## INTRODUCTION.

HERE is in human nature an enthusiasm constantly arising from the pursuit of any favourite object, which in some measure prejudices the judgment of the cooleft and most temperate men, and in spite of themfelves biaffes their opinion, and influences their representation of things. This propenfity of the mind has in no instances been more strikingly shown, than in the introduction of new medicines; with regard to which it has been found, that the greatest intentional candour and honefty have not preferved men from offering to the world equivocal facts, with bold conclusions deduced from them. It would be an eafy, though invidious tafk, to point out many cafes, where practitioners have been much suprized to find a remedy, A

#### INTRODUCTION.

remedy, powerfully recommended to them upon the authority of a great and refpectable name, fall infinitely fhort, in real efficacy, of what they had been taught to expect. Inftances of this unhappy deception are more frequent, in proportion as the national or perfonal character of the author is inclined to credulity or vanity; and when we have reafon for fufpecting a strong biass to either of these, it becomes us to be extremely cautious and referved in our admiffion even of facts, and still more of conjectures. To the honour of our country, it may be confidered as the place where the literary opinions of all Europe are weighed with the most candid and impartial ferutiny; where a great name will not fanctify an absurdity, nor a cloud of credulous and prejudiced attestations evidence an extreme improbability. This fpirit of free enquiry, and philosophical scepticism, can alone preferve science from being overwhelmed with a number of contradictory opinions, fo equally recommended as to confound

iii

confound all distinctions of truth and falfehood, and can alone contribute to the afcertaining that experimental knowledge, which constitutes real advancement in any purfuit of the mind.

MR. GOULARD, a surgeon of eminence at Montpellier, has lately written a treatife on the external use of Saturnine preparations, in which he confiders them as a fort of panacea in the practice of furgery, and makes them, in fact, the only topical remedies required in any cafe. An intelligent reader will at first fight perceive an air of empiricism in the indiscriminate recommendation of a medicine, for diforders fo very various and different as those which come within the furgeon's province; and if, upon a further examination, he finds reafon to fuppose it really valuable for some purposes, he will wish to separate and diffinguish what may be depended upon, from the fanguine additions of a prejudiced author. It is precifely with this view, that I have undertaken a set of observations upon sa-A 2 turnine

#### iv INTRODUCTION.

turnine topics. Senfible that Mr. Goulard has faid many things in their favour which well deferve attention, I would attempt to put thefe medicines upon the rational footing of others in common practice, and candidly fhow what may, and what may not be expected from them, and in what rank they ftand with refpect to other topics; and in doing this, in whatever points I am obliged to differ from Mr. Goulard, fo it be done with modefty and good-temper, I cannot confider myfelf as ftanding in need of an apology.

I SHALL only beg leave further to premife, that it is not merely upon the confidence of theoretical reafoning that I prefume to judge of this matter, but alfo upon a very extensive and accurate obfervation of the effects of these medicines in real practice.

#### SECTION I.

# On the Medicinal Preparations of Lead.

EAD is used medicinally, either in the form of a calx, or corroded or diffolved by the vegetable acid. THE calces of lead seem to have no active qualities. Their only use is to give confistence to plasters, which they are extremely well qualified for, on account of their folubility in oil. Litharge is chiefly used for this purpose. The London and Edinburgh Dispensatories afford three forms of lead combined with the vegetable acid;

CERUSSE—which is a fimple corrofion; Sugar of lead—a cryftallifed falt; and A 3 Acetum

#### Medicinal Preparations

Acetum Lithargyrites—a solution by infusion.

THE basis of Mr. Goulard's preparations is what he calls extractum saturni, which is a decoction of litharge in vinegar, and in no respect differs from sugar of lead and vinegar of litharge, but in degree of concentration. It is evident from the directions given us for making it, that its strength must be extremely uncertain, depending upon the strength of the vinegar, and the time of boiling, neither of which is precifely fixed. This circumstance perhaps is of small importance in a topical application, which though it was determinate with regard to quality, could never be fo with regard to quantity, yet it gives us room to be furprized at a claim of invention and perfection, for a preparation which is neither new nor judicious. The only circumstance in which the extract feems to have the advantage of fugar of lead, appears to be in the greater quantity of the acetous acid contained in it, which proves

2

PART I.

of Lead.

3

the

proves an excellent affiftant in many cafes, and the fugar of lead, when once crystallifed, cannot be brought back to that state of folution in vinegar in which it was before; yet where a large quantity of watery menstruum is added, as in Mr. Goulard's faturnine water, it is as well to make a folution of fugar of lead in the water, and add the vinegar afterwards, as to mix them both together in the form of extract. He has a variety of formulæ of the extract mixed with unctuous and emplastic fubstances, contrived by their different confistences and strength to fuit various purpofes. Our dispensatories have likewise two very elegant faturnine ointments, and a variety of faturnine plasters.

ONE of Mr. Goulard's compositions is a mixture of the extract with foap, for the idea of which he profess himself indebted to the Duc de Richlieu. This I will venture to fay is a very injudicious formula; fince the acid in the extract will probably unite with the alkali of

A 4

#### Penetrability of

4

the foap, and leave the lead in the ftate of an inert calx. In effect, on attempting to make this composition, I have seen a large white flaky sediment, which I imagine was the lead united with part of the oil in the soap.

THE faline preparations of lead, difcover to the tafte a remarkable fweetnefs, and an intenfe flypticity. The calces are perfectly infipid.

of, silited by an

5

## On the Penetrability of Saturnine Preparations.

MR. Goulard, in accounting for the effects of these topics, speaks of their minute and fubtile particles entering the pores, forcing through obstructions, grinding down and dividing concreted juices, and then bringing them back through the pores, and all this with as much confidence as if he had actually feen them at work through a microfcope. It is this licentious spirit of conjecture which has brought medical theory into difrepute, and retarded the progress of real knowledge, fince it is impoffible for any opinion to be advanced, which an ingenious man may not attack or defend upon principles fo vague and fanciful. Let

#### Penetrability of

6

Let it be our bufinels to confider, from the known laws of the animal æconomy, and the fenfible qualities of the fubstance treated of, affisted by analogy with others, the effects of which are better afcertained, what is most likely to happen relative to the penetration of faturnine topics.

ABSORPTION of fluids applied to the furface of the body, is a well known phenomenon. This is performed through the minute pores of the fkin, and the mouths of a fet of veffels appropriated for this action, which befides the property of capillary tubes, posses also a contractile power from irritation. Yet are we much too ignorant of the theory of abforption, to form conclusions a priori of the fubstances best fitted to enter the fyftem in this way. Without embaraffing myfelf therefore with uncertain and inconclusive reasonings of this kind with regard to lead, I shall rather attempt to establish practical rules concerning its use, upon the furer grounds of real observati-

on

#### PART I. Saturnine Preparations. 7

on of its effects, and analogy with other medicines.

THE effects of any substance absorbed from the furface of the body, and thence carried to the mass of blood, and distributed with it through the whole fystem, may naturally be expected to be very fimilar to those consequent upon its abforption from the internal furface of the alimentary canal. This in many instances has been observed to be real fact, and in none more eminently than with regard to mercury; a medicine which is more familiar to us, and better known from its effects, than perhaps any in the whole materia medica. Its efficacy in overcoming the venereal virus, and its diftinguishing property of exciting a falivation, are now univerfally allowed to follow its admission into the fystem, through whatever channels it is conveyed, or in whatever form of combination it is exhibited; with fome difference only as to the certainty and speed with which it produces these effects. A long experience has at length

#### Penetrability of

length triumphed over fanciful theories and interested pretensions, and has established it as an important and undoubted axiom, that mercury, whether internally exhibited in the form of a most corrosive falt, or rubbed into the fkin combined in its crude state with the mildest unctuous fubstance, acts precifely in the fame manner on the animal fluids. Experiments of this kind with regard to other medicines are not numerous, nor very well ascertained, but in several instances the refult has been the fame. Even fome purgatives, which one would fuppofe confined to a topical action upon the inteffinal canal, have been found to produce their effects from external application.

THE noxious effects of lead taken into the ftomach, are extremely well defined and authenticated. The fymptoms it occasions are certain and conftant, and though at first they indicate a partial affection of the intestinal canal, yet the general paralytic diforders supervening, supervening, thew a communication of the injury through-

#### PART I. Saturnine Preparations.

throughout the fystem. But this is not the only method of exhibition by which its poifonous property is shown. The workers in lead-mines are found to be extremely subject to the paralytic affections, and general diforders of the nerves, which discover the faturnine poison; and in them the particles of lead must probably be received, in combination with a fulphureous vapour, into the lungs. This feems also to be the cafe with refpect to plumbers and fome other artificers in lead. There is fome doubt concerning the manner in which painters receive the poifon; fince if we confider the adhefive quality of the compositions of lead used for paint, and the little care these people. take to keep their hands clean, we may eafily conceive that a confiderable quantity may be fwallowed along with their food; however, vapour has probably fome share, as the smell of a newly painted room has been known to occasion these disorders in a slight degree.

THUS

9

#### Penetrability of

Thus we recognize two ways, in which particles of lead received into the fystem produce noxious effects which are evident and diffinguishable; and from analogy we might very naturally imagine, that fimilar confequences would follow its application to the furface of the skin. But Mr. Goulard, though he is very fanguine in his idea of the powerful action of lead absorbed in topical application, is yet strenuous in maintaining that its most liberal external use is never attended, in the fmalleft degree, with any of the pernicious effects of its internal exhibition. He confirms his own extensive experience by that of others; and from a large and careful observation of its effects, I can add an unreferved testimony to this fact. I have feen numerous inftances where his faturnine preparations were used for a length of time, in large quantity, and in all the circumstances which could be fupposed to favour its absorption, without any of the fymptoms attending its admission into the stomach or lungs. What

are

10

#### PART I. Saturnine Preparations. II

are we to conclude from an event fo unexpected? Would it be too much, to make use of it as an argument that no absorption of the faturnine particles really takes place ? might not this fuppofition be corroborated, by confidering the remarkable ftyptic quality of lead, which feems to contract and shrivel up every fibre, and certainly must render the pores lefs capable of abforbing? This perhaps would be too hafty a conclusion, fince our ignorance of the real operation of medicines, and the caufes of the variety observable in their effects, renders the argument rather merely negative than positive. Yet I think we may fafely affert, that it entirely deftroys Mr. Goulard's analogy of lead with mercury, and the theory of its action founded thereupon; for certainly he has no right to avail himself of the activity of a medicine in a favourable confideration of it, whilft he denies those noxious effects by which its activity is difcovered.

