of Natural Philoſophy, Arts, Trades, and Manufactures. For though this be the general Deſign of our whole Courſe, yet we judge it proper to beſtow our laſt Lecture expreſsly upon the Subject. We ſhall therefore (1) divide Chemiſtry into its ſeveral Branches, and ſhew how each of them may be farther improved; (2) exhibit a ſet of Experiments tending to that End; and (3) offer a few Rules for its farther Application and Enlargement.

Chemiſtry divided, 2. *Chemiſtry*, in general, may be uſefully divided into Philoſophical, Technical, Commercial, and Oeconomical Chemiſtry.

Into Philoſophical, 3. By *Philoſophical Chemiſtry* we underſtand Chemiſtry practiſed in Miniature, after the Manner of our preſent Courſe; ſo as to find out the Cauſes of phyſical Effects, and to make new Diſcoveries in Nature *.

* See below § 7.

4. By

4. By *Technical Chemiſtry* we underſtand the Application of Philoſophical Chemiſtry to the immediate Service of ſome Art; ſo as to invent, form, aſſiſt, promote, or perfect it in the large Way of Buſineſs. *Technical,*

5 By *Commercial Chemiſtry* we mean the Application both of Philoſophical and Technical Chemiſtry to the eſtabliſhing, ſupporting, and improving any Branch of Trade or Commerce. *Commercial,*

6. And by *Oeconomical Chemiſtry* we mean the Application of Philoſophical, Technical, and Commercial Chemiſtry to the Service and Accommodation of a Family. *And Oeconomical.*

7. Philoſophical Chemiſtry conſiſts of three Parts; *viz. Invention*, *Rationale*, and *Experiment*: Whence we may define it a particular Exerciſe of the rational and inventive Faculties of the Mind, leading to Experiments, and thence to the Diſcovery of Cauſes; ſo as to form Axioms, that ſhall rationally Account for Phænomena, and diſcover Rules of Practice for producing uſeful Effects. And thus Philoſophical Chemiſtry is not only a Key to all the other Parts, but of itſelf diſcovers the Cauſes of many natural Phænomena; as particularly Earthquakes, Vulcanos, Vegetation, the growth of Minerals *&c.* *Philoſophical Chemiſtry; its Parts:*

8. This Branch of Chemiſtry alſo explains the general Forms and Qualities of Bodies, whereon their Properties and Effects depend; as Volatility and Fixedneſs, Fluidity and Firmneſs, Colours, Taſtes, Odours, Effervescences, Fermentation, Solution, Precipitation, Congelation, Extraction, and the like. *Its Office.*

9. To this Part of Chemiſtry it likewiſe belongs to bring new Inventions to the Teſt, ſo as to diſcover their Validity or Inſufficiency. Thus when any Hint is ſtarted for a new Trade, or

Method invented for the Improvement of an old one, before any Attempt is made to apply it in the larger Way, the proper Aſſay or Experiment muſt firſt be performed in Miniature; where if it prove ſucceſsful, this may rationally encourage the erecting of ſuch a Diſcovery into an Art, or its Application to the Improvement of Buſineſs.

Illuſtrated. 10. To have an Example of this whole Procedure, we need but reflect upon the general Office of the Aſſay-Maſter; who before-hand diſcovers, in Miniature, the Quantity of Metal contained in any Ore aſſigned; thereby giving a Direction to the Operator at the larger Furnace. And thus Philoſophical Chemiſtry plays directly into the Hands of the Technical, Commercial, and Oeconomical Species.

Its Improvement, by a portable Laboratory. 11. But before it can do this to the beſt Advantage, there are ſeveral Deficiencies therein that require to be ſupplied: And firſt, the Labour, Time, and Expence neceſſary to procure the proper Furnaces, Veſſels, Utenſils, and Subjects, for the ready and commodious Exerciſe of this Art, have been a great Hindrance to its Advancement. Upon which Conſideration we have endeavoured to collect together a commodious *Philoſophical Laboratory* in a portable Form attended with as many Conveniencies as the Nature of the Thing will allow *a)*.

By practiſing it, without Fire or Furnace. 12. In our Definition of Chemiſtry *b)*, we endeavoured to avoid the common Error of confining this Art to the ſole Uſe and Application of Fire. We hope to have ſhewn *c)* that it has a Right to employ the other Elements, Air, Water, and Earth; to which we may add Cold,

a) See the Eſſay for introducing a Portable Laboratory.
b) *Lect.* I. *in init.*
c) *Lect.* I. II, III, IV.

and

and various Kinds of Motion. And if it be remembered, that Chemistry is the Art of analysing and compounding Bodies by Means of all the Instruments we can procure; an Attempt to introduce Ways of working in the Art, without Fire or Furnace, will not appear surprizing.

13. Nay, if a due Estimate were made, and the full Scope and Extent of Chemistry considered; a large and curious Part of it would appear to depend more upon other Things, than upon the direct Use of Fire: Thus for Example, the whole of Fermentation and Putrefaction, two Extensive Operations in Nature and Art, are performable without the Use of either Fire or Furnace. Farther, the Action or instrumental Efficacy of Air, Water, and Earth might, with regard to chemical Operations, be opposed to the Action of Fire; which has still a more direct Antagonist, or rather Correlative, *viz.* Cold; whose Efficacy in Chemistry is extremely great, and separates the more useless and aqueous Parts of Bodies from those that are more spirituous and essential; as we see in the Concentration of Wines, Vinegars, and other spirituous and saline Liquors by Frost *. *Particularly by means of Cold.*

14. There is farther wanting to the Improvement of *Philosophical Chemistry*, a Collection of all that is hitherto known and practised in the Art, to shew the present State and Condition thereof. And this, perhaps, would make no very large Volume; for the original Experimental Writers are very few, in Comparison of the Collectors and Transcribers: But the more useful Part of such a Work is not to be found in Books; and can be had only from observing, collecting, *Chemistry improveable by collecting the Experiments and Practices of Artists.*

* See the last of three Essays in Artificial Philosophy, or Universal Chemistry, *Ann.* 1731.

and

and digesting the daily Practices of mechanical Operators; such as Refiners, Assay-Masters, Smelters, Dyers, Sugar-Bakers, Soap-boylers, &c. And till the Secrets and Mysteries of these Arts are known to the chemical Philosopher, he will want many things that are necessarily required to the Improvement of Philosophical Chemistry.

A List of Desiderata.

