ARGUMENT

SULPHUR OR NO SULPHUR IN WATERS DISCUSSED:

WITH A COMPARISON OF THE

WATERS OF AIX-LA-CHAPELLE, BATH AND BRISTOL: .

WHEREIN

The SULPHUR is reftored to the two Firft, and the CONTENTS of the Laft are afcertained with a fomewhat greater degree of Precifion than in the ESSAY of a late ADEPT; and the injured Credit of divers other falutiferous Springs is vindicated, from the EVIDENCE of that Author's own Ex-PERIMENTS corroborated by many others:

BEING

The Subjects of a Correspondence between the Author of the METHODICAL SYNOPSIS of MINERALWATERS, and W. R. Esq; and some others.

And to this is fubjoined

A more explicit ACCOUNT of the NITRE of the ANCIENTS.

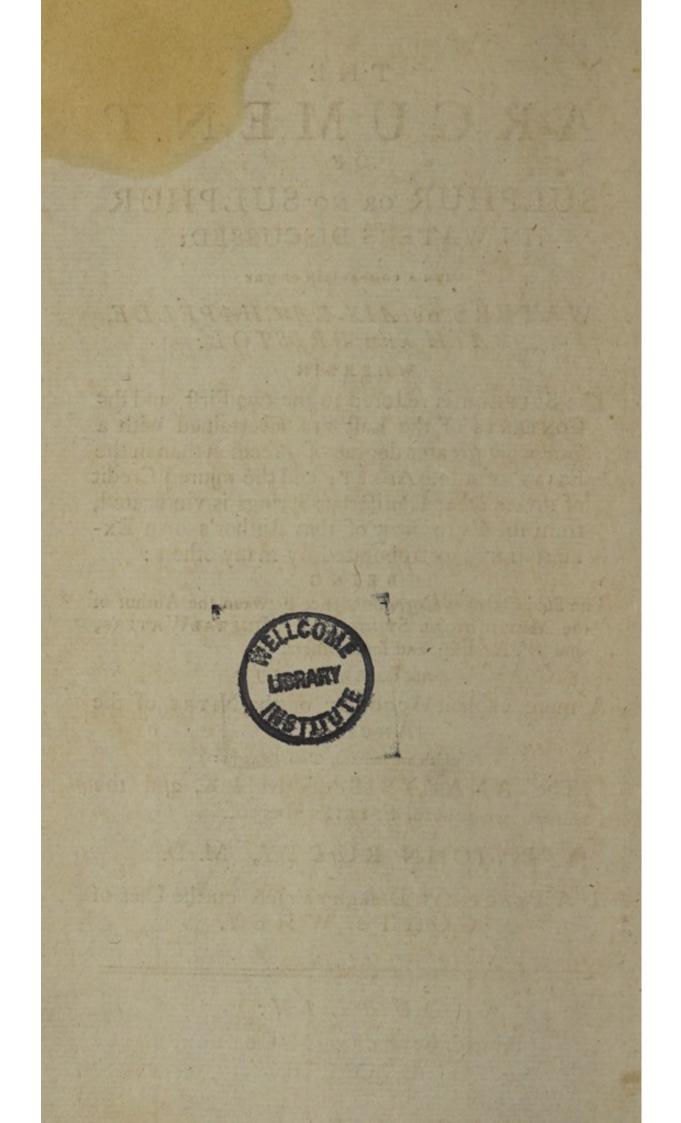

To which are annexed, Two TRACTS:

I. The ANALYSIS of MILK, and the feveral Species thereof.

By JOHN RUTTY, M. D.

II. A PRACTICAL DISSERTATION on the Uses of GOAT'S WHEY.

> DUBLIN: Printed by ALEX. M'CULLOH, M,DCC,LXII.

To the AUTHOR

OF THE

METHODICAL SYNOPSIS of MINERAL WATERS.