THERE

#### Penetrability of

THERE is a farther confideration which may ferve to invalidate Mr. Goulard's opinion, that faturnine topics act from an intimate penetration of their particles. In many of the cafes in which he celebrates their virtue, the difease is deeply feated in the muscles, glands, and cellular fubstance beneath the skin. Now the lymphatic veffels, which have been almost demonstrated to be the canals by which all abforption is carried on, and have been very accurately traced, by feveral great anatomists, particularly Hunter, Monro, and Hewfon, are found, as far as injection can be pushed, to have little or no connexion with the parts immediately fubjacent, but to run on in a direct courfe to the next conglobate gland; and the progress of some diseases, and effects of various ftimulant applications, have affifted to trace out this courfe. Admitting therefore that particles of lead in an active state may be absorbed, yet if instead of pervading and foaking through the skin and cellular membrane by tranfudation,

#### PART I. Saturnine Preparations.

13

fudation, they are carried directly and fuperficially along the lymphatic veffels, it cannot be conceived that they can produce any other effects on deep-feated parts, than such as arise from a sympathetic communication by means of the nerves. To give this argument its full force, we need only have recourse to the numerous facts relative to abforption, related by the favourers of the lymphatic theory.

UPON the whole, I conceive it a method much less exposed to doubt and uncertainty, and confequently much more useful in a practical view, to form our judgment of the uses of faturnine topics, from their fenfible and primary effects upon the parts with which they immediately come into contact, than from a theory of the intimate penetration of their particles; a theory which must be merely hypothetical, fince we are confeffedly deprived of affiftance from the analogy of their internal action. I shall therefore proceed upon this principle, endeavouring

#### Primary Effects of

14

ing to elucidate and confirm observations of the real effects of these medicines, by a theoretical reasoning, simple and intelligible; which however I would willingly include in that modest apology of Tully: Nec tamen quass Pythius Apollo, certa ut sint, et sixa, quæ dixero; sed ut bomunculus unus e multis, probabilia conjectura sequens.

SEC-

#### SECTION III.

### On the primary Effects of Saturnine Applications.

THE most manifest effect of faline preparations of lead externally applied, is contraction of the fibres. An animal fibre is capable of being shortened or contracted in two different ways; either from the property common to all matter of its particles being brought nearer to each other by external causes, or from an internal power of action refulting from the vital principle.

THE first species of contraction is produced by astringents, which exert their efficacy equally on dead and living flesh. The second is excited by stimulants, for the operation of which the vital principle is necessary. These powers may exist se-B 2 parate

#### Primary Effects of

16

parate from each other, or they may be united. In general, most of the medicinal applications belonging to either of these classes, which we are acquainted with, unite in various proportions a stimulant and astringent quality.

THERE is no doubt concerning the *af*tringency of lead. The fenfes bear a fufficient testimony to this effect.

WHETHER or no it has a *stimulating* quality is much more dubious.

In order to confider this queftion more clearly, we must premise, that there is a great difference between impreffing the nerves with an immediate fenfation, and rendering them more fusceptible of impreffions. Many fubstances produce the first effect in a great degree, and yet totally deftroy the latter. All faline bodies without exception applied to the tongue, or to any part divested of the cuticle, prove immediately stimulant, yet their effect may be afterwards to render the part less sensible of another stimulus. A faline preparation of lead, applied in a concentrated form to a very fenfible part, will

#### PART I. Saturnine Applications. 17

will therefore stimulate the fibres to immediate action, yet there is great reason to believe that its lasting effects will be quite opposite.

THE fymptoms arising from the internal use of lead, all show a remarkable power in destroying nervous influence. The obstinate constipations, tremors, and paralytic affections consequent upon it, proceed from this cause. Yet in what degree its external application can produce this, is very questionable. Mr. Goulard speaks, in many places, with great applause of the sedative virtue of faturnine topics; and indeed the facts related feem fully to justify what he fays on this head. At the fame time, he no where allows of any bad effects arifing from the destruction of nervous influence, fuch as palfies, and the like; nor have I ever observed their freest application attended with any fymptoms of that kind. But how can we conceive that just fo much power is exerted as to prove beneficial, and that it never proceeds to be injurious? I apprehend nothing can ac-

B 3

count

#### Primary Effects of

count for this, but what was before laid down concerning the confined action off these topics. We may easily imagine, that by diminishing the sensibility of the nerves of the skin they may appease pains feated there, while, not being able to penetrate to the nerves supplying the muscles, they cannot affect the moving powers of the body.

THE antiseptic quality of faturnine topics is also celebrated by Mr. Goulard. Putrefaction in a living body may be refifted, either by fuch applications as ftimulate the moving powers to a more vigorous action, or by fuch as have a chemical property of checking this process in the animal folids and fluids. Every combination of a metallic body with an acid is chemically antifeptic, fo that in this view the extract of faturn will rank among this class of medicines; though did its fedative quality penetrate confiderably to the moving powers, it would produce an opposite effect with respect to them. Simple aftringency however is found to render a body lefs liable to putrefaction;

#### PART I. Saturnine Applications.

19

trefaction; fo that upon the whole we may expect a good degree of antiseptic power from faturnine topics, especially the faturnine water of Mr. Goulard, which has a portion of vinous spirit added to it.

SATURNINE preparations outwardly applied, appear therefore to exert an aftringent and antifeptic property on the fimple folids and the fluids they come into contact with, and a fedative property on the living folids; and this, as far as I am able to judge, feems to be the whole of their primary action. The fecondary effects refulting from thefe, particularly with regard to the motion of the fluids, will be hereafter treated of.

IT is to observed that a difference will arife in the effects of faturnine water, according to the degree of heat in which it is applied. This is referable to the effects of fimple heat and cold; with regard to which it is univerfally known that heat relaxes, and cold constringes the fibres-the former applied in a moderate degree will therefore affift its fedative, the latter its aftringent property. SEC-

Repellent Quality of

#### SECTION IV.

## On the Repellent Quality of Saturnine Topics.

MR. Goulard very copioufly infifts on the efficacy of lead in difcuffing tumours of every kind, and even abceffes after the matter is formed, and in difperfing eruptions; yet he takes great pains to prove, or rather indeed to affirm, that it has no repellent quality. As this polition feems fomewhat paradoxical, and he has by no means cleared up the paradox, it may be ufeful to make fome general obfervations upon Repellents and Difcutients.

In every tumour there is a præternatural congestion of fluids, which may be faulty, either from the too great quantity in which they are collected, or from a mora morbid affection added to this. In the first case, no bad consequences can ensue from causing them to re-enter the circulation, and flow in their natural course; but in the latter, throwing back a vitiated humour on the blood, from whence an effort of nature has separated it, may give rise to diforder in other parts of the system.

In either cafe, the congested fluids seem to have no other poffible way of efcaping, but by an external difcharge, or by a return into the circulating mafs; which last, if terms mean any thing, must certainly be understood by the word repulfion. Mr. Goulard has therefore done nothing towards the proof of his favourite position, that lead does not repel, by supposing its particles capable of penetrating to the fluids in a tumour, and producing great changes in their texture and properties; fince, if after all they reenter the circulation, they are still repelled; and no advantage is gained with respect to the dreadful idea of repulsion, except

#### Repellent Quality of

except it were proved that their vitiation was corrected by the faturnine particles, and confequently the repulsion rendered innocent.

HE has indeed related, what I believe will appear very extraordinary, and fcarce credible to most furgeons, that in an abcefs where matter was evidently formed, the application of a faturnine cataplasm has evacuated it externally by way of transudation through the pores of the fkin, fo that the dreffings were moiftened with real pus, and the abcefs gradually vanished without opening. This phænomenon, fo contradictory to what we know of the nature of abcefies, and the operation of medicines, merits a stronger confirmation, than a few cafes in which the fact feems rather to have been taken for granted, than clearly demonstrated. It may indeed eafily be conceived, that a powerful ftimulant or aftringent may repel into the blood the matter of an abcefs; and we find this fometimes naturally happen in cafes of Metastafis,

PART I. Saturnine Topics.

Metaftafis, though the event is rare where the pus is fully formed; but if it were poffible for a tranfudation to take place, we ought rather to expect it from emollient applications, which powerfully relax the folids and dilute the fluids, than from topics which have a manifeft aftringent quality. The cuticle, while entire, we know is capable of retaining the ferum of a blifter, a fluid of far greater tenuity than pus. Mr. Goulard's theory to account for this effect of Saturnine topics, is fo very artificial and improbable, that it does not deferve a refutation.

HE does not however pretend that this transudation commonly happens in the dispersion of a tumour; therefore, as its contents usually find an internal issue, that is, return into the circulation, they are in every true sense of the word, repelled, and observations accumulated to prove the strong discutient quality of lead, do in effect prove its repellent quality.

THE

## Repellent Quality of

THE fame reafoning will hold good with regard to eruptions, which like tumours contain a congested fluid, either innocent or morbid. The powerful effects of lead in causing these to disappear, have long been well known, and much dreaded. Mr. Goulard may have proved that the use of lead is faster than has been imagined; but certainly he has not shown, that when eruptions which roughened the whole surface of the body, suddenly disappear without any visible external discharge, they are not repelled.

He brings an obfervation from the cure of the itch, to fhow that lead is not repellent; which is, that upon its firft application, the eruptions are increafed inftead of being diminished. It is very extraordinary that in his long chapter on this diforder, not one word is mentioned of the prevailing opinion among medical writers that the itch is occasioned by animalculæ; an opinion apparently well founded, and, one would imagine, univerfally known. But this circumstance rendered

rendered the, inftance much lefs fit for his purpofe, fince it deftroys the analogy with morbid matter in general, and gives room to account for the fact in a different way.

