C'est une erreur de croire, q'une experience aveugle,
et une habitude mechanique, tiennent lieu de principes
surs, et de maximes fondées sur un solide raisonne-
ment

Traduct. d'un discours sur la commerce, par

M. le Marquis BECCARIA.

INTRODUCTION.

THERE is no art, unless this term can be applied to religion, which seems to require in its professors such a perfect harmony of opinion, as the art of medicine. For there is none in which error is of so much consequence, or where a fluctuation of the mind between opposite sentiments is attended with such anxious distress. Yet medicine has its schisms; and the sages of our art, while they appear devoted to Truth, forget her peculiar caprice; that, though she loves to be pursued with ardour, she must still be addressed with indifference.

THE keenest shafts of ridicule have frequently been levelled at this trait in

vi INTRODUCTION.

the medical character. Our singular gravity and solemnity placed us, as it were, in opposition to the free, the gay, and the witty; and they eagerly seized a circumstance, which seemed to reduce this extraordinary figure to the common size; and to show, under a face of great wisdom, much ignorance and uncertainty.

WE have replied to these gentlemen, that physic, like the other sciences founded on experience, is continually progressive, and therefore subject to perpetual change; so that, without the suggestions of vanity, we may sometimes be tempted to differ from our venerable ancestors. And it might have been subjoined, that physicians, notwithstanding some curious external differences, which would deceive perhaps an unexperienced Houyhnhm, are yet no better than mere Yahoos. But it seems to be agreed, among the philosophers who have examin-

INTRODUCTION. vii

ed this species with the greatest accuracy, that *to associate* is not more a principle of human nature than *to separate*. For, though men have been allured by the prospect of advantage, or compelled by force, to unite themselves in vast bodies; yet it was always observed, that where the political bands which held them together were weak, and they could follow their natural tendency, these huge piles soon broke into a number of pieces. And in all the countries where the arts of policy had scarcely taken root, the inhabitants have been found divided into numerous tribes, inflamed against each other with a mutual animosity. In like manner, proceed these philosophers, we have seen a set of religious notions overrun half the globe: but the torrent soon split into a multitude of streams; and numerous sects arose, who persecuted each other with an unrelenting fury. It is not attraction alone which governs

viii INTRODUCTION.

the material world; the laws of repulsion have also their influence; and it looks as if they had both their analogous principles in the moral system.

BUT these internal factions, which range us under the banners of so many leaders, are equally opposite to a set of men who will acknowledge the authority of neither. The sticklers for different systems, however averse to each other, unite like the domestic parties of restless Britons against a common enemy. It is hard to say when this quarrel began between empirics and dogmatists, or when it will end. It seems to be as ancient as the origin of reasoning in physic, which could not be long after the beginning of observation itself; nor will it cease, most likely, until our philosophy has acquired perfection; an æra still more remote.

EVERY

INTRODUCTION. ix

EVERY step of experience approaches towards system; since, by discovering the natural relation of things, it prepares us for establishing principles. And theory, or the application of these principles in explaining the phenomena around us, is the favourite process of the human mind. So delighted are we with it, that we cannot wait the necessary preparation; and our eagerness would fain anticipate those principles which yet remain to be discovered. A vapoury gleam of fancy is mistaken for the ray of science; and we pursue it through all the treacherous ways of hypothesis.

FOR, though things, being related in nature, present themselves in a certain order to the view of the observer, he does not immediately discover that order which is invariable. Amidst the variety of circumstances which surround any fact, to seize that whereon it necessarily depends, requires a close attention, and
commonly

x INTRODUCTION.

commonly a varied experience. But the mind will follow in the mean time its propensity; and theories are produced, and destroyed, by successive observation.

SYSTEM has so often fallen under the stroke of experience, that we have been led to imagine a natural enmity between them; which, by an easy transition, is extended to their several patrons. A theorist and an empiric are, in medicine, terms of mutual reproach, and as much the badges of two opposite parties, as those of Whig and Tory used to be in politics.

AMIDST the recriminations of both sides, it seems to be acknowledged, that improvement in our science has ever been the fruit of growing experience; and that a multitude of errors have been sanctified by the authority of systems. And it is imagined that we go but a little farther, when we affirm that these
are

INTRODUCTION. xi

are useless, and even dangerous; that, far from aiding the progress of medicine, they lie in its way, or mislead its steps.

BUT their danger, in the present state of physic, is surely imaginary. If they inflict a wound, they bring along with them its remedy.

*Qua cuspidē vulnus
Sensit, et hęc ipsā cuspidē sensit opem.*

THE continual succession of systems prevents their acquiring an influence injurious to philosophic liberty. Their opposition has had the same effect in science, that the quarrels of contending popes produced in religion. It banished the notion of infallibility, which is so apt to be fostered by the blind veneration of a sect. Those gigantic forms of superstition, and authority, that were encountered with difficulty, and even danger, by the first literary knights-errant, no longer bar the avenues to science. Every
subject

xii INTRODUCTION.

subject is discussed by a free dispute; and the repeated appeals to reason and common sense, prove that we acknowledge no authority which is not derived from them.

THIS notion of a dangerous influence in systematics, may suit a supine, an ignorant, and a superstitious age; but has no relation to the present, which is so remarkable for its free and active spirit of enquiry.

BUT shall we grant that they are useless; and is it credible that the industry of these gentlemen should be so active to no sort of purpose? A system cannot be built without materials; and these can be furnished only by observation. Empirics claim this field as their own: but it is evident that the dogmatic also must cultivate it; and he will cultivate it with greater ardour, and probably with more success. It is passion which excites the talents,

INTRODUCTION. xiii

talents, as well as virtues, of the soul to their most admired efforts. We are astonished at his unwearied industry, whose curious eye seeks every where support for a favourite doctrine. And it is a certain fact, that the sphere of observation has been farther extended by dogmatics, than by the men who pretend to give it so much merit.

YET it is not a mere acquaintance with particulars in detail; but a knowledge of their relations, and especially of that important one by which they are fitted to produce one another, that we are chiefly interested in acquiring. And this knowledge should naturally result from the full and large comparison, which must precede every attempt at arrangement. Observations which had long remained solitary and neglected, are brought together, and acquire an useful importance. Some steps are made in forming principles; and the mass of confused experience

experience begins to put on regularity and distinctness.

AND though our associations should not be exactly agreeable to the order of Nature, yet they have some advantage, as they assist the memory; which with difficulty retains a set of unconnected facts. Without the aid of system, the informations of experience must slide imperceptibly down the tide of oblivion; for no one could collect any number of them; and he would be still less able to deliver them to others. On this account, system is necessary in physic, as it is in natural history. In the former, indeed, it pretends to explain the animal operations, and to show us how we may influence them; and is founded, therefore, on the relation of cause and effect. As this is no object of the senses, but an inference of our fallible reason, it is extremely apt to be mistaken. The attempts of the medical systematic will frequently miscarry;

INTRODUCTION. xv

carry; yet still it must be acknowledged that his errors are readily detected. His course is regular, and may easily be traced.

BUT while he feels a warm affection for the child of his own fancy, he pursues, with severest scrutiny, the schemes of every rival theorist. He expunges what was absolutely false; and limits what an enthusiasm, similar to his own, had extended beyond its proper bounds. A succeeding dogmatist shows him the same impartiality; and lops, with as little tenderness, the luxuriant growth of an over-heated imagination. One is ready to believe that this ardour, so well adapted to invention and new combinations, corrected by that *sang-froid* which a man possesses in examining the works of another, though a perpetual source of private dissension, must tend, at least, to the general good, and quicken the progress of science.

AND

xvi INTRODUCTION.

AND accordingly we observe, that as the rise and struggle of parties denote firmness and health in our excellent political constitution, so the perpetual growth and contention of systems is a mark of vigour in the state of medical knowledge. When Europe was sunk in ignorance, and every sort of improvement languished, Galen tyrannized for ages in the schools of physic. The first dawning of the rays of science

———*Ubi pulsam Hyemem sol aureus egit
Sub terras, cælumque æstivâ luce reclusit.*

seemed to restore some activity to the torpid minds of men, and disclosed the buds of another system. But, since that period, they have been germinating continually; and their decay seems to be proportionably accelerated. Boerhaave acquired the greatest authority in modern times; but his own pupils have thrown it off, and introduced innovations of the utmost importance.

This

INTRODUCTION. xvii

This prolific birth, as well as transitory existence of systems, are evidently connected with the progress of experiment and observation. They remind us of the antient fable of Saturn and his offspring, while they appear to devour the theories to which they gave origin. Yet it is unjust to charge the surest faculties of our nature with these unnatural, and short-lived productions. The information of the senses is right and true; though the opinions which we form in consequence are often erroneous. It is these opinions, the precipitate combinations of that busy organ the fancy, which experience dissipates in its course, while it unveils the more beautiful order of Nature. And if, in its progress through the series of connected being, it should ever reach the ultimate point, our system will be that of the world, and represent exactly the disposition of things, which flowed originally from Almighty Will. In any other point of this progress,

a gress,

xviii INTRODUCTION.

gress, our arrangements must evidently be deficient; and, from a strong propensity of the mind to carry things to perfection, and to give them the appearance of a whole, we shall be continually supplying something from the imagination. This, I confess, should prevent our being wedded to a system: yet we may certainly treat it as a mistress; embrace it with ardour at present, and discard it whenever we are disgusted with its defects, or attracted by the superior qualities of another. For, the best system is only the expression of our degree of knowledge, at the time of its production; and their continual change, while it discovers their weakness, is a mark of their growth and tendency toward perfection.

BUT, as these systems are the offspring of observation, so do they guide, and assist its steps. They present a mixed prospect, where some parts are fully illumined by experience; while others
are

INTRODUCTION. xix

are only faintly distinguished; or buried, perhaps, in a total obscurity. This is the chaos of science; and it is the business of the human mind, while it traces with wonder the operations of the divine, to diffuse over it the beauty of order. And though a difference of disposition, or more frequently of situation, will lead one to observation, and another to arrangement; their labours, far from being opposite, are mutually necessary. The quarrel between empirics and dogmatics is unnatural. As well might the senses quarrel with the intellect, and each pretend to exercise their function separately. Every one sees, that they are useful only as combined; and that their excellency consists in their aiding, and correcting each other.

To exclaim against every kind of system, has been reckoned a proof of earnest zeal for observation. Yet what is it, really, but to declare, that we must rest stupid,

xx INTRODUCTION.

and indifferent spectators of the train of facts continually passing before us? For, in viewing them with any care, we soon perceive that some in the succession are intimately related. The attention excited pursues these through a variety of cases, proportioned to the extent of our sphere of observation. And a more than natural coldness must guard the temper, which escapes the effect of an emotion that hurries the mind into theory. A mere observer is a very uncommon creature; and we are rarely presented, with facts, unmixed with speculative notions. More frequent is that precipitation, which from observing the connection of certain facts, in a few instances, pronounces it to be constant and necessary. A perfect indifference about the matter may secure us from this error; but surely a fever of the mind, which tends, though irregularly, to use and improvement, is preferable to a fatal torpor, suspending its most important operations.

The

INTRODUCTION. xxi

The error will be corrected by the progress of experience; and frequently, in an inquisitive age, the having formed a false opinion will lead to the discovery of the truth; because it directs the attention, that source of all discoveries, to a particular point.

THE number of absurd theories should not, therefore, inspire us with an antipathy to the term; nor must a panic terror of them banish physicians from the sacred temple of philosophy. To be hurt with the imperfect, and puerile commencements of reasoning in physic, and to relinquish the hopes of a rational theory, is to be offended at the childish prattle of infancy, and to expect nothing better from a maturer age. That Being; who formed the mind of man peculiarly capable of improvement, and though he fixed the limits of existence, and of the acquisition of knowledge in the individual, appointed no such boundaries in the
a 3 species;

species; has implanted in our breasts, together with curiosity, a fondness of system; and it is justified by the relations of things. Experience, while it discovers these relations, gives occasion to the exercise and display of that passion. If, therefore, we are determined to reject all system in medicine, let us oppose every obstacle to the natural progress of knowledge. We may begin with rejecting those sciences, anatomy, chymistry, and every branch of physics, which delude us continually with the hopes of penetrating into the secrets of the œconomy. Impenetrable dulness should henceforth be as necessary an appendage to the profession, as inflexible gravity. Genius must quit, in despair, a walk so little accommodated to his exertions; and the art, considered as a mere species of traffic, must fall into the hands of the stupid, and sordid part of mankind.

LET

INTRODUCTION. xxiii

LET the sons of dullness, and indolence; or if there should be found a physician of extensive practice, with a naturally barren, and little-improved understanding, let him deny the use of theory. We believe, most sincerely, that he is ignorant of its proper use; and when he finds that all the profits of medicine can be reaped without such a troublesome instrument, he may really think it unnecessary,

Gestit enim Nummum in loculos demittere, posthoc Securus. —

YET there are some, it is said, to whom the progress of our art is less indifferent, that have adopted the same notion. Diseases, they apprehend, like the other productions of Nature, are known and distinguished by their sensible properties; and their cure is only taught by experience. What occasion then for theory, which has so often deceived us? The knowledge of diseases, and of their remedies,

xxiv INTRODUCTION.

can only be acquired by an assiduous attention to practice; and an hospital is the only useful school of physic.

NOR shall we deny, that a certain assemblage of symptoms gives to diseases their sensible form. It is the arrangement of these forms, according to their relations and differences, which makes the business of nosologists. They adopted the method, that had appeared so successful in the distribution of animals and vegetables. But these are multiplied continually in the same form; and Nature has drawn a line between their several species, which effectually prevents their confusion.

WHAT are the species of diseases? A fever, a diarrhoea, a jaundice, an epilepsy, are apprehended to be all of a distinct nature; yet they sometimes concur in the formation of one disease. From the different constitution of the machine in
individuals,

INTRODUCTION. XXV

individuals, the conspiracy of its parts, and the influence of those external powers to which it is continually exposed, its disorders appear under a great variety of forms. To determine what symptoms, in any combination, are essential, and mark the specific nature of the disease, must frequently be a difficult task. It will certainly require that symptoms be traced to their origin; that the historian should turn philosopher; and we may probably differ as much in our nosological arrangement, as in our reasoning on the phenomena of diseases.

IN the mineral kingdom, the method of the botanists was found insufficient; and soon yielded to one erected on a chemical investigation. For here, the limits of combination are so wide, and the consequent productions so various, that our attention was confounded, when we directed it only to their external and obvious qualities. An enquiry into their
composition,

xxvi INTRODUCTION.

composition, has furnished us with an useful distribution of them, according to essential differences.

The symptoms of diseases may be considered as a language in which Nature addresses us; as signs whose meaning we are to investigate. We must not be contented with merely observing them, any more than with simply remarking the phenomena of the inanimate world; but should endeavour to trace them to those laws of the œconomy on which they depend. The improvement of anatomy and chymistry, the dissection of morbid bodies, and experiments on living animals, have certainly carried us some-way in this enquiry; and by settling the theory of diseases, have contributed to mend, or confirm our practice.

If this practice had attained perfection; if every disease was defined, and the best method of treating it exactly determined; there would, indeed, be no
occasion

INTRODUCTION. xxvii

occasion for theory. Yet, though we could suppose that men, conducted by their mere feelings, had reached this pitch of excellence, in the most difficult of human arts; we must still have commended that curiosity, which, not contented with simple imitation, should attempt to draw the veil; and by discovering the reasons of this successful proceeding, establish it on the best and surest ground. But if we modestly acknowledge a practice, which is so various, to be still imperfect; and if diseases will occur either entirely new, or so altered that the mere light of experience cannot guide us in their treatment; we shall not readily give up those principles, which must conduct us where example fails. Yet it cannot be denied, that successful modes of practice have grown up, we know not from what origin; or have been introduced by the most ignorant empirics. But have not very useful machines been invented by people, who were ignorant

of the principles by which they were governed? And does it follow, that a knowledge of the laws of mechanics is of no use to the artist?

BUT theory carries the mind through the whole circle of sciences, in its search after analogous phenomena to explain those of life; and in its enquiry into the powers which influence the animal operations. And some have imagined that this diffusion of the attention is unfavourable to the progress of medicine. Their idea seems to have been taken from a view of those arts, which are brought to perfection by means of their subdivision into the minutest branches. Nor do they find any absurd analogy in supposing, that as our shoes are much better, since each manœuvre in their structure has employed the whole skill and address of a reasonable creature; so the management of diseases might

INTRODUCTION. xxix

might be rendered much more dexterous, by limiting the attention of the physician. And, in consequence of this doctrine, they have proposed to make every disease the care of a particular person; just as wisely as ancient superstition believed that every tree of the grove required its tutelary deity.

THE mere arts may be improved by repeated subdivisions; but those which partake of the nature of sciences require a different method of cultivation. It is the remark of a celebrated historian, that the art of war, for some centuries the only object of attention to all the gentry of Europe, acquired little improvement in the hands of men, who despised every other sort of knowledge. A personal dexterity in the management of their arms was common enough; but an extensive system of operations required an acquaintance with principles,

xxx INTRODUCTION.

ples, which mere habit could never teach.

THE Reader, I hope, will not find any thing whimsical in this comparison of arts, which have equally the appellation of murderous; nor be led to fancy that a dogmatic and an empiric differ like a Marechal Turenne and a savage warrior; chiefly because the former pursues more scientifically his destructive schemes. A less exceptionable illustration may be found in the progress of an art very closely connected with medicine.

WHILE the knowledge of chymists was confined to the operations within the laboratory, their art, though destined to throw a light on so many parts of nature, was full of mystery and confusion. The variety of phenomena, multiplied by every day's experience, inspired an admiration that arose to enthusiasm, and
gave

INTRODUCTION. xxxi

gave probability to their absurdest fancies. They did not attempt to explain these phenomena, by shewing their relation to what happened in other parts of Nature; for they were acquainted with no other part. But the mind will always be striving to generalize its notions; and system is as natural to mankind as invention. Certain facts made a more forcible impression on them: to these they referred every phenomenon which had any appearance of analogy; and they erected them into governing principles of the world. They beheld every where the operation of acids, alkalis, nitre, and sulphur; and corrupted the theory of medicine. The eye of a philosopher pierced this cloud, which the manœuvres of a thousand artists seemed only to render more thick and obscure. It was indeed a philosopher; one who looked through Nature, and discovered the springs of that variety of movements
which

xxxii INTRODUCTION.

which form the changing scene of our world. It was Sir Isaac Newton!

THE sciences, like the graces, march hand in hand; and nothing would be more vain than an attempt to pursue any one of them separately. Yet it will be objected, perhaps, that the animal œconomy has so little in common with the rest of Nature, that its facts can never be explained from any view of the phenomena of the inanimate world.

AND indeed, the first movers in our machine seem to have little analogy with other natural powers; and to be past finding out. But is it certain that they will always appear under this aspect? The most common phenomena of electricity, and the lightning of heaven, had presented themselves together to the view of mankind for some thousand years: yet no one suspected that appearances, which
affect

affect the senses and the imagination so differently, could have a common origin. But may not other Newtons, and other Franklins, extend still farther the boundaries of science? We can say nothing concerning the unknown parts of Nature, except from the notion of a consistency in the whole plan. And many philosophers, observing that the various appearances of the universe are traced to a few ultimate principles, which seem to be themselves related, were tempted to imagine a common source of all the activity observed in the material world.

BUT, however distinct our machine may be in its kind, it makes a part of the general system; and is subjected to the action of all those powers by which it is surrounded. And though, perhaps, no animal operation can be understood from mere mechanical, or chymical principles; yet it does not follow, that

b

these

xxxiv INTRODUCTION.

these have not really their influence. For the operations are the result of the mutual action of several powers; and generally, in the combination, some occur that are unknown, and whose effect we cannot value. Our theory, therefore, is rather incomplete, than false; and instead of being discouraged from its use, we should be stimulated to advance it gradually to perfection.

AND though the animal system were solitary, and unconnected with the rest of Nature, a general knowledge would be necessary to a physician. For it must still be admitted that medicine, like the other sciences founded on experience, is capable of acquiring from induction principles of its own. And we cannot better learn the method of giving it this improvement, than by tracing the progress of the mind, in collecting from observation the laws of Nature.

INTRODUCTION xxxv

THE knowledge of a certain routine of hospital, or other practice, is not sufficient therefore to prepare one for the exercise of our art; unless we would have it to be stationary. And there is even a probability, that a man may be continually conversant with diseases, without getting acquainted with them; as one may grow up in his own country, without knowing its characteristic manners. Objects must be seen in different lights, that our attention may be excited to observe them. Mere curiosity, though a lively, is a transitory passion, and is satisfied with superficial views. And when once it is satisfied, the same thing may return a thousand times, without making any impression. But when it is compared with similar, or contrasted with opposite facts, it acquires, as it were, a fresh novelty; and our attention is as powerfully roused as by the first emotion of curiosity. And here lies a principal advantage of system,

founded on experience, to the man who applies himself to observation. Each fact, that presents itself, being viewed with relation to a number of others, all its circumstances become conspicuous: and every thing being connected with something else makes a deeper impression, and is longer retained by the memory.

BUT if there is truth in what has been said, nothing can be more absurd than the vulgar notion of a certain quackish dexterity in medicine; which leads men to confide in ignorance, supported by its constant companion, Presumption. This notion, which tends to degrade physic from the rank of sciences, is not even applicable to surgery; though it is confessedly more purely an art than physic. The celebrated Petit, of Paris, constantly declares in his lectures, that the separation of physic and surgery is unnatural; and that it would be for
the

INTRODUCTION. xxxvii

the advantage of both, again to unite them. Yet, as far as simple dexterity is concerned, the chirurgical art has certainly been improved by the separation; and when this is carried farther, and surgery splits into several branches, the dexterity continues to increase. We may appeal to those fine manœuvres, for which the oculists, aurists, and dentists of the present times are so much celebrated. But it is not from the dexterity which we see displayed in artificial productions, that we are to judge of what is required in operations on the animal machine. In the former, it is art which does every thing; but in the latter, all the nicer changes are performed by Nature, who completes and finishes what the medical artist rudely prepares. It is not, therefore, a mere dexterity which we require in a surgeon. We expect that he should be acquainted with the powers of the machine, and be able to tell “*quid ferat, atque faciat natura.*” And thus, his art is so strictly connected

xxxviii INTRODUCTION.

medicine, as to justify the remark of Petit; and though it may be useful to practise them separately, they should certainly be studied together.

BUT it must be remembered, that when we take up the defence of system, it is merely in a general view. Nor should a vindication of the privilege of reasoning in medicine, be extended to all those modes of exercising it, that have frequently proceeded to the length of licentious abuse. A description of the variety of opinions which they have produced, would look like an attempt to give a history of the caprices of the human mind. Some of them were scarcely born, before they were buried in oblivion,

Ostendunt Terris hunc tantum fata, &c.

Fate show'd them—but so quickly dropt the scene,
'Twas straight forgot that they had ever been.

While others, winged with stronger fancy, mounted above the weak view of their age; and

drawn

INTRODUCTION. xxxix

Through a cloud
Drawn round about them like a radiant shrine,
MILTON.

they shone, for a time, the object of universal admiration. But they were mere meteors of the night; and as soon as we were in a condition to examine them, they disappeared. Perhaps, many of those theories, which at present look so firm and durable, are destined to a similar fate. One would think that, like the bodies of the sensible world, they were continually decaying, and continually reproduced in new forms.

NOR are we surpris'd at this account, when we reflect, that a system is an attempt to explain the phenomena of the living body in health, and in disease; and that to make it complete, a perfect knowledge of all the powers of the œconomy, and of their relation to one another, as well as to external agents, is absolutely necessary. But no one imagines that medical science, even in our enlightened age, has reached this point

of perfection: and all are agreed that our predecessors, the nearer we approach to the origin of experimental philosophy in Europe, were plunged in a still deeper obscurity. Much, therefore, of every system, though not of every one indifferently, must be merely conjectural. But this is the region of fancy, fruitful in prejudice and error; where a variety of circumstances, even accident itself, have frequently a greater influence than reason and common sense. And if such is the temper of mankind, that there is scarcely an absurdity which authority cannot set up, and habit establish, they should treat with some indulgence the common frailty,

————— *Æquum est*
Peccatis veniam poscentem reddere rursus.

