For a COURSE of

CHYMISTRY,

To be PERFORMED by

HENRY PEMBERTON, M. D.

Profeffor of PHYSICK in GRESHAM COLLEGE,
and Fellow of the ROYAL SOCIETY.

THIS COURSE is to begin as soon as Twelve shall have subscribed, and to be continued every *Monday, Wednesday, and Friday*, till it is finished.

THE terms to the subscribers are Five *Guineas*, one to be paid at the time of subscribing, the rest on the day, the Course begins; and those who attend this Course, are free to be present at any other *gratis*.

A
S C H E M E

For a COURSE of

CHYMISTRY.

THE design of this course is, in the first place, to perform the several operations of chymistry; both in preparing all the chymical medicines now in use; and also in the smelting, refining, and such like processes on metals; together with other operations in those trades or employments, which depend upon the principles of chymistry.

IT is proposed, in the second place, to describe in the plainest and fullest manner the method of proceeding in each operation, and to deliver all the cautions necessary to be observed in them.

IN the last place, it is intended to have a particular regard to the use of chymistry in natural philosophy. The processes are disposed in such an order, as may be most conducive towards shewing the reason and true effects of each operation; and all the discoveries, which have hitherto been made

in nature by chymistry, will be particularly explained, together with some attempts towards farther advances.

I N the progress of these experiments will be given an account of the essential difference between animal, vegetable, and mineral substances; of the nature of nutrition, vinous fermentation, and putrefaction; of the nature and different operations of menstruums, wherewith bodies are dissolved; of the nature and operations of the air, how aqueous vapours and clouds are suspended in it, by what means it causes bodies to burn, and why it is preyed upon by them in burning; how air is generated in fermentations and distillations.

I N general, it will be shewn, to what principle bodies owe the conservation of their distinct forms, and what powers procure the natural changes, whereby the face of nature is perpetually varied and renewed.

T H E subject of each lecture follows.

L E C T U R E I.

T H E threefold design of chymistry; the production of metals, the improvement of medicine, and of natural philosophy. The rise and progress of the art. The nature of heat explained upon Sir Isaac Newton's principles, and illustrated by experiment.

LECTURE II.

CONCERNING volatility and fixity. Of the difference between distillation and sublimation, with the instruments of each. Of digestion, and its instruments. The instruments for melting and calcining. Of lutes, and hermetical sealing, with the method of cutting off the superfluous parts from glasses. The various kinds of heat; that of water, of sand, the open fire, and the two kinds of the reverberatory fire, with the furnaces for each of these heats; also the blast, and wind furnaces; as likewise the athanor for continuing an equable degree of heat any length of time without intermission, and with small attendance; also Vigani's extempore furnaces composed of loose bricks only, and to be set up and taken down at pleasure, wherewith all the operations of chymistry may be commodiously performed by those, who have not a fixt laboratory. Of the several sorts of fuel. Of clays and bricks; particularly Windsor bricks and loam, and the Stourbridge clay. Of the several sorts of weights.

LECTURE III.

OF the chymical principles. Of water; why it dilates in freezing; experiments with freezing mixtures, and the cause of their operation. Of salts and spirits; the acid,

alkaline, and neutral; the criterions, whereby to distinguish acids and alkalis. Of oils and their inflammability: burning considered, with the office of the air in it illustrated by experiment, also why water extinguishes fire. Of the aerial vapour separable from bodies in distillation.

LECTURE IV.

ANIMAL and vegetable substances distilled; all of the animal and some of the vegetable shewn to produce an alkaline spirit and salt besides an oil; the rest of the vegetables shewn to contain an acid spirit and another oil; all leaving a black coal. Milk and urine considered particularly: why milk is useful in hectic fevers; and experiments made with the phosphorus of urine.

LECTURE V.

THE purification and analysis of the salts, spirits, and oils of the preceding lecture. How oils are separated from watry liquors. The distillation of the natural balsams exemplified in turpentine; whence rosin, both yellow and black: how turpentine is gathered, and how tar and pitch are made. Essential oils distilled, and flowers of benjamin sublimed, also camphire: why these oils and resins rise so freely, while other oils, lighter than several of these, can be obtained only by expression. The use of the cold still.

LECTURE VI.

ON fermentation and putrefaction. What relation sweetness bears to vegetable fermentation: here sugar distilled: fermentation described in its whole progress to the making first of wine, then of vinegar; and the nature of this operation inquired into: the inflammable spirit distilled from wine, and farther purified; vinegar also distilled: the original of tartar, and other essential salts: tartar purified into cremor tartari, also distilled. The effects of putrefaction; whence animal digestion explained.