UPON the whole, confidering the number of well ftated facts adduced by Mr. Goulard, of the difperfion of tumours and eruptions by Saturnine applications, where no bad confequences have enfued from throwing back the matter on the fyftem; we muft conclude, either that lead has a remarkable property of deftroying various noxious qualities in the fluids; or that our opinions concerning fuch noxious qualities, are erroneous and ill-grounded.

THE first supposition is rendered improbable, by the arguments before laid down against the penetrability of Saturnine topics. Nor can it be conceived, allowing them to mix with the fluids, how by a fort of miraculous power they are able equally to prevail against almost every

# Repellent Quality of

every kind of vitiation of which the fluids are capable.

On the other hand, feveral cafes of tumour and eruption, prefuppofe no noxious quality in the fluids, and confequently we have no reafon to 'apprehend any bad effects from caufing them to reenter the circulation; and from many facts that have appeared fince the modern changes of practice in the treatment of the fmall-pox and other eruptive fevers, which have flown that cuticular eruptions are rather a fymptom, than a neceffary crifis of these diforders, and that such a treatment as is calculated rather to check than to promote them, will render the difease milder and less dangerous, we have great reason to believe that the repulsion of fluids usually supposed to be vitiated, will not always produce those fatal confequences that have long been fo much dreaded.

THERE is no occasion therefore, by imaginary hypotheses industriously to conceal

#### PART I. Saturnine Topics.

ceal the real action of lead, or to change the term by which its action fhould be fpecified; fince, if its utility and innocence be clearly proved by facts, calling it a *repellent* will not, in this country at leaft, deter practitioners from making use of it.

dicines, are fuch as have been utually

On Emollient Topics.

ternt by which its action that

# SECTION V.

# On Emollient Topics.

MANY of the difeafes for which Mr. Goulard recommends his medicines, are fuch as have been ufually treated with emollient applications; againft which he brings very fevere charges, and feems defirous of totally banifhing them from the practice of furgery. The difference between thefe two claffes of topics is fo great, that it is impoffible the ufe of both in fimilar cafes can be generally proper. I fhall therefore examine the nature and properties of Emollients, in the fame manner as I have done thofe of Saturnine preparations, in order to bring them to a comparifon.

EMOL-

PART I. On Emollient Topics.

EMOLLIENT TOPICS are fuch as relax the folids, and oppose acrimony in the fluids.

THIS feems to be the whole of their action, primarily confidered.

THE fubstances which enter the class of emollients, are water, oil and mucilage.

WATER is abforbed with great facility from the whole furface of the body, and either in its liquid form, or that of vapour, is poured out into every cavity, and moiftens every fibre. If we imagine a fpongynefs or porofity of texture in the fimpleft fibre of the human body, we may conceive how particles of water foaking into it may have a mechanical effect of enlarging its bulk, and confequently of relaxing it. Water when warm may alfo contribute to relaxation by being the vehicle of heat, which is more intimately and conftantly applied to the body through its medium than that of air.

WATER is the most universal diluter possible of the animal fluids, fince with

the

#### On Emollient Topics.

the affiftance of heat, it may be united with almost all of them; confequently it is a powerful opposer of acrimony.

THE effects of oil in relaxing the folids are univerfally known and acknowledged. It feems to perform this office by abforption into the fubftance of the folid fibre. It is alfo capable of mixture with many of the fluids, on which it will act as a diluent and fheather of acrimony. Oil is not liable to evaporation or coagulation from a moderate heat; it is however fubject to a ranceffency and putrid acrimony from warmth and ftagnation.

MUCILAGE is lefs capable of abforption than the other two, and requires diffufion in a large portion of water to enter the pores and fmall veffels. It feems peculiarly adapted to cover acrimony in the fluids, by its remarkable fheathing or obtunding property.

As most of the fluids in the body contain a portion of oil and mucilage united by means of water, it seems probable that an artificial mixture of this kind, would be

#### PART I. On Emollient Topics.

be best calculated for answering every purpose of an emollient. In the proportions we should allow a larger share to water than to mucilage, that it may be well fitted for absorption. Its application should be affisted by a warmth fomewhat greater than that of the human body, and by gentle friction. An impure oil obtained from some animal substances by means of heat, fuch as neatsfoot oil, is a mixture of this kind, and is celebrated as a peculiarly excellent emollient. The fynovia of the joints is a liquor of this fort, prepared by nature as the best fitted for counteracting the injurious effects of violent friction.

I SHALL now confider the fecondary effects refulting from the primary action of emollients.

EMOLLIENT applications are

1. SEDATIVE. WE may suppose pain to be owing either to an excessive tension of the sensible fibres, or to a chemical acrimony corroding them. The following example will serve to illustrate both C 2 these

#### On Emollient Topics.

these causes of pain. If a puncture be made in a tense membranous part, a violent and continued pain will be produced, which must be owing to an unequal tenfion of the nerves, proceeding from a partial division; for compleating the divifion by a free incision will remove the pain.

But fuppofe this puncture be made by the bite of a viper or fome other venomous animal; here is not only the former caufe of pain, but a new one fuperadded, which is, the corrofive matter introduced; and the fame treatment will not give relief. Emollient topics, by relaxing the folids and oppofing acrimony in the fluids, are calculated to remove both thefe caufes of pain, and therefore are moft truly fedative.

THE relaxation occasioned by emollients is found not only to remove the painful tension of the parts to which they are immediately applied, but from the universal fympathy of the nerves throughout the body, to relieve pain in a distant and

#### PART I. On Emollient Topics.

and deep feated part. Thus we find that the warm bath is the most powerful fedative in nature.

UPON the fame principles, emollients have a claim to the title of

2. ANTISPASMODIC. SPASM and pain very frequently accompany each other, and proceed from the fame caufes. Whatever relaxes and appeafes irritation must prove truly antifpasmodic, not only to the part in contact with it, but to a distant one by sympathetic communication.

A CONTINUANCE of the relaxing power will cause emollients to prove

3. DEBILITATING. IN a natural flate of the fibres, there is that due degree of tenfion, which enables them to contract in fuch a manner as to act with the greateft poffible advantage. When they are lengthened by relaxation, it is obvious that the fame contractile force cannot produce equal effects; as part of the power will be loft, in bringing them firft to their natural degree of tenfion. All C 3 motion

#### On Emollient Topics.

motion therefore being produced by the contraction of muscular fibres, whatever impairs their contractile power, weakens the moving powers of the body.

THIS debilitating quality of emollients, when applied to a part overloaded by congefted fluids, will certainly render it lefs able to free itfelf by a valid contraction of the fibres; on the contrary, the veffels by relaxation will become capable of admitting a larger quantity of fluids, and confequently their determination to the part will be increafed. Further, the facility with which emollient liquors are abforbed and affimilated with the animal fluids will ftill augment their quantity.

FROM these confiderations it would feem quite erroneous to attribute a *discutient* power to emollients; at least in any other view than as they may render hardened and coagulated juices more fluid and fit for circulation : but this is only a preparatory action, and it will be still requisite to give the vessels that due tone and

#### PART I. On Emollient Topics.

and elasticity, which may enable them to get rid of their contents. It may indeed be alledged that warm emollients, by foftening the skin and opening its pores, will facilitate the exhalation of the contained fluids. But whoever will attend to the nature of oily and mucilaginous fubstances, must perceive that by entering the minute pores of the skin, and mouths of the exhalant tubes, they will rather tend to block up the accumulated fluids, than to promote their difcharge. And this is confirmed by experiment. Let an emollient poultice composed of a mucilaginous farina, oil, and an aqueous fluid, be applied to the unbroken skin over a tumour; in a few hours it will be found that instead of acquiring additional moifture, it will have loft most of what it had, by abforption.

FROM what has been faid it appears, that emollients have a much better claim to be confidered as

4. SUPPURATIVE. SUPPURATION is produced by a kind of diffolution and fer-

mentation

C 4

# On Emollient Topics.

mentation of the ruptured folids with the extravafated fluids. It is evident that whatever increafes the congestion of the latter, and weakens the texture of the former, must contribute to this effect; which will also be further promoted by emollients as they are

5. SEPTIC. THE heat employed in the use of emollient applications will tend to increase putrefaction, when there is otherwife a predifposition to it; and the accumulation of the fluids, and debilitation of the folids will frequently give this predifposition. The tendency of oily fubstances to acquire a rancidity and putrid acrimony has before been remarked : this is very apparent when they are mixed with the purulent discharge of an ulcer, and greatly tends to promote and increase putrefaction. Upon this principle it is that those caries of bones, where the medullary oil is affected, become fo peculiarly and intolerably fætid.

On a comparison between emollient and

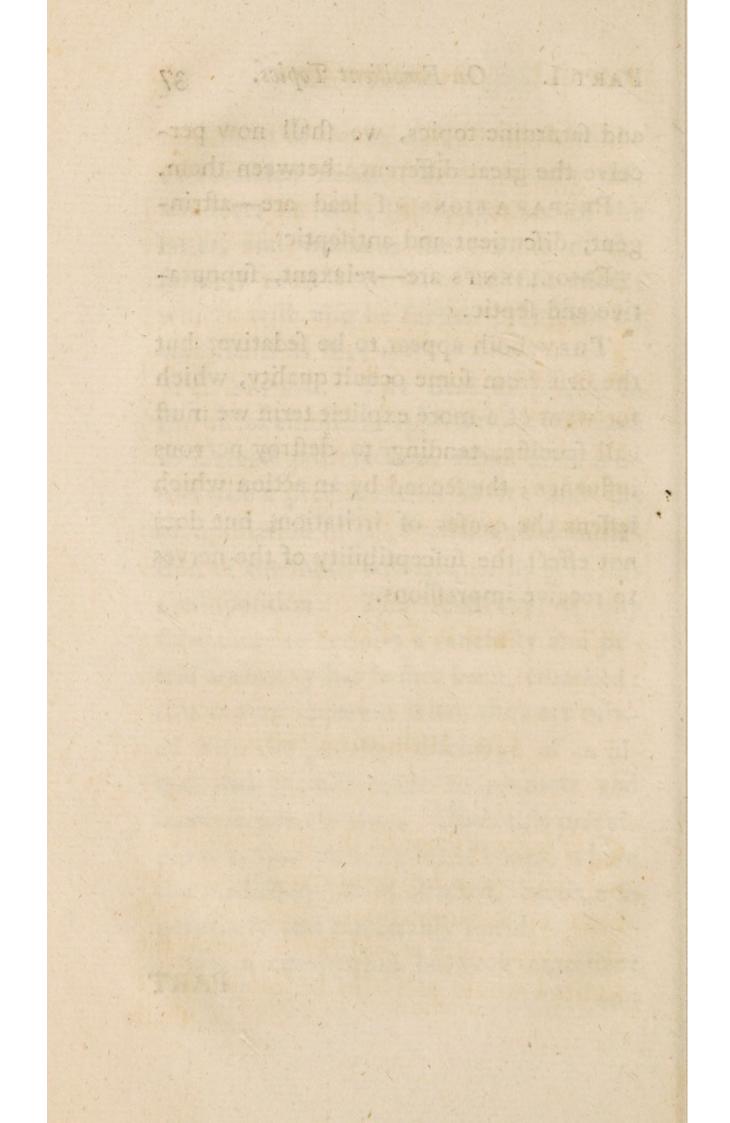

#### PART I. On Emollient Topics.

and faturnine topics, we shall now perceive the great difference between them.