By attending to the animal operations, we discover facts of a very different kind; some of them having an evident analogy with the phenomena of the inanimate

inanimate world, and seeming to be explicable from known principles; while others appear to be totally distinct in their nature, and cause. The former are considered as the effects of some of those powers, which we distinguish by the general appellations of chymical, and mechanical; while the latter are said to depend on an energy peculiar to animals. And thus we arrange, in separate classes, the informations of experience concerning the animal machine; and each of them is to furnish us with principles for explaining its phenomena.

BUT nothing can be more different than the notion of the limits of these systems, and of their importance in the œconomy, in the minds of different theorists. Like the undetermined bounds of the powers of our political constitution, they vary continually with the prejudices of the individual. People are extremely apt, from contemplating the operation
of

xlii INTRODUCTION.

of certain energies in a variety of instances, to grow possessed with the idea of their consequence, and to imagine their influence where it is not evident. Physicians, from the circumstances which direct our habits of thinking, have become chymists, or mechanics; and applied their favourite principles on every occasion. Their systems grew up in the retirement of the closet; where men frequently indulge themselves in speculations, which they never think of applying to the busy scenes of life.

BUT they who delivered themselves more to observation, and the study of the animal machine, perceived something in all its affections, which distinguished them from every other natural operation. And when they saw that analogies from the inanimate world were inadequate to the explanation of the phenomena, they began to think that they should be altogether rejected.

In

INTRODUCTION. xliii

In vitium ducit culpæ fuga, &c.

THE animal operations, they believed, must depend on the energy of that being, which resides only in animals; uninfluenced by mechanical or chymical laws, since we get our idea of it, by denying it every property of matter. But reason informs us that it is endued with intelligence, and that self-preservation is the powerful principle of its action. They naturally therefore fell into the doctrine of final causes; and conceived that the only way of explaining any fact in the history of the œconomy, was to shew that it was useful, or necessary.

AND thus have arisen those systems of physic, which, with the titles of Mechanical, Chymical, and Stahlian, have made the greatest figure in modern times. They are liable to the common objections against systems in general. They owe their premature birth to our eager desire of explaining every

every thing; which cannot wait until the progress of observation has ascertained all the principles that are necessary to a perfect theory. Their authors are led away by an excessive fondness of simplicity, which they consider, perhaps, as ornamental to their ideal fabric. They pretend to explain all the operations in the animal body, from the view of one set of causes; just as they trace all the various affections of the soul to one common principle.

THE animal machine, though it is connected with the other parts of Nature, is distinguished from them; and, while it acknowledges the influence of the common laws of matter, is governed by a principle peculiar to life. Nor do I mean, by the vital principle, the soul of the Stahlians; but that energy which discovers itself particularly in muscular contraction; and is evidently different from elasticity, or any other known power in nature.

nature. Its exertions do not depend merely on the intelligent mind; since we observe them in muscles cut out from the body, and excited to action by heat, and other irritations. But, though we perceive its action independent of intelligence, it would be difficult to imagine a mind, such as ours, unconnected with this power. Unless we could conceive a mind without ideas, or ideas without sensations; pleasure and pain without feeling, or the passions relative to these without their objects; and, finally, volition without the capacity of action. By muscular motion alone are we led to the belief of an immaterial principle in animals. And if this was not the only, as well as sufficient ground of our belief, vegetables, nay minerals, for ought we know, might be possessed of souls full of differently combined ideas, and subject to all the variety of passions; since without this power, and machines like muscles which it might set

xlvi INTRODUCTION.

in motion, they could never discover themselves to our senses. Every man can perceive in his companion the strong emotions which agitate his soul; especially where the natural behaviour is not confined by the rules of politeness, or rendered perplexing by the complicated influence of several passions. Yet he sees only the effects of certain changes in the muscular power; which naturally should lead him no farther than their immediate cause. But it seems, the connection of these changes with certain states of the mind is so constant and necessary, that we pass from the signs of the former directly to the latter.

ON this is founded the science of physiognomy, whose first rudiments may be discovered in the unexperienced infant. Nature teaches herself those relations, the knowledge of which is necessary to our existence; and this, among the others, so essential to a social being, who in his

INTRODUCTION. xlvii

original state had no arbitrary language. But the science can be greatly improved by observation; if we may believe what is told us of the people, who have employed themselves particularly in this sort of investigation. The method adopted by one of the most eminent physiognomists in history deserves our attention. It is said, that when he wished to discover any one's inclinations, he used to fashion every gesture of his body into a perfect resemblance with him; and then, from the change produced in his own mind, he collected the situation of the person's whom he imitated. Thus, while by an effort of the will he produced a certain condition of that power, which is the source of muscular motion; he produced at the same time the particular frame of mind connected with it. And may we not, in this way, explain the contagion of passions, so remarkable in many species of sensible creatures? Every one knows how apt we are to catch
the

xlviii INTRODUCTION.

the gestures of others; and has seen the gaping of a single person spread itself through a whole company. The propagation of convulsive disorders, among people of delicate and mobile habits, is a noted fact of the same kind. And they make it probable, that the motions which accompany the passions are communicated to the beholder; and, becoming certain conditions of the source of muscular action, produce, as in the former instance, the states of mind with which they are connected.

THE material principle of motion, in animals, appears to be the same with that of feeling. The voluntary contraction of any muscle in the body is rendered impossible, by dividing the nerves with which it communicates; and every sensation, we know, may be prevented, either by hindering the impression upon our nerves, or by stopping the communication of its effect through
them

INTRODUCTION. xlix

them to the brain. All our sensations are, without doubt, so many different states of the mind; but they are the necessary consequences of certain determinate changes in the power we have been considering.

AND the faculty of retaining ideas, of comparing, and variously combining them, seems to bear the same relation to the conditions of the common origin of the nerves. It has been weakened, altered, or entirely destroyed, by topical and evident affections of this organ. But, when the memory, the imagination, and the judgement, undergo such remarkable changes from diseases, and from material causes operating upon the body; must we not believe that these qualities of mind, like the others we have mentioned, depend upon certain states of the nervous power, and vary with them? It seems probable, therefore, that every modification of the soul, as far as it re-

I INTRODUCTION.

lates to the corporeal world, or can become the object of a physician's attention, will be found in some condition of that energy which belongs to the nervous fibre of animals.

THEY pretend, indeed, that there is no possibility of conceiving either the beginning, or the continuance of motion in our machine, except from the action of an immaterial principle. Yet it is certain that the animal motions would never have begun, and would cease immediately, unless they were supported by the influence of external physical causes. In the impregnated egg is any activity ever discovered, without the application of heat? The soul had slept for ever, and the machine continued motionless, but for the action of this energy. We believe, with the greatest reason, that the brain is the seat of the intelligent principle. But in those foetuses which are nourished, and arrive at their full growth,

INTRODUCTION. 11

growth, without any brain, what shall we suppose to have been the source of motion and activity?

WE certainly discover marks of intelligence in every work of Nature; and of these the animal machine appears to be the most perfect and exquisite. Their supreme Author has directed, by fixed laws, to the wisest purposes, the operation of brute and insensible matter. To neglect the investigation of his laws, and refer these purposes to some inferior intelligence, resembles the superstition of those idolaters, who adore in the sun the source of all the beneficent changes in Nature. Such notions are the offspring of ignorance; which leads us to derive from a Being of a superior kind, what we cannot explain from the view of any material energy. And they tend to make that ignorance perpetual, by setting bounds to the progress of the mind in its enquiry after physical causes.

lii INTRODUCTION.

IT is in the contemplation of Nature, struggling with the powers which have a tendency to destroy life, that the Animists chiefly triumph. But the efforts of the œconomy to re-establish its order when disturbed, seem to depend rather on the constitution of the machine, than on any endeavours of the intelligent principle. For they do not vary with the condition of the intelligent principle in different animals, but with the state of the machine. And we certainly observe, that the *vires medicatrices naturæ* are much more perfect in a *polypus* (whose share of intelligence we may believe is not very considerable) than they are in a man. Since, while they cure with some difficulty a small wound in the latter, they form, from each of the divided pieces of the other, a compleat animal.

IT was easily perceived that every analogy from the sensible world must be insufficient to explain the phenomena of

life: and so far there could be no mistake, for the thing rested on simple observation. But they drew too hastily their conclusion, that the phenomena must certainly depend on an immaterial cause. For as yet physicians had given very little attention to that peculiar energy, which resides in the nerves of animals; and though a material agent does not, as far as our observation goes, resemble any other in nature. Was it then surprising, that in their attempts to explain operations, which, however subjected to the common laws of matter, must still be influenced by this vital power, they were so often contradicted by experience? They resembled the speculative mechanic, who, having constructed a machine with a view only to certain principles, is disappointed on trial by the influence of some power which had never entered into his calculation.

ONE is ready to imagine, from what we know of digestion, that this process can be explained by the facts which relate to mixture, and to fermentation. Yet an excellent anatomist *, who has enquired, by experiment, into the state of this function in living animals, declares that it is not analogous to any chymical operation; and, to mark its peculiar nature, he has given it the name of Animalization. But digestion seems to be, in this sense, a chymical, and a fermentative process; as it changes the qualities of certain animal and vegetable substances, in a determinate way, reducing them constantly to a matter of the same kind. We cannot explain its distinct and specific nature, because we are not acquainted with all the powers which concur in the operation. We calculate pretty well the effect of the animal heat, the air, the motion; and, since the ingenious experiments of Sir John Pringle, of the saliva

* Mr. J. Hunter.

INTRODUCTION. lv

mixed with our food. The influence of other fluids, which may be present in the stomach, is more obscure; and we know still less of the effect of the vital power. We perceive, indeed, that nothing favours digestion more than a chearful serenity of mind; while an afflicting piece of news at once disturbs it, and seems to change the state of fermentation in the contents of the stomach: and we know that passions of the mind can only affect this function through the nervous influence. The abovementioned ingenious observer discovered, that the process of animalization was more perfect, and sooner compleated, in a vigorous animal than in one that was weakened; in a hungry animal, than in one which shewed no appetite. But vigour and hunger can only be referred to certain states of that power, which is the source of motion, and of sensation. It has therefore naturally, we may suppose, a considerable share in this operation. And, as

lvi INTRODUCTION.

we cannot pretend to imitate its action out of the body, we must not expect to find a perfect analogy with digestion in any artificial process,

BUT if those animal operations, which discover the greatest affinity with what is observed in the other parts of Nature, are still very different, and seem to owe their distinctness to the nervous influence; is it not surprising, that the consideration of this power should have been so long neglected by systematics? The simplest observation must have informed them, that sensation, and spontaneous motion, distinguish animals from every other kind of being. Was it not, therefore, reasonable to believe, that in explaining the animal operations, the facts which relate to sensation and motion must be of principal importance? But they were less occupied with examining and comparing the animal phenomena, than with attempts to illustrate them by known and obvious

INTRODUCTION. lvii

obvious facts, Mechanics, and chymistry, supplied a large field for analogies. Some of their principles were ascertained; and to men possessed with the idea of the efficacy of these powers, and of these alone, their application in the theory of the animal functions appeared to be easy, and natural. For the same reason, that the first theory of chemistry was taken from the mechanical properties of bodies, the first theories in physic sprung from our knowledge of the other parts of Nature; and were either mechanical, or chymical. But the laws of the nervous power could only be determined by attending closely to the phenomena of life, and to that relation between them which might allow their being associated under general heads. The labours of the illustrious Haller were the basis of this work; which has since been enriched by other observers. And in the hands of a professor* eminent for his genius,

* Dr. Cullen of Edinburgh.

and

lviii INTRODUCTION.

and his extensive knowledge of the animal œconomy, it has grown into a system : whose principles are as true as any in chymistry or mechanics, being founded, like them, on the sure ground of observation ; and are of far more extensive application in the theory of physic.

WE have seen the connection of medicine with the other sciences, and how naturally its improvement follows their progress. We acknowledge ourselves indebted to philosophy, for many rational views of the œconomy, as well as for all our knowledge of external agents, the means of life, and fruitful source of diseases. Theory was nursed by it, and grew up under its wings. Mankind seem to have an instinctive notion of the relation subsisting between every part of Nature ; so that the view of one of her operations always suggests some opinion concerning another. This move-

INTRODUCTION. lix

ment of the soul will often precipitate us into error; but it is constant and necessary.

What can we reason, but from what we know?

WHEN it was believed, that fire and water were Nature's principal agents, and concerned in her various productions, it was easily imagined that they exerted an equal influence in the animal œconomy. And on this ground was adopted the notion of hot, cold, moist, and dry temperaments, and of their several combinations. But, like every other hypothesis, it must be supported by an appearance of observation. The phenomena which occurred to the most superficial view; as the evacuation of different fluids in different states of the constitution; and the various appearance of the countenance, that seemed to indicate a variety in the proportion of the animal fluids; supplied this basis. And thus the
terms,

xi INTRODUCTION.

terms, Sanguine, Phlegmatic, Choleric, and Melancholic, which carried a more particular reference to the conditions of the œconomy, were associated with the former. The terms of the ancients have descended to us, so sanctified by long usage that we continue to employ them; though, in general, they convey certain collections of ideas very different from those to which they were originally annexed.

WHEN chymistry began to make some progress, and had not yet acquired just principles of its own, its adepts believed, through ignorance and enthusiasm, that they could discover in it the principles of every other science. And as these rude philosophers, from the relation of chymistry to the Materia Medica, were particularly connected with medicine; they presently introduced into its theories the most striking phenomena of their art. Every appearance in the œconomy was traced

INTRODUCTION. lxi

traced to some ebullition, or effervescence; some effect of an acid, an alkali, nitre, or sulphur.

MECHANICAL notions are so extremely obvious, their objects so familiar to the senses, and concerned in our usual occupations, that we naturally recur to them first for the explanation of any phenomenon. They very soon, therefore, obtained a place in medical theories; but they made no extraordinary figure there, until the laws of motion in solids and fluids were better ascertained, and the road of the circulation discovered. Then indeed this system, with a band of mathematicians proceeding in all the form of demonstration, grew exceedingly formidable.

OUR attention to electricity particularly, and its considerable improvement in the present age, have they not contributed towards turning our thoughts to
the

lxii INTRODUCTION.

the nervous system? For though it is by no means demonstrated, that the nervous power is the same with that which occasions the phenomena of electricity; and the laws of this power are as independent on any such hypothesis, as the laws of gravitation are upon the hypothesis of an ethereal fluid; yet the contemplation of such active and subtile energies has enlarged our views, and drawn the attention from those principles of mechanics and chymistry, to which it was before too slavishly attached.

THUS medical systems put on different appearances, according to the different lights which they receive from philosophy. But these reflected rays, too weak of themselves to dispel the darkness, could only produce indistinct, and frequently monstrous images. It was not till the sun arose in our own hemisphere, and that spirit of observation, which has distinguished the
latter

INTRODUCTION. lxiii

latter ages of Europe, began to exercise itself on the animal machine, that we acquired clear and accurate notions. The ignorant simplicity of the ancients, the mad whimsies of the chymists, and the more solemn fooleries of the mathematicians, disappeared by degrees; and were forced to quit, though reluctantly, their hold on the minds of men. We learned to fix the bounds of those analogies, which we drew from the other parts of Nature; nor was our progress stopped when the light of analogy failed, and there seemed to be an end of all connection of the animal system with the rest of the world. Observation still conducted us, in our attempts to collect the laws of the œconomy from a full induction of facts.

THIS sort of knowledge is so valuable, that every endeavour to extend it is meritorious. It will shew a laudable inclination, and some degree of judgement in the
choice

lxiv INTRODUCTION.

choice of our road, though the state of our abilities, or opportunities, may deny us the praise of a considerable progress. And even when we fail of producing a clear conviction, it is rare that, in the collision of facts, no sparks are struck out to show a future adventurer his way.

EXPE

EXPERIMENTS

UPON THE

HUMAN BILE.

THE Bile is so distinguished among the animal fluids by its active qualities with regard to the senses, and by the peculiar apparatus for its secretion, that it seems to have attracted, in all ages, the attention of Physicians. The Ancients (we must acknowledge it in spite of our reverence for them) saw only a very small part of that chain of causes and effects which operate in the œconomy. Was it surprising then that, in their attempts to explain from this narrow view the whole series of phenomena, they should ascribe too large an
B influence

influence to the powers which presented themselves the most obviously to their senses? These were the animal fluids; and more especially the Bile, whose properties convey an idea of greater energy, and whose frequent appearance in the diseases of their climate led them to suspect every where its action. The chemists received and cherished this notion of the importance of the fluids, because their art suggested various degeneracies to which they were exposed, each the source of some active substance, capable of disordering the whole machine. But particular Physicians have gone farther than seemed to be permitted even by the prejudice of system. Greulichius attempted to prove, by a variety of misapplied facts, that the Bile in its natural state is the proper stimulus to every function, and the chief minister of the great Archæus, and that its degeneracy is the source of almost every disease. And, even in our own time of sounder philosophy, and more enlarged views of the œconomy, the remarkable changes observed

observed in this secretion, and their connection with certain disorders, have persuaded some eminent authors that it has a considerable importance in the animal system.

IF we were better acquainted with the nature of the Bile we might speak with a greater precision of its effects. Boerhaave, who has given the tone to medical reasoning in the present age, took it into his head to call this fluid a soap; a term he seems to have been fond of, and to have applied on other occasions without a chemical accuracy. The notion does not appear to have been suggested originally by any enquiry into the composition of the Bile, but merely by the use which artists made of it in removing the stains of clothes, or mixing oils with water for the purposes of painting and varnishing; and perhaps also by its ancient application in medicine as a detergent. It was convenient to the theorist,

4 EXPERIMENTS *on*

as it afforded a ready view of the chief intention of nature in preparing this fluid; that it might serve as a medium for uniting the oily and watery liquors in the first passages.

BUT if this was the origin of the opinion, it should have been remembered that there are other substances which have no relation to soap, and yet are capable of rendering oils miscible with water. Such are the vegetable mucilages, and the gelatinous animal fluids; to which an obvious quality of the Bile, its viscosity, might have led them to suppose it related. Yet so great a weight did the authority of Boerhaave give to this fancy, that it has been implicitly received by the most eminent physiologists and pathologists of Europe, by Haller and by Gaubius. Nay, the sanction of experiment is pretended to be given to it, in a paper of the Academy of Sciences, by *Monf. Cadèt*; from which we chiefly
2 learn

learn how small a degree of proof is supposed necessary to confirm a belief, already established in prejudice. The author having been able, by the force of fire, to obtain from the Bile some oil, and some fixed alkali, immediately concludes that it must be a soap. With equal reason may the milk be called a soap, from which we get a much greater quantity of oil, and also some fixed alkali, according to the experiments of Mr. Beaumè.

THE Thesis of Dr. Ramsay presented us with a different view of this fluid; but his limited time prevented the ingenious author from completing his enquiry. Indeed, at any rate, as his experiments relate only to the Bile of an animal that subsists entirely on vegetables, a farther research was absolutely necessary. It seems to have been demonstrated by Reaumur, that other fluids employed in digestion differ considerably in

6 E X P E R I M E N T S *on*

the animals, which naturally make use of different kinds of food. Was it absolutely certain that the Bile was susceptible of no such variety? Other experiments have been made by foreign authors, of which I have not been able to procure a sight. But if we may judge from the Synopsis which Dr. Haller has given of those he was acquainted with, they have a good deal of confusion and uncertainty, and give no satisfactory view of the nature of this fluid. It is said to be saponaceous, to be resinous; and amongst the most modern authors there are some who pretend to derive its active properties from a portion of iron, which experiment, it seems, has detected in it. And thus, while the question of the nature of the Bile is continually recurring to physiologists and pathologists, their answers are extremely different; and who shall decide among them? If our opinion is to be determined by authority, we shall still be at a loss, for very opposite notions are supported

supported by names equally respectable. Happening last winter to employ myself in dissection at an hospital in Paris, I found an opportunity of indulging my curiosity, and attempting to remove my doubts. The events of my first experiments were communicated to some medical friends, who admitted them with much doubt and hesitation, they were so different from the received idea. If this is the case, I said, their novelty must give them some value: I will repeat them, and tell them to the world. They may serve at least to rouse the attention; and then, in such cities as London and Paris, where there are so many able observers, and such convenient opportunities of pursuing this enquiry, it cannot fail of being quickly pushed to the length of giving a clear and accurate knowledge.

THE Reader will not expect, I hope, what is commonly called an analysis of the Bile. The power of fire has already been

B 4 employed

8 EXPERIMENTS *on*

employed on this subject, by more experienced hands, in the midst of the conveniences of a laboratory. The state of a Voyageur, unfurnished with any thing like a chemical apparatus, and sufficiently occupied with other matters, would have been rather unfavourable to such an operation. I have only attempted to throw some light on the nature of the Bile, by mixing it with other bodies, and marking the phenomena; which, though a less artificial, is frequently a more useful method of investigation.

THE Human Cystic Bile, the subject of the following Experiments, is a brown viscid liquor, with a sweetish bitter taste. But these qualities are liable to some variety, as appears from the accounts of dissections. In the early foetus, the Bile is naturally without colour, and without bitterness; and, in certain diseases, it has been found in the same state. It has sometimes appeared of a yellow, of a saffron,

fron, of a bloody, and of a black colour. I have seen it perfectly black, and with such a consistency at the same time, as to resemble common pitch. When it is first taken out of the bladder, it has a faintish disagreeable smell; but, after being kept some time, it acquires a brisker, saccharine, not unpleasant odor, somewhat like that of fermenting beer. A gentleman said that he had been struck with the same smell from milk in a certain stage of fermentation; and I remember to have observed an odor in rennet-whey that resembled it very nearly. I do not find that this change has been taken notice of, yet it constantly happened in all the Bile which was not putrid before I got it, and was preserved in a clean and close vessel. After a longer or shorter period, which in some cases has been twelve days, the approach of putrefaction is discovered by the exchange of this smell, for one resembling that of rotten eggs.

The

The fœtor increases until it becomes very intolerable.

THE Bile mixes uniformly with water, whether cold or boiling, as well as with milk. But I could not, by means of agitation in a phial, unite it in any degree with oil; for however these fluids might be confused together during the motion, they constantly separated on standing, and there was as perfect a division between them, as there would have been between oil and water.

THE mineral acids have frequently been joined with the Bile; but the phenomena of these mixtures have not been so much attended to as they seem to deserve. In the common authors many of them are not mentioned, and others are falsely described. Baglivi, whose experiments were likewise made upon Human Bile, seems to be the fullest and most accurate in his history, as far as it extends.

EXPERIMENT I.

STRONG spirit of vitriol being poured upon some Bile in a phial, produced an instantaneous coagulation of it. The coagulum, swimming in a clear liquor, was then of a pale colour; but presently it became green, as well as the liquor about it; and on shaking the vessel the coagulum disappeared, and there was formed a turbid green solution. Some water being poured to this, and the vessel left at rest, there fell to the bottom a plentiful green sediment, the liquor above remaining clear, and of a beautiful green colour. These phenomena were the same in every repetition of the Experiment, except that the production of the green colour and turbid solution was sometimes instantaneous, without any previous coagulation*.

EXPE-

* I MET once with some Cystic Bile which differed from the ordinary appearances of that fluid.

It

E X P E R I M E N T I I.

STRONG spirit of salt, being applied in the same manner, did not, that I perceived, coagulate the Bile, but gave at once the turbid green solution, and the other phenomena, as in the above Experiment.

It had exactly the colour, and soon after its being put into a vessel acquired the sweet smell of melasses, or common treacle. The vitriolic and muriatic acids dissolved it; yet the solution was not green, but brown, and turbid. There was heat produced during both solutions, especially during that with the vitriolic acid. On pouring this, while fresh, out of one glass into another, and putting some hot water into the first glass, in order to wash it, I perceived that the water immediately got a fine green colour. The coagula of this Bile formed by the weak acids was not of a greenish yellow, but of a dusky brown colour, approaching to black. And the tincture it gave to sp. vini was not a yellow, but a reddish brown, yet quite clear and transparent. See Exp.