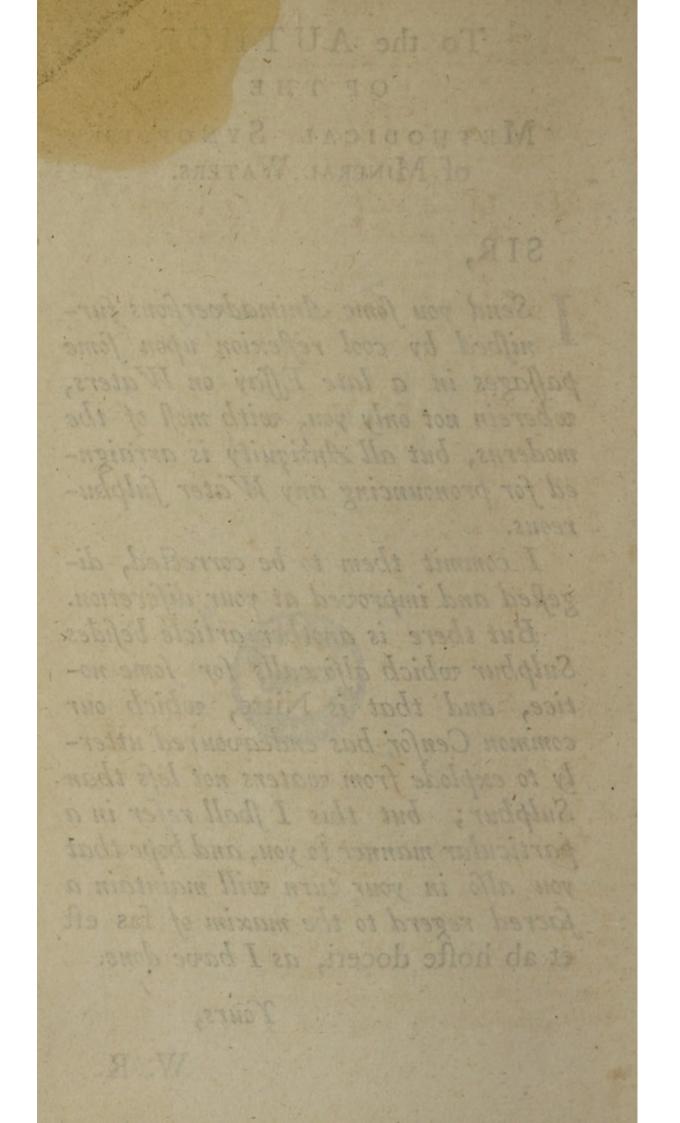

SIR,

I Send you some Animadversions furnished by cool reflexion upon some passages in a late Essay on Waters, wherein not only you, with most of the moderns, but all Antiquity is arraigned for pronouncing any Water sulphureous.

I commit them to be corrected, digested and improved at your discretion. But there is another article besides Sulphur which also calls for some notice, and that is Nitre, which our common Censor has endeavoured utterly to explode from waters not less than Sulphur; but this I shall refer in a particular manner to you, and hope that you also in your turn will maintain a facred regerd to the maxim of fas est et ab hoste doceri, as I have done.

Yours,

W. R.

THE

PREFACE.

HE design of the following treatise is not to detract from the real merit of the Author of the Effay on Waters, who having devoted his retirement from bis native land to the making of several useful experiments on the mineral waters abroad, has thought fit to offer them to the public, but being pretty much a stranger to those nearer home, appears to me to have placed them in an injurious light : neither moreover are the following animadversions now publisted from a peculiar deference to the sentiments of this author, but as an effay to settle a point in Hydrology not yet determined, viz. whether Sulphur in Substance be or be not contained in waters; for besides Hoffman, who is in doubt concerning it, a late eminent French Academician censures the writers on these subjests for confounding Bitumen (in other terms the Oily Matter) with Sulphur, and alledges that what is obtained from waters under the denomination of Sulphur, is a creature of the fire in the operation, being the meer refult of a new combination of Bitumen and the vitriolic Acid; but that Gentleman and the rest of the compilers of the Memoirs-are more excusable than our Author; for indeed, as far as appears from those Memoirs, they were but little acquainted with the waters called Sulphureous, which are frequent in G. Britain and Ireland, of which our Author might have informed himself from the various experiments and observations which had been made on them, shewing that those waters, fresh drawn, antecedent to any new combination

nation of parts, either by the fire or by putrefaction, but in their natural state, have the same effects on the organ of smelling and in discolouring metals as the Solution of Sulphur, and what is of more importance, in their operation on the human body.

Had I indulged the spirit of resentment, a certain Author might have been here represented in a light which would have moved laughter in my readers; but I chose not to be ludicrous on a serious subject, and at the fame time do gladly embrace the present opportunity of paying proper regard to every degree of real merit in bis performance, and particularly with respect to those Experiments of some importance confirming the presence of a volatile sulphureous Acid, and likewise of the Nitre of the Ancients in the Chalybeate waters of Spa, and in those of Aken and Borset; and I have cheerfully submitted to the drudgery of extracting, Separating and digesting these and some other Experiments from amidst a farrago of extrinsic matters with which they stand blended in his book, and of applying them to the elucidation and cfablishment of the point in question, the' advanced by him with a contrary intention.

And this may ferve as an anfwer to the Objection that has frequently been made to the prefent undertaking, viz. that the Author is not worthy of the ferious and folemn confutation here bestowed on him; but perhaps it were better that those who made this Objection should abate a little of their pride, and recollect that feveral of the Adepts, although bad reasoners, have left us many valuable Experiments which have proved useful to posterity and been applied to far better purposes than the authors of them ever imagined or intended.