15. The last particular we shall at present intimate, as wanting for the Exercise and Improvement of Philosophical Chemistry, is a List of the Chemical *Desiderata* in all Arts and Trades, in order to procure the readiest Ways of supplying them: For such a List would contain so many Problems for the Philosophical Chemist to solve.

Technical Chemistry divided.

16. We now proceed to *Technical Chemistry*; which, for the Sake of Use and Commodiousness, we divide into four Parts: as it relates to Subjects of the animal, vegetable, and mineral Kingdoms; or to several of them at once. Thus under animal Arts comes the Art of preparing Size and Glue, Tanning, Ivory-Staining, the Dying in Wool, Silk, &c. Under vegetable Arts comes the Art of Timber, or the Ways of preserving it sound against the Injuries of the Weather, the Sea, &c. the Art of making Rosin, Pitch, Oil of Turpentine, Charcoal, Pot-Ash, &c. the Art of Brewing, and Fermenting for Wines, Vinegars, &c. the Art of Sugar-making, and Refining; the Art of Soap-making, &c. Under mineral Arts come the Arts of Salt, Copperas, Vitriol, Borax, Pottery, Metals, Foundery, Smithery, &c. And lastly, under mixed Arts comes the Art of Paper, the Art of Ink, the Art of Japanning, the Art of Glass, the Art of Pigments, the Art of Pharmacy, the Art of Fire-Works, &c. all which are

proper

proper chemical Arts, that fall under Technical Chemiſtry.

17. It were eaſy to give a Catalogue of a large Number of new, and probably advantageous, Arts or Trades, that might be ſet up in *England*. Thus, for inſtance, we would recommend the Introduction of *Engliſh* Arracks and Brandies; which might be plentifully afforded by the Tappings of our Trees, and all Kinds of Summer-Fruits: Nor need Wines themſelves, even from the Grape, be here excepted; eſpecially as we have an excellent Method of improving all poor and thin Wines, by adding fine flavourleſs Sugar in the Fermentation *. *How to be improved.*

18. We have endeavoured to ſhew, in the preceding Lectures, that many of our Trades are improveable; particularly Brewing, Diſtilling, Soap-boiling, Pharmacy, Metallurgy, *&c.* And for new Trades, that the refining and making of various Commodities may be as advantageouſly practiſed in *England* as elſewhere: And among theſe may be reckoned the refining of Borax, Camphire, Tartar, Manna, *&c.* the making of Salt-Petre, the obtaining of Sulphur, the making of blue Vitriol, Porcellane, artificial Gems, and numerous other Commodities of Price and Uſe.

19. The great thing wanting to the Advancement of Arts, and the Perfection of this whole Affair, ſeems to be the joint Concurrence of certain Perſons, who ſhould contribute to the carrying it on. The Compaſs of Knowledge allotted to a ſingle Man or two, bears no Proportion to that required for the due conducting of this Work: Nor, perhaps, is the Knowledge in being, of the Kind here principally required.

* See *Lect.* XI.

Arts

Arts and Sciences muſt receive their Improvements chiefly from *Phyſical Knowledge*; that is, a Knowledge drawn from the Nature of Things, which is to be acquired only by converſing with natural Bodies, and obſerving their Properties, by putting Bodies together, and ſeparating them again. And this general Proceſs is to be conducted in the way of a *ſagacious Experience*; which is a Matter of Judgment, not caſual or accidental, but formed upon ſome certain Principles and Analogy of Knowledge. Thus we ſee, in ordinary Life, and the Practice of Trades, that Men educated to them have an acquired Sagacity, or Habit of judging each in his own way; which Sagacity is rarely to be found in Men differently educated. The Qualifications therefore required for our preſent purpoſe may be termed, *Phyſical or Chemical Habits of judging about Things relating to Arts and Trades*, acquired by ſome competent Experience, or by being for ſome Time verſed in this Way.

20. If Choice were made of a Set of Men ſo qualified, and Rules given them to purſue, with due Care to regiſter all their Experiments, and form them into *Tables*, from whence ſome ſhould derive Canons and Axioms, others deduce the more uſeful Things for the Service of Arts and Trades, *&c.* So as to make an uniform and ſteady Buſineſs of the whole; there is good Reaſon to expect that, in the compaſs of a few Years, conſiderable Improvements might be made in the preſent ſet of Arts and Sciences.

Commercial Chemiſtry divided.

21. *Commercial Chemiſtry* conſiſts of three parts, *viz.* (1) The Exerciſe of all the Chemical Arts, in a large Manner; ſo as to ſupply more than the Demands of a ſingle Country, and afford a Surplus of Commodities for Exportation and foreign Conſumption; (2) The various Ways of con-

condensing, curing, preparing, securing, and fitting natural and artificial Commodities for Carriage and Transportation; And (3) the Ways of supplying the chemical Necessaries to Voyagers and Travellers, for founding, supporting, and improving Trade, Traffic, and Commerce, in different Countries.

22. And thus a Knowledge of *Commercial Chemistry* will easily direct us in *England*, to the Arts that may be extended and improved, so as to undersell some other Nations at the foreign Markets; provided the Duties and Drawbacks are in our Favour: For example; We conceive, that Malt-Spirit may be produced in *England* cheaper and better than in *Holland*; that Wines, Vinegars, Brandies, and Arracks, may be made, either here, or in our Plantations, as good as, and perhaps cheaper than, in their present places of growth and Importation; that White Lead, Verdigrease, Sal-Amoniac, Pot-Ash, Hard Soap, *&c.* may be prepared as cheap and good in *England* as in any other Part of *Europe*. *How to be improved.*

23. We are likewise instructed by *Commercial Chemistry*, to reduce Goods to their least Volume or Bulk for Exportation; and again to secure them from the Injuries of the Sea, the Weather, and other Accidents. Thus Metals come to be exported instead of their Ores, Sugars instead of the Juice or Rob of the Sugar-Cane, Salt instead of Sea-Water, Raisins instead of Grapes, high Spirits instead of low Wines, Pot-Ash instead of refuse Wood, *&c.* And thus it is that, by means of Technical and Commercial Chemistry together, different Countries are supplied with Lead, Tin, Iron, Silver, Oil, Tallow, tanned Hydes, Pitch, Rosin, Brimstone, Wax, Wines, Brandies, Salt, Sugars, Treacle, Paper, *&c.* whereby all Trade,

Trade, Traffic, and Commerce, is ſupported. And to diſcover this Kind of Contrivance, or Reduction, is the Office of Commercial Chemiſtry. Thus, inſtead of importing many Tuns of a foreign dying Wood, we are taught to extract its tinging Parts, and bring them away in the Quantity of a few Pounds. And to do this more generally, as it may be done, would tend to perfect the Trade of the Dry-Salter, and leſſen the Expence of the Dyer.