PREPARATIONS of lead are-aftringent, discutient and antiseptic.

EMOLLIENTS are—relaxant, suppurative and septic.

THEY both appear to be fedative, but the first from some occult quality, which for want of a more explicit term we must call specific, tending to destroy nervous influence; the second by an action which less the causes of irritation, but does not effect the sufceptibility of the nerves to receive impressions.

## PART II.

I SHALL now proceed to confider fome of the particular diforders, in which faturnine topics are recommended by Mr. Goulard, and compare their effects with those of emollients, and other applications in common use.

#### SECTION I.

# On Inflammations.

So large a share of the practice of surgery may be comprized under the head of inflammations, that to treat the subject fully would much exceed the limits I would preferibe to this work. I shall

fhall therefore only endeavour to lay down fome general rules concerning topical applications in these cases; which may be done the more freely, as inflammations, from whatever cause they proceed, have such a general similarity with regard to their several symptoms, stages, and terminations, that any peculiar mode of treatment will apply more universally than might at first be imagined.

I SHALL not here pretend to enter into a theoretical difcuffion of the proximate caufe of inflammation : nothing has been more varioufly accounted for ; and in all probability it is intimately connected with those operations of the minutest parts of the body which we are at present, and perhaps shall ever remain ignorant of. A careful attention to the symptoms and appearances, will prove a much better direction to our practice, than the most fubtle hypothetical reasoning.

THE fymptoms of every inflammation, are, a painful tumour, with increased heat, redness, and sensibility.

THESE

THESE plainly shew, a congestion of fluids, a more frequent action of the moving powers, and a violent state of the nerves disposing them to communicate fensation in too great a degree.

INFLAMMATION must terminate, in refolution, suppuration, or gangrene. Schirrus is justly confidered by some late writers rather as a peculiar disease, than as a termination of inflammation.

I. RESOLUTION. AN inflammation is faid to be refolved, when the fymptoms go off gradually, and leave the part in the fame state in which it was before the disease took place. This is therefore the termination always to be preferred, unless the inflammation has been produced by morbific matter, which we chuse to discharge externally.

MR. Goulard very justly observes, that emollient topics are in great measure contrary to the indications that are to be fulfilled in resolving an inflammation. The tumour owing to accumulated fluids, must be increased by applications which add

add to their quantity, and at the fame time render the veffels more yielding to their impulse, and less able to carry them off.

THE increased action of the veffels, and fenfibility may feem indeed to require the fedative power of emollients; but as whatever augments the tumour must add a cause of pain and heat from the tension of the sensible parts, emollients will in this view counteract, their own effects.

SATURNINE topics, on the other hand, feem peculiarly calculated to anfwer every indication of a refolvable inflammation. The aftringent and fedative properties combined, tend to give a tone to the fibres, and make the veffels capable of emptying themfelves, and at the fame time to moderate the increafed motion and fenfation. From numerous inflances that have fallen under my own infpection, and from Mr. Goulard's multiplied obfervations, I make no queftion of the efficacy of faturnine above emollient topics

pics in procuring refolution; I have only fome doubts concerning the preference due to faturnine preparations, above the fimple aftringents and ftimulants in common use.

IT may be remembered that the specific fedative property in lead outwardly applied was supposed to act very superficially, principally from this argument, that no bad confequences to the nervous influence in general were ever observed to attend its use. Now if we imagine the pain and fenfibility of an inflammation to be subsequent to the formation of the tumour, and owing chiefly to the tenfion occasioned by a congestion of fluids, it will follow that the fedative virtue of faturnine topics in this cafe may be beft accounted for, merely from their aftringent quality; and confequently that other aftringents, and even ftimulants will likewife prove sedative. This opinion is rendered probable by the fuccefs attending aftringents and stimulants in the most painful inflammations, fuch as those attending

44

tending burns, in which even rectified fpirit of wine is often applied with relief.

THE fwelled tefticles frequently accompanying a gonorrhea will very well illustrate the effects of emollient, saturnine, and common aftringent and ftimulant topics. Thefe ufually come on very fuddenly, increase to a large bulk, and are extremely painful and fenfible to the touch. The prefent practice of applying an emollient poultice indifcriminately to every kind of inflammatory tumour, has given me, and (I fuppofe) almost every surgeon, frequent opportunities of obferving the effects of thefe topics : and I will venture to appeal to the experience of any practitioner, whether fuch a treatment does not always prove extremely tedious, painful and confining; and whether the cure is not generally incompleat, a confiderable hardnefs of the epidydymis remaining perhaps for life. Saturnine applications have been used in these cases with great success. I have feen the faturnine water made pretty ftrong,

ftrong, applied cold, and affifted by proper posture and-bandage, remove the tumour and pain in a short time, and duly continued, take away all hardnefs. Common aftringent and ftimulant applications have also been recommended, and I once had a striking instance of their efficacy. A perfon fuddenly attacked in the morning with a fwelled tefticle, was obliged on account of neceffary business to walk about all that day. I applied a folded handkerchief well foaked with rum to the part, retained by another tied round the body. This was wetted twice or thrice during the day, and at night I found, notwithstanding his exercise, that the bulk was greatly reduced, and the pain and fenfibility diminished. This application, with the addition of vinegar, was continued fome days longer, and the part perfectly recovered without any confinement to the patient. I have heard a justly celebrated professor advise the emollient method in these cases, and condemn the use even of camphor as too ftimu-D

46

ftimulating; but fuch a cafe as this, and many fimilar ones that are to be met with in practice, would prove, to me at leaft, a fufficient affurance against any ill confequences that might be apprehended theoretically from the use of this class of topics in inflammatory tumours; and I am well convinced that emollients are peculiarly ill calculated for the refolution of inflammations of lax glandular parts, while medicines pretty ftrongly ftimulant may be applied with great fafety and advantage. Where the part has not much fenfibility, as in fcrophulous tumours of the lymphatic glands, repeated experience has shown, that a blifter is the most efficacious of all topical remedies.

AMONGST those inflammations, of which art should be particularly folicitous to procure the resolution, are the erysipelatous. Mr. Goulard has, in an able and striking manner, shewn the abuse of emollients in this point of practice. The corroding inflammation spreading along the skin, will most certainly be increased by all

all relaxing topics; and the acrimony of the discharge, frequently tending to gangrene, will be aggravated by the feptic quality of oily and greafy application. These cases have indeed been long confidered by many as exceptions to the general use of emollients, on account of the particular dread of a suppuration; and thereby a ftrong though involuntary teftimony was given, that fuch topics were by no means to be depended upon to procure a refolution. The faturnine water by its mild aftringency, its fedative and antifeptic quality, feems peculiarly adapted to this difease; and I have been witness to its good effects. Yet, though there is no doubt of its power to cure an eryfipelatous inflammation, I would not mean to answer for the internal bad confequences which may fometimes proceed from its repellent quality. Where the eryfipelas is occasioned by external injury, and is not preceded by, or attended with diforder of the fystem in general, it is a mere local complaint, and no danger, I D-2 imagine,

48

imagine, can arife from repellent applications; but where it feems to be a critical effort of nature to throw off fomething pernicious, and fenfible relief is found from it, great caution may be neceffary in its external treatment. Faithful obfervation can alone determine, how far we may venture the ufe of faturnine topics, or others of a like nature, in this cafe.

2. SUPPURATION. THERE are various cafes in which the refolution of an inflammation cannot poffibly be effected. This may happen in the most fimple caufe of inflammation, external injury, which may be fo violent and attended with fuch destruction of the folids, that suppuration or mortification must be the confequence; but will more particularly be the cafe in fuch inflammatory tumours as are owing to the deposition of morbific matter, as those attending malignant and variolous fevers, the venereal lues, &c. In these cases the cause of the inflammation, existing in the fluids, cannot be removed without immediately correcting their

their peculiar aerimony, or giving them a discharge; and the first can very rarely be effected foon enough to ftop the progrefs of an inflammation.