E X P E-

EXPERIMENT III.

STRONG spirit of nitre being poured on some Bile, gave the appearance of a thin cake suspended in a fluid. On the surface of the cake was spread a green circle, with a quantity of bubbles; which Baglivi, who made the same experiment, describes in these words, *Statim bullæ viridifcentes, cum telâ veluti cœruleâ natante*. This coloured film disappeared in a little time, and there remained a turbid brown solution. I observed that agitation hastened the escape of the green circle, and increased the appearance of bubbles on the surface.

THE turbid brown solution, being set by in an open vessel, was found constantly covered with a froth, though it was left perfectly quiet. The brown colour disappeared by degrees, and there remained a turbid whey-coloured liquor, with
a quan-

a quantity of whitish sediment. No heat was applied in this Experiment.

E X P E R I M E N T I V.

HAVING put a little Bile into some nitrous acid, which was pretty strong, without being fuming, I corked the phial, and exposed it to heat. The vessel was presently filled with a flame-coloured elastic vapour, which drove out the cork with great impetuosity. At the same time the frothy bubbles, which covered the surface of the liquor, disappeared, and it became more clear and transparent. I stopped the phial more closely, and set it again in the heat, where I allowed it to continue for some time filled with the flame-coloured vapor. I then removed it from the fire, and I observed, that as these fumes disappeared, being condensed by the cold, and falling back on the liquor, this gradually acquired a deep-green colour.

E X P E-

EXPERIMENT V.

I EXPOSED a mixture, the same as in Experiment IV. to the heat, in a phial that was not corked. When first set down, its surface was covered with bubbles, but as the red vapour ascended, and filled the neck of the phial, these disappeared, and the mixture grew paler and clearer. I afterwards removed the mixture into the cold, where the flame-coloured fumes soon vanished, but the mixture never acquired a green colour. It continued clear and transparent, and of a permanent yellow colour, though left open and exposed to the air. There was no froth observed on the surface of this solution, as in Exp. III. nor was there the same deposition to the bottom of the vessel.

EXPE-

EXPERIMENT VI.

I THEN took the mixture which had acquired the green colour, as has been related in Exp. IV. and exposed it again to the heat. The vessel was soon filled again with the flame-coloured vapor, which at length drove out the cork. I left it open, and presently removed it into the cold. The fumes disappeared, and I found that the solution had lost its green colour, and acquired that of Exp. V. This solution continued clear and transparent; its yellow colour was permanent in the open air; and there was no appearance of froth upon it's surface.

EXPERIMENT VII.

ON the turbid green solutions of the Bile formed by the vitriolic, and the muriatic acids, I poured some strong spirit of
nitre.

nitre. It immediately destroyed their green colour, and produced the brown solution which it forms itself with the Bile (Exp. III.), and this being set by in an open vessel, was affected in the same manner as in the Experiment referred to. Pouring some nitrous acid on the clear green liquor of the same solutions, (Exp. I, II.), I observed that their green colour disappeared first in a circle at the bottom of the glass; but, when I shook the vessel, this change took place at once in the whole liquor.

EXPERIMENT VIII.

THE clear green liquor of the solutions I, II. being evaporated to about half their quantity, resembled very much the turbid solutions of the same Experiments. Evaporated to dryness, they yielded a black paste, which received and retained impressions, and was con-

C

siderably

siderably acid. Affusion of water removed the acidity, and left the black matter, toughish between the teeth, perfectly insipid, and equally insoluble in spirit of wine and in water.

THE turbid solutions yielded the same matter in greater quantity.

THE residuum from the nitrous solution was of a pale yellow colour, and resembled the coat which whites of eggs leave on a vessel in which they have been exposed to heat.

ONE of the most curious circumstances attending the mixture of the mineral acids with the Bile, is the production of the fine green colour. It is also a leading phenomenon, and marks the commencement of a vigorous action of the salt upon the fluid. For the Reader has seen (Exp. I.) that the vitriolic acid, on its first addition to the Bile, simply coagulated

gulated it; and that the appearance of the green colour was the first sign of any change tending to the solution of that fluid. And he will see presently, that the mineral acids considerably diluted merely coagulate the Bile; and, being incapable of any farther action upon it, do not produce the green colour. We cannot therefore have any theory of the action of the strong mineral acids upon the Bile, without enquiring into the origin of this colour.

EVERY one knows, that the several concretions of the Bile are inflammable, and more remarkably so than other bodies which seem to contain an equal portion of oil. We should expect therefore to find, in this fluid, the principle on which inflammation depends; and which, in all its various combinations, whether it makes a part of oil, of sulphur, or of any other body, is known to the chymists by the name of Phlogiston.

And as the concentrated mineral acids, especially the nitrous, have a stronger attraction for this matter than for any other, we shall not be surpris'd to see them unite with it, on their application to the Bile, and produce those phenomena which accompany their action on the phlogiston in other cases.

THE remarkable resemblance between the solutions of the Bile and those of iron in the same acids has been used as an argument for the colour of the Bile, and the changes it suffers from the acids, being an effect of its iron. But the green colour of those metallic solutions evidently depends upon the phlogiston of the iron uniting with the acids; for the nitrous solution, when fresh made, and charged with this principle, is of a fine green colour; but as that very volatile matter, which arises from the combination of phlogiston with the nitrous acid, escapes, this solution changes its colour

to a ruffet-brown. And the muriatic solution is at first green, but afterwards becomes brown by keeping; and that this change depends upon the gradual loss of the phlogiston, appears from the following observations *. If the metal be deprived of its phlogiston, or reduced to a calx, before it is put into the acid, the solution is of a brown colour from the beginning: and if you add fresh bits of metal to the solution, which at first was green, and is become brown by keeping, you restore its green colour; which certainly depends on your restoring the proper quantity of phlogiston.

BUT it would seem, from our Experiments, that the green colour of the solutions of the Bile is to be explained in the same way. For we find (Exp. IV.) that there is in the Bile a considerable quantity of the principle of inflammability, which discovers itself by convert-

* Dr. Black's Lectures on Chemistry.

ing the nitrous acid into the flame-coloured elastic vapour. And from attending to the phenomena of the IVth, Vth, and VIth Experiments, it will appear evidently, that the green colour in the nitrous solution depends on the union of the phlogiston of the Bile with the acid. For, when the flame-coloured vapour is confined, and obliged to mix itself with the solution, the green colour is produced; which does not appear when it is allowed to fly off: and when the green colour has been produced in this way, it is made to vanish again, by expelling from the solution the flame-coloured vapour.

HAVING premised this view, the phenomena of the preceding Experiments become clear and intelligible. As soon as the concentrated mineral acids touch the Bile, they are carried by that force of attraction, which is so remarkable between them and the principle of inflammability, to act upon, and dissolve it.

And

And, during this operation, the bright green colour is produced, in the same manner as it is produced during the action of these acids upon iron. The combination of the nitrous acid with phlogiston is, perhaps, the most volatile body in nature; and hence the green colour, which appears during the action of this acid upon the Bile, is extremely evanescent. In the open vessel it flies off almost as soon as it is formed (Exp. III.); and by the time that the first vehemence of the action of this acid upon the Bile is over, the green colour has entirely disappeared. The frothy bubbles, the *bullæ viridifcentes* of Baglivi, which shewed themselves on the surface of this solution, and not of the others (Exp I. II.), did they not indicate the escape of this volatile matter? And is not this the reason of their being increased by agitation, which also hastened the escape of the green colour, and produced both these effects, by assisting the action of the acid

upon the phlogiston? When the solution was exposed to the fire (Exp. IV.), these bubbles disappeared, and the heat, increasing the force and quantity of the volatile matter, gave it the visible form of elastic red fumes.

BUT it appears, from Exp. III. that, as in the metals, in the *phosphorus urinæ*, so also in the Bile, while a part of the phlogiston is easily and quickly separable, there is another part which adheres more closely to the rest of its substance. Is it not this part which gives, with the nitrous acid, the ruffet solution; and which at length escapes in the open vessel, though slowly and gradually? It was some days before the brown colour disappeared in the nitrous solution, and it was all the time covered with a froth, which indicated now I presume, as before, the escape of the nitrous acid volatilized by the phlogiston of the Bile.

THE

THE green colour of the vitriolic, and muriatic solutions is permanent in the open air; which depends, in some degree, on these acids not being so apt to be volatilized, and to fly off with the phlogiston, as is the nitrous acid. It appears likewise from the Experiments (Exp. III.) that the attraction of the nitrous acid for the phlogiston, or the principle of colour in the Bile, is so violent, that it separates it entirely from the rest of the matter of that fluid. But the vitriolic, and muriatic acids dissolve, together with the phlogiston, a considerable quantity of a fixed matter, which discovers itself on evaporating the clear green liquor of these solutions (Exp. VIII.); and it is, I imagine, the union of this fixed matter which makes the combination of the phlogiston of the Bile with the above-mentioned acids less volatile, and less apt to fly off. So too when the nitrous solution has been exposed to heat, and losing its turbid appearance, becomes clear

and transparent, (which depends most probably on the acid's being enabled, by the heat, to dissolve more perfectly the fixed matter) then the yellow colour becomes permanent in this solution, though it be exposed to the air. And this happens, I suppose, because the union of the fixed matter represses that volatility which the phlogiston would otherwise give to the nitrous acid. And accordingly we do not discover, on the surface of this solution, that appearance of frothy bubbles which was remarkable in the other (Exp. III.) that had never been exposed to the heat. And is not this a farther proof, that the frothy appearance depends upon the phlogiston, or the principle of colour in the Bile, uniting with the nitrous acid, and converting it into an elastic vapor?

BUT, if the green colour of the vitriolic, and muriatic solutions (Exp. I, II.), depends on the union of the phlogiston
of

of the Bile with these acids, we see clearly why the nitrous acid, which has a stronger attraction for this principle, and always forms with it a volatile compound, should, as soon as it is poured on those solutions, separate their phlogiston, and discharge their green colour, as in Exp. VII.

THUS it appears, from all the phenomena, that the action of the concentrated mineral acids upon the Bile, by which they change and decompose it, depends on their violent attraction for the principle of inflammability. And as there does not remain, after this action of the acids, any trace of the bitterness of that fluid, we may suppose that it is strictly connected with the abovementioned principle. That this principle is the source of the colour of the Bile will be admitted from the general analogy of nature *;

* Gaub. Patholog. 135. Inflammabile Coloris Sedes. *Diét. de Chymie*, Phlogistique.

and

and seems to be demonstrated by the Experiments related above, and particularly by Exp. III. where the nitrous acid separates entirely the colour of the Bile, and, during this process, is converted by it into an elastic vapour. And we shall find, hereafter, that the menstruum, which extracts the colour of the Bile, extracts at the same time its bitterness *, and that the Bile, deprived of its colour by this menstruum, no longer gives those phenomena which have appeared to us to depend upon its phlogiston †.

HAVING seen in what manner the Bile was affected by the mineral acids, I was curious to know the changes it would suffer from the vegetable.

* Exp. XI.

† Exp. XIV.

EXPE-

EXPERIMENT IX.

I POURED a little vinegar on some Bile, and I observed that this fluid was immediately coagulated, its colour changing at the same time to yellow, *in vitellinum crassum*, Bagliv. This has been called a precipitation, but surely with great impropriety, since there is no separation of parts, no decomposition, but the whole of the Bile takes the form of a consistent curd. Yet, when authors * talk of the precipitate of the Bile being soluble, in part, in spirit of wine, they certainly mean this coagulum; since what may properly be called a Precipitate, the sediment of the solutions (Exp. I. II.) appears from Exp. VIII. to be in no degree soluble in spirit of wine.

THERE seemed to be a fluid squeezed out from the Bile in the instant of coa-

* Fordyce, Ramsay, &c.

gulation,

gulation, for the limpid liquor, which swam about the curd, was more in quantity than the acid which had been applied. This liquor had an evident acidity, while the coagulum was considerably bitter.

EXPERIMENT X.

JUICE of lemons poured on the Bile produced exactly the same phenomena. As these Experiments (IX. and X.) are very inconsistent with an opinion which has been adopted under the sanction of Experiment, and made the basis of some important medical theories, I took care to repeat them on the Bile of at least a dozen different persons. Nor did I ever find any difference in the event, when the Bile was not in a putrid state.

HAVING poured a little juice of lemons on some Bile in a large spoon, and
set

set the mixture by, I found, at the end of twenty-four hours, that the more fluid part had still acidity, while the more solid part was considerably bitter. I added to it some salt of tartar, which raised a considerable effervescence, dissolved the coagulum, and restored the brown colour. The mixture had now an intense bitterness, without any acid, but rather with an alkaline acrimony.

I Poured more lemon-juice on some Bile than was sufficient to coagulate it. I then stirred these liquors strongly together for some time, endeavouring to mix them. I set the glass aside; and, after it had stood three days, when I came to examine it, I found a solid matter of a dark colour at the bottom, and a brown liquor swimming at top. The first taste of the liquor was acid, but when it had stood a little on the tongue, I found a nauseous bitterness. It coagulated milk, and some fresh Bile on
which

which it was poured. The solid matter underneath this liquor in the glass was most intensely bitter.

THIS coagulum, when authors were possessed with the notion that the Bile contained a vast quantity of oil, has sometimes been mistaken for fat. The *amarus adeps* which Schaper obtained from treating the Bile with tartar, and the *solidus adeps* which Homberg, by shaking the Bile with alum, precipitated to the bottom of the vessel, could be nothing more than this bitter curd formed by the coagulant power of the acids they employed. Yet Haller has quoted these experiments, very seriously, as proofs of the quantity of oil contained in the Bile, and discovering itself without the torture of fire.

I NOW returned again to the mineral acids, with an intention to see their effect on the Bile, in a state of dilution

lution, when they are brought nearer to the condition of the vegetable acids.

EXPERIMENT XI.

I PUT into three several glasses the three mineral acids, weakened by a large addition of water; and then poured into each glafs a small quantity of Bile. I observed, in each, that as soon as a drop touched the acid liquor, it became yellow in its under part, and, being spread out into a coherent film, supported the upper part of the drop, which was still unchanged in its colour and consistence. But when I shook the glafs, and allowed the liquor to come into contact with every part of the Bile, the whole of it became at once a consistent curd. It resembled exactly that which was formed by the vegetable acids, except that it was a more compleat yellow, while the

D

vegetable

vegetable coagulum verged a little towards green.

THE event of this Experiment, compared with that of the first, second, and third, may surprize one who has seen, in Dr. Haller's Synopsis, such positions as the following: *Cum omni acore minerali cogitur (Bilis) dum satis meracus fuerit*; and again, *Eo magis cogitur quo ipse acor est meracior*. But when, without any prejudice of authority, he consults Nature, and reflects on the phenomena, the event of this Experiment will appear to have been suggested by the former. The concentrated mineral acids, at least the vitriolic and the nitrous (Exp. I. III.), coagulated the Bile as soon as they touched it; and I have endeavoured to prove, that the remarkable appearances which accompanied, or followed this effect, depended on the action of these acids on the phlogiston of the Bile, in consequence of their vehement

ment attraction for that principle. But it is known that the vegetable acids, in their common state, have comparatively very little of this attraction; and that the mineral acids lose much of its force when they are combined with a large proportion of water. We should expect, therefore, on applying the vegetable, and diluted mineral acids to the Bile, to see their coagulant effect quite pure, and unmixed with those phenomena, which marked the strong action of the concentrated acids upon the phlogiston of the Bile, in the first set of Experiments.

EXPERIMENT XII.

I POURED a little Bile into some spirit of wine, and I perceived that it was instantly coagulated; but as it was tending to the bottom, the spirit nearest it grew yellow, and this yellow colour was

presently diffused over the whole liquor. There fell to the bottom a brownish corrugated concrete, and the spirit had extracted, together with the yellow colour, a sweetish bitter taste.

E X P E R I M E N T XIII.

I SET some Bile to evaporate in a common stove; and when I came to examine it, I found in the bottom of the vessel a quantity of hard brittle flakes, resembling aloes extremely, both in appearance and taste. This matter, put into water, gave it a turbid brown colour, and an intense bitterness. An acid poured upon the watery infusion, caused a plentiful precipitation of brownish flocci, and rendered it clear and transparent. The same matter taken out of water, and put into spirit of wine, gave it a deep brown tinge, and sweetish taste, without much bitterness. It was not entirely

tirely soluble in either; but the caustic alkali dissolved it perfectly into a brown viscid liquor. From comparing the above phenomena with those of the coagulum of the Bile, in the same circumstances, it seems probable that the Bile was coagulated by the heat employed for its evaporation.

AFTER viewing these Experiments, I could not help enquiring what that was in the Bile, which rendered it coagulable by all the acids, by spirit of wine, and apparently by heat *? Can it be any other than that animal matter, which, in the blood, in the milk, in the egg, and everywhere discovers itself by the same quality? The colour, the

* A piece of a human stomach having been previously well washed, was infused in cold water twelve hours. Some of the infusion, mixed with the Bile, produced the appearance of a number of little yellow specks, which, subsiding to the bottom, formed a sediment that would not mix again with the Bile, nor with water. I had no opportunity of repeating this Experiment.

inflammability, and the bitterness of the Bile had appeared to be connected with a part, which gave plain indications of an abundant, and an evolved phlogiston; and I was tempted to believe that its viscidty, and its disposition to coagulate depended on a true lymph. I was struck with the analogy between the blood and the Bile. In both there seemed to be a colouring matter, united with a coagulable, and with a more watery fluid which separates on concretion. But the union of these several parts appeared to be more perfect in the Bile than in the blood; as we shall endeavour to show when we come to compare these fluids. And this I imagined was the reason why we never saw any spontaneous separation of the coagulable from the colouring matter of the Bile, and had never, therefore, been able to demonstrate the existence of the former.

BUT as these parts appeared to have different chemical relations, I thought
that

that it might be possible to separate them entirely. Spirit of wine, while it coagulated the Bile, extracted its taste and colour; but not perfectly. The action of strong spirit of nitre upon the colouring matter of the Bile was much more violent, and sufficient to separate it altogether; but then it broke down the texture of the coagulable part. Yet the same acid, when weakened, simply coagulates the Bile. Thinking of this, I determined to try the effect of these two bodies combined in *sp. nitri dulcis*.

EXPERIMENT XIV.

I Poured a very small quantity of Bile into a phial of this liquor, and I got a bright rust-coloured tincture, with a sweetish, rough, bitter taste; at the bottom of which rested a coagulum perfectly white. When the spirit was poured off, and the coagulum put into water, it resembled exactly those polypous concretions which are sometimes found

in the heart, when they have been well cleaned from any adhering red globules*.

E X P E R I M E N T X V .

A BIT of this coagulum being thrown into spirit of wine, did not communicate any thing to it, nor was it changed itself by the spirit, except in being rendered somewhat more crisped,

E X P E R I M E N T X V I .

SOME of the same matter, being put into a solution of caustic alkali, was readily and entirely dissolved by it. This solution was a little viscid, and had a slight yellowish tinge. An acid added caused a plentiful precipitation to the

* An extemporaneous composition of three parts *sp. vini*, with one of *aq. fortis*, extracted perfectly the colour of the Bile, leaving a pure white coagulum. This tincture was transparent, and of the colour of the former; but it grew paler by keeping, and at length colourless,

bottom,

bottom, which had the floccous appearance.

EXPERIMENT XVII.

A BIT of the same coagulum thrown into spirit of salt, was slowly dissolved; and the solution was opaque, with a bluish cast, which was however scarcely perceptible.

THE suspicion of a coagulable lymph in the Bile, which had been suggested by the former Experiments, seems to be carried by the present to the length of a clear conviction. The colouring matter spread over it, though it could not destroy its chemical relations, concealed it from our senses. But, in the XIVth Experiment, this veil being removed, the coagulable lymph discovers itself to the eye. It must, however, be remembered, that if the quantity of Bile is too large in proportion to the spirit, the whole of its colour will not be extracted,
but

but some tinge will remain on the coagulum.

As this part of the Bile, when separated from the colouring matter, is not in the smallest degree soluble in either spirit of wine or water, it appears to be of the same nature with that which was obtained from (Exp. VIII.) the solutions of the Bile in the mineral acids, by evaporation. We have already observed, that these acids, in a concentrated state, decompose the Bile; and, as it appeared before that they acted upon, and separated its phlogiston, so we perceive now that what remains is the coagulable matter, somewhat altered indeed by the violence of that action.

BUT the Experiments XV. XVI. XVII. serve to show, that the coagulable matter of the Bile, while it has all the sensible qualities of the true lymph, is also affected in the same manner by those
chemical

chemical relations, which are said to be most characteristic of that fluid *.

WE saw before, that the part of the Bile which was not soluble in spirit of wine, was changed by it into a firm concrete; and it appears, from Exp. XV, that when this part is separated from the rest, and coagulated, the coagulum becomes more crisped in *sp. vini*; and from these facts, as well as from Exp. XXII. we may believe that *sp. vini* is one of the strongest coagulants of the Bile, as it is of the coagulable lymph. It seems therefore a little extraordinary, that we should meet with the following observation in Dr. Haller's account of the Experiments, — *Neque bilem coit (spiritus vini) nisi aliquando debiliter.*

THE vegetable acids, we have proved already, do not decompose the Bile; and the reason of this difference between their

* Butt. Thes. de Sanguine.

operation

operation, and that of the concentrated mineral acids, appeared to be the inferiority of their attraction for the phlogiston of this fluid. The coagulum of the Bile, formed by the vegetable acids, is still therefore a combination of the colouring matter of this liquor with its lymph; and it is this substance which we shall next examine.

E X P E R I M E N T X V I I I .

THE concentrated vitriolic, and muriatic acids, being poured upon the coagulum, dissolved it; and produced the fine green colour, and the same sort of solutions exactly, which they form with the pure and unaltered Bile (Exp. I. II.). The nitrous acid gave immediately the turbid brown solution, Exp. III.

E X P E -

EXPERIMENT XIX.

SOME of this coagulum being thrown into *sp. nitri dulcis*, a quantity of bubbles were separated from it, and it was buoyed up to the surface of the liquor; where it continued to give out bubbles, while the spirit extracted from it a fine green colour. Then it fell to the bottom, perfectly white, with all the appearance of a pure coagulated lymph.

EXPERIMENT XX.

COLD water poured upon the coagulum, extracted from it a sweetish bitter taste, and a greenish yellow colour, and got a viscid turbid appearance. The pieces of coagulum arose at first to the top, and afterwards subsided to the bottom. This infusion, after standing some
time,

46 EXPERIMENTS *on*

time, was found covered with a white scum resembling animal fat.

EXPERIMENT XXI.

THE same coagulum put into spirit of wine, gave it a deep green colour, and a sweetish bitter taste, and became hard and crisped.

EXPERIMENT XXII.

SOME of the coagulum, which had remained for some time in water, and had thus become soft, and acquired a mucous consistence, being put into spirit of wine, gave it a green tinge, and became firm and corrugated. A bit which had been in spirit of wine, being thrown into water, grew softer, but was not otherwise affected, nor did it give to that fluid either colour or taste.

EXPE-

EXPERIMENT XXIII.

UPON some of this coagulum, which had been in both water and spirit of wine, and had imparted to each as much as it was capable of yielding, I poured a little vitriolic acid. The vessel being placed in a gentle heat, was presently filled with a white smoke, which, from its strong peculiar smell, appeared to be the volatile, sulphureous acid. There remained in the bottom of the vessel a very dark-coloured viscid solution.

EXPERIMENT XXIV.

THE coagulum being put into a solution of caustic alkali, was perfectly dissolved by it. Its yellow colour was changed at the same time to a brown; and thus the solution, being viscid, resembled
5 very

very much the Bile before it was coagulated. Spirit of vitriol effervesced strongly with this solution, and precipitated to the bottom a quantity of dark green sediment. And this liquor, being afterwards evaporated, yielded the same kind of residuum as the solution of Bile in spirit of vitriol (Exp. VIII.).