24. Another Advantage of *Commercial Chemiſtry* is, that it affords the Neceſſaries for long trading Voyages. Thus, in particular, it directs us to a *Chemical Cheſt*, and a *Portable Furnace*, with its Apparatus of Flux-Powders, for aſſaying Ores; a Screw-Preſs for Oils, and a Still for examining fermented vegetable Juices. It alſo directs us to the certain Rules of diſcovering the Sophiſtications practiſed in Wines, Brandies, Vinegars, Arracks, Gold-Sand, Gold in Bars or Ingots, counterfeit Gems, *&c.* and to the ways of aſſaying Pot-Aſh, Tincal, Amber-greaſe, Muſk, and all other Drugs. So that to improve this Part of Chemiſtry, little more ſeems required than the bringing it into more general Uſe; which might be done to great Advantage, if Philoſophical and Technical Chemiſtry were firſt improved to any conſiderable Degree.

Oeconomical Chemiſtry divided.

25. We now come to our laſt Diviſion of Chemiſtry, *viz.* the *Oeconomical* Branch; which is of great Utility and Extent, ſo as to be capable of improving all the reſt. This Branch we chooſe to divide with regard to the ſeveral Offices of a Houſe, in which, as in ſo many different Laboratories, it may be commodiouſly practiſed: For Inſtance, in the Brewhouſe, the Store-Room, the Kitchen, the Dairy, the Laundry, and the Cellar. Thus, by Means of

Oecono-

Oeconomical Chemistry, we are instructed in the best Ways of brewing with Malt, Treacle, Hony, Sugar, or other vegetable Juices; the best Ways of raising and preserving Yeast, or Wine Lees, for baking or brewing; and of imitating the natural Wines of foreign Growth. This Art directs us how to procure the simple and compound Waters of Vegetables, in their greatest Perfection; and to make a Set of Brandies or Cordial Waters, even from the gross Lees, Sediments, or Bottoms of our Wine or Ale Casks. Hence also we learn the Methods of preserving Fruits in Sugar, and several vegetable Productions in the Way of Pickle, *&c.* The Art of Cookery also is by this Means improveable: So are all the Dairy Productions, and the Business of the Laundry; as by rendering hard Waters soft, *&c.* But to shew this fully, and to improve the Design, would require a particular Treatise, under the several Heads of the *Brewhouse*, the *Store-Room*, the *Kitchen*, the *Dairy*, the *Laundry*, and the *Cellar* *.

II.

26. We now proceed to our Experiments; the *first* whereof will shew that Sal-Ammoniac may probably be made to as great Advantage in *England* as in the *Levant*; the *second* will shew the Method of making a Varnish of Amber, with a View to improve the Arts of Japanning, Embalming, *&c.* the *third* will shew how to make a very hard Glass, for improving the Art of Glass, Enamelling, and the Business of artificial Gems; the *fourth* will shew how to prepare a Foil for foliating figured Glasses, and

Purport of the Experiments.

* See the first of the three Essays in *Artificial Philosophy, or Universal Chemistry*, published in 1731.

turning them into Speculums; the *fifth* will ſhew a Way of making a curious and uſeful Glue; and the *ſixth* and laſt will ſhew a Method of giving Copper a Gold Colour, and a greater Degree of Ductility, by Way of directing an Enquiry after Methods of introducing other uſeful Changes into Metals.

EXPERIMENT I.

That Sal-Ammoniac may be advantageouſly made in England.

Sal Ammoniac prepared.

27. We took four Ounces of the common volatile Salt of Ox-Bone, and ſaturating it with ſtrong Spirit of Sea-Salt, evaporated the ſuperfluous Moiſture; upon which we found a Cake of true Sal-Ammoniac left behind.

Uſe of the Experiment.

28. This Experiment regards both Philoſophical and Technical Chemiſtry; as not only ſhewing that Odours may depend upon the Mechanical Structure or Texture of the Parts of Bodies; but alſo leading to a cheap Way of obtaining Sal-Ammoniac in other Countries, as well as in the *Levant*.

In Philoſophical Chemiſtry, or the Doctrine of Odours.

29. The volatile Salt here employed has a very quick and pungent Odour; ſo likewiſe, though in a leſs Degree, has the Spirit of Salt: but theſe two, upon mixing, deſtroy each other's Odour, ſo as to leave the Cake of Sal-Ammoniac ſcentleſs. The Reaſon is, that theſe two odorous Liquors loſe of their Volatility by Mixture; ſo that their fine Parts can no longer fly off briſkly, and ſtrike the Nerves of the Noſe, on which all ſmelling depends. But if a little of the Sal-Ammoniac be ground in a Mortar, along with another ſcentleſs, but more fixed, Body, *viz.* an equal Quantity of Salt of Tartar; this

Salt

Salt of Tartar laying hold of the Acid of the Sea-Salt, leaves the volatile Salt at Liberty to aſcend and ſtrike the Noſtrils as briſkly as before: Whence we ſee that Odours may be mechanically produced and deſtroyed. The ſame is confirmed by many other Inſtances of Philoſophical Chemiſtry, and holds equally of Taſtes.

30. Hence we may derive ſome Rules for improving the Odours of certain Perfumes, or for recovering them when impaired, or almoſt deſtroyed. Thus it is known to Perfumers, that Sugar being ground with Muſk or Ambergreaſe, opens the Body thereof, and makes theſe Subſtances go farther in the perfuming of Waters, Powders, or the like: And this the Sugar does chiefly, by attenuating, reſolving, and ſubtilizing the viſcous Parts of thoſe Sweets, ſo that they now move more freely, and ſtrike the Noſtrils more briſkly, than before. And when theſe, or other Perfumes, have almoſt loſt their natural Odour, it may in good Meaſure be recovered by the prudent Addition of a little volatile, animal Salt; as that of Hartſhorn. And hence we ſee the phyſical Reaſon why decayed Perfumes are ſometimes ſuſpended in a Jakes, to recover their loſt Odour; for all ſuch Places abound with volatile Salts, continually ariſing from the Urine, and other animal and vegetable Matters, which are there in a State of Putrefaction.