49

IT may, I think, be laid down as a rule in practice, that, when from the nature of the cafe, refolution feems impracticable, we should use no endeavours to attempt it, but immediately employ fuch means, as are most likely to promote a fpeedy and favourable fuppuration. Refolution and suppuration are entirely different operations of nature. In the first, the folids are preferved entire, the fluids return to their usual course of circulation, and the inflamed part comes to its former state without fuffering any change. The indication here is obvioufly, to affift nature by fustaining the tone of the folids, and leffening the determination of fluids to the part. In suppuration, on the other hand, the folids are ruptured, the fluids are extravasated, and undergoing a fermentation with the broken fibres, procure themselves an evacuation by pushing outwardly D 3

wardly through the teguments. Here, the indications are, to dilute and foften the fluids, that the pus formed may be bland and free from irritation, and to relax the folids that they may yield kindly, and without violence. Now this is the very action of emollient topics; and I cannot discover upon what principles Mr. Goulard recommends faturnine applications in these cases, which do not seem to answer any one indication. In effect, nothing can have a greater fanction from practice, than the application of warm emollient fomentations and cataplaims in fuppurating tumours. The eafe and comfort they procure, and the favourable digestion and maturation of the pus, speak fo ftrongly in their favour, that no prevailing fashion in medicine will probably ever supersede their use. Indeed, if the plan of refolution be carried fo far as to attempt the discussion of tumours not only tending to suppurate, but containing pus actually formed, if it be found that faturnine topics will effect this, and that

that no bad confequences will enfae from fuch a practice; I would willingly join with Mr. Goulard in fparing my patients the pain of a wound, and the deformity of a fcar. But referring to my own experience of these remedies, and to the nature of the cafe itfelf, I am almost convinced that fuch an event would fo feldom happen, as by no means to authorife a change of common practice. Can it be conceived from what we know of the nature of inflammation, after a violent injury, a fevere symptomatic fever attended with pathognomic fhiverings, the fure figns of forming matter; when the folids are ruptured, and the fluids extravafated and changed in their nature, that all this mifchief can be repaired, and every thing brought into a natural state, by any external application whatever? I have no doubt that the proper means to effect a refolution, will frequently prove fuccefsful beyond what common practice has given us reason to expect; but the discussion of a confiderable and well matured suppuration D 4

ration, is a phœnomenon that requires a weighty attestation indeed to make it credible.

IN abceffes proceeding from morbific matter, practitioners in general would be averse to resolution, could it be obtained; and the remarkably good effects to the constitution often attending fuch critical depositions, justify their caution in this respect. Indeed where we can charge the fystem in general with a certain antidote to the virus, as in the cafe of venereal buboes, it may be worth while to fpare a delicate patient the pain of opening an abcefs; though even in this cafe I believe a prudent furgeon would rather wish he was allowed to promote the difcharge that nature has pointed out, than hazard the effects of morbid matter ranging at large through the fystem. It is too like letting the lion in at the door, in order to turn him out again. It is to be observed that most of the instances related by Mr. Goulard of the refolution of a maturated abcefs, are in cafes of venereal

nereal buboes; in all of which the use of mercurial frictions was subjoined. Now it is a fact well known, that these tumours will frequently disappear without any external application whatsoever, when the virus is overcome by the introduction of a sufficient quantity of mercury into the system.

WITH regard to large wounds, violent contusions, and other confiderable injuries, where there is no probability of bringing about a cure by the first intention as it is called, that is without fuppuration; it is I believe univerfally allowed by the best furgeons, that this operation of nature should be promoted, and not retarded. Emollients therefore feem plainly indicated, and are in general ufe. The fame may be faid of all artificial wounds made in furgical operations, in which a kind and speedy maturation is always confidered as the most favourable symptom. I do not therefore understand what Mr. Goulard would attempt by the use of saturnine water as a defensative after

ter the great operations; or upon what principles he would use it as a lotion for fresh wounds. Very contrary to this is the practice, fuccessfully followed in some of the London hofpitals, of applying a large emollient poultice immediately after amputations; and in my opinion much better calculated to prevent the access of a violent symptomatic fever. There seems to be a confiderable analogy between the application of aftringent topics, and tight bandage, in these cases. Both restrain the fibres from gradually yielding to the impulse of the fluids, and disturb the natural progress of that inflammatory tumefaction, which always precedes a kindly fuppuration. The one is now universally banished from practice, and the other, upon the fame principles, will not probably obtain admission.

3. WITH regard to the third termination of inflammation, gangrene or fphacelus, it is the bufinefs of art never to promote, but always to oppose this event; yet as it is fometimes inevitable, the

the furgeon will be required to limit its progrefs, and prevent its fatal confequences. In order to direct our practice in this point, a confideration of the caufe and particular state of the difease is neceffary; for the want of which an indifcriminate and empirical treatment has too much prevailed. Mr. Kirkland has contributed a good deal to establish this upon a proper footing, by pointing out the diftinction of gangrene from an internal, and from an external cause.

WHEN the violence of an external injury has totally deftroyed the organization of the living fibres, all the part thus affected may be confidered as dead flefh; and this ftate, to which the term mortification may be properly applied, is not confequent upon, but preceding inflammation. It is the fpreading gangrene which must be regarded as one of the terminations of inflammation; and this is produced by a putrefaction generated in the mortified flesh, and communicating its ferment to the furrounding part. The indications

PART

indications to prevent or limit the progress of a gangrene from this cause, are therefore feparation of the dead flesh, or checking the putrefactive fermentation in it. The first, if not performed by an operation, feems most likely to be effected by emollients; for the relaxation of the folids, brought on by their use, affifts the action of the uninjured fibres in pushing off the dead parts. Yet fince emollients have a tendency to promote putrefaction, their use may be prejudicial with regard to the other part of the indication, unless care is taken to ballance this effect by a proper mixture of antifeptics. Practice therefore has rightly introduced the application of warm poultices composed of farinaceous substances, and vinegar, ftrong beer grounds, and the like; and the cataplasm made with faturnine water appears very well calculated for this purpose. These applications will be found much preferable to spirituous and aftringent fomentations; which by hardening and contracting the fibres, tend to increase the

the inflammation of the furrounding parts, and counteract the operation of nature in throwing off the mortified flesh. But when a fpreading gangrene comes on from an internal cause, a different topical treatment will be requifite; though indeed very little is to be expected from external remedies of any kind. These usually happen in dropfical and leucophlegmatic habits, or in extreme old age, and fhow a debility and want of power in the folids to carry on the animal functions. In fuch cafes the difease can hardly be confidered as topical, and feparation of the affected part cannot be procured without giving a general vigour to the vital powers. As the fibres are already too much relaxed, emollients of every kind are certainly to be avoided, and the warmest ftimulants and most powerful antifeptics are indicated. Much more effectual and fuitable applications than faturnine topics may be thought of for this purpose ; fuch particularly as spirituous and terebinthinate

ACOCIDE A

#### On Inflammations.

nate medicines, and all the natural vegetable balfams.

IT may be proper here to add a word or two concerning fchirri, which, as we before observed, cannot indeed be confidered as one of the terminations of inflammation, yet are a good deal connected with it. I wish it was in my power to fecond the fanguine hopes Mr. Goulard conceives of faturnine topics in thefe cafes; but neither reasoning nor experience feem to confirm them. With refpect to the diffolvent power of lead, on which he relies fo much, what has been faid in a former chapter concerning its penetrability will ferve, if justly founded, to lessen our expectations from this supposed quality. And if schirri generally depend upon fomething conftitutional, as I believe may be fafely afferted, there will be still lefs reafon to hope for a cure from external remedies. I have frequently feen Mr. Goulard's topics tried in these cases, but never with any striking efficacy; and if a remarkable cure should sometimes happen

58

#### PART II. On Inflammations.

happen from their ufe, it would feem to me more rational, to attribute it, either to the friction employed in rubbing in the foap ointment, or to fome tonic power communicated fympathetically to the fibres of the affected part, from the outward application of an aftringent, than to any fpecific property in the particles of lead.

no stillinger from art. All shat bandling on

contrainely well, "I ney gently forcen the

60

### SECTION II.

#### On Ulcers.

A N inflammation, terminating in fuppuration or gangrene, produces an ulcer.

WHEN the inflammation has been owing to external injury in a found flate of the body, the healing of an ulcer is merely a work of nature, and requires little or no affiftance from art. All that is to be attempted by topical applications, is to maintain the fibres in fuch a moderate flate between laxity and rigidity, as will render them moft able to carry on this natural operation. As long as the inflammatory hardnefs fubfifts, emollients, particularly in form of cataplafm, anfwer extremely well. They gently foften the folids, and produce a mild fuppuration, free

#### PART II.

#### On Ulcers.

free from a putrefactive tendency. Afterwards, dry-lint, and moderate aftringents will be advifeable, to give a tone to the new flefh; and the faturnine water may be ufefully applied for this purpofe. A prudent ufe of thefe means, with great cleanlinefs, and cautioufly avoiding every caufe of putrefaction, will in general render this part of furgery eafy and fuccefsful. But the great difficulties attending the treatment of ulcers, arife from their connection with general difeafes of the fyftem; and to this is owing their many different appearances and complicated fymptoms.

WE may remark concerning fuch ulcers in general, that little dependance is to be had on external remedies alone of any kind. The particular vice of the habit must be first corrected by fuitable internal medicines, before any important change can be effected by topical applications. Nevertheles, as external treatment will very much influence the cure of ulcers, according as it is appropriated to

E

PART II.

their particular state, it will be worth while to enquire into the principles upon which it is founded.

THE circumftances to be attended to in the appearance of ulcers, are, the ftate of the furrounding flesh, and the condition of the discharge.

THE most common fault of the lips or margin of an ulcer is callofity. This in a particular manner attends some kinds of ulcers from an internal cause, as the venereal and cancerous. Those ulcers of the legs also which have been much neglected, though at first proceeding from an external cause, as well as those which come fpontaneoufly in a depraved habit of body, are extremely fubject to callofity. In fuch cafes, the hardness of the fibres prevents that shooting out, and elongation of the vafcular parts, which is neceffary to the production of new flefh. It has long been a common practice to treat all callofities with escharotic medicines ; but this method has been justly exploded by fome of our best late writers, as tend-

62

12min

ing

#### On Ulcers.

ing to increase the difease by the continual inflammation it excites, and to render the vessels still more impervious and incapable of acting.