I do also most cordially acknowledge that the Author's censure of the lax and vague sense in which the word Sulphur has been used, is undoubtedly just, and may may prove a happy occasion of introducing a greater degree of precision in treating on these subjects, as I humbly hope it has luckily furnished the opportunity of the present exhibition of the following Experiments and Observations tending to establish the existence of Sulphur, and of its volatile Acid in waters.

To conclude, as I apprehend that a blind adherence to the distates of Antiquity on one hand, and an affectation of novelty and spirit of contradiction on the other, are equally enemies to the discovery of truth and promotion of science, it will give me great satisfaction, if in the judgment of the impartial, I have, in handling this debate, steered clear of both these extremes.

THE

ARGUMENT, &c.

SECTION I.

Of the PHLOGISTON, SULPHUR, and OILY MATTER, according Dr. LUCAS.

HE Phlogiston he describes to be a fimple elementary body, the cause of Inflammability, Colours and Odours in bodies; that it is one and the same in the subjects of the three kingdoms: that Vegetables and Animals abound with it; so do Sulphur, Coal and Bitumen, and no Minerals are perfectly exempt from it: that it is the Sulphur of all the medicated Waters of the moderns, or that the principle impregnating the Waters called Sulphureous is Phlogiston, being wholly distinct from Sulphur, and from the Oily matter.

Thus does this great Reformer of our Language utterly difcard Sulphur from any fhare in the impregnation of Waters, fubfituting the Phlogifton in its Place, and alledging that the Oily matter has often been confounded with it; but of how great importance these diffinctions are, and whether his manner of treating them tends to throw light or darkness upon the fubject, may be judged by the following Scheme, exhibiting in one view, the scattered accounts given chiefly by himelf, of the three articles mentioned.

B

I. It does not appear from the foregoing Table that our Author, who uses great freedom in cenfuring others for confounding these three Principles which he pronounces to be fo widely different, viz. Sulphur, the Phlogiston, and the Oily matter, has yet made any notable advances beyond his predeceffors, in fettling their feveral proper and diftinguishing characters: For according to him, Sulphur agrees to Phlogiston in the Smell, in tarnishing Silver, in blackening the Precipitations of the folutions of Silver and Lead, and in Volatility; in fhort, in every character except the reduction of the calx of Lead to its priftine metallic form, and for an obvious reason, viz. its abounding with a very large proportion of acid to its Phlogiston, whereby it is rather adapted to keep metals in a corroded state than to reduce them to a perfest metallic one: But his Oily matter agrees to the Phlogiston in this last mentioned character, and in every other except Volatility, and when volatilized by putrefaction agrees to the other accounts of the Phlogiston in the Table.

The following may ferve as a Specimen of the fuccefs of his endeavours to diffinguish the Oily matter from the Phlogiston: Part II. p. 21. Such waters as contain the Phlogiston lose it on being beated, but the Oily matter may be found with the Residuum after evaporation of the aqueous bumidity.

A very peremptoty and decifive account of the matter truly: What pity it is but it were a juft one? But alas! when we come to apply this rule to facts, as fhall be done in the fequel, we find feveral undeniable inftances of the *Phlogifton* being retained in the *Refiduum* after the evaporation of the aqueous humidity, and fo we are left equally bewildered as before; and the decomposition of *Sulphur* by the flying off of the *Phlogifton* in evaporation will hereafter be fhewn to be imaginary. But, to do him juffice, it must be confessed he has taken care elsewhere (a) to lay down the diftinguishing Marks of Sulphur and its Hepar; but it is also observable that most of those marks are actually found in the waters called Sulphureous, or in their natural products, as shall be exemplified in the sequel.

2. The congruous appearances exhibited by the Sulphur and Phlogiston in the above Table should feem to fhew their fimilar nature, except in the greater proportion of acid in the former; but according to our Author, thefe two fubftances are wholly diffinct, and fo far diffimilar that the appearances common to Sulphur and Phlogiston in the above Table, are not owing to Sulphur qua Sulphur, but to the difengaged Phlogiston or inflammable principle alone (b), fo that the discolouring of Silver, and of the Precipitates exhibited by the folution of Silver and Lead, which have hitherto been laid down as marks of Sulphur, are by him deftroyed as fuch and appropriated to the Phlogiston : For (proceeds he) Before the Phlogiston is set at liberty by breaking in some fort its connection with the universal acid in Sulphur, by the interposition of alcali's, lime or other matters that abforb or overcome the acid, Sulphur alone, or the concrete Sulphur, is not found to gild Silver or tinge it yellow; but as foon as the connection aforefaid is broke, and the folution of Sulphur is made by lime or alcalis, then the difengaged Phlogiston flies off, strikes the sense of smelling with a putrid stench, tarnishes Silver, &c.