Rules for improving Perfumes.

31. Sal-Ammoniac is alſo obtainable in *England*, by ſubliming a Mixture of Wood-Soot, Urine, and Sea-Salt; but it ſeems eaſier and perhaps it might prove cheaper, to prepare it in the Way of the preſent Experiment. The volatile Salt for the Purpoſe will be abundantly ſupplied by the Pith of Horns, Blood, the Refuſe

Sal-Ammoniac obtainable.

of a Slaughter-houſe, putrified Vegetables, &c. and the Spirit of Salt may be made at an eaſy Rate, in a proper Furnace.

The Experiment extended. 32. But the preſent Experiment might prove ſtill more ſerviceable, by leading to a Way of procuring other ſaline Bodies beſides Sal-Ammoniac: For it ſhould ſeem that ſeveral Salts may be artificially compoſed by the Union of their conſtituent Parts; as we here ſee in Sal-Ammoniac. For Example; the Making of blue Vitriol may be attempted, by boiling Copper, inſtead of Iron, in the raw Liquor of the Pyrites, from which the common green Vitriol is made. And if this Hint were duly purſued, perhaps it might lead to the Diſcovery of ſeveral new Arts and Trades.

EXPERIMENT II.

An Amber Varniſh.

Amber diſſolved. 33. We took four Ounces of Amber, and putting it into a Crucible, juſt melted it with a ſmall Degree of Heat; then poured the fluid Maſs upon the Iron Plate. When the melted Matter grew cold, we reduced it to Powder; and adding thereto two Ounces of drying Oil, (that is, Linſeed Oil prepared, or thickened, by boiling it with a little Litharge) and one Pint of Oil of Turpentine, we diſſolved the whole together into a Varniſh.

Uſe of the Experiment. 34. This Method of making the Amber Varniſh is kept as a Secret in few Hands; but deſerves to be made publick, as a leading Experiment, to direct the Means of perfecting the Arts of Varniſhing and Japanning, or the Ways of diſſolving Amber; whereon the Perfection of various Arts may depend. Thus, in particular, the

the Art of Embalming would be highly improved, if we could preſerve the human Corps in a tranſparent Caſe of Amber; as we ſee the Bodies of Flies, Spiders, Graſhoppers, *&c.* are, to great Perfection.

35. An uſeful Subſtitute, or Approximation, in this Way, has been tried, by boiling fine Roſin to Colophony, or a tranſparent and hard, though brittle, Subſtance. This being diſſolved by Heat, and the Bodies of ſome ſmall Animals dipped therein ſeveral times ſucceſſively, they have been thus coated over with Colophony; which in ſome Degree reſembles Amber, but requires to be carefully kept from Duſt, in order to preſerve its Tranſparency. *Approximation.*

36. But if Amber could be diſſolved without impairing its Tranſparency; or if one large Maſs could be made of it, by uniting a Number of ſmall ones, it would thus not only tend to perfect the Art of Embalming, but likewiſe come to be uſed, on many Occaſions, inſtead of Wood, Marble, Glaſs, Silver, Gold, and other Metals: for then various Kinds of Veſſels and Utenſils might be commodiouſly made thereof. *Uſes of diſſolving Amber.*

37. To forward the Diſcovery, our preſent Experiment ſhews, that Amber contains a certain ſlimy, aqueous, or mucilaginous Part, which in the ordinary Way requires to be evaporated by a ſcorching Heat, before the Amber will readily diſſolve in Oil; with which however it afterwards unites into a Subſtance of a Nature compounded of that of an Oil, a Gum, and a Roſin. Nor would the thin ethereal Oil of Turpentine diſſolve it, unleſs firſt thickened, and fitted for this Purpoſe, by Means of the drying Oil. Hence, as it ſeems plainly intimated that Amber is not only reſinous, but alſo mucilaginous, whoever would attempt to melt ſmall Pieces *How to attempt its Solution.*

of Amber into large ones, would do well to consider the Subject as a mucilaginous Rosin, and consequently (1) fitted to dissolve, in a thick Oil, after a previous Evaporation of its aqueous Parts, or the Destruction of its more mucilaginous Nature; (2) that it may possibly be dissolved, by boiling in a Lixivium of Salt of Tartar, and Quicklime; or if any could be found, as there may, still sharper, and more alkaline; and (3) that the Digestor seems well adapted to dissolve this mucilaginous and resinous Substance, by Means of an expressed Oil added to the Amber, finely powdered and kept from scorching by the Interposition of Water. And here we recommend a long and moderate Digestion, rather than a violent Heat. Thus, therefore, our present Experiment points out to us three Methods for dissolving Amber, which either do not considerably destroy its Texture, or at worst leave it in a State reducible, by an easy Operation, to a Kind of Amber again.

EXPERIMENT III.

A harder Glass than the common.

Borax Glass. 38. We took four Ounces of Borax, and an Ounce of fine white Sand, reduced to Powder, and melted them together in a large close Crucible, set in a Wind Furnace, keeping a strong Fire for half an Hour; then taking out the Crucible, and breaking it when cold, we found at the Bottom a pure hard Glass, capable of cutting common Glass almost as well as a Diamond.

Use of the Experiment. 39. We have here an Experiment, which, being duly varied, may lead to some considerable Improvements in the Arts of Glass, Enamels, and artificial Gems: It shews us an expeditious Method

Method of making Glass, without the Use of a fixed Salt; which has generally been thought an essential Ingredient in Glass, and which is the Ingredient that gives the common Glass its Softness. But Borax is a neutral Salt, which, being urged by the Fire, does not turn any Way alkaline; but, of itself, without Addition, presently runs into Glass. And whether other Ingredients might not here be advantageously substituted for soft Sand, particularly calcined Flints, powdered Crystal, *&c.* we recommend to farther Experience; so as to attempt making a Glass that shall, in some Degree, approach the Hardness of a Diamond.

40. If a pure transparent Glass, of this Degree of Hardness, can be tinged in the ordinary Manner, by Means of the prepared metalline Calces, it should seem that the Art of making counterfeit Gems would then have gained its Perfection; for the Colours thus introduced are in no respect inferior, but perhaps superior, to the natural Colours of the Sapphire, Emerald, Ruby, *&c.* So that nothing more seems wanting to perfect this Art, than the Discovery of a dense, hard, crystalline Glass, that shall polish like Crystal, and not scratch in the Wear.