WELL chosen emollients affisted by gentle warmth, feem the best calculated to answer every indication of a callous ulcer. Without bringing on any deftruction of the folids, they produce fuch a gradual change in their texture, as brings them to that due flate of tenfion which is the most favourable for their action; and by enlarging the diameter of the veffels, they give admiffion to the nutritious juices neceffary for the generation of new flesh. This effect of emollients is plainly demonstrated from the luxuriant fungus brought on by their use, which though it frequently requires suppression in order to bring the skin over it, yet in some degree or other is a neceffary fymptom in a healing ulcer. By the use of a fimple poultice, and a reclined posture strictly obferved, I have often feen the most unpromifing and formidable ulcers of the legs E 2

#### On Ulcers.

legs heal kindly, with very little affiftance from internal medicines. I have observed with great pleafure the opaque callous edges gradually foften and change colour, and beautiful ramifications of the arteries appear fpreading through them, giving an evident proof to the fenfes of the natural progrefs of healing, and the propriety of emollient applications to affift it. This will feem extremely difficult to reconcile with Mr. Goulard's idea of the efficacy of faturnine topics in these cases; with regard to which he goes fo far as to alledge that they are as fpecific in the cure of callous ulcers, as mercury for the venereal lues. He grounds this affertion upon the fuppofition of a remarkable diffolvent power in lead, which however I have not been able either theoretically or practically to discover; and if his observations fuffice to prove great fuccefs in the treatment of ulcers of this kind, I would attribute it to the application of his topics in form of cataplasm, in which, from the warmth and quantity of aqueous fluid,

#### PART II.

#### On Ulcers.

fluid, a confiderable emollient power will probably refide. Confidered as mere aftringents, I think we may very fafely affert that they cannot be favourable to the diffolution of callofity.

A FAULT entirely opposite to callofity, is a flabby, fpongy texture of the flesh furrounding an ulcer. This frequently happens in languid, relaxed constitutions, and is almost the inseperable attendant of fcrophulous ulcers. In this cafe the natural operation of incarning goes on very flowly, and the ulcer remains for a long time in the fame state. The manifest indication here is to stimulate and brace the infenfible and inactive fibres, and emollients are as improper, as they are fuitable in the former cafe. Aftringents and ftimulants of almost every kind will fupply their place with advantage, and among the rest saturnine topics in the form of the faturnine water, or the pure extract, may be usefully applied. Yet in many cafes remedies that have a stimulant

#### On Ulcers.

PART II.

lant as well as aftringent property will fucceed better.

THE discharge from an ulcer may be faulty in feveral respects; but as most of these are consequent upon diseases of the folids, and will of courfe be remedied in proportion as they are, we cannot properly have an eye to them in topical applications. We have only to confider the action of topics upon the fluids already discharged, and stagnating on the surface of an ulcer, and in this view the correction of acrimony feems to be our fole object. Acrimonious matter may be produced in two ways; either from good pus running into putrefaction, or from an internal disease in the fluids, which gives them an acrimony when first discharged.

As every animal juice, ftagnating and exposed to a confiderable warmth and the contact of the air, is ftrongly inclined to become putrid, we fhould be particularly careful to correct this disposition in the dreffings of an ulcer. I have formerly remarked the propensity of oily subftances

66

#### On Ulcers. PART II.

ftances to contract a putrid rancescency, and to increase the putrefaction of the animal fluids. Practitioners in many cafes have been fenfible of this, yet in others they feem to have forgot it. The use of oily applications in caries, that is ulcers, of the bones has long been condemned; and in eryfipelatous inflammations their bad effects have been juftly dreaded. Yet in various cafes where the putrid disposition is equally strong, they are still in daily use. Where emollients are indicated, warm farinaceous poultices offer an innocent and a more efficaceous form; and from attentive observation I am convinced, that if the application of oily and greafy dreffings to the naked flesh of an ulcer was in every case totally prohibited, furgery would gain much more than it would lofe. In general, foft dry lint changed fufficiently often will prevent any mischief from stagnation; yet if there be a peculiarly ftrong tendency to putrefaction, as in carious ulcers, antiseptics are certainly indicated, E4 and

67

#### On Ulcers.

PART II.

and the faturnine water of Mr. Goulard is a very useful medicine of this class. As the corrofive acrimony of the difcharge frequently excites great pain, the fedative quality of faturnine topics will make them more fuitable than the ftimulant antifeptics or common aftringents.

ULCERS which have a peculiar acrimony in their difcharge, are principally those from the venereal and cancerous virus.

For the first of these, we are furnished with a real antidote in mercury, and accordingly mercurial preparations topically applied have the fanction of practice in these cases. Yet as the general use of mercury is always combined, and our great dependance is upon this alone, I am inclined to think that the usual indications for suitable topics ought to take place of the specific indication for mercury. Indeed mercurial preparations are for various, that suitable topics may be chosen from them in almost every state of a venereal user, but if there was rea-form.

PART II.

#### On Ulcers.

fon to think in any cafe that different applications would fuit the ftate of the ulcer better, I fhould not hefitate to give them the preference. And as the faline preparations of mercury are ftimulant, whereas those of lead are fedative, perhaps the latter may be more advantageoufly employed in irritable habits, and where the ulcer is attended with much pain.

CANCEROUS ulcers are the most melancholy of all the difeafes to which the furgeon is called. Neither art nor nature can ftop their dreadful ravages, and a man of humanity finds himfelf in the painful fituation of being a witnefs to afflictions which he knows are not to be removed. Still however fomething may be done to palliate and alleviate. External applications in these cases should be calculated to correct the acrimony of the discharge, and to mitigate the acute pains in the part; or rather only the former, fince the fole cause of pain perhaps which topical remedies can relieve, is the corrofive

#### On Ulcers.

rofive matter preying upon the naked fibres.

THE usual dreffings for a cancer, are the most mild and simple ointments; and indeed if oily fubstances feemed to poffefs a property of fheathing the cancerous venom, like that of a viper, their application would be proper. But practice fhows us nothing of this; and as a high putrid tendency accompanies the difcharge, which according to what has been before observed should be increased by every thing oily, I imagine the indication for antiseptics is more important. Of these, the faturnine water, made very dilute and with little or no fpirit, feems extremely well calculated for the purpose, and its fedative property may give an additional advantage.

MR. Goulard indeed has very fanguine expectations from faturnine topics, not only for the palliation, but the radical cure of cancers. I have before endeavoured to fhow how little adequate thefe applications are to the refolution of a fchirrus;

70

PART II.

#### On Ulcers.

fchirrus; and these arguments will weigh fill more against their efficacy in cancers, which are confeffedly in great measure constitutional. The very few observations related of the cure of cancers by this method, are fo extremely equivocal, that only one of them deferves much attention, and it is prefumed, after fuch repeated and unexpected difappointments in this particular difease, the public will expect much ftronger proofs before they give credit to the efficacy of any new remedy. At prefent I cannot express my fentiments on this head, fo well as in the words of that very candid and judicious furgeon Mr. Pott, by whole free and unprejudiced spirit the art has been so much benefited. "As I do not know what " will cure a cancer, I leave the difcuffi-" on of this to those who fay that they do; " most fincerely wishing that it was in " my power to fay, that I had, once in " my life, known them to have fulfilled " their promise."

IF a cure for cancers be ever discover-

ed,

#### Qn Ulcers.

ed, we have reafon to think that it will not be in a topical remedy; for how can any external application do more in removing the cancerous virus, than an operation which at once takes away all the affected part? Yet we fee that even this is very rarely attended with lafting fuccefs.

WITH regard to fcrophulous ulcers, I can fpeak of their treatment with the full confidence of a very extensive experience. This has convinced me, that emollient applications of all forts are highly improper and injurious. By weakening the folids already too much difpofed to relaxation, they prevent all endeavours of nature to bring about a firm incarnation; and by giving the fluids an acrimony, to which in this difeafe they are not remarkably difpofed, they occafion a kind of eryfipelatous corrofive fpreading of the fore, which often makes a cafe, at first trifling, appear truly formidable. The mischiefs of this practice are still more clearly shown, by the speedy change produced

#### PART II.

#### On Ulcers.

duced by almost every kind of topics of the opposite classes, the aftringent and stimulant. The most simple of these, cold water, has frequently a very good effect, on throwing afide every dreffing and washing the fores with it. The Malvern waters in Worcestershire, much celebrated in scrophulous cases, are acknowledged to act externally and internally, merely as a very pure cold water. Water with every kind of faline and mineral impregnation, is also used to advantage, and in particular sea water has been found very beneficial. I have feen Mr. Goulard's faturnine water employed in a very great number of these cases, and with a manifest advantage over all emollient topics, but without any peculiar efficacy above others of the aftringent and antifeptic class. With regard to the faturnine ointments of Mr. Goulard and others, I conceive their good effects, as preparations of lead, to be over ballanced by their injurious effects, as greafy applications, in all cafes where emollients are prejudicial.

ted in forophulous cafes, are acimo

7 ARIOUS are the causes which may destroy or impair the mobility of a joint. One of these, the coalition of the opposite bones by offeous matter, is justly reckoned among those difeases which in their nature are abfolutely incurable; and in most of the others, the operation of remedies is extremely precarious and uncertain, on account of the difficulty of coming at the feat of the diforder. Neither in many cafes are we clear with refpect to the part affected; and there are few difeafes in which we have been more amufed with hypotheses concerning the cause, founded merely upon conjecture. Of this kind feems to be the notion of inspissation of the synovia, which some of the

#### On Anchylofes.

the beft anatomifts in our times confider merely as the Iuppolition of profefied theorifts willing to account for every thing, without the fupport of any authentic obfervations. Yet it is upon the imginary diffolvent power of faturnine topics in this fuppofed caufe of anchylofis, that Mr. Goulard's application of them in thefe cafes appears to be founded.

THE most fimple case of a stiff joint, is that which is confequent upon long continued confinement of a limb in one posture, as frequently happens in the treatment of a fracture. The vulgar expreffion to describe this difease, is that the joint is finew-grown; and it is not the only inftance where illiterate perfons, judging merely from external appearance, have decided better than those who have carried their refearches deeper. The evident rigidity of the tendons in these cases, justifies the idea of their being the feat of the difease; whereas the notion of inspissation of the synovia does not seem confonant to what we conceive of the ufe 61 and

#### On Anchylofes.

76

and nature of this fluid. Its use is supposed to be counteracting the effects of violent friction, and for this purpose its fecretion must be proportional to the motion of the joint, and influenced by it. Therefore when the joint is perfectly at rest, in all probability little or none of the liquor is generated. Neither does the fynovia appear to be a fluid very fusceptible of coagulation or inspissation from stagnating, much less fo than the semen, which yet is never found inspissated much beyond the usual degree, though stagnating ever so long in the seminal vesicles.