IT appears, from these Experiments, that the colouring matter of the Bile is affected by the same relations in the coagulated fluid, as before the addition of the vegetable acid. It gives, with the concentrated mineral acids, those phenomena which depend upon their attraction for its phlogiston. It is perfectly extracted by *spiritus nitri dulcis*, and less completely by spirit of wine. And we perceive now that it yields itself to water likewise, by simple infusion. As far as we could judge from our little Experiments, it seemed that the sweetness and bitterness of the Bile were almost equally well extracted

extracted by spirit of wine, and by water, but that the colour yielded itself more completely to the former liquor.

YET the colouring matter appears to be somewhat changed by the action of the vegetable acid, for the colour of the coagulum is different from that of the original Bile; and so is the colour of the extracts made from these two substances by *spiritus nitri dulcis*, and by spirit of wine, Exp. XIX. XXI.

WHATEVER this change is, it seems to approach the colour of the Cystic Bile to that of the Hepatic; and as the brown colour of the Cystic is brought back by the addition of an alkali, one might be inclined to think that this colour depended on an alkaline nature acquired by the Bile during its stagnation in the gall-bladder. And the other chief difference of the Cystic Bile from the Hepatic, being, it is said, the greater bitterness of

E

the

the former fluid, this suspicion might be strengthened by an observation of Baglivi. He found that, on the addition of a fixed alkaline salt to the Bile, *amarities ejus nimium aucta vomitum præ amaritie vehementem statim movebat* *. But it must certainly be difficult to determine the difference of force between two sensations, which are both extremely intense, and exceedingly disagreeable. I tried it, and I could only say that the alkaline acrimony made the taste of the Bile, if possible, still more nauseous. But I fancy that Baglivi's Italian sensibility magnified exceedingly the force of these disagreeable impressions. For he says, in another place, that, spirit of salt being added to the Bile, he found, in the mixture, *Ingrata amarities quæ parum gustata veluti vomitum ciebat*. This acid, diluted, certainly does not increase the bitterness of the Bile (Exp. XI.), and when it is applied in a concentrated

* Baglivi, Experimenta de Bile humanâ capta.

state, it destroys entirely that quality (Exp. VIII.). Yet Dr. Haller, from this remark of Baglivi, and from some other authority, asserts the very opposite fact, *Si idem salis spiritus meracior fuerit utique Bilem in offam coagulat. auget idem amarorem.* If I was not deceived by my senses in the Experiments already related, here are two affirmations in a breath, which are directly contrary to the truth; for, the stronger acid dissolved the Bile, while the weaker only coagulated it; and the stronger acid, far from increasing the bitterness of the Bile, made it disappear entirely. These reflections do not affect Dr. Haller, who, in delivering the observations of others, is certainly not accountable for their inaccuracies.

ONE cannot decide whether the Cystic Bile is alkaline or not, by the common experiment on the purple vegetable infusions. For, when I poured into diluted syrup of violets some pure Bile, and

some Bile containing salt of tartar, the change of colour they produced was nearly the same, and in neither could it be called a green.

THE caustic alkali, being the best dissolvent of the coagulable part of the blood *, dissolves most perfectly the coagulum of the Bile, which seems to consist chiefly of that matter (Exp. XIV. XXVI.). But, as this mixture effervesced strongly with an acid (Exp. XXIV.), we must suppose that there is fixed air in the Bile, by which the alkali was rendered mild, and capable of effervescence. But is it from this notion that we are to explain the extraordinary appearance in Exp. XIX.; where the coagulum mounts at first to the top, and, after giving out a number of bubbles, sinks again to the bottom; its specific gravity being increased, perhaps, by the loss of its fixed air? And, in Exp. XX. we observ-

* Butt. Thes. de Sanguine.

ed something analogous to this appearance, for the coagulum arose at first to the top of the water, and afterwards subsided to the bottom; which might depend upon the same circumstance. Yet, what is very remarkable, during the solution of the colouring matter of the uncoagulated Bile in *spiritus nitri dulcis*, there was no such phenomenon (Exp. XIV.). How did the vegetable acid give occasion to this difference?

THE coagulum becomes firmer in spirit of wine, and gets a mucous consistence in water (Exp. XXII.); and these are the changes which Dr. Butt observed to happen to the coagulable lymph in the same circumstances, and are to be explained therefore from the presence of this matter in the Bile.

THE dark coloured solution, which spirit of vitriol forms with this coagulum, after the greater part of its colour-

ing matter has been abstracted by water, and by spirit of wine (Exp. XXIII.), seems to correspond exactly with the solution of the coagulable lymph in this acid, as it is described by the same author. It produces nearly the same kind of solution with white of eggs. Whether the sulphureous acid, which arose during the solution, depended on the action of the vitriolic acid upon some remains of the colouring matter, or upon a decomposition of the lymph of the Bile, I shall not pretend to determine.

E X P E R I M E N T XXV.

THE several extracts of the colouring matter of the Bile in *spiritus nitri dulcis*, and spirit of wine mixed uniformly with water into a clear transparent liquor. Nor did they suffer any change from the addition of an acid. But an alkali being
being

being added to the clear solution in *spiritus nitri dulcis* (Exp. XIV.), it grew turbid, and there fell to the bottom a large white floccous sediment. But the colour of the solution was rather deepened.

EXPERIMENT XXVI.

I Poured, on the same solution, some of the alkali prepared for making Prussian blue. There was precipitated a quantity of white flocci, as in the former Experiment, which shewed no tinge of blue.

EXPERIMENT XXVII.

THE same alkali being added to the solution of the pure coagulable matter in the muriatic acid (Exp. XVII.), gave a precipitate which had exactly the same

E 4 appearance,

appearance, but was in much greater quantity.

EXPERIMENT XXVIII.

I MIXED some powder of galls with the solution of the colouring matter in *spiritus nitri dulcis*, and it did not, that I perceived, produce any remarkable change of colour.

EXPERIMENT XXIX.

THE same powder was put into the clear green solution of the Bile in the vitriolic acid (Exp. I.), and I did not observe that it produced any such alteration of colour, as one would expect in a solution of iron.

MONS. DURADE of Geneva has asserted, in his ingenious treatise upon
nutrition,

nutrition, which obtained a prize from the Royal Academy of Berlin, that iron is the material cause of the colour of the Bile *. This metal, or the principles of its composition, is so generally diffused through Nature, that we are not surprized to meet with it in animals. It has been discovered in human bones, in calculous concretions, where it seemed to rest idle and inactive; but when it shewed itself in the animal fluids, we imagined that it had an important part to play in the œconomy. I did not repeat the Experiment on which Mons. Durade founds his opinion; for, as he observes that the phenomena are not striking, and are slow in appearing †, I thought that perhaps some degree of prepossession was necessary, in order to perceive them. But the tincture in *spiritus nitri dulcis* being a very perfect extract of the co-

* La Cause Materielle de sa Couleur. *Traité sur la Nutrition.*

† *Ibid.* p. 119.

louring matter of the Bile, it seemed a proper subject for trying the truth of this notion. The Reader must determine whether the means employed were not sufficient to have detected the iron, if it had been present, in the form and quantity required to produce the effects which are ascribed to it. Mr. Margraaf observed, in the gall-stone of an ox, after he had calcined and treated it with spirit of vitriol, and the alkali prepared for making Prussian blue, some slight marks of a mixture of iron *. But it appears, from his manner of expressing himself, that the urinary calculus, the bones of a sheep, and the human scull, gave yet more evident tokens of their containing iron. We cannot suppose, therefore, that the iron had any relation to the colouring matter of the Bile; since it is chiefly in this matter that it differs from those other animal substances which

* Opusc. Chym. tom. ii. p. 64. "Ont a peine donne quelque indice observable," &c.

furnished

furnished a still greater quantity of the metal, while it resembles them exactly in its coagulable part.

THE precipitate, from the solution of the colouring matter of the Bile (Exp. XXVI.), was so perfectly similar to that which was obtained by the same means from the solution of the pure coagulable matter, that I must believe them to be of the same nature. And if this was the case, we perceive how intimate the union is between these two matters; since, by means of that, *spiritus nitri dulcis* becomes capable of dissolving a portion of the coagulable matter, which otherwise it could have no tendency to do, as it is one of the strongest coagulants. One is inclined to believe, from the same view, that the coagulable matter makes the greater part of the composition of the Bile; and that the colouring principle, as was suggested by the first set of Experiments, is of an extremely subtile nature.

ture. The most remarkable qualities of the Bile appear to be connected with it; but throughout the world a great activity is always found united with a proportionable subtlety; and Nature animates the grosser kinds of matter by powers whose fineness escapes our senses, though we perceive evidently their operation. That principle to which the metals owe their colour, splendour, ductility, and every characteristic quality; to which the most active parts of vegetables, their essential oils, owe their peculiar and distinguishing properties, we only discover by the universal effects which it produces in the bodies it unites with. We are informed, by these effects, that it is present in the Bile; and apparently, from its phenomena with the mineral acids, in a state similar to that in which it is found in the metals; where, as it is not fettered with a variety of attractions, it has more of these to satisfy, and is a source of more active qualities in the body with which it is combined.

IN considering the Bile as an agent in the œconomy, it is particularly important to know its relation to putrefaction. This fluid is employed ordinarily in the passages where fermentations, approaching in their progress very near to putrefaction, are continually going on. It is sometimes effused there in extraordinary quantities; and frequently it passes the limits which Nature seems to have appointed it, and mixes with the general mass of fluids.

THE opinions entertained on this head are as different as the circumstances to which they owe their origin. Some authors were struck with the analogy of the Bile to the vegetable bitters, and believed, with Glisson and Baglivi, that Nature had provided, in this fluid, an antiseptic balsam. There are others, and among them Boerhaave and Senac, who, chiefly from preconceived notions of the nature of diseases, imagine that the Bile
is

is extremely prone to putrefaction. Nor do the observers seem to be much better agreed than the theorists. Dr. Haller has quoted from M. Gaber an experiment to prove that the Bile begins to stink in a cold place, within two hours after death. And this seems to have persuaded him, that the Human Bile is a very improper subject for experiments, as we may be deceived by phenomena which are merely the effects of putrefaction. If M. Gaber's experiment is admitted as conclusive, Dr. Haller's comment is certainly just, and I may be supposed to have mistaken, through the whole course of these Experiments, a putrid fluid for one that seemed to be nearly in its natural state. But when I find that Bile taken out of a body which is yet warm, and Bile which has lain in the bladder three or four days after death, have exactly the same properties, and, particularly, are both firmly coagulated by the vegetable acid, I am inclined to
consider

consider M. Gaber's case as somewhat singular. We know, that the effect of putrefaction upon the coagulable animal fluids, is to diminish, and gradually destroy their disposition to coagulate. And can we suppose that this cause has been operating for some time, without producing, in the smallest degree, its constant and necessary effect?

THERE is reason to believe, that the Cystic Bile may vary in regard to this circumstance in different subjects. It will probably be more putrescent, where the general mass, from which it is separated, is farther advanced in the septic degeneracy. And it is besides exposed to particular causes, which may influence this process; as the time of its stagnation in the bladder, and the state of the vapour in the communicating cavities, which is sometimes quite putrid very soon after death. It may happen, therefore, that the Bile shall become pu-
trid

trid very soon after death ; but generally, as I have already observed, there is a fermentation, or at least a spontaneous change of qualities, which precedes this stage, and is distinguished by the production of the saccharine odour. The senses discover accurately enough when this terminates in putrefaction, by the exchange of an agreeable enough smell, for one that is fetid and disgusting. And then only do our Experiments shew such a change in the nature of the Bile, as might be expected from a beginning putrefaction.

E X P E R I M E N T X X X .

THE concentrated vitriolic acid being poured upon some putrid Bile, dissolved it immediately, with some violence and production of heat, into a viscid black liquor. Water was added to this solution, which then acquired a dull green colour,

colour, and continued always turbid, though it was left perfectly quiet. This solution being evaporated, gave the same kind of residuum as the solution Exp. I.; only that it seemed to have less tenacity.

EXPERIMENT XXXI.

THE mineral acids diluted coagulated the putrid Bile. But the coagulum was rather of a saffron than a yellow colour (Exp. XI.); and so weak and brittle, that, on the least agitation, it broke to pieces, and gave the appearance of a turbid solution.

EXPERIMENT XXXII.

THE vegetable acids poured upon the Bile did not give to the whole the form of a consistent curd (Exp. X.), but produced

duced a number of small broken curds; nor was the thinner liquor clear and limpid, but turbid, yellowish, and without acidity. I observed that the putrid Bile, from the addition of the acids, got an odour, which approached very nearly to that of rancid bacon.

E X P E R I M E N T X X X I I I .

SOME putrid Bile being put into spirit of wine, gave to this liquor a deep brown or black colour, and an intensely bitter taste. The precipitate to the bottom was made up of a number of broken pieces, and the spirituous extract was not clear and transparent, but viscid and opaque. It gave to water an opaque yellow colour, with considerable bitterness. Some vitriolic acid being added to this mixture of the spirit and water, rendered it turbid; and there fell to the bottom a quantity of brown flocci.

E X P E-

EXPERIMENT XXXIV.

SOME of this Bile was evaporated by gentle heat to the consistence of a soft extract, and had then a most intensely bitter taste. When it was mixed again with water, a part of it subsided on standing, which required agitation to keep it united with the water. I cannot say that I was struck with the smell of musk in any of these Experiments.

EXPERIMENT XXXV.

SOME putrid Bile being joined to a mixture of bread and water, gave to it its own peculiar fetor. But this mixture being set to ferment in a heat between 90° and 100° Fahr. soon lost this fetor, and acquired a strong empyreu-

matic odour, like that of burnt feathers, which continued in it for a long time.

IT appears, from these Experiments, that the coagulability of the Bile is diminished, as we should expect, by putrefaction. It even becomes miscible in a certain proportion with spirit of wine; discovering itself by the viscidty which it communicates to the spirituous tincture of the putrid Bile, as well as by the precipitation formed from the tincture by an acid; neither of which were observed in the same circumstances of the sound Bile. With respect to the sensible qualities of this liquor, as there is no mention made of the sweet taste in the last Experiments, I presume that its principle was decomposed, and destroyed by the previous fermentation. But the bitterness of the Bile is so far from being diminished by the beginning putrefaction, that it seems even to be augmented by it; at least the spirituous tincture of the putrid liquor
was

was more intensely bitter than the same preparation of the Bile in a sound state. It appears, therefore, that the bitterness of the Bile resists the effect of putrefaction in changing the qualities of bodies, and continues unaltered when the coagulable matter has proceeded far in its degeneracy. It is not improbable then that this quality in the Bile, as well as in other bodies, is connected with an antiseptic power, though it cannot entirely prevent putrefaction in a matter that, like the coagulable lymph, is peculiarly disposed to it; and in its long course to reach the biliary pores, as well as during its stagnation in the gall-bladder, is subjected in a singular manner to the animal powers which tend to induce this process.

WHEN the Bile has been coagulated by the vegetable acid, it is no longer miscible with water (Exp. XX.), but it communicates to this fluid its taste and

colour, together with a portion of its coagulable matter, sufficient to give to the infusion a degree of viscosity and opacity. If the bitter of the Bile is really antiseptic, and the putrescency of this fluid depends on the coagulable lymph, which seems, from our Experiments, to make the greatest part of its substance, we may expect to find that the infusion of the coagulum (Exp. XX.) is more antiseptic than the original Bile; since it contains the bitter, together with a smaller proportion of the coagulable matter.

E X P E R I M E N T XXXVI.

INTO each of three several phials, which I shall distinguish by N^o 1, 2, 3, I put an ounce of raw beef. To the first I added water only; to the second an equal quantity of a light infusion of the coagulated Bile in water; to the third the same proportion of water, with two

I tea-

tea-spoonfuls of Bile. These mixtures, being close stopped, were exposed to a heat between 90° and 100° Fahr. Examining them twenty-four hours after, I found, in N^o 2, and 3, that sweetish, sprightly smell which one perceives in fermenting mixtures; and, in N^o 1, a strong odour of spirit of lavender. This surpris'd me, till I recollected that the cork of this mixture, being an old one, had probably been used for stopping a phial containing spirit of lavender, some portion of which adhering, the odour had been exalted, and diffused through the mixture by the fermentation. At the end of four days, during which time the lamp of the furnace had been twice allowed to go out, but the mixtures were never quite cold, I took them out, and placed them in a chamber, the heat of which was generally near 60° Fahr. I examined them every day, and about eight days afterwards I observed, in N^o 3, a peculiar smell, which reminded me

of a rotten melon. But N^o 1, and 2, remained sweet about a month longer, the former smelling strong all the time of spirit of lavender. At length N^o 2. acquired the same fetor exactly, which had been observed in N^o 3; and N^o 1. began to stink soon after.

E X P E R I M E N T X X X V I I .

I CHOSE three phials of the same size, and put into each half an ounce of raw mutton; to N^o 1. I added seven tea-spoonfuls of water; to N^o 2. six tea-spoonfuls of water, and one of Bile; to N^o 3. the infusion of a tea-spoonful of Bile, coagulated by the vegetable acid, in seven tea-spoonfuls of water. These phials were corked, and left in a room which had a constant fire in it. Two days after, Tuesday the 24th of March, the mixture N^o 1. had acquired an evident fetor; and, in N^o 2, I observed that

6

sweet

sweet smell which precedes the putrefaction of the Bile. On Thursday the putrid smell was to be perceived in N^o 2; but N^o 3. continued sweet. By Sunday this mixture had also acquired a beginning fetor.

EXPERIMENT XXXVIII.

I REPEATED the same Experiment, and joined to N^o 1, 2, 3, another mixture (N^o 4.), containing, together with the meat and water, a tea-spoonful of lemon-juice. I observed, in N^o 1, a strong acid odour, like that of the sweat of some people, which preceded its putrefaction. It stunk before there was any perceptible change in the other mixtures. One of the phials happening to break at this time, I took out their corks, and let them all stand open. N^o 2. and 3. acquired the putrid fetor sooner than in the former Experiment, but in the same order;

der; N^o 2. beginning first to smell; N^o 4. kept the longest sweet. It was distinguished from the other mixtures by its pale white colour, while the others had a florid bloody appearance. But, when N^o 4. began to stink, it lost its white colour, and became florid also. The surface of this mixture was covered with a mould which I did not perceive in any of the others *.

It has been observed, that the milk of carnivorous animals, when they were fed on meat and water only, was still acescent, and to explain this fact, it has been imagined, that the powers of secretion were capable of reproducing the vegetable nature in animal matter. But it appears,

* This, I believe, might be a reason of its keeping longer sweet; for, in another Experiment, when this mould was prevented, by frequent agitation, the mixture with the acid, and that with the infusion of coagulated Bile, began to smell about the same time.

from

from the last Experiment, that a mixture of lean mutton and water simply, passes through the acetous stage of fermentation before it putrefies. And it is perhaps on this account, that a diet of long-kept salted meat has such pernicious effects upon the constitution, it being most probably incapable of this fermentation. The use of fresh butcher-meat is found to be very advantageous to sailors, who have become scorbutic by a long course of salted meats, and to have an effect similar to that of fresh vegetables.

BUT, with respect to the chief object of these Experiments, there is one difference among them which I shall not pretend to explain, because I do not know whether it will be found to be constant, or merely accidental. It seemed as if the application of a heat, in the beginning, sufficient to excite a brisk fermentation, had enabled both the Bile, and the infusion of its coagulum, to re-
tard

tard longer the septic process. But this, I think, may be fairly deduced from all the Experiments, that the Bile, far from being so extremely putrescent as many have imagined, is rather antiseptic; and that, when it has been coagulated by the acids, it imparts to water a stronger antiseptic power than we observe in the pure and unaltered Bile. The Bile employed in Exp. XXXVI. had lain, to my knowledge, three days in the dead body; and when the gall-bladder was taken out, there was a very offensive smell in all the abdominal *viscera*. Yet this fluid, being poured into a phial, and closely stopped, acquired a sweet smell, which continued some days before the putrid fetor began. And we find, from the Experiment, that it had a greater effect than so much water in retarding putrefaction, and in making it less offensive. But the watery infusion of the coagulum being more antiseptic than the Bile, must be much more so than mere water.

THIS

THIS antiseptic principle of the Bile cannot reside in the part to which it owes its coagulability; and which appears to be exactly analogous to the lymph of the blood. It is probably connected with the bitterness of this fluid, and is like that, a quality of the colouring matter. And thus are we persuaded, that the authors who, merely from considering the bitterness of this animal liquor, imagined in it an antiseptic power, were not deceived by the analogy of Nature. But as they were ignorant of the composition of the Bile, they affirmed of the whole what, properly, belongs only to a part.

THE READER beholds, with pleasure probably, the end of this tedious investigation. But, although the harbour seems so near, and his impatience invites us into it,

*Crebrescunt optatae Auræ portusque patefcit
Jam propior*—————

we cannot so soon stop our course. The Experiments suggest opinions, which, by their novelty, captivate the mind, and hurry it into theory. In spite of ourselves we are carried into that sea which has so often proved fatal to observers; and whose rocks, though frequently pointed out, are so difficult to be avoided. We shall give the reflections, as they naturally arise from the subject we have been examining, without searching after any other order.

AND this is the first which presents itself. Of all the animal fluids, the Milk and the Bile seem to be the most analogous

BILIARY SECRETION. 79

gous to one another, and to the common mass of blood. The basis of these liquors is a coagulable matter, which, though it gets some variety from the progress it has made in the septic animal process, and from its state of union with other substances, possesses the same general characteristic properties. From the milk we obtain a matter analogous to the sugar of vegetables; and that somewhat of the same kind is contained in the Bile seems evident from its sweet taste, extracted by spirit of wine, and by water; as well as from the fermentative process which precedes its putrefaction. It is believed, with appearance of reason, that the same substance resides in all nutritive matters, whether animal or vegetable*; and consequently in the blood. We may suppose that it is evolved, and rendered more evident, by the animal process for the secretion of the milk, and of the Bile, in some such manner as it is

* Dict. de Chymie, *Sucre*.

evolved,

evolved, in the farinaceous feeds, by the vegetable process attending their germination. I had no opportunity of examining the saline contents of the Human Bile; but *Monf. Cadet's* analysis of the Bile of the ox furnished him with some common salt, some fixed alkali, and some of that little known matter which has been named the essential salt of milk, from its being first discovered in this liquor. And we are assured, by *Monf. Beaumé*, that these are the very salts which he obtained from the milk of that sort of animals *. I do not know whether the saline contents of the blood have been so particularly enquired after; but it seems probable that we shall find these fluids as similar in their ferous, as in their coagulable part.

AND here the connection seems to be at an end; for the colouring and bitter part of the Bile differs much from the

* *Diét. de Chymie, Lait.*

colouring

colouring matter of the blood; and this is still more different from the oil of the milk. Yet the greatest chemists of our age, as Gaubius, and the author of the *Diët. de Chymie* are persuaded, that the colouring matter of the blood is of a nature analogous to the oil of the milk, or of the chyle; and that its differences are to be explained from the changes, which our fluids undergo in the course of the circulation. But surely, if the powers of circulation can convert the oil into the colouring matter of the blood, as the same powers continue to operate, they may change this substance into the colouring matter of the Bile; for the relation between these seems to be still more intimate.

And what are the powers of circulation to which we principally attribute the abovementioned changes? They do not seem to belong to the mechanical class; for these are incapable of changing the properties of bodies. The effects of the circulation, when car-

ried farther in the same fluids than Nature intended, discover very plainly the power which has most influence there. If an animal is denied all food, while his vital functions subsist in vigour, there follows soon a putrid dissolution of the circulating mass. But the stages of fermentation tending towards putrefaction, though we have marked but a few of them, exist, perhaps, in infinite variety; and those we are acquainted with are remarkable for their power of producing new bodies. And if the changes of the fluids from the circulation are, in an extreme degree, the effects of an advanced stage of the septic process, is it not probable that intermediate changes are the effects of some intermediate stage in the same process?