The Experiment extended.

41. In order to give our Glass the desired Degree of Hardness, it may be proper to continue it long in the Fire; which is constantly found to add Strength and Hardness to Glass: Insomuch that common Glass, by being constantly kept in a strong Fusion for a Month or six Weeks, has become of a stony Hardness; a large Part of the fixed Salt thus going off in the Fire; and consequently leaving the Glass less charged with Salt, or nearer approaching to the native Hardness of the Flint or Sand employed in the Preparation.

42. If the Uſe of Borax ſhould, in this Manner, be found to have a conſiderable Effect, it will be proper to enquire farther into its natural and chemical Hiſtory, which ſeems at preſent to be little regarded. Perhaps it may not be impoſſible to find this uſeful Subſtance in ſome Parts of *Europe*, or to imitate it by Art, and to diſcover better Ways of refining it than thoſe now uſually practiſed.

43. The Facility wherewith this Salt runs into Glaſs, or the ſmall Degree of Heat, and the ſhort Time required for that Purpoſe, if well attended to, may be capable of enriching Chemiſtry, and more particularly the Hiſtory of Glaſs; at leaſt we have good Reaſon to believe that the preſent Experiment is capable of being largely diverſified, and improved to the Service of ſeveral Arts.

EXPERIMENT IV.

A Foil for turning ſpherical or other figured Glaſſes into Speculums.

The Silvering Amalgam. 44. We took half an Ounce of clean Lead, and melted it with an equal Weight of pure Tin; then immediately added half an Ounce of Biſmuth, and carefully ſkimmed off the Droſs: Now removing the Ladle from the Fire, we added, before the Mixture grew cold, five Ounces of pure Quickſilver, and ſtirred the whole well together; then put the fluid Amalgam into a clean Glaſs.

How to be applied. 45. When this Amalgam is uſed for Foiling, or Silvering, let it firſt be ſtrained through a linen Rag; then gently pour ſome Ounces thereof into the Glaſs intended to be foiled. The Mixture ſhould be poured into the Glaſs by Means of a paper Funnel, reaching almoſt to the

the Bottom, to prevent its flying to the Sides; then dexterouſly inclining the Glaſs every Way, endeavour thus to faſten the Foil. When this is once done, let the Glaſs reſt for ſome Hours; then repeat the Operation, till at length the fluid Maſs is evenly ſpread and fixed over the whole internal Surface; as it may be known to be by viewing the Glaſs againſt the Light. The ſuperfluous Amalgam being now poured out, the Outſide of the Glaſs may be poliſhed with Putty, Chalk, or Tripoli, ſprinkled upon a Cloth: And thus the Operation is compleated. In this Manner are made thoſe ſhining ſpherical Glaſſes (appearing like Glaſſes filled with Quickſilver) which we ſometimes ſee hung up in Parlours, near the Cieling, to invite the Flies in Summer from the Windows, and other Parts of the Room, where they might prove more offenſive.

46. The Operation has conſiderable Advantages, as being performable in the Cold; and is not attended with Danger from the poiſonous Fumes of Arſenic, or other unwholeſome Matters, uſually employed for this Purpoſe. And how far it is applicable to the more commodious foiling of the common Looking-Glaſſes, and other Speculums, may deſerve to be conſidered. *Advantages of the Operation.*

Experiment V.

A curious and uſeful Glue.

47. We took an Ounce of Iſing-Glaſs beat to ſhreds, and put it into a Pint of Brandy; where, by Means of a little Heat, or gentle ſimmering over a common Fire, it gradually diſſolved: We then ſtrained the Solution through a Piece of fine Muſlin, and thus obtained a Glue, *Iſing-Glaſs Glue.*

Glue, that ſhould be kept in a Glaſs cloſe ſtopped.

Its Uſes. 48. This Glue, with a very gentle Heat, diſſolves thin, tranſparent, and almoſt limpid: When uſed in the Manner of common Glue, it joins the Parts of Wood together, ſtronger than Wood is joined to itſelf; ſo that the Pieces thus joined will break in any other Part rather than where they are glued. It is alſo remarkable, that if Saw-duſt, or powdered Wood, be made into a Ball with this Glue, the Ball will prove ſolid and elaſtic; ſo that it may be turned and uſed as a Bowl, without breaking. And whether, by Means of ſuch a Glue as this, ſomething conſiderable may not be effected in the emboſſing of Wood-work, we leave to farther Experience. The Glue being thus made with Brandy, will keep long without corrupting; and is therefore a proper Form wherein to preſerve Iſing-Glaſs ready diſſolved for the fining of Wines, or other Uſes.

Extended. 49. Another curious Uſe of our Glue is, that it ſerves excellently for taking off the Impreſſions of Medals, or Coin: Thus if a little of this melted Glue be poured thinly upon a Guinea, ſuppoſe, ſo as to cover the whole Surface of the Piece, and the Glue be ſuffered to remain thereon for a Day or two, till it becomes thoroughly dry, it will appear hard and tranſparent, like a Piece of *Muſcovy*-Glaſs, with the Impreſſion of a fair Guinea in *Entaglio*, as they call it, on one Side, and in *Relievo* on the other.

And improved. 50. This Glue, therefore, dries into a very ſtrong, tough, and tranſparent Subſtance; not eaſily to be hurt or damaged by any Thing but aqueous Moiſture, which would ſoon diſſolve it: So that it is not fit to be uſed in any Work that muſt be expoſed to Wet or Weather. But for a Glue

Glue to ſtand the Weather, let choice be made of the common Glue diſſolved with Linſeed-Oil.

51. The natural and experimental Hiſtory of Glue might greatly tend to the Improvement of Chemiſtry. For it ſhould ſeem as if all animal and vegetable Subſtances were either originally made of, or might at laſt be reſolved into Glue or Jelly. Doubtleſs a Knowledge of the Nature of Ropineſs, Viſcidity, Sizineſs, Mouldineſs, *&c.* would give conſiderable Light to Natural Philoſophy and Medicine, and lead us farther into the Effects, Nature, and Proceſs of Growth, Fermentation, and Putrefaction. This Enquiry, therefore, ſhould be proſecuted with Care; beginning, for Example, with that viſcous Subſtance the White of the Egg, or Serum of the Blood, in their natural States; and obſerving how their Tenacity is altered, by moderate Degrees of Warmth or Cold. The Enquiry might next proceed to the mucilaginous Matter of Snails, Frog-Spawn, Fiſh, and other Animals in Embrio, Vegetables, *&c.* and gradually deſcend to Subjects of the mineral Kingdom. And this Enquiry, we apprehend, may be uſefully proſecuted without the Aſſiſtance of a chemical Apparatus; ſo as to diſcover the beſt Ways of preparing Cements, Glues, Sizes, Jellies, *&c.* for various mechanical and oeconomical Uſes.