A STIFF joint is frequently the confequence of external injury, as a violent contufion. Here there can be no pretence to accufe the fynovial liquor, as the fuddennefs of the complaint, and fenfibility of the joint, plainly flow the caufe to be an inflammatory affection of the ligaments. Arthritic, and rheumatic humours falling upon the joints, and impairing their mobility, feem likewife to affect the ligaments, from their tendency

to

#### PART II. On Anchylofes.

to attack other ligamentous and membranous parts, and from the painful tumefaction they excite.

BUT the most frequent and dangerous fpecies of anchylofis is that melancholy difease called a white swelling, which I believe is always owing to the fcrophulous virus. I have diffected many of these joints after amputation, but have never found the least appearance of an inspissated fynovia, gluing, as it were, the ends of the bones together. In all of them there was a great thickening of the ligaments, confounding the feveral parts, fo that they could fcarely be known; together with collections of crude matter forming finuffes through this undiffinguished mass, and generally erofion of the articular cartilages and ends of the bones.

WHERE a stiff joint proceeds merely from rigidity of the tendons, nothing can be more evident than the indication for emollient topics. Every remedy of this class may be usefully employed; but unctuous liniments affisted by warmth and F

77

#### On Anchylofes.

78

friction feem the best adapted, and the mucilaginous oil obtained from certain animal substances, called neats-foot oil, appears to succeed as well as any artificial combinations that can be contrived.

WHERE an inflammatory state of the ligaments feems to occasion immobility of the joint, it should be treated with remedies proper for the refolution of inflammation in a deep feated part; which I have before attempted to flow are rather those of the astringent and stimulant, than the emollient class. The antiphlogiftic power of faturnine preparations may give them place in these cases, but perhaps more active medicines are generally requifite to reach the caufe. Blifters, which have the fanction of experience in deep feated inflammations beyond any topics we are acquainted with, have been frequently employed with fuccess in recent anchylofes; and in all probability their action was the discussion of inflammation in the ligaments. This is an event we are with the utmost affiduity to promote,

### PART II. On Anchylofes.

promote, fince the dreadful confequences of fuppuration in a joint are known to every furgeon. We must therefore condemn as dangerous trifling, the use of any means less powerful than others we are acquainted with.

WHEN the cafe is become more inveterate, and the rigidity of the joint habitual, we shall find ourselves much at a loss for remedies which we can depend upon. There are a few instances of a cure being affected by means of a stream of warm water falling on the joint from a height. This application the French call *la douche*, and it is much more in use there than in this country.

MR. Le Dran's Observations in Surgery, afford two remarkable cases of its efficacy (Obs. 93 and 94) to which is subjoined, a theoretical exposition of its action; but like most attempts to account for the operation of medicines, it is rather specious than satisfactory. In all the instances Mr. Goulard brings of the success attending saturnine applications in F 2 anchy-

#### On Anchylofes.

anchylofes, we find the chief remedy was a *douche* of the faturnine water; and I think we may very fafely infer that this produced its effect, merely as warm water applied in a peculiar mode, and not as a preparation of lead. I am ftill further convinced that his obfervations prove no fpecific power in lead against this difease; fince the only faturnine preparation which he used in concert with the *douche* was the ointment with foap, which, as was before observed, can fcarcely contain a particle of lead in an active state.

WITH regard to fcrophulous affections of the joints, they are as defperate cafes as any in the whole practice of furgery. Even from the very beginning they feem to refift every remedy, and though topics of every clafs have had their trial, all have proved entirely inadequate to the defired effect. I am forry to fay, from an extensive observation of this difease, that when it was arrived to any considerable height, I have never seen topical applications of any manifest fervice whatever. I have

#### PART II. On Anchylofes.

I have been witnefs to the use of Mr. Goulard's medicines in these cases, much more than he himfelf appears to have been; and the utmost I can fay in their favour is, that when the joint has ulcerated externally, their antifeptic power renders them as good palliatives as any we can use, and much preferable to emollients. But till fome general remedy be discovered for the scrophulous virus, we must, I fear, despair of expelling it from a joint which it has once attacked; and amputation, though justly proferibed by fame late writers in many cafes of external injury, will keep its place in this difeafe, as the only certain palliative, and very frequently the radical cure.

WITH regard to ftrains, and relaxation of the ligaments, there feems to be no doubt of the preference due to aftringents of any kind above emollients, which are certainly opposite to every indication of cure. However the common application of vinegar and brandy, uniting a ftimulant with an aftringent property, ap-F 3 pears

#### On Anchylofes.

pears to rank higher in efficacy than a fimple aftringent.

ONE can fcarcely forbear fmiling, to fee incomplete luxations put among those diforders which faturnine topics are expected to cure—certainly Mr. Goulard can only mean to recommend their antiphlogistic virtue, in the contustion and inflammation attending this accident.

SEC-

PART II. On the Herpes and Itch. 83

## SECTION IV.

## On the Herpes and Itch.

HE idea of an intimate connexion between cutaneous eruptions, and internal depravation of the fluids, is of very antient date among the articles of medical belief, and it appears to be one of those opinions, which, from a fort of implicit affent and veneration, have hitherto escaped that free examination, which it is the peculiar glory of the prefent age, to apply indifcriminately, without regard to the perfonal authority with which any dogma is delivered. It would be an undertaking highly useful to the healing art, and well worthy the employment of a man of abilities, to profecute a strict and extensive enquiry into the nature of these diseases, and how far,

#### On the Herpes and Itch.

84

and with what limitation the principle of internal depravation may be admitted. I am fenfible of my own inequality to the tafk, which would require great experirience and minute inveftigation; yet I will venture to offer a few remarks, which may tend to fhew that there are in fact fome errors in the common doctrines on this fubject.

THERE is no flate of the human body in which the fluids can be conceived fo pure and free from morbid impregnations, as that of an infant just born; yet as far as my acquaintance with medical authors reaches, I find that they univerfally impute the red eruption constantly attending this state to an internal cause; and though experience has convinced practitioners that the cuftom of purging is unneceffary, yet the notion of the caufe remains the fame. But may not this appearance be much more fimply and probably accounted for, by confidering the great change of climate and atmosphere, that the tender skin undergoes at this time,

## PART II. On the Herpes and Itch. 85

time, from maceration in a liquor of the animal heat, to exposure in air perhaps not half as warm ?--- a change even in the adult body, capable of producing very visible effects on the skin. A peculiar disposition to cutaneous eruptions continues during childhood, which feems evidently connected with this tender state of the skin, rendering it more liable to irritation from external acrimony. This is exemplified by the difagreeable eruptions behind the ears, and fpreading over the whole scalp, which are so frequent in children, and which, though in fome cafes perhaps connected with particular habits of body, yet in all may be certainly produced by want of care and cleanlinefs, and therefore are not in general to be looked upon as conducive to health, or dangerous to be cured. There are various other eruptions which in like manner are the offspring of filth and neglect; and in general, cutaneous diseases are most prevalent in those countries, and amongst that rank of people, where

## 86 On the Herpes and Itch.

where these occasional causes most take place.

IF we form our distinctions of cutaneous eruptions from varieties in their appearance, a great number of classes may be made, fince the appearance is not exactly fimilar in any two patients; but in a practical view numerous distinctions are unneceffary and fuperfluous, and almost the only circumstance which requires attention is, whether the difeafe be merely local, or connected with internal depravation of the fluids. The fame class of topics will apply almost univerfally for the cure of local cutaneous eruptions, and are as univerfally to be avoided when the eruption is beneficial by the discharge of morbific matter.

THE cure of *herpes* by aftringent and ftimulant topics has long been familiar to practitioners, and a great latitude has been allowed in the choice. There is no reafon to doubt of the efficacy of faturnine applications in this cafe; they have been celebrated both in antient and modern

#### PART II. On the Herpes and Itch. 87

modern practice in this and every other species of cutaneous eruptions; Mr. Goulard's observations amply confirm their use, and I can freely add my testimony. So far we may fafely join him; but when we find him making a formal diffinction of herpes into local, and connected with internal depravation, when he ftrongly condemns the use of aftringents in the latter on account of their repellent quality, but as highly extols faturnine topics, inventing an artificial theory of their action, repugnant to their obvious and fenfible effects, we cannot in too ftrong terms disapprove of a hypothefis that may become as dangerous as it is chimerical. If it be urged that his facts in reality prove the fafety and efficacy of these topics in every kind of herpes, let us boldly make the more rational deduction, that this diforder is in all cafes merely local, and that all aftringents and repellents may be used with equal fafety.

THE

#### On the Herpes and Itch.

THE efficacy of faturnine topics in curing the itch, is much extolled by Mr. Goulard, and feems well confirmed by numerous observations. I have before taken notice of his apparent ignorance of the doctrine of animalculæ caufing this disease, which yet is a circumstance of moment with regard to its treatment. Various topics have from time to time been employed in the cure of the itch, particularly those of the ftimulant and astringent classes, both from the vegetable and mineral kingdom, but principally the latter. In all of these, except fulphur, it has been found neceffary to apply the remedy topically to every affected part; even mercury will fcarcely cure unless this rule be observed, as instances are related of perfons passing through a falivation for the venereal lues, without obtaining a cure of the itch. Sulphur however proves effectual, when only rubbed into a fmall furface of the skin, as the palms of the hands and foles of the feet, and therefore may be confidered

88

#### PART II. On the Herpes and Itch. 89

dered as a specific for this disease. This is also a confirmation of the doctrine of animalculæ, fince the deleterious effects of fulphureous vapours upon all animals is well known, whereas its efficacy, as an internal medicine, is by no means confiderable. Upon this principle, bleeding, purging, and alteratives, have been very much rejected from the cure of the itch in this country, and dependance has been folely had on the external use of fulphur. The certainty of this remedy above mercury and all the common topical applications, is established beyond difpute, and in the prefent improved method of partial frictions, it is not very liable to the objections of an ill fmell, and uncleanlinefs. It feems therefore very questionable whether it would be a real improvement in practice to reject sulphur in favour of lead, which feems in this cafe to act merely like other topics of the fame class, and requires, like them, a general application to the affected skin. We may easily conceive

#### 90 On the Herpes and Itch.

of circumstances in which it will be inconvenient, and even dangerous to apply an aftringent wash to so large a surface, whereby perspiration may be checked, and other accompanying eruptions, which it would perhaps be unsafe to repel, may be struck in. In military hospitals particularly, it may often be necessary to treat a person for the itch, while under a mercurial course, a case in which there would be no doubt of the impropriety of the faturnine water.