I confess I am not without sufficient that an affectation of superior Science, and particularly an excelfive fondness of the greek Word above mentioned pretty much a stranger to vulgar ears, may have betrayed our Author into an utter neglect of

(a) Effay on Waters, Part III. p. 35. (b) Ibid. p. 278. the the evidence of common fenfe: For where is the alcali to let loofe the *Phlogifton* in an ointment of brimftone and butter fo offenfive to delicate ladies in the cure of the itch? And, taking for granted that the difcolouring of other metals by *Sulphur* proceeds from the fame principle, as that of Silver, has he forgotten the colour induced to quick-filver by *Sulphur* in the Æthiops mineral by meer trituration? But not to evade the teft by Silver, a filver tea-fpoon by a fingle immerfion into the melted flowers of *Sulphur* receives an almoft indelible ftain: And is not all this effected by the concrete *Sulphur*, or *Sulphur* alone? Vain therefore are his endeavours to deftroy thefe obvious marks of *Sulphur*.

Our Author however proceeds without referve or fubterfuge (not to fay without caution) to affert that the fetid fmell and tarnifbing Silver in putrifying Waters (to which he compares those called fulphureous) is owing to the Phlogiston, and not only fo, but to Phlogiston alone. (a)

I shall therefore shew that the effluvia of putrid Waters do not furnish an adequate proof of this polition, because it is certain that they do not confift of Phlogiston alone, but contain also a volatile alcaline fpirit and falt, as has been proved by particular Experiments on putrid Sea-Water, and putrid Rain and Spring-Waters, and therefore it does not appear that the above-mentioned Phenomena of fetor and tarnishing Silver are owing to the Phlogiston alone, but rather to a combination of it with the volatile alcali; and this may be of notable use in diffinguishing the great difference between Waters become fetid by putrefaction and the natural fulphureous Waters, in this important respect, that in the first the Phlogiston is combined with a volatile alcali, whereas in the laft it is found

(a) Ib. p. 279.

found to be combined with a volatile acid, as shall be shewn in the sequel, and even from some of our Author's own experiments.

In the mean time it would be neceffary to examine the *Phlogiston* in a ftate of fimplicity, or in fuch a form where it makes the nearest approach thereunto, or at least that fubtile fluid or fluids wherein it is found in greatest abundance, as far as cognizable to our senses and capable of being subjected to experiments, in order to determine how far the fetor and the tarnissing of Silver in waters is or is not owing to the *Phlogiston* alone.

In this inquiry we are not to take in every inflammable vapor or fubtile matter, not even that which conftitutes the fulminating damp in mines, taking fire at the approach of a candle, for this, according to the description given us of it, (a) leaves a ftrong fmell of brimftone; but there is another Phlogiston which approaches much nearer to fimplicity, being found void of all fmell, and that is, the fubtile inflammable vapor which immediately catches fire at the approach of a lighted candle, being found floating on the furface of divers waters, and even of fome earths, and is the genuine production of the Petroleum, and often found in the neighbourhood of Coal-Mines; and the confideration of this species of the Phlogiston will be more to the present purpose because of its affinity to that of Sulphur, which is allowed to be composed of some bituminous matter united to the vitriolic acid.

The following inftance of one of these phlogistic vapors has been transmitted: "In some Derbysbire Lead mines near Whetstone-edge, have been observed some small drains or rills of clear water trickling down a Lime-stone rock: The workmen at night, when leaving off work, for

(a) Lowthorp Abr. Phil. Transact. Vol. II. p. 377.

one

one or more days, only by holding a candle to this water, fet it on fire, which continues burning with a blue flame till they return to their work and light their candles at it again, and extinguish the finall pascent flame on the water's furface. Here was a true Phlogiston without fmell or damp, and no perceptible acid, which would have effectually spoiled the fine rich Lead ore. In the fame mines was an abundance of pretty large Boulder-stones, whose furface was only a shell full of a whitish grey folid matter, which liquified before the fire, manifefting itfelf to be a clear Bitumen." And near akin to this is the flame emitted from a certain fpot of ground on a fide of the Appenine mountains, mentioned in the Philosophical Transactions (a), which is also without fmoak or fmell.

Here then is a notable fpecies of Phlogiston, and which makes the nearest approach to fimplicity, which is both inflammable and utterly void of fmell, nor moreover is it effential to the waters on the furface of which this Phlogiston floats, to tinge Silver : for the burning Well near Wigan in Lancashire, is a ftrong inftance to the contrary, the water of which does not tinge Silver, whereas according to our Author's theory, one would imagine that fuch waters where the Phlogiston was in greatest abundance ought to have the greatest effect in tinging Silver, and that these phlogiftic vapors are entirely and specifically different from those of the waters called fulphureous, appears from hence, that these last are ever diffinguished by their fetid fmell, and are not inflammable at all, which is agreeable to the nature, not of meer Phlogiston, but of Sulphur, in which the acid fo greatly predominates over the Phlogiston: from all which appears the rafhness of our Author's pofition,

(a) Lowthorp, Ib. p. 385.

fition, that the fetid finell and tarnishing of Silver in Waters is owing not to Sulphur qua Sulphur, but to the Phlogiston alone.