Hiſtory of Glues wanted.

EXPERIMENT VI.

Copper made more ductile, and turned of a Gold Colour.

52. Make an Amalgam, of one Part pure Copper, and three Parts clean Quickſilver; boil

Copper advanced somewhat nearer to Gold. boil the Amalgam in River-Water for two Hours; then diſtill off the Quickſilver, and cohobate it once or twice; laſtly, fuſe the Copper that remains in the Retort, and it will be of a Gold Colour, and more ductile than common Copper. This Experiment was not brought to Perfection in the Courſe, on Account of the Difficulty then found of amalgamating the Copper, which was attempted thus: We diſſolved as much Copper in *Aqua fortis* as the Menſtruum would take up; then diluting the Solution with ten or twelve Times its own Weight of Water, we put Iron Plates into it, which precipitated the Copper in fine Powder: This Powder was edulcorated, or waſhed, in ſeveral Waters, to clear it of its adhering Salts, and afterwards dried; then ground in a Stone-Mortar, along with an equal Weight of Quickſilver; but no Amalgamation enſued. It has been uſually thought difficult, and by ſome impracticable, to make an Amalgam of Copper by Heat: In which Method, indeed, it is not eaſy to ſucceed perfectly, the Copper requiring ſuch a Heat to keep it fluid, as will exhale the Mercury; which beſides does not readily unite with that Metal. In the preſent Method the Thing may be effected without Heat; *viz.* by firſt reducing the Copper to an exceeding fine Powder; which here ſupplies the Place of Fuſion, and might put us upon enquiring whether Trituration may not, in ſome other Caſes, be advantageouſly ſubſtituted for Fuſion.

Its Uſe. 53. This uncommon Experiment of M. *Homberg* ſhews us a Method of advancing Copper ſome Degrees nearer to Gold; ſo as to fit it for Watch-work, Cane-heads, Snuff-boxes, and other ſmaller Machines and Utenſils, and eſpecially for Gilding. It is remarkable that the Quick-

Quickſilver loſes an eight Part of its Weight in the Operation.

54. The Experiment is here employed as a leading one, capable of ſhewing that uſeful Changes may be wrought upon the common Metals; ſo as, in ſome Meaſure, to introduce a new Set. It is known to ſome, that Copper may be ſo far whitened and ſoftened, as to ſerve on many Occaſions for Silver. Lead, by a ſlight Application, is capable of being whitened, hardened, and rendered more uſeful for many Purpoſes. And if Perſons acquainted with the Nature and Effects of Metals, Minerals, and their Fumes upon each other, were to proſecute the Enquiry, many uſeful Things of the like Kind might doubtleſs be diſcovered. *Extended.*

55. A little prepared or fixed Arſenic will inſtantly whiten Copper throughout; though thus indeed the Copper proves brittle, or rotten: But there are other ſecret Ways of whitening it, ſo as to leave it extreamly ductile. *Exemplified.*

56. The farther Proſecution of this Subject would lead us into the ſublimer Metallurgy; which is a Part of Chemiſtry by no Means hitherto cultivated as it deſerves, ſeeing it is highly capable of enriching the known mechanical Arts, and ſtriking out new ones. *The Proſecution recommended.*

III.

57. We now come to offer a few *Rules* for conducting chemical Experiments in the Way of an Art; ſo as to improve the ſeveral Branches of Chemiſtry above mentioned *. *Rules for improving Chemiſtry and Arts.*

58. Let the firſt Rule be, with Care and Diligence to obſerve the Proceſſes uſed by Nàture in

* § 2, *&c.*

the

the Production of all thofe things we would endeavour to imitate. For Nature, the moft expert Chemift, employs the very Inftruments which Men alfo employ; *viz* Fire, Water, Air, and Earth; as we have fhewn in our Lectures upon the Elements.

Illuftration. 59. To illuftrate this Rule by an Example; it appears, by numerous Inftances, that there is an acid or faline Liquor naturally contained in the Bowels of the Earth; which acid there mixing with various Kinds of earthy Matters, and acting as a Menftruum upon them, changes their Natures, or makes them appear under different Forms. And hence common Brimftone, Alum, the native Vitriol, *&c.* feem to have their Origin.

60. For by an exact Scrutiny and attentive Confideration it appears that, when this general Acid diffolves a certain bituminous Earth, it makes Brimftone; when a chalky Earth, Alum; when Iron or Copper, Vitriol; *&c.* And accordingly, by ufing the fame Kind of general Acid (which may be procured by burning Brimftone under a glafs Bell) in the fame Manner as Nature feems to employ it, we can likewife, by Art, produce Brimftone, Alum, or Vitriol, when and where we pleafe. And thus, if we could univerfally difcover the Proceffes and Inftruments which Nature employs in the Production of her Effects, we fhould have certain Rules for imitating her.

Rule II. 61. Our fecond Rule is, to gain a Habit of transferring, diverfifying, enlarging, and improving an Experiment, till it ends in fome certain Difcovery, either of Light to the Underftanding, or of Ufe in Life; one of which points all juft Experiments will end in, when duly profecuted and confidered.

62. For

62. For unſucceſsful Experiments are no leſs inſtructing than thoſe that ſucceed: Which ought to be well remarked. The Head muſt in all Caſes co-operate with the Hands: So that the Mind ſhould be ever caſting about to diſcover the Cauſes of Failure, as well as of Succeſs. And this is a Sagacity which may be procured by Uſe, and turned into a Habit of Invention and Diſcovery: So that no ſingle Experiment ſhall be performed, but ſome Advantage will be immediately derived from it; nor any Experiment be made, without ſome reaſonable Grounds of Hope for Succeſs. *Illuſtration.*

63. Our third Rule is, To proſecute Experiments in an orderly Series, with a View to ſome particular Enquiry that may be of Uſe in Life; and to let the Enquiry ſuit the Genius and Temper of the Enquirer, ſo as that it may be proſecuted by him with Vigour and Pleaſure. *Rule* III.