THIS process is regulated by the circumstances of the subject which is exposed to it. Thus the coagulable lymph, out of the body, in favourable circumstances, produces, by a sort of fermentation, a mild *pus*. But if those conditions

tions are not present, which serve to govern the process, and stop it at this point, it hastens on to the stage which is called *putrefaction*. So we imagine that the same process, regulated by the laws of the œconomy, produces, in the course of the circulation, useful changes in our fluids; as the conversion of the oil into the colouring matter of the blood, and of this into the colouring matter of the Bile; nor does it, except when these laws are broken through, proceed to the putrefactive stage.

THIS is the hypothesis, which naturally was suggested by the almost perfect analogy of those fluids. And Gaubius imagines, that the oily origin of the red globules is manifested in their form, which depends, he supposes, on their repulsion to the watery fluid around them. And when the red colour of the blood is diffused in water, this, he thinks, is owing to the intervention of the serum,

which has an effect like that of other viscids, in rendering this oily matter miscible with water. And hence, says he, it happens, that the application of a boiling heat to water, tinged by the red globules, deprives it of its colour, by coagulating, and causing a separation of the serum or lymph *.

YET I found, by Experiment, that boiling water, poured upon the crassamentum of the blood, and stirred with it, extracted a fine clear red colour, while it precipitated to the bottom of the glass a quantity of coagulated lymph, which had still some tinge. But it appeared, that all the lymph was not precipitated, and that some of it remained united with the colouring principle in the transparent watery solution; for, upon adding to this a little nitrous acid, the red colour disappeared, and there fell to the bottom of the glass some white grumes.

* Patholog. § 342.

Thus

BILIARY SECRETION. 85

Thus it seemed, that the principle of colour in the blood resembled the same principle of the Bile, in its strict union with the coagulable matter, and in being of such a nature as to fly off with the nitrous acid.

I THEN, applied to the crassamentum the strong mineral acids, all of which formed with it turbid solutions, of a deep brown colour. The addition of water to these solutions caused a plentiful precipitation, and the colour seemed to follow the precipitated matter, and appeared in a circle at the bottom of the glass.

SOME of the crassamentum being put into spirit of wine, seemed, after a couple of days, to have communicated very little to the spirit. And this circumstance distinguishes it remarkably from the Bile; whose colouring matter we have seen is very readily dissolved by spirit of wine.

Spiritus nitri dulcis extracted from a bit of the crassamentum a dark tinge; but more slowly and imperfectly than it separates the colouring matter of the Bile. Yet, a very small quantity of fluid blood being poured into a phial of *sp. nitri dulcis*, was entirely stripped of its colour; and there fell to the bottom some pure white coagulated matter. This tincture was opaque, like the same tincture of the yolk of the egg, not transparent like that of the Bile.

IT seemed, from these Experiments, that the colouring matter of the blood, though probably of a nature analogous to the colouring matter of the Bile, is yet in a different state; since they do not give the same phenomena in their mixture with the acids, &c.

THE yolk of the egg, being intended for the formation of blood in the young fetus, is, probably, adapted to the feeble
condition

condition of the animal powers in the commencement of life. We should expect to find it a blood half-prepared by the mother, and requiring only a slight change from the tender organs of the chick. Dr. Haller thinks that he has observed, with the microscope, the gradual change of the yellow matter of the egg to red blood, in the vessels of the young animal. But it seems to be composed, like the milk, of ingredients very analogous to those of the common mafs. Indeed, as it is provided for the nutrition of a still weaker animal, it seems to be still more similar to blood. It contains a colouring matter, which, like that of the blood, and of the Bile, flies off with the strong nitrous acid. This matter is dissolved by *spiritus nitri dulcis*, or by a mixture of *aq. fortis* and spirit of wine, and leaves a white curd, which seems to be a pretty pure coagulable lymph.

THUS have we a scale of animal fluids, of which all are similar, yet all different; the milk, the yolk of the egg, the blood, and the Bile. The two former may be considered as preparations for the other two, to which they gradually approach; the yolk being the most analogous. It is their common character to contain a coagulable matter, united with another, that has for its chief ingredient the phlogiston. In the milk this principle is so fettered by its union with other matters, as to get very nearly the form of the vegetable expressed oils. It seems to be gradually evolved by the animal process, and at length, in the Bile, gives evident indications of its being present in a more simple and active state. There may be in the animal body, for aught we know, an apparatus for separating this matter in a pure and uncompounded form. Perhaps the brain, and its productions, is the organ intended for this function; and the phenomena of sensation and motion
would

BILIARY SECRETION. 89

would almost tempt one to imagine it *, if it were allowable to indulge conjectures in medicine, that are incapable of demonstration.

IF one were to take the two extremes of this scale, and compare the colouring matter of the Bile with the butter of the milk, he would say that their difference resembled that between the bland, and the essential oils of vegetables. For, while the former is readily dissolved by spirit of wine, the latter seems to be little affected by it; and while the milk is perfectly mild, and free from all stimulus, the Bile, though it is said not to be bitter in every animal, is in all possessed of considerable acrimony and power of irritation. The colouring matter of the Bile discovers also a much stronger attraction to the mineral acids, and gives indubitable marks of a more evolved phlogiston. If he were to suppose that this change is

* Vid. Thesis de Calore, Edinburg. 1770.

wrought

wrought by the animal septic process in the course of the circulation, he would in some measure be justified by our observing, that an analogous change is produced in the bland vegetable oils, by a spontaneous fermentation. For this, as well as the application of heat in distillation, approaches them nearer to the character of the essential oils. But it must be remembered, in considering this, and every animal operation, that

“ ’Tis but a *part* we see, and not the *whole*.”

POPE.

We know that there is a fermentative process continually going on in our fluids, which tends to putrefaction; but we know also that it is regulated by the animal powers, in a manner which we do not understand, and shall never be able to imitate.

IF then, according to the idea that has just now been expressed, we range these fluids in the order in which they have sustained the process of animalization,
the

BILIARY SECRETION. 91

the milk and the Bile will be directly opposed to each other. In the former, this process seems to have advanced farther than in the common circulating mass; but not so far in the latter; and this agreeably to the purpose of Nature in preparing these liquors. The milk, being intended for nutriment merely, should partake of the vegetable nature; since, without reasoning on the affair, we find, by Experience, that a mixture of vegetable matter in our aliment is absolutely necessary. But the Bile is to aid that process by which vegetable is converted into animal matter; and therefore, we might suppose, could scarcely be too much animalized.

ONE is the more inclined towards this hypothesis, by observing Nature's care to select, for the secretion of the Bile, that blood in which the septic animal process may reasonably be supposed the farthest advanced. She does not employ here, as in the other secretions, arterial, but
venous

venous blood; returning too from parts where fermentations, the nearest to putrid, are continually going on; effused, and stagnating, perhaps, in the spleen; and spread out afterwards through the sluggish system of the *vena portarum*.

BUT, if the hypothesis is well founded, we must observe, that whatever accelerates the septic animal process, has a tendency to increase the Biliary Secretion; since it favours that change of the blood which fits it for becoming Bile. And is it not in this light that we are to view the large secretion of Bile, which seems to be always the consequence of a continuance of hot weather; and which shows itself, more remarkably, in the intermittent, and remittent fevers of the warm climates, arising from putrid miasmata? For, that this symptom is not so much the effect of the intermittent paroxysm, as of a certain state of the fluids in the hot season, appears from an obser-

observation of Mr. Cleghorn's; that when the intermittents of the Summer continued until the cold weather set in, they lost their malignity and contagion, and were no longer attended by the excessive redundancy of Bile. And the icteric colour, which characterises the same kind of fevers, when they seem to have most of the putrid nature, is it not to be explained in the same manner? Some have doubted whether this appearance had any connection with the redundancy and absorption of Bile; but it seems a probable opinion, from considering the relation of this fever to those which have been called bilious; and the only observation, which we find directly in point, appears to confirm it. It is remarked by Dr. Lind, that the serum of the blood in a fever distinguished by this symptom, and named on that account a *yellow fever*, had a bitter taste.

THE abundance, as well as acrimony of the Bile, which have been observed in animals that were starved to death, do they not correspond exactly with this notion? Morgagni imagines, that the distension of the gall-bladder, which occurred in these cases, depended on the emptiness of the stomach preventing the ordinary compression of that reservoir*. But Dr. Haller found the stomach, as well as gall-bladder, full of Bile, in an animal that was starved to death†. And another observer has remarked a vomiting of Bile, and jaundice, among the consequences of a privation of food; and, we suppose, of that increased tendency to putrefaction which presently follows‡.

BUT there are other considerations, which support the opinion of a connection between the oil, the colouring mat-

* Ep. Anat. Med. XXVIII. § 6.

† Physiolog. L. XIX. f. ii. 11.

‡ Fanton. Diss. Anatom. p. 39.

BILIARY SECRETION. 95

ter of the blood, and that of the Bile. In the early fetus, both the blood and the Bile are without colour, and no fat is to be found in the cellular membrane. Afterwards the red globules appear; the oil is deposited along the course of the arteries; the Bile acquires colour, and at length acrimony. The life of the fetus is little more than vegetable, and the animal septic process is then extremely weak. It would seem, that the first tinge of the Bile was derived from the red globules passing the Secretion, without much previous change *. Dr. Haller thinks it perfectly evident, that the red globules are formed, in the chick, from the matter of the yolk; for, the first appearance of colour in the blood, as it flows through the umbilical vessels, is yellow; then a mixture of yellow and red; and so on to the fine florid colour of a thoroughly compleated blood. But when

* Elem. Physiol. L. XXIII. s. iii. 1. in fetu constanter dulcis est (Bilis) mucosa, rubra, insipida.

we observe, that the first appearance of colour in the Bile is red, does it not become equally, probable that the red globules are the source of the colouring matter of the Bile, which the feeble powers of life are yet unable perfectly to form?

AND, even in the adult, when the vital powers languish; when the red globules are formed with less facility, and water, instead of oil, is deposited in the cellular membrane, as in cachexy and dropfy; the Bile is found without its usual colour and acrimony. Among the many cases of this kind, the Reader must allow me to mention one from Glisson, together with the reflections which it suggested. He will see, that this accurate observer, and subtle theorist, had formed nearly the same notion of the Bile, that I, before I had consulted him, was led to by my Experiments. *Erat nempe apud nos mulier cachectica, in cujus vesiculâ felleâ deprehendimus*

*prehendimus humorem serosum, pallidumque, minimè amarascentem, sed insipidum potius, dulcique proximum. Credibile sanè est, in eâ calorem vitalem pauperiorem fuisse quam ut adustionem effecerit, adeoque excrementum illud sine amaritudine expurgatum esse. Utcunque indicio est serum necessariò ad humoris fellei structuram concurrere. It would be easy to multiply facts of this kind. Let me add another, taken from Rivalerius by Lieutaud, *Inter exenterationem cadaveris viri chachectici, et Leucophlegmatiâ diuturnâ extincti, in conspectum veniebat vesicula fellea, humorem albicantem, et merè lacteum continens—inculpatis cæteris visceribus* *. In the case of a dropsy following an intermittent fever, from Storck, *Cystis fellea continebat humorem albumini ovorum plane simillimum* †.*

* L. 1. Obs. 850.

† L. 1. Obs. 618. Vid. etiam, Obs. 903, 983. et Morgagn. Ep. XXXVIII. 19, &c.

THUS it appears, that the Bile is sometimes without any colouring matter, a mere serum; and that these are the cases in which the red globules are defective, and the process for making them considerably impaired. And does not this confirm our idea of the origin of the colouring matter of the Bile; that it is produced from the red globules, by the abovementioned process a little farther extended?

PERHAPS another observation may set this in a stronger light. Though proper aliment be taken in, the powers of circulation are not capable of furnishing soon a great quantity of red globules; and they are rendered still less capable by being weakened. After large, and repeated evacuations of red blood, the florid colour disappears in the vital stream, and frequently cannot again be restored.

BUT there is another case of exhaustion, where the blood is not recruited by
aliment;

BILIARY SECRETION. 99

aliment ; and, the vital functions going on, it is dissipated by a spontaneous degeneracy. We find it remarked, in the dissections of some people who perished by fasting, that their vessels were quite empty*.

LET us now consider the influence which these different cases will have on the biliary secretion. If the Bile is as analogous to the Blood as the Experiments persuade us, and the colouring matter of the one fluid is derived from that of the other, the loss of such a quantity of red globules as the system is unable to restore, must produce a defect of colour in the Bile. By examining the accounts of dissections, we shall find whether this conclusion from theory corresponds with the fact. Morgagni, in his thirty-sixth epistle, and eleventh ar-

* Morgagni, Ep. XXVIII. 4. " Venas, et arterias mirabiliter inanitas."

ticle *, presents us with a history exactly to the purpose. A young man died, after repeated evacuations of blood by vomiting; *Cadavere dissecto, mirum fuit quam modica in vasis omnibus portio sanguinis superesset. Itaque ventris viscera insueto pallore, et quasi candore ad se oculos alliciebant.* He adds afterwards, speaking of the gall-bladder, *Bilem continebat paucam, coloris maxime diluti, cui similis in ventriculi fundo non deerat.*

MORGAGNI seems to doubt, whether this remarkable appearance did not depend upon the acrid particles of the Bile being retained in the circulation. *Atamen, ipsa Bilis paucitas, ipseque adeo dilutus color, an acriores particulas in sanguine retineri significarent, existimare tu poteris.* It is unnecessary to allege the improbability of this supposition, which is founded on an opinion now generally rejected, that the matter of the Biliary Se-

* De causis et sedibus morborum.

cretion is present, under its proper form, in the circulating mass. But the phenomenon is perfectly agreeable to our theory, and therefore serves to confirm it.

THE other case of exhaustion, from a mere privation of food, must affect this Secretion in a very different manner. For here the red globules are in their due proportion, and can only escape by those ways which Nature provided, when she determined that their degeneracy should make room for their renovation. But a consequence of this sort of degeneracy is the formation of the colouring matter of the Bile. While the blood disappears, therefore, in the vessels of starving animals, from the exercise of the vital functions, we should observe a plentiful and an acrid Biliary Secretion, with its full proportion of colouring matter. But this is really the fact; and it differs from the

former, in the manner we should expect from the theory.

It appears, therefore, that the process for the evolution of oil, and the production of red globules, in certain circumstances of the constitution, is too weak, and imperfect; and that in different, and seemingly opposite circumstances, their conversion into the colouring matter of the Bile is too much precipitated. These may be called the Phlegmatic, and the Bilious constitutions; and, in both, the oil and the red globules seem to be defective; since in the one they are not formed, and in the other they are too hastily used, and abstracted. Their excess is seen only in disease; but smaller gradations are consistent with a state of health; and may become general, from some cause to which men are universally exposed, as the influence of climate.

THERE is yet another constitution, in which the evolution of oil, and the production of red globules, seem to proceed more rapidly than their use and degeneracy. We see many people who, with a moderate consumption of food, are liable to a constant plethora; and must be relieved by Nature, or Art, procuring successive hæmorrhages. A temporary plethora seems to be natural to every animal, soon after feeding; especially if there are long intervals between the meals. For, during the interval, the red blood is continually proceeding in that degeneracy, which terminates in its separation from the circulating mass; and this loss must be repaired by the production of new blood, as soon as the nutritious fluid is furnished to the vessels. Dr. Haller assures us, that he has observed the pale liquor, in the vessels of a languid frog, acquire from one good meal a florid colour, and become full of globules.

THIS leads to the consideration of a fact, which seems to agree with some of our preceding reflections. The ingenious Mr. Hewson has collected a number of observations, relative to the appearance of oily globules floating on the blood, and giving to its serum a near resemblance with milk. He shows us that this is not the mere effect of an admixture of chyle; since it appears in the animals whose chyle is transparent; yet, only when their blood is inspected within a short time after feeding.

Now I cannot help fancying, as we know the process for making red globules to proceed briskly soon after the introduction of aliment, that this appearance should be considered as the beginning of the process, and the first step towards the production of red globules. After a certain period, the oily particles are no longer to be seen; because, most probably, they are used by this time;
being

being in part converted, by the powers of circulation, into the colouring matter of the blood.

AND we observe in all the cases, given us by Mr. Hewson, of this phenomenon in the human serum, that the process for making red blood was in excess; since the persons had symptoms of plethora, though they took but little food, and were all relieved by large and repeated hæmorrhages. It would seem, that the evolution of oil, and its conversion to red globules, (which are found to have place naturally during a certain time after the admission of aliment) from some peculiarity in these people, were going on constantly, and furnishing such a quantity of blood, as made its frequent evacuation necessary to the œconomy.

THE excellent observer, to whose work I refer, supposes that this appearance depended

pended on the oil of the adipose membrane being conveyed into the blood-vessels, for the purpose of nutrition. But if the oil is laid up in this membrane, to answer the exigencies of Nature, why is it improvidently absorbed when there is no occasion for it; while a quantity of fresh aliment is mixing itself with the blood? And though animal fat, when it has undergone the powers of digestion, supplies the system with a very nutritious fluid, does it follow that fat itself is the matter employed in nutrition? or is there so exact a resemblance between the transparent chyle of birds, and globules of oil, that Nature uses them as vicarious instruments*.

WE may now take some notice of the coagulable part of these similar fluids. The lymph of the blood appears under two different forms; as merely diffused in the watery liquor, and separating from it

* Experimental Enquiries, p. 149.

when

when left at rest, the sooner if it be at the same time exposed to the air; or as intimately blended with, and dissolved by it in the form of serum. The consistence of the blood seems to depend chiefly on the former; in preparing which, one intention of Nature was probably to confine a certain quantity of the fluids within the vascular system. We should not expect, therefore, to find this sort of coagulable matter in the secretions, where there is no occasion for it. But the serum seems to be continually produced during the exercise of the vital functions, and to be continually passing off by the secretories. And it is probably formed from the diffused coagulable matter, by the powers of circulation; for, while these powers produce the serous discharges, they lessen continually the quantity of that matter. And hence, where fresh aliment is not taken in, the blood loses its natural consistence, is no longer confined to the vascular system, but is effused

fused from the vessels of the nose, of the intestines, &c.* And it would seem, that this change of the coagulable matter of the blood was the effect of the septic animal process, which takes place in the circulation; for it appears to be accelerated by hot weather, by the cause of putrid fevers, by half-putrid aliment producing scurvy.

BUT, as we suppose that the differences of the Bile, from the blood, depend chiefly on the effect of this process, in changing continually the qualities of the latter fluid; we should not expect to meet with any of that diffused coagulable matter, which separates spontaneously, and concretes on exposure to air, in the Biliary Secretion. The coagulable part is here intimately blended with the watery; and both with the colouring matter. We generally observe in the blood, when from any circumstance it is long in concreting,

* Haller Physiolog. L. XIX. f. ii. 11.

that

that a part of the coagulable matter separates, and, arising to the surface, produces the buff-coat; and, even in the body, such separations frequently happen, and give rise to what are called *polypi*. But we do not discover in the Bile, though it never concretes spontaneously out of the body, any such separation of the coagulable from the colouring matter. It is said also that, by simple agitation in water, a part of the coagulable lymph may be obtained quite pure from red globules. But we find it difficult to obtain any portion of the lymph of the Bile, pure from all admixture of the colouring matter; and it can only be done by applying to the Bile the peculiar solvent of this matter. As the Bile advances towards putrefaction, the union of the coagulable and colouring matters seems to grow still more intimate; so that spirit of wine extracts, together with the latter, a quantity of the former, sufficient to render it extremely viscid. And does
not

not this look like the continued progress of an effect, corresponding with the progress of its cause? We suppose then, that the union of these parts of the analogous liquors is gradually rendered more perfect, by the continuance of the animal septic process. And if we return to the scale of fluids, which was formerly proposed, we shall find that in the milk, at the one extreme, this union is the least, while, in the Bile, at the other, it is the most complete.

THUS having seen that the Bile was nearly related to some other animal fluids, and particularly to the common source of all, the mass of blood; we have since endeavoured to make it appear probable, that its differences are the effects of a power, which is continually operating in the animal body, and changing the qualities of its liquors with their state of mixture. And this notion is the more satisfactory, as it seems to correspond

respond with that peculiar mechanism, which Nature has employed for the Secretion of the Bile; and, at the same time, to explain one of the most remarkable facts in the history of this Secretion. I mean, at present, that great redundancy of Bile, which is commonly produced by a continuance of hot weather; and is particularly connected with the intermittent and remittent fevers, and the dysentery of warm climates. This connection is so constant, that it has been supposed necessary; and, from the circumstance alone of the altered Biliary Secretion have been derived all the other phenomena of these diseases. But we frequently see vast quantities of Bile discharged into the intestines, without producing either fever, or dysentery. And this is especially the case in the *cholera morbus*; which shews itself sometimes in this climate about the autumn, and in hotter countries before this period, during the course of the Summer; and appears to be the true
and

and genuine effect of heat. The disease consists in a more abundant, and probably a more acrid Secretion of the Bile; and it is to be explained from the known effect of a continuance of hot weather, in favouring the spontaneous degeneracy of our fluids, and in accelerating that septic animal process, by which we imagine the blood is converted into Bile.

THE intermittent and remittent fevers, and the dysentery of the warm climates, are nearly related to each other, and have the altered Biliary Secretion for their common attendant. That they do not, however, depend upon it as a cause, appears from what has been already mentioned; and observations made in the countries, which are especially infested by these annually returning plagues, prove that they are more intimately connected with another circumstance. They rage violently in certain places, while in others very little distant they are not known. And

it appears, from the fullest induction of facts, that this difference depends merely on the situation of the place with respect to marshes, and such like sources of unwholesome exhalation. The nature of this exhalation is more obscure. It does not seem to be mere water; for the banks of rivers are healthy situations, unless the water, escaping its bounds, has formed a contiguous marsh. And, on draining the fossæ around a fortified town, such a quantity of malignant intermittents have appeared, that it has been found necessary to open the sluices, and let in the water again. Fresh water descending in showers upon the marshes, and rivers overflowing them, have sometimes stopped the fury of the endemic. And it has been observed that the fevers did not rage, until the water was so far evaporated, that the mud began to appear.

NOR should we expect the noxious effects of marshes from a mere watery vapour. The inhabitants of hot climates find this as convenient to health, as to luxury; and have been ingenious in contriving the means of surrounding themselves constantly with such an atmosphere. The coolness produced during the evaporation affects most agreeably the sense of the epicure, and is not forgotten by the poet in his voluptuous descriptions.

BUT the vapour of marshes discovers, in certain cases, a power equal to that of the strongest contagion *. The effluvia from prisoners, shut up in a close place, and allowed no change of clothes; whose perspirable matter, retained about their bodies, degenerates into a poison; do not more certainly and immediately produce a fever, and that of the worst kind. It is probable that both these miasmata are derived from a similar source. The marshes

* Lancisi. Lind.

contain

contain subjects extremely disposed to putrefaction; as a mixture of dead animals and vegetables. One may see in Lancisi a curious experiment, to shew the quantity of animal matter in these nurseries of disease *. They are perfectly innocent during the winter. Heat is required for the production of the active vapour, whose malignity still increases with the heat. It is also necessary, as has been already observed, that the greater part of the water should be evaporated, and the access of the air permitted. Thus are the circumstances, which are necessary to putrefaction, essential to the production of this vapour; and the matter which yields it is extremely putrescent.

WOODS have been accused of producing, in warm climates, the same kind of pernicious effects as the marshes. And it appears, from an experiment of Dr. Hales, that the perspirable matter of ve-

* De nox. Palud. Effluv. lib. i. pars i. cap. xvi. f. xi.

getables is not mere water, but a putrescent liquor. The action of the vapour seems to correspond with this idea of its origin. It is said to accelerate the putrefaction of animal substances; cause a solution of old cicatrices; and convert the smallest sore into a putrid spreading ulcer. They observed in the hospital of Jamaica, while it was situated near a marsh, that a disease, which had the form of a simple intermittent when the patient came in, acquired presently a malignant nature; that the yellow fever frequently appeared there, with blood dissolved, and escaping from every passage; that convalescents from the dysentery, upon taking the smallest quantity of animal food, even a little broth, relapsed again into the disease*.