## SECTION V.

the diferte much at full be se

## On Herniæ.

**T**OPICAL applications of very different, and even oppofite qualities, are recommended by authors to affift the reduction of herniæ; but in order to diftinguish practice founded upon rational principles, from that which is merely empirical, it will be neceffary to confider the nature of the disease, and the state of the parts concerned.

In confequence of fome fudden effort, part of the contents of the abdomen are forced through the interffices left between the tendinous expansions of the abdominal muscles, for the passage of nerves and blood vessels, and a tumour is formed which is called a hernia. This accident being unattended with rupture,

or division of the containing parts, the whole of the difeafe must at first be confidered as a change of fituation in the contained parts; and as fuch, were they immediately returned and kept in their place, the difease would entirely cease. But continuing in that preternatural fituation, they are prefied upon by the tendons through which they pass, and the circulation of blood being obstructed, inflammation and mortification fpeedily fupervene; which however is not owing to any change of state in the tendons, but merely to their natural elasticity, acting upon an increased and yielding subjacent bulk. The obstacle to reduction of the prelapsed contents, is therefore the increafed bulk which they have acquired from stricture, making them incapable of returning through the fame paffage at which they escaped. This is to be removed by fuch remedies as caufe the veffels to contract, thereby diminishing the bulk of the folids, and repelling the fluids, and not by fuch as expand the folids, and

and make them more yielding to the impulse of the fluids. The former action belongs to cold, aftringents, and ftimulants; the latter to heat, and emollients. We are not to apply these last with a view of relaxing the tendons, fince they have only their natural degree of tenfion, which can be very little altered by external applications of any kind. I have read a cafe (in what author I do not at present recollect) which will ferve extremely well to illustrate this idea of herniæ. A boy having thrust his penis through the ring of a key, it immediately fwelled in fuch a manner, that he could not get it off again, and alarming fymptoms foon came on. The cure was performed by dipping the part in cold water, and certainly no body in this cafe would think of applying a warm poultice to relax the iron ring. It appears to me that not lefs abfurd is the application of emollients to relax the tendinous ring in a hernia; and it is to be observed that this treatment, if ineffectual for the purpofe

## On Herniæ.

pose designed, must do great mischief with regard to the indication respecting the hernial contents. Not only from this ftrain of reasoning, but from experience I would heartily join with Mr. Goulard in the fubstitution of cold aftringents to warm emollients, as topical remedies for herniæ; and I have feen in particular his faturnine water eminently useful in affisting reduction. Still greater confidence however would I place in the very gradual method of the taxis which he judicioufly recommends. It is furprizing what may be done towards emptying overloaded veffels by a gentle and continued manual compression; and I cannot forbear relating an inftance in which this effect is very happily demonstrated.

FREQUENTLY in children, and fometimes in adults, the prepuce, by friction, or fome other external injury, becomes vaftly tumified, and producing a ftricture where the fkin is attached to the root of the glans, occasions a troublefome and alarming paraphimofis. Among feveral useful

#### On Herniæ.

useful lesions, in points of practice where books give little affistance, which I learnt under Mr. White of Manchester, was a very fimple and fuccefsful method of treating this accident by a gradual, patient, and gentle compression of the tumefied skin with the fingers, affisted with fmall bolfters of foft linen, which, as the tumour is rather of the ferous and ædematous, than of the phlegmonous kind, may be fo managed as to give little pain. On continuing these efforts for fome time, the veffels become vifibly lefs diftended, the fwelling grows flaccid, and at length the stricture gives way, and the diforder is terminated. A fimilar method is to be observed in those prolapsus ani, which from their bulk are not eafily reduced, and become strangulated. In all these cases it is egregious trifling to wait for the effect of topical applications, which can only perform in a very inconfiderable degree, what manual operation does compleatly.

G 2

SEC-

On the Action of Bougies.

.96

## SECTION VI.

## On the Action of Bougies.

THE causes affigned to obstructions in the urethra are fo various, and fo little certainty has been obtained with regard to them, even from anatomical enquiries, that we need not wonder at the variety of opinions concerning the action of remedies in removing them. The remarkable efficacy of bougies is acknowledged on all hands, yet much obscurity prevails concerning their mode of action, and confequently the most fuitable forms of their composition. Mr. Daran, who has probably made a more extensive and successful use of these remedies than any man in Europe, has rather involved the matter in greater obfcurity, than thrown any new light upon it, by

## PART II. On the Action of Bougies. 97

by keeping his composition fecret; rather chufing to acquire wealth under the unworthy character of an empiric, than just reputation in his profession under that of a candid and ingenious furgeon. He has however published his opinion of the mode of action of his bougies, in which he chiefly attributes to them a suppurative quality. Mr. Goulard on the other hand, who has extended the use of preparations of lead to the composition of bougies, conceives the action of his faturnine bougies to be that diffolvent and discutient power, which in every instance he fo warmly arrogates to his favourite metal. Mr. Sharp, who has written with great candour and judgment on this subject, seems cautious of advancing any thing politively concerning the action of bougies, yet rather inclines to the idea of their acting by compression, and in some measure also by suppuration. The compositions which he gives for bougies, and those in common practice among us, are chiefly mercurial, which doubtlefs

were

## 98 On the Action of Bougies.

were first thought of on account of the venereal affection, of which difeases of the urethra are so frequently the offspring. In order to estimate properly the validity of these different opinions, let us attend to the following facts.

MR. Daran pretends to a fpecific action in his fecret, very different from, and fuperior to that of any other kind of bougies.

MR. Goulard, without attempting the leaft proof that his faturnine bougies are fimilar to Daran's, feems willing to allow the exclusive excellence of these, only ftipulating for an exception in favour of his own.

MR. Sharp clearly fhows, and daily practice in this country evinces, that bougies of various forts are fuccefsful, and nearly equally fo, if ufed with equal manual fkill; infomuch that it is common for our beft furgeons to commit the care of making them to the inftrument-makers, being little folicitous concerning the ingredi-

# PART II. On the Action of Bougies. 99 gredients, if they be exact in form and texture.

FROM hence we may infer, that fince bougies of very different compositions fucceed in the cure of diforders in the urethra, they do not act by means of any peculiar qualities in their composition, but by means of some property common to all.

THIS must be their mechanical form and texture; and therefore their mode of action must probably be, fimple compression.

THE efficacy of mere compression in many cases of constriction is well known, as in the use of sponge tents to open a callous sinus, to widen a natural passage, as the rectum or vagina, when streightened by cicatrifes. Now admitting the most probable causes of obstructions in the urethra to be a constriction from cicatrized ulcers, and projection of the spongy substance of the urethra into the canal (which among the various opinions on this subject seem in fact the best authenti-

## 100 On the Action of Bougies.

thenticated) we may eafily conceive that a gentle, continued, elastic compression will in time overcome the difeafe. We may readily account for the inferior efficacy of metallic or whalebone bougies, from their not having the property of fwelling with moifture, and therefore not making fo equal a compression. With regard to the effect of bougies in procuring a discharge of matter, there is no question but the mechanical stimulus of a foreign body in fuch a tender part, though free from difease, must produce it in fome degree, and that this will be varied according to the chemically irritating quality of the composition, and the irritable state of the urethra; but it feems an abfurdity of practice to apply a topic made uniform throughout, to the whole length of a canal, with a view of producing extraordinary effects upon a particular part of it, by means of fome powerful quality in the ingredients. It is not difficult to account for the appearance, observed in the use of bougies, of that part

### PART II. On the Action of Bougies. 101

part being more covered with matter which was in contact with the difeafed portion, fince the difeafe will probably render it more fusceptible of irritation.

ON the whole we may allow Mr. Goulard to rival Daran in his bougies, without fubfcribing to the violent degree of felf approbation he affumes from it; and I fee no reafon for fuppofing either the fecret of the one, or the fpecific of the other, at all preferable to the candid and unaffuming varieties of compofition propofed by Mr. Sharp, and admitted in common practice.

rendered it very obvious what indemen

caules, or the darts occupied by them.

ubei onit hue tenoitkaimant ophilt eit

# CONCLUSION.

TE have now gone through an examination of the properties of faturnine topics, both in a general view, and in many particular cafes in which their virtues are celebrated by Mr. Goulard. In looking over his catalogue however, the reader will find feveral which I have totally omitted. My reafons were, either that the fimilarity of these cases with others before treated of rendered it very obvious what judgment to form, or that they appeared too trifling to require particular notice. Of the former kind are the numerous claffes of inflammations diftinguished by their caufes, or the parts occupied by them. It will be very eafy to refer these to what is faid of inflammation in general, with its three terminations, and the indications to be observed in each.

ALTHOUGH

#### CONCLUSION. 103

ALTHOUGH a review of Mr. Goulard's book has ferved me as a ground work for the observations which seemed worthy of offering to the public, it would, I apprehend, be a too limited view of my defign, to confider this little pamphlet merely as a piece of criticism upon an author, whose reputation, though in his own country it may have attained an eminent rank, yet in this, has not acquired fuch distinction as to render the canvaffing his merit an interesting object. The plan I have gone upon, has been to lay down certain principles, which though here particularly applied to faturnine topics, may be capable of application to topical remedies of all kinds; and if the public are pleafed to approve of the defign upon which this piece is executed, I may poffibly be induced to purfue it to its full extent, and to attempt a work never yet performed, in an improved and fcientific manner, a general treatife on the external applications used in furgery. Great improvements have, no doubt, been

been made by late writers, especially of our own country, in particular points relative to this part of furgery; and that taste for simplicity which has wrought fo great a reformation in the pharmaceutical part of internal medicine, has also extended its influence to external remedies. But I cannot help thinking that a methodical softem is still wanting, to bring this branch of our profession near to that certainty and perfection, which the operative part has in a great measure required; and I have a striking remembrance, how much my thoughts on this subject were embarassing the second s

For the prefent, and any future attempt, I would befpeak the candour of the reader in favour of one, who, while it is his aim to afford inftruction, will at all times most willingly receive it, even though the purport of it should be to show him his own errors.

The END.

improvements inver, no