I shall give but one instance more in support of the truth of this conclusion, which, tho' it be of a production of art, and chiefly from a vegetable, yet as the *Phlogiston* or principle of inflammability is declared to be one and the fame in the vegetable, animal and mineral kingdoms, will scarce be deemed impertinent, and that is Æther, being one of the most inflammable of all liquids, and which, like the vapor on the waters before mentioned, catches fire at the approach of a lighted candle, being the highly attenuated oil, phlogistic or inflammable part of wine, and which in several appearances exactly refembles that most subtile Bitumen called Naphtha.

I procured therefore a fpecimen of the vitriolic Æther exquitely pure from Dr. Francis Hutchefon, Professor of Chymistry in Dublin, and immersed Silver in it, and exposed Silver to its vapor, but found that it had no effect in tinging the Silver; neither moreover had it any effect in producing any difeolourations with the folutions of Mercury, as appears in the Table annexed : But when in the fubsequent part of the process the Phlogiston is fo far combined with the acid of Vitriol as to conftitute the volatilized acid called the Gas of Vitriol or Sulpbur, this has manifest effects on Silver and its Solution; and on the folution of the cryftals of Quickfilver, as appears in the fame Table: So that this affords another inftance of one of the molt highly phlogiftic bodies having no effect in difcolouring Silver, even not until it makes a nearer approach to Sulphur by being combined with a notable proportion of acid.

Upon the whole, it appears from these instances how arbitrary and destitute of support from experiment periment this novel dicifion of our Author is, that the *Phlogiston* or inflammable principle alone is the cause of the fetor and of tarnishing Silver in *Sul*-

pbur or any waters supposed to be therewith impregnated.

SECTION II.

Objections against the existence of Sulphur in waters considered.

I. THE first Objection is, that altho' they, and particularly the Aken waters, agree to a fulphureous impregnation by their smell and fome other effects, yet they are absolutely colourless, whereas a much smaller portion of actual Sulphur than appears to be in these waters would give a sensible yellow colour to a much larger quantity of water (a).

Anfw. This unphilosophical objection, whilft it shews an utter inattention to the extreme divisibility of matter, proceeds upon a supposition that the solutions in the pitiful processes made in our elaboratories are as perfect as those of nature, which is far from being the case : on the contrary, the minerals taken up into waters in nature's workmanship, are in a most incredibly attenuated state, and to this extremely subtile state of the dissolved minerals, do we justly impute their supparently the case, particularly in the Sulphureous, whose vapors diffused many yards round affect the nose, and sometimes metals in the pockets of those that are near them.

But were I inclined to condefcend to the dull and grofs conceptions of our Author in these matters, as if Colour were an effential mark of *Sulphur* in waters, I could swell my book with an account C of

(a) Effay on waters, Part III. p. 69.

of the various operations of nature in this respect by enumerating great numbers of waters of this fort which are as colourless as those of Aken, whilst others are of a bluish cast, or of a reddish brown, and fome of a milky colour, particularly the Aqua Zolfa found on the road from Rome to Naples, mentioned in the Memoirs of the French Acadamy, A. D. 1750, but I rather haften to a more direct answer to his declaration that a much smaller (a) portion of Sulphur than appears to be in these watersby any known means of art diffolved in them, would give a sensible yellow colour, by informing him that an artificial fulphureous water was lately prefented to a certain medical Society in Dublin by that ingenious Apothecary Henry Barton, author of the new method of the improvement of the manufacture of Drugs, being a folution of Sulphur which had all the marks of the natural fulphureous waters, and from which I myself precipitated a Lac by spirit of Vitriol, and yet was as transparent as common water, the method of preparing which, together with fome other useful matters the Author intends to divulge at a proper feafon : in the mean time I endeavoured to imitate the above by a lefs faturated folution of Hepar Sulphuris in the proportion of 21 grains to a quart of foft water, which was fo diluted that it still retained its transparency, and agreed to the natural fulphureous waters in the flavour, and particularly in the fetid fmell, upon adding Spirit of Vitriol, in order to precipitate the Sulphur, tho' there appeared only a fubtile white cloud fufpended in the upper part of the glass, (even as in divers of the natural purer fulphureous waters, agreeable to the fubtilty of their impregnation;) and moreover it tinged Silver and its folution in the fame manner as the natural fulphur-waters do.