64. Thus, if any one ſhould be averſe to the Uſe of Fire and Furnace, he may ſtill improve Chemiſtry and Arts, or perform many ſerviceable chemical Operations, without much Apparatus, or Expence, or without the Utenſils and Inſtruments commonly employed in that Art: Which may, therefore, be practiſed as well in a Study or Parlour, as in a Laboratory. And to thoſe diſpoſed to operate in this Way, may be recommended the Buſineſs of Fermentation, the Concentration of Liquors by Cold, and the Proſecution of the Nature and Hiſtory of Cold, begun by Mr. *Boyle*. We might alſo recommend the extracting of the finer Eſſences of Vegetables; the making of the more noble and ſpirituous Infuſions, Tinctures, and Elixirs; the examining and tabling the ſolutive Power of Water with regard to Salts, and of Spirit of Wine with regard *Illuſtration.*

regard to different Oils and Rosins; the determining the Force of all known Menstruums in the Cold; the Discovery of new Menstruums, and particularly of a Solvent for the Stone. These, and many other chemical Enquiries, may be prosecuted without the Use of Fires and Furnaces: And even such Tempers as are more delighted with Speculation than Practice, may greatly contribute to the Improvement of Chemistry, by sorting, ranging, and digesting Experiments into Tables; shewing what they prove, and how far they reach; how far they fall short, and how they may be carried farther: Others might employ themselves to Advantage, in drawing Things of Use from the Experiments already known and published: And lastly, others might, from a due Consideration of Experiments, deduce new Directions and Rules of Practice for producing, in a sure and constant Manner, much greater Effects than are usually hoped for.

AXIOMS *and* CANONS.

1. We learn from the present Lecture, that Chemistry is an Art of very extensive Use in Life; insomuch that not only Natural Philosophy, but also Trades, Commerce, and all active Businesses, have a Dependence upon it, and may be improved by it *.

2. That therefore the Disesteem, which Chemistry has generally met with, proceeds from a Want of knowing its proper Office, Extent, and Usefulness; and from the frequent Misapplica-

* See the whole Lecture *passim*.

tion

tion of it to Things of a deluſory or phantaſtical Nature.

3. That a large Part of general Chemiſtry may be advantageouſly practiſed, and many Diſcoveries and Improvements made therein, for the Service of Arts, without the direct Uſe of Chemical Fires, Furnaces, and the common *Apparatus* a).

4. That numerous Diſcoveries and Improvements remain to be made in Chemiſtry itſelf; and that theſe Improvements may be made in a direct, rational Manner; and, if once made, might greatly enlarge and illuſtrate Natural Philoſophy, improve various Arts, and introduce a Set of new ones b).

5. That, in particular, Sal-Ammoniac, an Amber-Varniſh, a hard Kind of Glaſs, a Foil for Glaſſes, an excellent Glue, and a new Kind of Metal, may be eaſily obtained, for the Improvement of Pharmacy and Dying, Japanning and Embalming, the Art of Glaſs and the making of artificial Gems, the Foiling of Glaſſes, the Gluing of Timber, Emboſſing, and taking off Impreſſions, the Art of Watch-making, and for other mechanical Uſes.

6. That the Canons for the farther Improvement of Chemiſtry, and the Arts thereon depending, require, (1) a careful Obſervation of the Ways of working employed by Nature; (2) a Talent of Experimenting; and (3) the Diſcretion of ſuiting the Enquiry to the Temper and Genius of the Enquirer c).

a) See § 12, 13. and *Exp.* II. IV. V. and § 63, 64.
b) See the whole Lecture.
c) See § 58——64.

CONCLUSION.

WE are now come to the End of our Lectures, where it may be proper to ſtop a while, and look back upon the Ground we have gone over. We ſeem to ourſelves to have been travelling in a new Road, too little frequented either by Philoſophers, Chemiſts, or Men of Buſineſs. Our Aim has been to improve the uſeful Arts, by Means of a more Philoſophical Chemiſtry; and at the ſame Time to ſhew the Method of conducting Enquiries ſo as that they may terminate in uſeful Diſcoveries. With an Eye fixed upon this Point, we have purpoſely avoided the more entertaining and agreeable Experiments, wherewith Chemiſtry abounds; and have kept to ſuch only as were judged either beneficial in themſelves, or of Service in diſcovering Cauſes, Axioms, and Rules. And if there be any Merit in what we have done, we freely own it to be borrowed, and that it lies in the *Verulamian* Method we have purſued, that is, in endeavouring to rectify the Mind, guard it againſt Error and Illuſion, and conduct it to the Fountains of Nature and Uſe. We cannot indeed preſume to have diſcovered many of the true Cauſes of Things, or Axioms perfectly juſt and univerſal. To do this, requires that the ſeveral Parts of Philoſophy ſhould be better cultivated than they are. All we can hope for is, to have found and eſtabliſhed a few Rules that may direct to a ſerviceable Practice, and enable us to enrich and improve ſome of the preſent Arts and Sciences. Thus, for Example, we hope to have diſcovered this philoſophical Axiom, That *Sugar, or a ſaccharine Subſtance, is the Baſis of Wines, Beers, Vinegars, and inflammable*

mable Spirits : Whence we preſume, that the Arts of Brewing, Wine-making, Vinegar-making, and Diſtilling, may receive a great Degree of Perfection. And thus we deſire to have it obſerved, that the Diſcovery of a ſingle Axiom, or Cauſe, may often improve, or even perfect, a Number of Arts : For phyſical Axioms, duly diſcovered, muſt be pregnant with the Matter of many Arts and Sciences. And on this Account it is, that we have directed our Enquiries to the Inveſtigation thereof, as the beſt and ſureſt Means of improving the known Arts, and diſcovering new ones. Doubtleſs, if this Method were carefully and generally purſued, the Buſineſs of Invention would not long continue to be that caſual Thing it now is ; but be reduced to an Art, which, of all others, is, perhaps, the moſt wanted.

FINIS.

BOOKS Printed for and Sold by A. MILLAR, *over-against* Catherine-Street *in the* Strand, London.

1. OBSERVATIONS on the Diseases of the Army, in Camp and Garrison. In three Parts. With an Appendix, containing some Papers of Experiments, read at several Meetings of the Royal Society. The Second Edition corrected with Additions. By *John Pringle*, M. D. F. R. S. Physician General to his Majesty's Forces employed Abroad during the late War.