WE may add, to the other facts, a remark of the sagacious Dr. Lind; that the custom of hanging camphor about

* Lind.

the neck is by no means a despicable precaution against the effects of this vapour. Nor is there any necessity for believing, with the vulgar, that it acts as a charm; or in a manner which we cannot comprehend. Camphor, as appears from Sir John Pringle's experiments, is powerfully antiseptic; it is at the same time volatile in the common heat of the air; and we can scarcely conceive a more rational method of obviating the action of a putrid vapour, than the surrounding the body with an antiseptic atmosphere. The various fumigations, which have been so much extolled for their power of destroying, or of preventing the effect of this vapour, operate most probably in a similar manner. They all agree in the property of furnishing, during their consumption, a volatile antiseptic matter. A burning body, whatever may be its peculiar nature, must occasion the production of a large quantity of *mephytic* air; which has a most remarkable effect in correcting pu-

tridity. And it is worth observing, that Gun-powder, the substance which Dr. Lind recommends, as most effectual in the way of fumigation*, is especially replete with

* Essay on preserving the Health of Seamen, p. 116.—Yet I must not be supposed to derive all the advantage of these fumigations from mephytic air; since the antiseptic principles, which they furnish, may be as various as the volatile ingredients in their composition. The remark is chiefly by way of caution to those gentlemen, who confound, under a common name, the airs injurious to animal constitutions. Even Dr. Lind, whose industry and ingenuity can never be sufficiently commended, seems to have fallen into this error. For, after observing, that the air in the hold of a ship was *so poisonous*, that the people who descended into it were immediately suffocated, he adds, as something extraordinary, “ Yet “ this ship was remarkably healthy*.” The air, from its effect, must have been *mephytic*; and, though fatal at its source, its diffusion through the ship should rather oppose the disorders which are most destructive to seamen; as they are generally of the putrid kind.

* Lind, l. c. p. 113.

with this air, and owes to it that destructive quality for which it is chiefly valued.

To enquire, more particularly, into the nature of the miasma, we should be in a condition to subject it to a chemical investigation. How various are the causes of disease, that act in the way of miasma and contagion? We perceive, evidently, a difference in their operation; but we search in vain for that specific difference in their nature, on which it depends.

THOSE miasmata, which occasion fever, seem to be all the offspring of the septic process, and to have more or less tendency to accelerate that process in the animal œconomy. We are acquainted with two kinds of vapour, which are separated from

My friend Dr. Lettsom seems to promote this confusion, when he talks of mephytic air being produced, “in a peculiar manner, by the putrefactive fermentation;” and of its occasioning putrid diseases. *Naturalist’s Companion*, p. 41.

bodies during putrefaction; and are sufficiently distinguished from each other, by their different, and even opposite qualities. The one extinguishes flame, while the other is inflammable; and as the former is remarkable for its power of opposing putrefaction, so the latter, I imagine, rather tends to promote that process *. This inflammable air is the peculiar offspring of putrefaction; while the other, which has been named *mephytic*, is separated in much greater quantity during the previous stages of fermentation. The miasma which produces fever, appears, from its origin and its effects, to have a much greater analogy with the former, than with the latter kind of vapour.

THIS miasma, like the other vapours of the same species, like that of gangrene, which seems the most power-

* Or why is the putrefaction accelerated in a body, by preventing the free access of air?

ful of them all, operates on the nervous system as a sedative, and tends to destroy the force of the vital power. When it is in a concentrated state, it produces immediately a vomiting, and an excessive prostration of strength*. Whatever, therefore, diminishes the tone of the fibres, and weakens the nervous power, disposes to its action; intense study, grief, excessive venery, that relaxation even which accompanies sleep.

It is, I presume, in consequence of this operation on the nervous system that it produces fever; as an effect of the reaction of the vital power, or of the efforts of Nature to restore its diminished vigour. And therefore, where the vapour is exceedingly concentrated, it may, like the contagion of the plague in certain instances, destroy life without producing a fever †. As it appears to be a septic, this

* Lind.

† Is this the case in that pestiferous air which is known by the name of Samiel; concerning
ing

this action on the nervous system will be accompanied with such a change in the fluids, as may be expected from the introduction of a putrid ferment; and in this way it must influence the character of the fever which arises.

BUT these effects of the vapour, though generally complicated, are not always in the same proportion. The action of any power on the animal machine must be modified by its different states. *Non bruta homo machina est, quæ injurias a rebus noxiis sibi illatas iners excipiat, ac patiatur**. We know very well, that a gangrene happens in one person, from an injury which only excites inflammation in another; that a gangrene, after it has made some progress, is frequently checked by the powers of the constitution, without any assistance from medicine. But when

ing which Dr. Haller gives us the following observation from Chardin, *Continuo putrescunt quos ventus Samiel percussit, ut membra tracta manum sequantur?*

* Gaub. Patholog. f. 99.

we attempt to aid Nature, in her opposition to this most powerful of all septics, what do we do? We endeavour, by the use of the bark, to strengthen the nervous system, and to communicate a firmer tone to every muscular fibre. It seems that the constitution, in this state, can resist the action of septic powers; and the nearer it approaches to this state, the less will it suffer, probably, from the miasma operating as a putrid ferment. It may still produce fever; but the vigorous reaction of the system will give this fever, in its beginning, the inflammatory, rather than the putrid character.

WE are not surprized, therefore, to see in Lancisi * a description of two diseases, raging at the same time, and depending on the same cause, the marsh effluvia, yet of a very different form. The one, an intermittent fever, afflicted those especially, who had previously a weakened and bad habit of body, and were nearest

* L. ii. Ep. i. cap. v.

to the source of the exhalation. The other was a continued fever, and happened only to the robust and well-coloured, who were farther removed from the marsh. The intermittent was preceded by an icteric colour, and ushered in by excessive bilious vomitings. On dissection, the liver and the intestines appeared to have been the chief seat of the disease, *Grande morbose devastationis theatrum hepar et intestina*; and it was remarked particularly, *bilis cystica atri coloris passim occurrit*. In the continued fever there were not symptoms of an equal redundancy of Bile; nor did dissection show the same morbid appearances in the abdominal viscera.

Now, when I reflect, that the liver seems to be destined to the separation of degenerating blood, and the marsh miasma to operate as a putrid ferment, I cannot help fancying that we perceive a reason why the secretion of
this

this organ is peculiarly affected, in the intermittent and remittent fevers of the hot climates. And we observe, I think, in Lancisi's history, that where the miasma, from being more concentrated, and meeting with a body less capable of resisting its septic power, exerted this power in the highest degree, there the change on the Biliary Secretion was the most remarkable. As the urine or perspiration, the chief vehicles of the saline and watery parts of our blood, are generally increased by increasing the quantity of these matters in the circulating fluids; so the Biliary Secretion, being intended by Nature for the discharge of degenerating lymph and red globules, is augmented with their degeneracy.

AND thus it would seem, that the change on this secretion, far from being the cause of the bilious intermittent and remittent fevers, is a means which Nature employs in these

disorders for her relief. And is not this confirmed by an observation of Sir John Pringle, that a *cholera morbus*, or an excessive discharge of Bile both upwards and downwards, was the only critical evacuation which occurred in this fever; and sometimes gave a quick and happy termination to the disease *? And does it not agree with another remark of this excellent observer, that the vomits, of greatest use in the fever, were those which produced the most copious evacuation of Bile †? I should be inclined to think, that

* Diseases of the Army, p. 186.

† Ibid. p. 208. "I observed that vomits were
 " still more efficacious in the marshes, than in
 " the camp; inasmuch, that when a large quantity
 " of Bile was evacuated by an emetic, the fever
 " would often be removed at once." We find, in
 this remark, a confirmation of the opinion suggested by Lancisi's History; that where the active miasma is more concentrated, and consequently a stronger septic, there the discharge of Bile is more necessary to the constitution; and greater advantage results from augmenting it by the assistance of art.

BILIARY SECRETION. 127

that the general method of cure in these fevers, except where symptoms of topical affection required attention, should consist in promoting, by the safest and most expeditious means, the biliary discharge; and in correcting, by tonics and antiseptics, that state of the constitution which makes it necessary.

THOUGH the colouring and bitter part of the Bile has appeared to be the production of the animal septic process; yet we are persuaded by the Experiments that it is capable of opposing that process. Nor will this seem extraordinary, when we consider that vinegar, spirit of wine, and volatile alkali, the offsprings

Sarconi, in his account of a fever that raged at Naples, has repeated the observation of Sir John Pringle, with respect to the advantage of a spontaneous cholera. "*Molti eranfi felicemente sostrattia i secondi effetti del male, col' suffragio d'una celere, et spontanea colera.*" Hist. rag. de Mali osservat. in Nap. § 794.

of

of three determined stages of fermentation, are endued each with the power of resisting the process by which it was generated. We may suppose that Nature meant, by this substance, a kind of guard to the putrescent coagulable matter, through those tortuous passages in which the Bile, before its excretion, is often subject to considerable delay. In the intestines too it will cause that irritation, which seems to be necessary to their perfect action. There are few nations, I believe, however near to the fancied state of Nature, and ignorant of the arts of luxury, that do not join some stimulating substance with their ordinary food. But I suspect that something more was intended by this secretion; and it is this farther purpose of Nature, which shall be the next object of our enquiry.

PATHOLOGISTS are divided in their opinion, with respect to the manner in
which

BILIARY SECRETION. 129

which the Bile gets into the circulation in jaundice; whether it measures back its way through the passages by which it was secreted, or takes the course of the lymphatics. The latter notion seems the most probable, as it is more analogous to the ordinary method of the œconomy; and on account of the resistance, which the Bile must meet in its passage back, from the fluid in the secretory vessels moving in an opposite direction. It is even asserted, from anatomical facts respecting injections, that, while the passage into the duct is easy, the return through the biliary pores is extremely difficult*.

BUT we observe, in certain cases, that the Bile evidently gets into the road of circulation, by the absorbent system; as where there is no obstacle in the excretory duct, but a great increase of the secretion.

* Prælect. Anatom. cl. Monro.

THIS certainly happens in some fevers, as well as other more chronic cases of a redundancy of Bile. I knew a gentleman, subject to a disorder of the latter kind, who constantly became yellow after the operation of an emetic; which must depend, I imagine, upon the Secretion of the Bile being more increased than its evacuation, by the emetic stimulus. But it is objected to the notion of absorption, that this fluid is continually flowing into the intestines, and presenting itself to the mouths of the lacteals; and yet it does not, ordinarily, pass into the system. Is there any provision against the absorption of Bile, which, though sufficient for its purpose in the common state of the Secretion, is inadequate in the cases of a great redundancy?

WHEN I consider the common theory of digestion, and compare it with the events of the Experiments, I am ready to fancy that we are in condition to throw
some

some light on this question. The nature of the food, its circumstances in the stomach, and the phenomena it occasions there, are so agreeable to the doctrine of fermentation, that it seems now to be generally applied to the first changes of our aliment. But the experiments *, which Dr. Rush made upon the contents of his own, and of his friend's stomach, tend to persuade us, that this fermentation always proceeds to the acetous stage, and that there is a constant generation of acid from digestion. As soon as the acid liquor passes out by the *pylorus*, it must meet with the Bile in the *duodenum*, and the effect of this concurrence may be collected from Exp. IX. & *seq.* The Bile will be coagulated, and, after this operation, being neither fluid itself, nor miscible with the fluids of the intestines; which, with respect to their solvent power, may be considered I imagine as little superior to common water; it can-

* Thesis, upon Digestion, published at Edinburgh, 1769.

not be absorbed, but must pass off with the *feces*. But, in the cases of a great redundancy of this fluid, the proportion between it and the acid of the stomach will no longer be preserved; and, consequently, there we may see the absorption of Bile, unless it is carried off by an increased intestinal discharge.

THE Bile, after its coagulation, imparts something to water, and therefore to the fluid in the intestines; and this soluble part is probably capable of being absorbed. And we find, from the Experiments, that the watery infusion of the coagulated Bile is much more antiseptic than the unaltered fluid. By this sort of decomposition, therefore, which takes place in the intestines of the animal, the antiseptic principle of the Bile is somewhat evolved, and separated from the putrescent coagulable matter; and while the latter is left to the alvine excretion, the former is applied perhaps to useful purposes in the œconomy.

WHEN

BILIARY SECRETION. 133

WHEN we view this operation, by the imperfect light which the Experiments afford, it appears to be an exchange, made by the constitution, of one fluid for another endued with stronger antiseptic power. It will vary therefore, we may suppose, with the exigencies of the œconomy. And this gives us another view of the final cause of that larger Secretion of Bile, which is the constant effect of a long-continued heat. We considered it, before, as corresponding with the more rapid progress of the circulating fluids in their septic degeneracy. But it is agreeable to the wisdom of Nature, that she should, by the same contrivance, separate from the mass a matter which was growing pernicious, and prepare one that shall be useful. And, accordingly, she has taken the greatest pains to make the quantity of acid in the stomach, at this period, bear a proportion to the redundancy of Bile; that so the operation may be completed. She covers the earth with

a quantity of acid, or acescent fruits, as tempting to the eye as they are delicious to the palate. She diminishes our appetite of hunger, while she increases that of thirst; and thus, not contented with alluring us by pleasure, she seems willing to determine our choice of food by necessity. At the same time she diffuses over us an indolence and inactivity, that while they make a more substantial aliment unnecessary, deprive us of the inclination to seek it. Without the artificial distinctions of Society, neither bread nor meat could be obtained, except by the labour of the individual. But the fruits, in such climates and seasons, present themselves spontaneously

—————*Nullis hominum cogentibus ipse*
Sponte sua veniunt—————

AND what we collect from tracing the plan of Nature, is farther confirmed by experience. A most accurate observer
assures

assures us, that the people who kept the vineyards in Minorca, and subsisted chiefly on grapes, escaped the disorders of the hot season *. One properly imbued with a late fashionable theory, will derive all the advantage of such a diet, from the quantity of fixed air with which it would furnish the œconomy. But does this air ever enter the absorbents, and pass into the road of circulation, in its pure and simple state? Or if it did, would it not produce the most dreadful symptoms, terminating in a speedy death? But has it been proved that fixed air, in composition, retains the quality of resisting putrefaction, any more than its power of extinguishing flame? It is a fallacious notion, that the properties of compounded bodies are known from the effects of their ingredients, in a simple state.

* Cleghorne Dis. of Minorca, p. 179.

No point in physics seems to be better understood, since the ingenious and satisfactory Experiments of Dr. Black, than the nature of quick-lime, or its difference from the common calcareous earth, which effervesces with acids. It has been clearly demonstrated, that this difference depends on the fixed air; which is combined with the latter, but has been separated from the former by the action of the fire. Yet it appears, from the Experiments of Sir John Pringle, that chalk promotes putrefaction, while lime-water rather opposes it. And this is the only difference which we can discover between the septic calcareous matter, and the lime; that the first of these substances is fully saturated with fixed air, which the other has been entirely deprived of, to render it soluble in water. The patrons of this theory must reconcile it to such plain and intelligible facts as the present, before they pretend to talk of the effects of fixed air as an ingredient

cient in bodies, which are so compounded that we can form of them only general and indistinct notions. And, in the mean time, they must allow me to derive some share of the advantage, which results from the use of acids and acescents in all cases where the septic animal process is too much accelerated, from the effect they have upon the Bile. The secretion of this fluid is, in such cases, more abundant, and probably more acrid; and by its peculiar action on the intestines, may produce perhaps the instinctive craving, which people in this state commonly have, for the milder and more agreeable acids. Yet in whatever quantity these may be taken in, we do not suppose that they can enter the absorbents, and get into the road of circulation, in a pure and uncompounded form. But that antiseptic, to which they give origin by their operation on the Bile, most certainly may; for it is a native of the œconomy, perfectly animal, and homogenous with
the

the rest of our fluids. It is formed in the beginning of the *duodenum*, and therefore mixes with the aliment just before its absorption; being intended, without doubt, for retarding in some degree the effect of those powers of circulation, to which it is now to be exposed, and whose constant tendency is to induce putrefaction.

THAT progressive fermentation, which has place continually in our fluids, from their first change in the stomach to the time of their excretion, is regulated, we suppose, and kept from arriving at its last term by the colouring matter of the Bile; somewhat in the same way that the fermentation in beer is prevented from running precipitately through the successive stages, by the artful addition of hops. And Nature, it seems, has taken care, that the provision of this matter shall be increased by those very causes, which, as they accelerate the septic animal process, make a greater quantity of it necessary.

But

But we must concur in the operation, and make use of the acids and acescents, which she diffuses so liberally, and directs us to by the unerring voice of instinct. This voice, however, is frequently drowned by habit: we return constantly to a table prepared in the same manner; and instead of being guided by our appetite, we subject it to the government of fashion. If the natives of cold climates, when they migrate into warmer, could leave behind them their modes of living, and adopt others more suitable to their circumstances, they would probably escape much of that mischief, which the change brings upon their constitutions. Yet, a sudden transition from the plentiful, and invigorating diet of the north, to the weak, and slender subsistence of the south, might occasion such a debility, as would favour the operation of the chief cause of diseases in the hot climates. But this effect might be prevented by a gradual change; and it is no greater objection to the advantage
of

of a diet of fruits, and other parts of vegetables, in such climates, than the weakness, which attends the beginning of sobriety after a debauch, is to a temperate way of life. Yet sometimes, certainly, there occurs in these countries a force of miasma, which no power of the œconomy can oppose, though assisted by the best regulated life; and we may say in vain of our patients,

————— *Atqui non Massica Bacchi*
Pocula, non illis epulæ nocuere repostæ.
Fruētibus, et victu pascuntur simplicis herbæ;
Pocula sunt fontes liquidi, atque exercita cursu
Flumina; nec somnos abrumpit cura salubres.

AMONG the curious facts in the history of this Secretion, may be considered its relation to the passions. That it is remarkably affected by anger, is so generally known, as to be alluded to in the common expressions of most languages. And in medical observations, we find excessive discharges of Bile, and jaundice, related among the effects of this passion.

But

BILIARY SECRETION. 141

But the operation of terror, which, in the other circumstances, resembles so much that of anger, agrees with it also in the change of the Biliary Secretion. These passions, though apparently very different, are believed by Haller to be nearly a-kin to each other. They certainly both relate to self-preservation, and prompt us to oppose, or avoid any power which threatens danger. We should expect, therefore, to find the changes they produce in the body conducive to this end. And it seems the evident tendency of their operation, to give greater power, and a capacity of quicker and stronger motion. The heart beats more vehemently, and by a vigorous impulsion of the fluids, gives a more exquisite tension to the whole vascular system. The brain acts with more force upon every muscular fibre; so that paralytic limbs have sometimes been restored, by these passions, to their power of motion.

AND

AND here, I imagine, we must look for the final cause of that larger Secretion of Bile, which generally attends them.

THE vigour of the whole system depends upon the state of the moving power in its several parts. But there is a kind of prerogative in some of these parts, which gives them a more especial influence; and this is particularly remarkable of the stomach, and intestines. In an indolent, and luxurious age, when a weakness of these organs is so common a complaint, every one has an opportunity of observing, with what ^{an} general languor, and debility it is accompanied. We frequently find low-spirits, timidity, and despair itself, to be the effects of a feeble state of action in the alimentary canal.

AN opposite temper of mind is connected with an opposite state of this function; as well as with a vigorous
action

action of the heart and arteries. And it is this temper, fit to encounter danger, which Nature endeavours to procure by the physical effects of anger. For the same reason that she excites a more vehement contraction of the heart, she pours a quantity of bitter fluid into the alimentary canal, and stimulates it to a stronger action. Thus have I attempted to answer the question proposed by Haller, *In irâ quid in emotâ bile boni* *? Nor should it be counted an objection to the doctrine, that in particular constitutions, where this canal is too irritable, the stimulus of a larger secretion of Bile is sometimes productive of a diarrhœa. For Nature

Acts not by partial, but by gen'ral laws.

POPE.

THE mechanism, by which this effect of the passions is produced, must remain a secret, until we know more of the nature of the nervous power, and of the manner in which it influences the

* *Phyfilology*. L. xvii. Sect, ii. f. vii.

changes

changes of the fluids, in digestion, and in secretion. One might suspect the more violent circulation, which accompanies anger, to be the source of the larger separation of Bile. But the same cause must bring a greater quantity of blood to all the other glands, as well as to the liver. Why then is the secretion of milk dried up most commonly by a violent fit of passion? And sometimes, it is said, this liquor, which is generally so mild, and nutritious, is converted by anger into a poison, extremely injurious, or fatal to the infant. The same passion has been known to produce a sudden, and a fatal gangrene*. When one hears of such facts as these, he is almost tempted to imagine, that the nervous power has the same relation to the fluids of the animal, which the electrical power has to fermenting liquors; and that certain changes in its condition, can alter presently their state of fermentation, and with it their qualities.

* Hall. Physiolog. Loc. cit.

position of character, which has been remarked in them ever since; the same seriousness, solemnity, and steadiness on the one hand; the same levity, fickleness, and impetuosity on the other. There is one state of this power, in which the life of the animal is raised only a degree above that of a vegetable. It is the effect of excessive cold, and happens to those animals, which in the northern climates sleep during the winter. If we may credit the accounts of them, they continue sometimes six or seven months in a state of torpor, the slow and feeble motion of the heart alone discovering some remains of life; and during all this time, they take in no kind of aliment, and seem to have no sort of excretion. The septic animal process is so weak, that their fluids do not suffer the ordinary degeneracy, and consequently they neither require to be recruited by fresh aliment, nor to have their most altered parts separated. The men who inhabit
7 these

BILIARY SECRETION. 147

these climates, are able, by certain precautions, to preserve constantly the heat of their body at the ordinary standard. Yet this does not prevent the cold from having a certain effect upon them, both in diminishing their irritability, and in retarding, in some degree, the septic animal process. It has been observed that their pulse is much slower than that of the natives of a hot climate; so that, in comparison, the latter may be said to be in a constant fever. And it is well known that, the severity of their sky denying them vegetables, they use a very putrescent diet, consisting chiefly of fish, and yet are not subject to scurvy, or any other putrid disease.

THIS constitution may shew that which is exquisitely bilious, as it were by contrast; for it is its opposite. Here the irritability is augmented beyond the proper standard, the pulse is quicker, and the progress of that septic animal process to

which the Bile owes its origin is too much accelerated. As the former arises from the effect of great cold on the constitution, this is naturally produced by excessive heat, and the bilious temperament is the common one in warm climates.

BUT other causes, which affect the system in a similar manner, may have a tendency to induce this constitution. Such are, probably, a great and continued agitation of mind, either from the passions, business, or study; excessive and irregular muscular motion; a diet too stimulating, and without a just proportion of vegetables; the abuse of warm liquors; a too constant confinement to the hot and close air of a chamber; the residing in a large and populous city.

THE bilious constitution seems not to be natural to this climate, where the temper of the people is as distant from
the

the torpid strength of the inhabitants of the north, as from the too delicate and sensible habit of the southern nations. Their moderate irritability, joined with a sufficient share of vigour, is connected with that state of the powers of circulation, in which red blood seems to be formed faster than it degenerates. Hence their full and sanguine habit; so that an Englishman may generally be distinguished, among the southern people, by the *purpureum lumen* which shines upon his countenance. Yet we frequently see this sanguine *plethora* exchanged for a bilious one, in consequence of an alteration which the constitution suffers from a warm climate. Perhaps a similar change may be induced by the other causes which I mentioned; to some, or all of which, the people who, in this country, complain most of a redundancy of Bile are generally subjected.