(a) Effay on Waters, Part III. p. 69.

Q5-

[11]

Objection II.

OUR Author lays it down as an established axiom, (a) that Sulphur is not by itself foluble in water, and can be dissolved by no other means known than those of alcaline falts or earths: and that, if Aken waters (b) were fuch a solution of Sulphur as to contain actual and substantial Sulphur, an Alcali must be predominant in them.—whereas a volatile acid is evidently contained in them, and all the mineral acids, instead of causing any precipitation, as they must do in all solutions of Sulphur, increase and preferve the pellucidity of these waters.

Anfw. The whole force of this Objection refts on a fupposition no less prefumptuous than this, that for as much as our Author knows no other method of impregnating Sulphur with water, that therefore Nature itself has no other method of effecting this. It is therefore necessary to inform him that not only Nature, but even Art can diffolve Sulphur in water by other means than a meer Alcali: for, in the Experiment to be related in the next fection it will appear that Sulpbur may be divided into fuch minute particles by meer mechanical attenuation, as to be kept invifibly fufpended in water, for a confiderable time, and afterwards precipitated from it; and if the feeble art of man can effect this, the argument is ftrong that the power of Nature is not reftricted to alcaline falts as the fole medium by which Sulphur is foluble in water.

It were but juffice indeed to allow thus much in favour of this Objection, that the native Alcali is a very frequent ingredient of the waters called *Sulphureous*; but to infer from thence that Nature is to be confined within these narrow limits were very rash, and contrary to what is found to be the

(a) Effay on Waters, Part I. p 99. (b) Ib. Part III. p. 70. cafe

cafe in fome of the ftrongeft of these waters, particularly that of *Harrigate* in *Yorksbire* and the *Aquæ Badenses* in *Germany*, both which are impregnated not with an alcaline, but marine falt, in a notable quantity, and confequently fome other menftruum than an Alcali must be admitted for diffolving the *Sulpbur* with which both these waters are eminently impregnated.

If then Nature has other methods of impregnating with Sulphur than a meer Alcali, the force of the Objection from the want of a precipitation by Acids entirely vanishes: nevertheles fince the Aken waters in particular, which are allowed to contain the native Alcali, are specified as a stronginstance of this want of precipitation by Acids, I shall here minutely confider it, as it will give opportunity of making some observations tending to clear up this matter.

We are affured then, as above, that the mineral Acids, instead of causing any precipitation in Aken waters, are found to increase and preserve their pellucidity.

Perhaps there had been more candor in this Objection if, inftead of afferting this of mineral Acids only, it had been afferted that Acids in general caufe no precipitation; but the objector feems to be well aware that this would have not agreed to a subsequent experiment of his on a certain vegetable Acid, and therefore it was requifite he should confine his objection to the mineral Acids only; for we find in the course of his experiments on these waters that diffilled Vinegar (a) produces a milky bue or milkynefs with them, even with the water fresh from the sources and with the cold water, but not with the evaporated, and this he imputes to the Phlogiston present in the fresh and in the cold water, but not in the evaporated. It

(a) Effay on Waters, Part III. p. 89, 90.

It is probable other lefs accurate chymifts might call this milkyness an incipient precipitation or Lac of Sulphur, and the rather because it is well known that it is not peculiar to the mineral acids to precipitate Sulpbur from its folution, but that Vinegar and other diluted Acids do alfo effect the fame thing : but it will ftill be urged, Why do the mineral Acids exhibit no appearance of a precipitation? I answer 1st, by reason of the extreme subtilty and volatility of the Sulphur, and 2dly, perhaps by increasing the pellucidity of this water on another account, even by effecting a more intimate folution of the terrestrial matter contained in these waters, whereby they become more transparent, this being an ordinary effect of the mineral waters on this account : Perhaps this experiment with the mineral Acids on Aken waters may deferve to be reiterated with a little more attention : however, be the cafe of Aken waters what it will, it appears from the teftimony of others concurring with my own observations, that the mineral Acids have a very different effect upon feveral of the waters called Sulphureous than what they have upon those of Aken according to our Author, and which waters are more fimply *fulphureous* than those of Aken, even that they are fo far from increasing their pellucidity, that upon a minute and careful obfervation they are found to exhibit a milky cloud on being dropt into feveral of these waters, particularly those of Moffat in Scotland, which, when fresh always turned milky with Spirit and Oil of Vitriol and Spirit of Nitre; and the fame appearance is . alfo exhibited by the mineral acids added to the fons Wirfingavenfis in Silefia, and ours of Swadlingbar, Killasber and Lucan near Dublin.