LECTURE VII.

THE effects of burning animal and vegetable substances in the open air: the fixt alkaline salt of vegetables prepared; how pot ashes and pearl ashes are made; foot distilled. How the aerial vapour arising from animal and vegetable substances in distillation is to be collected.

LECTURE VIII.

CONCERNING menstruums: their action explained; why heat promotes it: experiments on the heat and cold produced in dissolutions, and the cause thereof considered: concerning precipitation. Compositions from the productions of the preceding lectures: fixt alkaline salt run per deliquium;

spirit of wine rectified by these salts: these salts fermented with the vegetable acid of vinegar and of tartar: soaps a composition of these salts and oils; here *sapo tartareus*: why these salts cause a sudden separation of the volatile salt from fresh urine: spirit of wine tintured by these salts: tinctures drawn from vegetables by wine and its spirit; here extracts and resins; how tinctures are assisted by fixt alkaline salt, particularly in myrrh: the volatile animal salt purified by spirit of wine: the luminous part of the phosphorus imbibed by this spirit, and the body of the phosphorus dissolved by essential oils: tinctures extracted by vinegar; and its acid converting earthy substances into a salt.

LECTURE IX.

OF the mineral salts, sea salt, nitre or salt-petre, alum, vitriol, and borax: their crystallization; and the different figures, into which salts shoot, considered: sea salt and nitre distilled with earth: the detonation of nitre, and the nature of the fixt alkaline salt of vegetables from hence farther explained: the calcination of alum and vitriol; from the latter *sal vitrioli*: alum and vitriol distilled, both before and after calcination; together with the rectification of their acid spirits, whence *spiritus & oleum vitrioli*: the distillation of borax. How each of these salts is obtained.

LECTURE X.

THE acid spirits of the preceding lecture fermented with the fixt alkaline salt of vegetables, with an account of the salts thence produced: the like experiments with the volatile alkali: here the composition of sal ammoniac, with its sublimation: the earthy part of all the mineral salts, except nitre, precipitated by alkaline salts; whence some light into the nature of nitre: the fixt alkali more powerful than the volatile; hence the decomposition of sal ammoniac by a fixt alkaline salt, the purification of animal salts by spirit of sea salt, *salia volatilia oleosa*. The nature of the pigments made with alum: the Prussian blue here prepared, and shewn why a large quantity of this coloured terrestrious substance is produced from two transparent liquors: the use of alum in dying. Homberg's phosphorus made. That the acid spirits dispossess one another: hence aqua regia by adding common salt or sal ammoniac to spirit of nitre; and the spirits of sea salt and of nitre extracted by oil of vitriol, whence Glauber's spirits of salt and of nitre; and by vitriol itself, whence common aqua fortis. The use of aqua fortis in dying scarlet. Why Glauber's spirits of salt and of nitre, as also aqua fortis, smoke incessantly; and why oil of vitriol exposed to the air increases in bulk. Here occasionally
how

how vapours are drawn into the air, and why condensed above into clouds. The acid spirits dulcified by spirit of wine; and their effects on oils and camphire: here explained why spirit of wine restrains the fermentation of vinous liquors, and why the serum of the blood is coagulated by heat. The sudden inflammability of Glauber's spirit of nitre with certain oils: hence the effects of the phosphori explained, and what part of the air aids the burning of bodies.

LECTURE XI.

OF mineral sulphurs. Whence common brimstone obtained: here general definition of spars, and of mundics otherwise called pyrites and marcasites: common brimstone decomposed; whence oleum sulphuris per campanam, and gas sulphuris: why the smoke of brimstone checks vegetable fermentation: how bitumina differ from sulphur: sulphur not to be analysed by simple heat, but sublimes intire into flowers: sulphur dissolved in oils, and, by the help of fixt alkaline salt, in water, and gives a tincture, by the same means, to spirit of wine: sulphur fulminated with nitre; whence sal prunellæ, and sal polycrestus: the composition of gunpowder, and of pulvis fulminans; why pulvis fulminans explodes in the open air more vehemently than gunpowder; why gunpowder must be corned to make explosion;

sion ; the general structure of rockets, bombs, granadoes, and other fireworks, with the reason of their effects. Orpiment here considered, and that ambiguous substance ambar.

LECTURE XII.

ON stones. What stones make glass: how glass is made from stones or sand: why glass, when melted, is wrought by blowing, whereas melted metals are cast in a mold. On lime: aqua calcis: the acrimony of fixt alkaline salts improved by lime into a caustic in the preparation of the lapis infernalis: the action of lime on fresh urine, and on sal ammoniac, whence spiritus salis ammoniaci cum calce: the use of lime in making soap; in preparing and refining sugar: sulphur dissolved by lime, whence lac sulphuris: Mr Boyle's fuming liquor with sulphur, lime, and sal ammoniac: sympathetic ink with lime and orpiment: lastly, the phosphorus Balduini.