2. A TREATISE of the SCURVY. In three Parts. Containing, An Enquiry into the Nature, Causes, and Cure of that Distemper. Together with a View of what has been published on that Subject. By *James Lind*, M.D. Fellow of the Royal College of Physicians in *Edinburgh*.

3. A TREATISE on OPIUM, founded upon practical Observations. By *George Young*, M. D. Physician at *Edinburgh*.

4. An ENQUIRY into the Origin, Nature, and Cure of the Small Pox. To which is added, A Prefatory Addresss to Dr. *Mead*, concerning the present Discipline in the general Administration of Physic in this Kingdom. By *Thomas Thompson*, M.D. Physician to his late Royal Highness *Frederic* Prince of *Wales*.

5. A SYNOPSIS of the *History* and *Cure* of *Veneral Diseases*. From the famous *Venetian* Collection of *Fifty-nine* Writers upon this Subject, published in *Latin* by the celebrated Dr *Boerhaave*, with his Preface and Praxis. The whole fully and compendiously translated and methodized by *J. Armstrong*, M.D.

6. ESSAYS MEDICAL and PHILOSOPHICAL. By *George Martin*, M. D Honorary Fellow of the College of Physicians at *Edinburgh*, and Chief Physician to the Forces in the Expedition under Lord *Cathcart*.

7. GEORGII MARTINII, M. D. de Similibus Animalibus, & Animalium Calore, Libri duo.

8. De RE MEDICA Dissertationes Quatuor. Auctore THOMA SIMSON, M. D.

9. A DISCOURSE on the PLAGUE: By RICHARD MEAD, *Fellow of the College of Physicians, and of the Royal Society; and Physician to his* MAJESTY. The Ninth Edition corrected and enlarged.

10. A FULL VIEW of all the DISEASES incident to CHILDREN. Containing *A Translation of Dr.* Harris's Book upon the *Acute Diseases of Infants*, and of the eminent Dr. *Boerhaave*'s Treatise upon *all their Diseases*, as well *Acute* as *Chronical*.

11. CHIRURGICAL OBSERVATIONS on the *Disorders of the Urethra*. Written originally in *French* by *James Daran*, Surgeon in ordinary to the *French* King, and heretofore Surgeon-Major to the Hospitals and Armies of the Emperor *Charles* VI. Translated into *English* by *Thomas Tompkins*, Surgeon. With the Addition of some remarkable Cases.

BOOKS Printed for T. *and* T. LONGMAN, *in* Pater-noster-Row.

I. THE Philosophical Works of the Honourable *Robert Boyle*, Esq; abridged, methodized and disposed under the General Heads of Physics, Statics, Pneumatics, Natural History, Chemistry, and Medicine. The whole illustrated with Notes, containing the Improvements made in the several Parts of Natural and Experimental Knowledge since his time. In Three Volumes 4to. The Second Edition corrected.

II. The Philosophical Works of *Francis Bacon*, Baron of *Verulam*, Viscount of *St. Albans*, and Lord High Chancellor of *England*, methodized and made *English* from the Originals; with occasional Notes to explain what is obscure, and shew how far the several Plans of the Author, for the Advancement of all the Parts of Knowledge, have been executed to the present time, in Three Volumes in Quarto.

III. A new Practice of Physic, wherein the various Diseases incident to the human Body are described; their Causes assigned, their Diagnostics and Prognostics enumerated, and the Regimen proper in each delivered; with a competent Number of Medicines for every Stage and Symptom thereof, prescribed after the manner of the most eminent Physicians among the Moderns; and particularly those of *London*. The whole formed on the Model of Dr. *Sydenham*, to execute the Design of his *Processus Integri*, in Two Volumes 8vo. The Fifth Edition corrected.

IV. New Experiments and Observations upon Mineral Waters, directing their farther Use, for the Preservation of Health and the Cure of Diseases. By Dr. *Frederick Hoffman*, Counsellor and Physician to the King of *Prussia*, and Fellow of the Royal Society. Extracted from his several Essays upon this Subject, and illustrated with Notes.

V. Three Essays in Artificial or Universal Chemistry, *viz.*

1st, An Essay for the farther Application and Advancement of Chemistry in *England*.

2d, An Essay for the Improvement of Distillation, in the Hands of the Malt-Stiller, Rectifier, Compounder, and Apothecary.

3d, An Essay for concentrating Wines, and other fermented Liquors, or taking the superfluous Water out of them to advantage.

All the above Books published by PETER SHAW, M. D. F. R. S. Fellow of the Royal College of Physicians in *London*, and one of His MAJESTY's Physicians in Ordinary.

BOOKS Printed for J. SHUCKBURGH *at the* Sun *next* Richard's Coffee-Houſe *in* Fleet-ſtreet.

(With the Allowance of the Judges.)

I. NOTES *of Caſes in Points of Practice:* Taken in *the Court of Common Pleas* at *Weſtminſter*, from Mich. Term 1732, to Hilary Term 1754, (incluſive) with a Table containing the Names of the Caſes, and an Index of the Principal Matters. By HENRY BARNES, one of the Secondaries of the ſaid Court. In two Volumes 8vo. Price 11*s.*

N.B. The Second Volume may be had alone Price 6*s.*

II. Debates of the Houſe of Lords, from the Reſtoration in 1660, to the Preſent Time, By CHANDLER, in 8 Vol. 8vo. Price 2 Guineas.

III. Seſſions Caſes adjudged in the Court of Kings Bench, chiefly touching Settlements, from the latter end of Queen Anne's Reign to the preſent Times. In two Volumes 8vo. Price 10*s.*

IV. A Practical Treatiſe of Fines, and Recoveries, Containing a greater Variety of Correct Precedents of all Kinds of *Fines*, and *Recoveries*, than was ever yet publiſhed, with the Methods of paſſing them not only in the common Form but where they vary; with plain and eaſy Inſtructions for Drawing, Entring, and Paſſing them through the ſeveral Offices, By a Gentleman of the *Inner-Temple*, Price 5*s.*

V. A Collection of Engliſh Precedents relating to the Office of a Juſtice of Peace, conſiſting of Summonſes, Orders, Warrants, Recognizances, Informations, Examinations, Paſſes, Settlements, and other Inſtruments; with References to the Statutes, and all other Authorities, on which they are founded, in an Alphabetical Order. By JAMES HARVEY, Eſq; Price 3*s.*

VI. Farriery Improved, or a compleat Treatiſe upon the Art of Farriery, By HENRY BRACKEN, Price 3*s.*