But, to return, as our Author by his repeated, peremptory declarations, that *Sulphur* cannot be actually or fubftantially diffolved in water without the the intervention of an alcali, would feem to take upon him to reftrict the powers both of nature and art within the narrow bounds of his own fcanty conceptions, I fhall here fhew that he is far from having founded the depths of the art in which he would feem to diftinguifh himfelf, by giving a clear and undeniable inftance, in a fhort chemical procefs, of *Sulphur* being fo far attenuated as to be diffolved or kept invifibly fulpended in water for a confiderable time without the leaft affiftance of an Alcali.

This experiment was communicated by a worthy brother of the profession, as having been first made by *Chrouet* in a treatife *de Aquis Aquis granensibus*, published in 1713, viz. He took two iron retorts into one of which he put four drams of *Sulphur*, into the other three pints of water, and inferting the neck of each retort into a hole at each end of an empty barrel, and placing each retort on the fire at the same time, the steams uniting in the barrel, and afterwards condensed, formed a liquor refembling the waters of *Aken*; but he observes that if the *Sulphur* be washed from its acidity, the experiment does not succeed.

This experiment feemed to be well worthy of being repeated, which accordingly was done, as follows, by Dr. Francis Hutchefon, Profeffor of Chymiftry in Dublin, with fome little variation, and withall fome further experiments on the product of the operation : he ufed glafs retorts inflead of iron ones, and flowers of Sulphur and pump water, and the fteams arifing from each of these being united and condensed in an empty barrel perforated as above, exhibited a clear water, not indeed of the finell of bepar fulphuris (nor resembling the Aken Waters as Chrouet affirms) but rather of the volatile Acid of Sulphur : however, that a real Sulphur was invisibly suspended in this water, appeared

peared from the following experiments: it had the like effect, not only on the folutions of Silver and of other metals, but on Silver in substance, (even by immerfion in the liquor and by the vapor) that the ordinary folution of Sulpbur has, as appears in the Table hereafter annexed, particularly in tinging Silver of a dark leaden colour, which is more than the volatile Acid of Sulphur does: to which add, that the precipitates formed in this water by the addition of mercurial folutions, being both feparately dried and thrown on the red hot iron, shewed pure Sulphur by the blue flame and fuffocating fimell : indeed the folution of fugar of Lead gave only a white cloud and a white grumous fediment, with a few black fpots at the bottom, an appearance perfectly analogous to what is effected by the mixture of Bath waters and that folution; but what puts this matter out of all doubt is, that this water left at reft three or four days, deposites a real flos sulphuris manifested by its appearances on the fire, and every other characteriftic of Sulphur.

Objection III.

OUR Author however, acquainted with no other means of diffolving Sulphur but an Alcali, proceeds upon a fuppofition of its being fo diffolved in water, to fhew that it would be impoffible to demonstrate it, for this reason, that as foon as the union of the acid and Phlogiston in the Sulphur is broken, and a folution of Sulphur is made by Lime or Alcali's, the Phlogiston flies off, whils the acid basis of the Sulphur unites with and faturates the alcaline falt 1y whose means it was diffolved (a): and that here is a perfect decomposition of Sulphur, is evident from this, that without adding an Acid, such a solution cannot be revived into Sulphur, whereas, by restoring what the Alcali destroyed, an Acid, all such folutions yield a precipitate of Sulphur.

(a) Effay on Waters, Part III. p. 279, 280, 316.

To

To this it is answered, that the Decomposition here afferted, and the entire flying off of the Phlogiston is altogether imaginary and unchemical: for ift, if the Phlogiston were really, as our Author fays, totally difengaged from the acid, whilft this united itself with and saturated the alcaline salt, Sulphur could not be reproduced without recalling or introducing new Phlogiston, which is contrary to daily experience in making Lac fulphuris, where the meer addition of an acid throws down the Sulphur in the white magistery of that denomination, which is a perfect Sulphur in inflammability and every other character. 2dly, The supposition of the Phlogiston quitting its own acid and leaving this to unite itfelf with the alcaline falt is directly contrary to the doctrine of the affinities of bodies, even as reported by himfelf, Part I. p. 11. of his Effay, where we find that the attraction between the inflammable principle and the vitriolic (or fulphureous) acid is the ftrongeft of all, and specified as fuperior to that between the fame acid and fixed alcali's; and that it really is fo appears from the production of Sulphur by the decomposition of Tartar vitriolatum and other neutral falts by fuling them with Charcoal, where the vitriolic acid having a ftronger affinity with the Phlogiston in the charcoal, quits the alcali and uniting itfelf to the Phlogiston forms Sulphur. See Macquers Elemens de Chymie pratique, Sect I. Chap. 1. And 3dly, politive experiment on the folution of Sulphur made in Lime water is against him: for this folution being evaporated, left behind it a real Sulphur : but to come to real facts in relation to the waters called fulphureous, it will appear that the union of the acid and Phlogiston in those waters is far from being fo lax as he supposes, and from a partial examination of a few of them haftily afferts. I will readily grant him that the Phlogiston is extremely volatile in