LECTURE XIII.

METALLURGY begun. An account of the gold and silver ores of America, of the gold sands of Africa, and how the metal is there extracted: how the same metals are obtained in Europe: on the ore of quicksilver, in particular native cinnabar: how lead, tin, copper, and iron are separated from
their

their ores by charcoal: how lead, tin, and copper are separated by pit-coal. Models shewn of the several furnaces. How essays are made, with the nature of the two kinds of flux-powders.

LECTURE XIV.

THE calcination of the metals. How lead, tin, copper, iron, and quick-silver are calcined by our fires; whence from iron crocus Martis astringens, from quick-silver Mercurius præcipitatus per se; from lead minium, litharge, and vitrum Saturni; from lead and tin together the powder, wherewith metals are polished, called putty, but not the putty of the glaziers, which is here also occasionally described: here the manner of glazing earthen ware; of what consist the red, white, and black glazing: flint-glass described. That all metals are calcined by the burning glass, and the particular phenomena of that calcination enumerated. How calcined metals may be restored. The cause of calcination, and of such restitution.

LECTURE XV.

OF refining, separating, and other preparations of metals. How silver is separated from lead, and how refined by that means; how this separation is performed at the mines, how by the refiners, and how in essays: occasionally how the refiners melt what

what they call their sweep: how silver is separated from copper in Germany, so as to preserve both metals,

LECTURE XVI.

OF the imperfect metals. How bismuth is melted from its ore. How spelter is produced. The production of antimony and operations upon it: vitrum antimonii: diaphoretic antimony prepared, and reduced to regulus: crocus metallorum, and vinum benedictum: regulus antimonii per se, cum tartaro & nitro, martialis, & stellatus: from the scoriæ sulphur auratum. On arsenic, zaphor, and smalt. On the mineral called black lead.

LECTURE XVII.

EXPERIMENTS and other operations on metals. Their specific gravities compared. Brass and steel made. Steel hardened, and tempered. Why silver and gold are alloyed: an account of our present standard, with the changes it has undergone. Other mixtures; whence bell-metal, cannon-metal, the metal of organ pipes, pot-metal, bronzes of all kinds, bath-metal, pewter, folders of all kinds; by what artifice the folders are made to join to the metals; how iron and copper are tinned, and how silver wire is gilt: amalgamas; how glasses are foiled with quicksilver, and how water-gilding is performed.

LECTURE XVIII.

THE action of the acid spirits on metals, with their different ways of operation, sometimes corroding the metals into powder only, sometimes dissolving and converting them into a salt capable of crystallization; precipitation of dissolved metals: whence the air or vapour, here produced, is generated. By the acid spirits of nitre and sea salt all the metals dissolved: whence causticum lunare; luna cornea; sal Martis Bat. Mercurius præcipitatus ruber, & albus. Mercurius sublimatus corrosivus & dulcis, with the reason for this dulcification, and other philosophical remarks on these two substances: here Mr Boyle's perpetually fuming liquor from tin and sublimate: lastly, flores salis ammoniaci Martiales, ens Veneris, and aurum Mosaicum: also gold refined from silver, and aurum fulminans. By oil of vitriol, sal Martis, and turbith mineral. The metals corroded by sulphur; whence factitious cinnabar, æthiops mineral, chalybs cum sulphure præparatus, and crocus Martis aperiens. By vinegar saccharum saturni, white lead, sal Jovis, chalybs cum aceto. With the acid of tartar chalybs tartarizatus of Bates, and Helvetius's styptic. Action of the acid spirits on the imperfect metals: whence magisterium bismuthi; butyrum & cinnabaris antimonii, Mercurius vitæ, spiritus nitri bezoardicus.

dicus. The effects of the alkaline salts on metals; whence aqua sapphirina, & chalybs sine acido.

LECTURE XIX.

GENERAL remarks on the foregoing processes; whereby it is shewn, that the repulsive force seen in nature is owing to sulphur, the attractive to the acid; and consequently, that the acid principle unites the parts of bodies, and preserves to each its respective form; unless an external acid is applied to the body under circumstances, whereby the body is broken, and a new compound succeeds. The nature of the air farther explained: that the air causes bodies to burn by the same principle, as acid spirits corrode metals, and other terrestrious bodies.

THE lecture concludes with some observations on colours, with the method of tinging glass, and dying cloth; also an explanation of the nature of mineral waters.