I ACKNOWLEDGE that we are exceedingly ignorant of the manner in which the fluids are changed in digestion, circulation, or secretion; for we are acquainted with no analogous process that can produce the same effects. There must always then be something obscure, and unsatisfactory, in our idea of these operations. With respect to the redundancy of Bile, we only know, that in the hot climates, where it is most remarkable, and, as it were, universal, it is connected with a greater irritability in the nervous system, a quicker circulation, and a greater tendency in the fluids to putrefaction. And the first of these affections seems to be that which is fundamental; for if it be true that the animal body preserves constantly the same temperature, in varying conditions of the atmosphere, its fluids may be considered as exposed always to the same degree of warmth. The external heat, in this case, can only affect the body as a
sensible

sensible and irritable machine; and its other effects must depend upon the change produced in the nervous system. And we find, that when this system is affected in a similar manner, that is, excited in an extraordinary degree by other causes, the circulation, and the septic animal process are both accelerated. In consequence of violent passion, of excessive muscular motion, of strong convulsions, in several instances quoted by Dr. Haller, a great tendency to putrefaction seemed to have been very suddenly induced.

ON the other hand, in the cases of a torpor, and low excitement of this system, the septic animal process seems to proceed more slowly than ordinary. It is remarked by Dr. Haller, that all the wonderful accounts of people, who had lived a long time without taking in any aliment, relate to persons whose irritability was considerably impaired. They

were either melancholy, foolish, stupid, lethargic, or insensible from some evident injury of the nerves *.

I SHALL be accused, perhaps, of an attachment to a system, in endeavouring to find every where a connection between the bilious constitution, and an acceleration of the septic animal process. And I confess, that having formed an opinion concerning the origin of the Bile, I cannot help being influenced by it. Yet let it be remembered, that in supporting this opinion, I only attempt to trace the relation of facts, so that my mistakes will be readily detected by observation.

THE excretories of the Bile are as much appendages to the alimentary canal, as to the liver; and being intimately connected with the former organ by their function, are so constituted by Nature as to sympathise with its different states. A nausea, by whatever cause excited,

* Physiolog. L. XIX. f. ii. 7.

BILIARY SECRETION. 153

the action of an emetic or purgative, seem to be always attended with a temporary increase of the biliary discharge. But these agents are so far from producing the constitution we were treating of, that they are to be reckoned, at least, among its palliative remedies. Yet, as a redundancy of Bile is generally connected with a disordered state of the alimentary canal, it may be doubted whether this is not always the primary affection, and the cause of the former. The agreement, however, of so many facts, tending to shew that this state of the Secretion is frequently the effect of a certain disposition of the circulating fluids, renders it equally probable that the redundancy of Bile is often the primary affection; and by the provision of Nature excites that nausea which conduces to its evacuation. A tincture of Bile in spirit of wine is said to be a very efficacious emetic *; and it appears probable that the fluid will have

* Arnauld Hist. Natur. des Anim. t. iv. p. 98.

this

this operation the more readily, where it is secreted in a more acrid state, and where the alimentary canal, and the whole constitution are excessively irritable; both which circumstances seem to occur in the cases of a redundancy of Bile, from a general disposition in the habit.

THOSE concretions which are found in the passages of the Bile, and in its reservoir the gall-bladder, have lately very much employed the attention of physicians. They were not thought of, until the dissection of human bodies grew into fashion; and since that time they occur so frequently, that he who is inclined to attribute to them much influence, has reason to suspect them in a variety of disorders. Yet it appears, that they very often rest idle and inactive, without producing any of the symptoms which are believed to be the most characteristic of them;

them ; and that they are sometimes consistent with a state of perfect health. And if, in certain cases, an indisposition of the alimentary canal, after continuing a long time, has at length been accompanied by a jaundice, we must not immediately conclude, that the preceding complaint was the effect of a gall-stone, which discovers itself at last by a more peculiar and distinguishing symptom. For it must be remembered, that the jaundice itself is no certain mark of the presence of a gall-stone ; since it frequently happens independent of it, particularly in the people who are subject to disorders of the first passages. But supposing that there is really a gall-stone in the case, it will still be difficult to determine which was the primary affection. Nor can we affirm, in our present ignorance of the cause of these concretions, that a disturbance of the ordinary motions in the alimentary canal may not contribute to their formation.

YET

YET I do not pretend that a gall-stone will not, in certain constitutions, produce effects before it presents itself in the passage to the intestines, and excites the efforts of Nature for its expulsion. But these effects are not so precisely determined, that we are capable of distinguishing them from the symptoms of other affections. And if they were, we should only feel the mortification of being obliged to rest spectators of a disease, in which art can do nothing of consequence, at least before Nature points the way. We should scarcely attempt, though we knew the means, to push into the ducts a stone, with whose size and figure we are unacquainted *. And if we consent that it shall lie undisturbed in the gall-bladder, can we expect to get rid of it in the gentler way of dissolu-

* Cave autem ne me propterea timidiorem voces, in eo videlicet morbi genere, in quo supra ostensum est quiescentibus calculis nihil sæpenumero molestiæ percipi. Morgagni, l. c. 50.

BILIARY SECRETION. 157

tion? It remains to be proved, that a urinary calculus was ever dissolved, in the body, by the remedies which we employ for that purpose? Its troublesome symptoms have been made to disappear; but that has sometimes happened spontaneously, or been effected by remedies which possess little or no dissolvent power. Yet certainly the bodies which are most active in this way, being all of the saline kind, have a better chance of passing by the kidneys, than by any other gland; they being naturally employed in separating this matter from the blood. But when we attempt to introduce such bodies into the interior parts of the œconomy, we act directly contrary to Nature's plan, and are opposed by her in every step. She either does not suffer them to go beyond the first passages; or by satisfying their attractions, she robs them of the greater part of their activity. And she seems particularly careful not to admit any foreign unassimilated

milated body into those animal liquors, which are separated, not merely for evacuation, but to be applied to useful and determined purposes. Thus, for example, when the Bile is diffused through the whole mass of blood in a jaundice, it passes freely by the kidneys, and discovers itself in the urine; but no trace of it is to be found in the milk. And on this account, it must be more difficult to introduce a solvent with the biliary than with the urinary secretion; Nature being more exact and curious in the preparation of the former fluid.

INDEED, the remedy which has been the most strongly recommended for answering this intention, need not much alarm her watchful care. It is not some powerful agent "*quæ subdolè irrepit, et positâ intus larvâ sese explicit*" to execute the purpose of art. When it is pretended to resolve these concretions by the use of grass, physicians seem willing to pay
a com-

a compliment to Nature, and by proposing to do so little themselves, to shew how much they expect from her. Yet I dare not deny, that people in jaundice have been relieved by turning them out to graze with the cattle; for the fact is supported by one of the most illustrious names in physic. But he must be credulous indeed, who can suppose that this diet, after having sustained the action of the animal powers, and been converted to chyle, to blood, and at last to Bile, is indued with the power of dissolving the biliary concretions. If we were to reason from analogy, we should expect the very opposite effect from such an aliment. It has been observed already how similar the Bile is in its composition to the milk; and we know that the milk of the animals, who feed on vegetables, is more disposed to concretion than that of carnivorous creatures; and that when the latter are fed upon vegetables, their milk becomes more concrescible. The Bile,

as

as well as the milk, is more viscid in the phytivorous animals, than in the human species; and this must depend upon the condition of that coagulable part, which is common to both these liquors. It seems likewise to be more disposed to a spontaneous concretion; for nothing is more common, according to Ruysch, than to find extensive concretions in the biliary pores of sheep and oxen. This appearance shews a great disposition to coagulate, which operates even where there is little opportunity for stagnation; and in all the dissections of human bodies by Morgagni and Valsalva, it was only once observed, *Vix uno in jecinore mihi accidit olim ut invenirem, Valsalvæ autem in nullo, quod sciam* *. It is not therefore probable, that a diet of grass has any tendency to promote the dissolution of biliary *calculi*, by the change which it produces in the general mass of fluids, and of consequence in the secretions. It seems

* Ep. Anat. Med. XXXVII. 11.

BILIARY SECRETION. 161

even to give a more concrefcible Bile, as well as a more concrefcible milk; and this we might have prefumed, from obferving that the animals, which want a gall-bladder, are of the herbivorous kind; while the carnivorous have all gall-bladders *, and thefe interlaced with large *plicæ* †; to favour, one would think, a ftagnation, which in the Bile of thefe animals does not fo readily produce concretion. And if, from the ufe of grafs, a jaundice difappears fooner than from the unaffifted efforts of Nature, this probably depends upon its effect on the inteftines. Almost every kind of fresh vegetables has a tendency to bring on diarrhœa; a circumftance fo favourable to the cure of jaundice, that we chiefly confide in the remedies which are capable of producing it.

THE evacuation of *calculi*, or *calculous grumes*, which was obferved by the Ba-

* Hall. Elem. Phyf. L. XXIII. Sect. ii. § 1.

† Ibid. § 3.

ron Van Swieten to occur very commonly during the use of the grafs, must be referred, I imagine, to the greater determination of Bile into the intestines, and to the increase of that action of the excretories of the liver, by which they deliver themselves from obstructions. But, as this effect may be obtained by a gentler and less disgusting method, I do not wonder that the use of grafs, which seems to have no specific quality against this disease, has been generally neglected in England; though the first hint to it was given by one of our own countrymen *, and it has since been patronized by the most eminent physicians abroad †.

SINCE, therefore, art can do so little in removing these concretions, it should endeavour to trace them to their origin, and discover, if possible, the means of preventing their formation.

* Giffon.

† Boerhaave, Van Swieten, Morgagni, &c.

WE have found the Bile composed chiefly of that fluid, which seems to be the source of most of the hard concretions observed in the animal. Those who have attended to the formation of the bones of the *fœtus*, of *calli*, of the shells of animals, assure us that they have all their origin in a coagulable matter. In a thesis published lately at Edinburgh, by my ingenious friend Dr. Baddeley, the Reader will find the strongest reasons for believing, that the urinary *calculi* are formed from the same substance. The cheesy concretions, which are frequently found in the *mammæ* of women, are certainly nothing but the coagulable part of the milk; and these do sometimes acquire a consistence that is perfectly stony*. The concretions occurring in the passages of the chyle †, which, in some descriptions, are said to be of a cheesy softness, and, in others, of a considerable

* Hall. Physiolog. L. XXVIII. Sect. i. 23.

† Ibid. L. XXIV. Sect. ii. 2.

hardness, have without doubt their origin in the same matter; for this fluid, we know, is easily coagulable. It has lately, it seems, been discovered in Sweden, that the ashes of bones are a composition of calcareous earth, and the acid of phosphorus. Mr. Margraaf observes, that these two bodies being united produce a jelly; which has this peculiar property, that it will not dissolve in boiling water repeatedly poured upon it, but remains of a tenacious gluey consistence *. And others have remarked, that the serum of the blood, being left to putrefy, degenerates into a calcareous substance. Does it not seem probable, when one compares these facts, that the coagulable part of the animal fluids is composed of a calcareous earth, together, perhaps, with the acid of phosphorus; and is on this account so liable to put on a stony form?

* Opusc. Chym. T. 1. Diff. VI. p. 168.

As it appeared, from the Experiments, that there was a considerable quantity of an evolved phlogiston in the Bile, so we find that its concretions differ from the others, in being generally coloured, and generally inflammable. Yet there are exceptions, with respect to both these qualities; for some appear perfectly white throughout their substance, and others as perfectly black; and these two kinds are said not to be inflammable*. Their colour is liable to great variety; which we must attribute to the various relations of the principle of this quality, and its being easily, therefore, susceptible of alteration.

THE biliary *calculi* appear to have been all soft in their original state, like the cheesy concretions of the milk; for they are sometimes found of this consistence †;

* Haller, Morgagni. They resemble the Bile calcined, or deprived of its phlogiston, by the vitriolic and muriatic, and by the nitrous acid. Exp. VIII.

† Nam vel majusculi interdum casei recentis molliem servant. Morgagni, XXXVII. 19.

and many of the harder stones appear to have been formed of a certain number of small concretions, compacted together while they were soft and yielding *; and often, when the external crust is quite stony, the internal part retains the colour, and nearly the softness of Bile.

THEIR external figure is extremely various; but in general it appears to have been round originally †, and that the deviations from this form have arisen from compression, while the concretions were in a soft state. With respect to the internal arrangement, many of them are composed of concentric layers, of a circular or other figure, corresponding with that of the stone. In others, there is an appearance of *radii* drawn from the center to the circumference; but this is much rarer, and the stones look as if they had undergone a chrySTALLIZATION. And there are many, which discover no resemblance

* Morgagni, l. c. et adversar. animadv. III. 28.

† Morgagni, l. c.

BILIARY SECRETION. 167

with either of the above forms; as the calcareous, and the black concretions, which were taken notice of before; and another kind, that, according to Morgagni, occur very frequently. These contain under the external crust a large *meditullium*, which appeared to the professor to be soft and natural Bile, and he was puzzled to guess how it should get there. And sometimes, where one stone is composed of several others, each has a different center, and some difference perhaps in the arrangement of its parts,

THAT vice of the constitution, with which these concretions are necessarily connected, seems to be buried in the greatest obscurity. It has been sometimes imagined to be the same with the disposition to urinary calculus. But this opinion is contradicted by one of the best established facts with respect to the constitution liable to Biliary concretions. For they never, perhaps, occur in infancy, and very rarely in youth. Morgagni assures us, that

in the whole number of people in whom gall-stones are said to have been observed, there are sixty-one aged, and only eight young folks *. Of the last the oldest is twenty-nine, and the youngest twelve; who is the only boy in the list. Another fact, which seems to be supported by pretty good authority, is their connection with an inactive life, and a want of bodily exercise. For, according to Boerhaave, the disease is, on this account, more common among literary men †. And Haller assures us, that the gall-stones occurred very frequently in criminals, who had been long in confinement. To the same cause might be referred perhaps their greater frequency in women; but this fact, though supported by Haller, Coe, and others, is denied by Morgagni, from a comparison of the whole number of observations. If it be true also, as Dr. Haller seems to suspect ‡, that they

* Ep. XXXVII. 15.

† De Vir. Medic. p. 301. ‡ Opusc. pathologic.
are

BILIARY SECRETION. 169

are found oftener in particular countries, this will probably be attributed to a particular food, and manner of living. Gaubius appears to be satisfied of the influence of the last-mentioned cause, and in accounting for the concretion, he combines it with the preceding. *Alimento cæterum sicciori, ac vitæ desidi concretio ista præcipue debetur* *.

BUT in these circumstances of the constitution, is the Bile separated with a greater disposition to concrete? Or do they only operate by favouring its stagnation? I fancy it will be difficult to determine these questions; for, though it is impossible to deny the former, its affirmation will be found, I believe, incapable of proof. Does the *vita deses*, a life with little muscular motion, produce a more concrescible state of the animal fluids? I am assured, that blood drawn from the animals which sleep

* Patholog. § 579.

during

during the winter, while they are in their torpid state, does not coagulate at all. And yet, all the circumstances of the *vita deses* seem to be present here in excess*.

BUT, will the Bile always concrete spontaneously, when it is allowed to stagnate longer than usual? There is a case in Lieutaud, taken from De Haen, of a tumour of the belly, which was found on dissection to depend, in part, on a vast distension of the gall-bladder. This organ contained in several loculi eight pounds of Bile, which was indeed very thick, because much of it must have stagnated a considerable time; but it is not said that any of it had concreted †. In the Human Bile, which I kept until it grew putrid, I never saw any concretions happen, that shewed the smallest

* Mr. Hewson has lately explained this fact, very ingeniously, from the mere effect of cold. Experiment. Enquiry.

† L. 1. Obs. 858.

resemblance

BILIARY SECRETION. 171

resemblance to the biliary calculi, in what is said to be their original soft state. Some specks of it only, here and there, would stick tenaciously to the sides of the glass; except when the Bile had previously been mixed with water; and then, indeed, there was always a large pale-coloured deposition, as soon as it began to putrefy. When the Bile stagnates long in the bladder, and grows more viscid, it generally, I believe, becomes more deeply-coloured; and the most viscid that I have ever seen, was as dark as pitch. But the colour of the soft biliary concretions is commonly very different; a yellow, verging to a green; or exactly that of the Bile coagulated by the vegetable acid. Such are the *molles viridesque pilæ*, which are frequently mentioned, as having been evacuated by people in jaundice, and are considered by Haller among the primordia of these concretions*. Of the same sort appear to be the *molles intus globu-*

* Physiolog. L. XXIII. S. III. II.

lique

*lique sebacei**; for we remarked before, that some observers had mistaken the coagula of the Bile, formed by the acids, for sebum, or fat †. Morgagni gives us a very particular description of a soft concretion found in the gall-bladder; and the terms agree exactly with the appearance of Bile coagulated by the vegetable acid; *habuit in Cysti—Massam ex fulvo obscuro cæruleam, et viridifcentem, eamque mollem* †. And in fact, we observe, that the animal which is more than any other subject to these concretions, has no gall-bladder; that they do not therefore depend upon stagnation, in this creature, but rather, as they are found in the stomach, upon a coagulation of the Bile, by the acid generally present in that organ, is extremely probable. I mean, at present, the animal that furnishes the bezoar; which, from the taste and colour it gives to water ‡, appears to be a real gall-stone.

* Page 32. † Ep. XXXVII. 45.

‡ Physiolog. Hall. L. XXIII. S. iii. 11.

BUT

BILIARY SECRETION. 173

BUT from what other supposition, can we explain the particular appearance of those calculi, which seemed to Morgagni to have been formed around a nucleus of soft Bile? Can we imagine that the natural Bile had insinuated itself through the firm, dense, external crust; or that the calculus was originally a hollow globe, its cavity prepared for the reception of this nucleus? Is it not much more probable, that the whole concretion was in the beginning a coagulum of the Bile formed by an acid; which neither in consistence, nor colour, differs much from ordinary Bile; and that while its external part was gradually altered by pressure, &c. its center defended from the action of these causes, retained the original colour, and softness? Morgagni tells us, that the size of this soft *meditullium*, was always larger in proportion to the size of the stone.

THE

THE only concretion of this kind, which I have had an opportunity of examining, upon being broken, and put into spirit of wine, gave to it not a yellow, but a green colour; and this, the reader will remember, was a distinction between the natural, and the coagulated Bile. (Exp. XXI.)

WE have considered the most ordinary appearance of gall-stones in their original soft state; which seems to correspond with the most ordinary appearance of the coagula of the Bile, formed by the vegetable acid. But there is a variety, which I am convinced by experience will sometimes, though less frequently, happen. I have mentioned some Cystic Bile, that, when coagulated by the vegetable acid, was not of a greenish-yellow, but of a dark colour*. This coagulum, after being kept some time, is now perfectly black throughout, and extremely

* Note, pag. 11:

brittle.

brittle. The Bile will sometimes probably, in the living animal, be in a similar state; and then, if it should happen to be coagulated, the colour of the concretion, as well as of the future stone, will correspond with the appearances which we have just described. And this observation may serve to explain the *concretiones pillulares nigricantes*; which are likewise taken notice of by Haller, while he is relating the descriptions of these calculi, in what seems to be their primitive state.

IT is extremely probable, therefore, that many of the concretions are originally Bile coagulated by an acid; which being no longer miscible with the liquor of this secretion, if they are not evacuated immediately, but allowed to stagnate, may acquire a stony hardness, like the cheesy concretions in the mammæ. But where is there any opportunity for
 7 the

the action of an acid upon the Bile, before it gets into the intestines, and quite clear of those passages, in which alone the biliary concretions seem to constitute a disease? This is difficult to determine; but I think the following appears to be the most obvious way of conceiving the operation. We believe that there is an influx of a liquor with some acidity from the stomach into the *duodenum*; and that naturally all the Bile, or the greatest part of it, is coagulated almost as soon as it gets into the intestine*. But may not a little of this acid insinuate itself sometimes into the end of the *ductus communis*; where if it but touch the Bile, so much of this liquor as has felt its influence, must immediately take the form of a cheesy concretion?

AND there are some observations that make this notion appear probable. For

* Pag. 131.

frequently

frequently such soft concretions are found in the end of the *ductus communis*; of which there is an instance in the case from Morgagni that we mentioned before*. Here, indeed, there was some of the same kind of soft concretion in the bladder, the cystic, and common ducts; and as that, in the last, appeared to be the hardest, Morgagni concludes with reason, that it had grown gradually firmer in its passage from the bladder towards the intestine. But, might it not have previously passed from the *ductus communis* into the bladder? And when Haller relates the history of a light-coloured coagulum in this duct, with some harder rounded pieces, *cum durioribus globulis*, in the gall-bladder, is it not evident, that, in this case at least, the concretion had begun in the *ductus communis*, and that its parts had been moulded, and

* Pag. 172.

N

gradually

gradually acquired consistence, in their passage through the duct into the bladder * ?

BUT how shall we explain that globular form which is perceived to have been original in all these stones †, except by supposing that they acquired it when soft and newly coagulated, from the pressure of the surrounding duct ? We find, that in general the concretions are exceedingly small, and correspond very nearly with the size of the extremity of the *ductus communis*; and that many of the large stones are composed of these elements, as it were, united together. But there are some observations, with respect to this kind of calculi, which seem to prove that each of the component concretions had been formed in the same mould. Such is the account of a calculous globe, that separated into six-

* Hall. Phys. L. XXIII. Sect. iii. § xi.

† Morgagni, Ep. cit. 19.

ty leffer calculi, each of which weighed a scruple *. This entire correspondence in size makes it extremely probable, that every one of the concretions had, in its origin, been confined by the same bounds; or, in other words, that they had been all formed in the extremity of the *ductus communis*.

THE fluid here, and in the cystic duct, is evidently susceptible of motion in opposite directions; and is naturally conveyed from the *ductus communis* into the gall-bladder, and from this reservoir back into the duct, and so into the intestines. There is probably interested in this motion a contractility of the ducts, similar to that which is observed in the alimentary canal; so that, according to the determination, the same muscular fibres propel the contents of the tube, either the one way or the other. Now, supposing such a coagulation, as we men-

* Morg. l. c.

† Morg. l. c.

tioned, to have happened in the extremity of the duct; while it is yet soft, and almost fluid, it will obey very readily any impulse, and may either be pushed into the *duodenum*, or carried into the gall-bladder, according to the determination of the motions in the ducts. If it passes into the *duodenum*, it will pursue with their contents the course of the intestines; and though it should be carried into the gall-bladder, it may still never become a *calculus*, if this organ evacuates its contents quickly and perfectly; for then it will pass through the ducts, in a soft state, without much difficulty, and perhaps without producing jaundice *. Indeed, if it were to continue in the passage where it is formed, the consequence must be a perpetual jaundice; and therefore the necessity of getting rid of it will prove a stimulus, we may suppose, to the irritability of the parts, and excite their action. And if, from a spasm

* Morgagni, l. c.

of the fibres of the *duodenum*, or from a distension of that gut, or from some other cause which we are not perhaps acquainted with, the passage into the intestine should be difficult, the concretion, together with the Bile in the *ductus communis*, and *cysticus*, may be pushed into the bladder. This will answer the present purpose of the œconomy, which is only the removal of an obstacle to the passage of the Bile, as well as if the coagulum had been thrown into the intestines.

IN young persons, we may believe, the irritability of these parts is more considerable; there is a more constant determination of Bile into their intestines, as appears from the natural frequency and colour of their stools; and little stagnation is allowed in the gall-bladder. In children, therefore, though the same coagulations happen, and most probably occasion those transient jaundices to which they are

liable; yet the natural contractility of the parts, excited especially by the stimulus of a purge, soon frees the constitution from them, while they are in a soft state. And in children, hard biliary *calculi*, are, perhaps, never found, though they are sometimes passed in the form of soft concretions*.

BUT in old age, naturally, and sooner, from certain causes, as particularly a sedentary life, the intestines, and their appendages become more torpid; the determination of Bile into their cavity is diminished, and its stagnation in the gall-bladder permitted. When coagulations happen in these circumstances, they have a greater chance of getting into the gall-bladder, as well as of continuing there until they acquire a solid consistence.

WE are not, after this view, surpris'd at the difficulty which Morgagni finds

* *Calculi ex puero annuo pisi mole molliculi multi. Hall. l. c. ex Adol.*

BILIARY SECRETION. 183

in distinguishing between biliary and intestinal concretions; nor will it seem extraordinary, that some, which had all the appearance of the former, should be only attended with the symptoms that belong to the latter *. For, since the Bile appears to be naturally and constantly coagulated in the intestines †, it may form there, whenever it shall be obliged to stagnate for a considerable time, concretions which must very much resemble those found in the gall-bladder, as they have the same origin.

ONE would imagine that Gaubius had entertained some such notion as this of the formation of biliary *calculi*; for he observes, that the *primæ viæ*, and the passages which have the nearest communication with them, as the organs destined to the Bile, are particularly liable to stony concretions. And

* Morgag. Ep. c. 45.

† Pag. 131.

he adds, *Dixeris ideo humores, qui crudorum permixtioni præ reliquis patent, præcipuè lithiasin contrahere* *; a remark which seems to be inexplicable, except upon the supposition which we have ventured to offer. For, however near the liver and its appendages may be to the alimentary canal, we certainly do not imagine that there is any matter in the biliary secretion, which has not gone through the course of the circulation, and been separated in the proper organ. Yet, as the observation of Gaubius is not confined to the excretories of the Bile, but includes, at the same time, the urinary organs; we must confess, we do not see how these have any particular communication with the *primæ viæ*, or can be liable, on that account, to an admixture of crude and unconcocted matter in the fluid they separate from the blood.

* Patholog. § 567.

BILIARY SECRETION. 185

ONE of the simplest forms of these concretions become calculi appears to be that, in which the external part only has been gradually changed, and by this sort of degeneration has acquired a white, hard, stony figure; while the internal part retains its original colour and consistence. If we suppose this degeneracy to have proceeded farther, and to have altered, by degrees, the whole texture of the concretion, we shall get an idea of that kind of calculi, which appeared to be calcareous throughout their substance. But the first sort of concretion, while it lies in the gall-bladder, or in any other place that is subject to the continual, or frequent afflux of Bile, may attract, from that fluid, its similar parts; and, in consequence of subsequent depositions, those concentric layers, which are commonly observable in the larger calculi, will be gradually formed.

ANOTHER

ANOTHER simple form of these concretions, is that which was observed to happen to Bile in a particular state, that differs, we know not how, from the ordinary one, in consequence of the action of the vegetable acid. These are dark-coloured at first, and gradually become quite black, hard, and brittle, throughout their substance*. And if we join to these reflections, that the form of the coagula, while they are in a soft state, may be changed by pressure, and that several of them may be compacted together, we shall have a notion of the origin of the greater part of those varieties of biliary calculi, which are upon record. There is one sort, however, which seems to have undergone an actual chrySTALLIZATION; nor will this seem very extraordinary, if we suppose that the coagulable lymph, which makes the chief part of these concretions, is a composition of calcareous earth, and the acid of

* Vid. Pag. 175.

phosphorus.

phosphorus. For may not it, like other combinations of this earth with acids, be disposed, in favourable circumstances, to suffer a chrySTALLIZATION?

YET we do not pretend to include in this idea every species of biliary concretion. There are some, as for instance those which are found in the biliary pores of oxen, that are evidently spontaneous. And their different appearance shews very plainly, that they differ in their origin from the stones of which we were treating. The continuity of the concretion, through the extent of several vessels, does not look like the very partial application of a coagulant, as in the former case, but like a general disposition in the fluid to concrete. *Sæpe mihi visi hujusmodi tubuli tantæ longitudinis, ut si modo integri eximi potuissent, plurimas pori biliarii ramificationes continuatâ lapideâ serie coralli instar retulerint* *. Concretions

* Glisson de Hep. p. 105.

of an analogous form, have sometimes, though very rarely †, been observed in the human liver; and we should naturally suppose, that they might happen more readily in the gall-bladder, where there seems to be a better opportunity for stagnation. I remember to have seen a biliary concretion, which appeared to be of this sort. It was an irregular mass, of a brown colour, that readily crumbled between the fingers; and a piece thrown into spirit of wine, gave it very quickly a yellow tinge.

I SHALL mention the few experiments which I have had an opportunity of making on these concretions, though they may be reckoned, perhaps, scarcely worth recording. There is a variety, in the account of their properties, that might lead one to imagine a considerable difference in their composition. But some of these properties; for instance their spe-

* See pag. 160.

BILIARY SECRETION. 189

cific gravity, according to the common way of determining it, seems to be easily alterable. A concretion being broken into two pieces, each of them was observed to swim in water. One was taken out, and thrown into vinegar; where it swam for some time on the surface of the liquor, but afterwards subsided to the bottom. Being now taken out of the vinegar, and put into water, it sunk immediately. The other piece continued a much longer time on the surface of the water, where it left an oily scum; but, at last, it fell to the bottom. Yet both these pieces, when they had remained some time in a dry place, were found to have recovered their property of swimming in water. Another round calculus, with a hard polished surface, continued in vinegar twenty-four hours, and was exposed to heat, without subsiding to the bottom.

OIL of vitriol, poured upon one of the stones, produced heat, changed its

colour to black, and softened it into a gelatinous or gluey consistence; so that it spread itself around the bottom of the glass, adhering tenaciously to the surface.

A PIECE of one of the concretions, with concentric layers, being put into aquafortis, and the vessel set before the fire, a flame-coloured vapour arose from the liquor, and the acid acquired a yellow colour. When the stone was taken out, and thrown into water, it ascended to the top, and showed a white, brittle, corroded surface.

PIECES of the same kind of concretion were put into *spiritus nitri dulcis*; which extracted from them a brown tincture. They were entirely stripped of their colour, and got the appearance of pieces of chalk. Strong spirit of vitriol poured on these pieces, produced heat, changed their colour to red, and then to black; and

BILIARY SECRETION. 191

and softened them into that gelatinous consistence already described.

SOME small black granular concretions, being put into spirit of wine, did not seem to be affected by it, in the cold. But others, of the same kind, being put into a mixture of spirit of wine and *aqua fortis*, a green tinge was observed arising from the stones, and spreading itself in the liquor; which, at length, acquired a rust-colour; but these concretions were not rendered white.

SOME pieces of the concretions, with concentric layers, were put into spirit of wine, and seemed to be little affected by it, in the cold; for they only communicated to it a slight yellowish tinge. But when heat was applied, for some time, the spirit dissolved them; got a viscid appearance; and an infinite quantity of little shining lamina, like bits of talc, were discovered swimming about in the solution.

SOME

SOME oil of turpentine being poured upon a concretion, and the vessel set in a warm place, the oil acquired a brown colour, and the stone was so softened, that it broke into small pieces with the little agitation that was used. Yet it did not appear to be dissolved, or to have mixed uniformly with the oil.

Two firm biliary calculi had been exposed to heat, in spirit of wine, for twenty-four hours; yet retained their size and form. Some oil of turpentine was added to the spirit, in each of these vessels; and a few hours after, in shaking and examining the mixtures, I found that the stones were fallen to pieces, and the liquor become brown and turbid.

IT seemed from this experiment, that Valisnerius had reason for ascribing to heated spirits of wine and turpentine, a superiority over the other dissolvents of these concretions*; if by a dissolution he

* Opere, t. 3. p. 6. Lett. 37.

meant,

BILIARY SECRETION. 193

meant such a change as has been described. And as the essential oils, particularly that of turpentine, seem not to be so much altered by the digesting powers, but that they retain some distinguishing properties in the circulation, it will be imagined, perhaps, that their efficacy may be conveyed into the Biliary Secretion.

THE alkaline salts, both volatile, and fixed, acquired a brown colour from some of these stones; and rendered them much softer. But it is pretended that simple warm water will produce, in many of them, the very same change. An alkali, altered by suffering it to lie on Prussian blue, extracted from them the deepest tinge. This alkali effervesced with all the mineral acids, and produced with them, instantaneously, a green colour. But with the weakest solution of iron, and of some other metals, it gave immediately a blue colour. Yet, when it had

O acquired

acquired a tinge from a gall-stone, it produced a green, instead of a blue, with the solution of iron. And I found, that it was altered in the same manner by dissolving in it a bit of the crassamentum of human blood. And when the clear red infusion of the blood in boiling water, was poured into a solution of iron, rendered blue by the above-mentioned alkali, it produced immediately a green colour. The addition of some human urine to this solution, was attended with the same change. These Experiments seemed to confirm the opinion of a relation between the colouring matters of the Bile, and of the blood. But I soon found that a resemblance in this property was extended through a variety of bodies. For an infusion of aloes, of tea, of powder of the gall-nut, produced the same effect. So did the addition of brandy; though pure spirit of wine did not seem to alter the blue colour. An infusion of saffron, likewise, gave immediately a fine green,

BILIARY SECRETION. 195

green, on being mixed with the solution of iron and Prussian alkali. These bodies seem to agree in no property, but that of communicating to water a colouring matter. Whether, in all of them, it is of the same nature, I will not pretend to say; though it has been asserted*, that the blush of the grape, and the florid colour of our vital current, depend on a common principle. Yet, when I poured some port-wine into the fore-mentioned blue solution, it did not produce a green, but a purple colour; which might depend however upon some foreign matter, as our common wines are seldom free from such a mixture.

THE concretions appear to be composed of the same materials with the Bile; except that they have undergone some spontaneous change, during their stagnation in the body. The colouring matter does not produce that fine vivid green with the acids, which the Bile itself, and

* *Traité de la Nutrition, par Mons. Durade.*

the fresh coagulum of this fluid exhibited in the former Experiments. And the coagulable part has acquired the appearance of a calcareous, or chalky matter. When some chymist shall bring us acquainted with the composition of the coagulable lymph, and with the particular nature of the colouring ingredient of the Bile, we shall probably be able to account for these changes.

THOUGH we seem to have found a source of biliary concretions in the acid of the alimentary canal, it will not, I hope, occur to any one's fancy, that their prevention must depend on destroying this acid, by means of absorbents. For if it appears probable, from a view of the only facts relative to this matter, that there is a continual generation of acid from digestion, it is equally probable, that this acid has some important uses in the œconomy. Nor are we to suppose, that it ever gives occasion to concretions in
the

BILIARY SECRETION. 197

the biliary duct, during a perfectly sound and natural state of the animal. Their production is most probably the consequence of some disturbance, or inversion, of the ordinary motions in the alimentary canal, and in the ducts its appendages. It is observed by an eminent physician, that several of his patients, after being troubled, for years, with complaints which they referred to the stomach, have at length been seized with a jaundice*. He suspected, therefore, that the preceding symptoms arose from biliary concretions, which had not yet entered the *ductus communis*; or, perhaps, had been evacuated before they acquired bulk enough to obstruct the passage of the Bile. What would be the symptoms in the latter case, it must be difficult to say; but we have numerous observations of stones continuing a long time in the bladder, without producing any kind of symptom.

* Medic. Ess. of the Col'lege of Physicians.

It seems exceedingly probable, that the disorder of the alimentary canal was primary; and that such a state of it is more favourable to the formation of these concretions. I am inclined to believe also, that this is a reason why biliary calculi are frequently connected with the gouty, and nephritic constitution; these distempers being so apt to affect particularly the alimentary canal, and disturb the natural order of its motions.

To escape the disease, we must endeavour to avoid those circumstances of the constitution, which appeared to favour its production*. Old-age, alas! we cannot avoid; nor its effect upon the irritability of our organs. It is almost as difficult for some of us, in the present artificial distribution of the employments and duties of mankind, to shun the mischief of a sedentary life. But the management of his diet is certainly in every

* Vide, p. 168.

BILIARY SECRETION. 199

person's power, whatever path of life he may happen to tread. And if proper care was taken in this respect, the influence of the other causes might possibly be prevented.

WE have already attended to that sympathy, which prevails so remarkably between the excretories of the Bile, and the alimentary canal*. It is probable, that the state of motion in the latter organ cannot be altered, without affecting the former. When the peristaltic action of the intestines is greatly accelerated by the stimulus of a purge, we observe that a vast quantity of Bile is very suddenly poured into their cavity. In the opposite state of the canal, when this action is too dull, and torpid, the motion in the excretory organ of the liver will probably be just as languid. The operation of old-age, of a sedentary life, of the *alimentum siccius*, in rendering the constitution more liable to biliary concre-

* Page 152.

tions, consists entirely, perhaps, in their producing the above mentioned state of these connected functions.

THIS is certainly no new disease, though it was unknown to the ancient physicians; yet I believe it to be more frequent at present, than it was in their time. For there are many more people now, who lose their vigour, either in an indolence that is disturbed only by the avocations of enfeebling pleasures; or in employments that vex or fatigue the mind, while they deprive the body of its natural exercise. And both these classes of men are very generally subject to a weakness, and disorder of the motions in the alimentary canal.

NOR does the ordinary way of living seem calculated to obviate, but rather to increase the influence of the causes we have mentioned. The common use of tea, has a tendency to injure the tone of the
intestines;

BILIARY SECRETION. 201

intestines; as well by the warmth of the infusion, as by its particular sedative quality. The debility which follows, in a temperament whose muscular power is naturally weak, or has grown so from want of exercise, must be remedied, when it becomes excessive, by something cordial and strengthening from the apothecary; or by an application of the same kind, prepared without his assistance. And both these practices, when long-continued, are equally pernicious, though they may not be equally shameful. But, perhaps, the debility is not sufficient to drive us to such resources; and only discovers itself in a longing, at the next meal, for something that shall raise our vigour, and spirits. This becomes a foundation for the use of spirituous liquors; which grow from custom to be a necessary mischief, entailed upon the constitution. For no one doubts, that the temporary vigour, communicated by this kind of irritations, is succeeded necessarily

cessarily by a weakness, which calls for a repetition of the former stimulus. And when they are long continued, the sensibility of the fibres is used as it were, and worn out; and they become torpid before the ordinary period of old-age. Our most common liquors have an astringent quality united with their stimulus. Our beer and wine, by their bitterness and roughness, augment more considerably the tone of the fibres; but it is probable, that in the same proportion they tend, by continued use, to exhaust the contractile power. From these qualities too, they are apt to occasion, especially when well-relished with cheese, a slower motion through the intestinal tube; a circumstance particularly favourable to the production of biliary concretions.

THE gout, with its doubtful face which regards at the same time the inflammatory, and the nervous diseases, frequently interrupts this course by an
unwelcome

unwelcome visit. Yet it seems to be a necessary, though painful operation; employed by Nature for supporting, in the best way that we have left her, the vigour of the system. One discovers in it the ancient strength of the northern constitution, struggling with the enfeebling modes of modern life. And, in a little time, it will be lost entirely in that train of more purely nervous disorders, which have lately become so numerous. These obtain different names according to the theoretical notions of the physician, and his patient. They are sometimes called disorders of the stomach, sometimes nervous, and at other times bilious disorders; and generally they have a right to every one of these appellations. For it is impossible that the nervous system should be much injured, and the functions of the alimentary canal remain entire, and unaltered; and such is the sympathy between this canal and the biliary organs, that they will commonly share

share in the affection. But it is certain, that they flow originally from a disorder in that power, which is the source of all the motions in the machine.

THE safest means of maintaining the vigour of the nervous power, and those which Nature seems to have appointed, are the application of cold in a certain degree, and proper bodily exercise. All those sources of irritation, which, under the name of spirits, bitters, astringents, by the short-lived force they occasion, have obtained the name of strengtheners, may answer, indeed, a temporary purpose; but their habitual use will certainly prove pernicious. Unhappily they are resorted to, for present relief, by those who have most reason to dread their debilitating effect. Such are the people who are confined to the close, and heated air of a chamber, in the pursuits of study, or business; a numerous, as well as respectable body in every polished society. They
7 should

should be persuaded, that a calm and regular tenor of the motions in the system, is best adapted to their way of life ; for, being deprived of the natural means of supporting the vigour of the moving power, they must manage it with greater caution. In them it is more easily excited beyond its proper pitch ; and they suffer more from its consequent depressions. They would certainly do right, in exchanging all the varieties of spirituous liquors for simple cold water. It would then be easy for them, to mix in their aliment a proper quantity of fresh vegetables, and particularly of the ripe fruits ; which commonly disagree with such people at present, because they are joined with fermenting liquors ; and their stomachs have been so accustomed to the perpetual use of heating substances, that they can bear nothing of an opposite quality. But this part of diet, Nature seems to have intended for accelerating, by its mild irritation, the peristaltic motion

tion of the intestines, and solliciting the determination of Bile into their cavity; effects which it very constantly produces.

IN such a state of the motions in the alimentary canal, and the biliary ducts, concretions probably will not be formed; or will be very quickly evacuated. The sensibility of the fibres will be preserved, until worn out by the necessary action of the œconomy, it yields to the influence of old age*. The whole nervous system, which sympathizes so much with the state of the alimentary canal, that we do not commonly think of affecting it, except by the changes produced in this organ, will acquire an equal, and a durable tone, less subject to

* The learned Dr. Haller attributes to his use of water alone, since his early youth, the present perfection of all his senses, and particularly of his eyes; although he has exercised them so much in microscopic observations.

those

those depressions which give occasion to the attack of a variety of diseases. The gout will probably be avoided; or if its rudiments were interwoven in the stamina of the constitution, its approach will be retarded; and when it does come, it will be as a friendly visitor, to increase our vigour and spirits, and not to attack the very seats of life. Our children will bless their parents temperance; and certainly it were better to insure them a good constitution, than to lose our strength in the anxious pursuit of wealth, that we may furnish their feeble bodies with the occasions of growing still more wretched. Perhaps, by such a management, we might at length exterminate this variety of nervous affections; which are not the native growth of a climate, whose temperature should produce in its men, as well as its horses, a state of the muscular power that gives equal vigour and agility; but are the hot-bed productions of luxury and indolence. And, certainly,

3

they

they are more troublesome both to the physician and the patient, even than those contagions which industrious and adventurous Europeans have imported from the torrid zone. Both together they are the curse of modern times; and mark a period in the history of Europe, distinguished by its commerce, its riches, and its wretchedness.

YET I feel, while I am writing, that these remarks will have little practical use. I shall not gain a single convert, even amongst those people whose refined feelings, and cultivated understandings, must make the perfect exercise of their faculties, more delicious than any sensual gratification. Yet the sensualist himself, if he is wise, will be temperate; and preserve that exquisite relish, which a perfect state of the functions communicates to every animal enjoyment. He remembers how poignant was every sensation, while his organs were yet fresh, and unworn;

worn; and will be careful not to waste, like a prodigal, that stock of sensibility which might furnish a life of pleasure. Nor can he pretend, without risking an imputation upon his taste, that any composition of the most knowing artist is half so agreeable to the palate, as the fruits which Nature herself prepares.

But to suppose that a temperate way of life will ever become general, in this country, might justly pass for an extravagant fancy. It has been frequently remarked, as characteristic of Englishmen, that they are prone to excesses of every kind. Virtue, vice, frugality, profusion, and every peculiarity of character, are said to grow to a more extraordinary height in this, than in any other clime. But their free spirit rejects the appearance of constraint, even in the most ordinary matters. In this favourable climate, and in constitutions which retain their

P native

native vigour, such excesses are followed by a punishment so tardy, that it is frequently confounded among the natural effects of old age.

OUR colonies, in the hot climates, retain the full and free manner of living of their more robust ancestors. They imitate, in this respect, the less polished but more hospitable state of their parent country; before a necessary oeconomy, an attention to more elegant pleasures, and the care of a debilitated body, had introduced a greater moderation. They are yet new in their settlements, and do not seem to have discovered the modes of living which are best adapted to their situation. In general these are regulated by fashion; and are not therefore, always, strictly rational.

———*Falsò plurima vulgus amat.*

YET

YET, I believe, in every country, which has been long inhabited, they will be found to bear a certain relation to the nature of the climate. Its temperature affects most remarkably the nervous system; and alters therefore the state of our appetites, which is always relative to the conditions of this system. And practices, which are suggested at first by instinct, are continued from an experience of their utility. The posterity of the Goths who settled in Italy observe, through habit and inclination, a temperance which the northern descendants of the same people feel the greatest pleasure in transgressing.

AND universally, in the civilized countries which are subject to great heat, the inhabitants are more sober and temperate. The bounds of moderation grow more contracted, as excess becomes easier and more pernicious. Yet an apology has been offered for the liberal use of

wine in the Indies, on account of its strong antiseptic power. But it should be remembered, that the animal machine will form its own fluids; and that, generally, we are not capable of altering these immediately; but only through the intervention of the powers which form and separate them, while we change the state of the motions in the oecconomy. The first and principal effect of most of our antiseptics, is certainly exerted on the living solid; and perhaps, when one is to be exposed, for a short time, to the influence of putrid *miasmata*, the supporting in the body an artificial temporary vigour, by repeated applications to the bottle, may prevent their operation. But it is undoubtedly true, that a continuance of this practice must co-operate with the heat, in bringing on a premature decay of vigour in the system. The same objection lies against a full and stimulating diet; for all great irritations must

must be pernicious, in an oeconomy which is wearing out too rapidly, and where the action is already excessive from the stimulus of external heat.

THE change induced on the nervous system, productive of weakness and irritability, seems to be the fundamental fault of the constitution in these climates: from which, as a common source, are probably derived the quicker circulation; the more rapid progress of the fluids in their septic degeneracy; the redundancy of Bile; the disposition to violent spasmodic disorders, and to fever. The most natural and obvious means of preventing these effects of the heat, is the application of cold to the surfaces of the body. Bathing, that act of equal voluptuousness and religion in the eastern countries; and all the methods of cooling the air by evaporation, which enter into their system of luxury; the inhabitants were led to by Nature, and continue, from an experience

ence of their salutary pleasure. To be in possession of ice and snow during hot weather, requires a little more management and contrivance. But, in some of the southern parts of Europe, the use of these refreshments extends through almost every rank of people. And we are assured by their physicians, that it is not only a very healthful luxury, but even a remedy of considerable importance in the disorders of their hot season. It is surprising, that the inhabitants of our American colonies do not endeavour to procure this enjoyment in their warm summers. They would find an ice in the afternoon, an admirable substitute for those warm liquors, with which they relax still more their enfeebled stomachs; and its expence would certainly be overpaid by its pleasure and utility.

THE acids approach the nearest to actual cold in their effects on the oeconomy. They produce a sense of coolness, relieve
thirst,

BILIARY SECRETION. 215

thirst, oppose putrescency, repress the inordinate disposition to motion in the system, and give a degree of astringency, with a gentle irritation to the parts more immediately subjected to their action, the alimentary canal and its appendages. They have been observed to relieve that languor and faintness, which are occasioned by excessive heat, when no benefit resulted from the common stimulating cordials*. Their peculiar operation upon the Bile, which seems to bear the strongest marks of Nature's providential care of the oeconomy, has been already considered †. And from that view alone we were convinced of the necessity of using them in greater quantity, whenever the body is exposed to the continued influence of great heat. They are then demanded by the appetite, and cordially received by the stomach; for in hot weather, and in a fever, we bear very well a quantity of

* Lond. Med. Obs. vol. i. p. 66.

† Page 134, &c.

acid,

acid, that would be apt, in other circumstances, to disorder the first passages.

THESE precautions against the heat appear to oppose its effects directly; while the spirituous liquors, and those warm spices of which the West Indians are so fond, although they remove for a time the languor of the climate, are hurtful by adding to that irritation which the heat has carried to excess. It is an unnatural purpose they answer, when, by rousing a feeble stomach, they enable a man to eat as much in Jamaica, as he would in England. If we were careful to preserve the strength of the system, by a way of life adapted to the climate, we should feel no occasion for their temporary use. And they ought certainly to be reckoned amongst the *presidia valetudinis*, whose purpose is always temporary; since it must never be supposed, that a man is to be ill his whole life. They can be of no advantage, while our system

retains

BILIARY SECRETION. 217

retains its natural vigour; and become necessary by habit, because they destroy that vigour. For the same reason, they render the stomach less capable of bearing the action of cold, and the acids; and may deprive us of those remedies which, by lowering the too great excitement that arises from the heat, are its proper and natural antagonists.