in the weaker and lighter waters of this class; but that this is the cafe in the ftrongeft fort I deny: for, befide the Harrigate water, (a) which retains its fmell even when a phial of it has been kept in a pan of boiling water a long time, the water of Drumasnave in Ireland retains its fmell when evaporated to the confumption of half: but ftill much more ftrong and clear is our Author's own politive testimony, shewing that the Sulphur in waters is neither decomposed nor loft upon evaporation, but deposited and still abides, even in the state of a fixed acid and Phlogiston, (the genuine and component parts of Sulphur) clofely united, relifting the action of the fun, air and winds, nor feparable but by the action of the fire : for he tells us (b) of the lower springs of Borfet, that whereever they touch the wood in their current, or ouze from the foil, these places are covered over with a white, Soft, filky boar, which being dried and thrown upon an ignited iron, catches fire, emits a blue flame and an intolerable acid vapor, being no other than one of the Conferva's, incrusted, (in his own words) with some particles of fine, subtile Sulphur. Such is the glaring evidence of Truth that it will out, even from the mouth of an adverfary in fome of his unguarded moments; and that this really is the truth will be confirmed in the fequel by a minute examination of the like white Cruft deposited by other waters of this denomination.

Objection IV.

THE fourth Objection is, that no argument can be drawn of the presence of Sulphur in any waters from their effect in difcolouring Silver, because this is an effect common to bilge water and other putrified waters, to the excrements

(a) Short's Hift. of mineral waters, Vol. 1. (b) Effay on Waters, Part III. p. 189. of

D

of animals, jakes and fewers in cities, to ftale urine, and to the yolk of an egg boiled or roafted hard, which are not to be deemed fulphureous from this circumftance alone, or bear no relation to Sulphur: (a) and elfewhere (b) fpeaking of one of the ftrongeft of these waters, he challenges us to prove by a fingle experiment that it is more fulphureous than putrid fea-water, or any of the other falt springs that putrify on ftagnation.

Anfw. This is a high fcandal upon the waters we call fulphureous, and if juftly grounded, ought to terminate in their utter rejection as a medicine, which however are found by experience to have intrinfic merit more than enough to fupport themfelves under these unjust reproaches.

I shall however give his Objection its due weight, and grant that it is indeed common to putrid waters and to those called fulphureous to tinge filver; but our Author has not vouchfafed to inform us whether they equally agree in other refpects, whereas upon a careful comparison it will abundantly appear that the respective contents of the waters become fetid by ftagnation and putrefaction, and the contents of those called fulphureous, are widely different, and even of oppofite qualities : for it is an undoubted fact that rain-water, fea-water and other waters, are fo far changed by putrefaction that the *fal medium* naturally contained in them is transformed into a volatile alcaline falt, fo that its well known that they yield an urinous falt and an alcaline fpirit, which is also the cafe of putrid urine, · &c. And on the contrary, it is no lefs certain from undoubted facts, that divers of the waters called fulphureous are fo far from yielding a volatile alcali, that they yield a volatile acid : of this we have a fenfible proof in fome of the fulphure-

(a) Effay on Waters, p. 280. (b) Analyfis of Rutty's method fynops. of min. waters.

ous waters in Italy, where they are frequent, and their fmell very offenfive to the paffengers, particularly on the road from Rome to Naples, of which we have the following account in the Memoirs of the French Academy of the Year 1750. Elles sont presque toujours plus chaudes que l'air de l'atmosphere, et d'une couleur laiteuse sembable a celle de girasol; la vapeur qui en sort penetre insensiblement les pierres le plus dures qui s'y trouvent exposees, elle les enduit de fleur de soufre, elle les calcine interieurement, et les dissout de telle sort qu'elles deviennent legeres et perdent beaucoup de leur consistance naturelle. And this is ftrongly corroborated by the analogous effects of the acid vapors of the waters of Aix-la-- chapelle, Borfet and our Bath waters, in corroding the iron works near them, as mentioned by our Author; (a) and indeed there are very few of the waters called fulphureous but what fo far manifest an acidity as in some degree to coagulate with foap and alcali's. This then is one confiderable article in which the Phlogiston in fulphureous waters differs from that in putrid waters, that in thefe it is combined with a volatile alcali, in those with a volatile acid, and their operation and effects are also very different; and fo the air impregnated with the effluvia of waters turned putrid by ftagnation in low fenny countries is always unwholefome, whilft the fteams rifing inceffantly from fulphur-waters into the air are fo far from caufing or promoting Epidemics that fuch an air checks and breaks their force by the volatile acid: and how the putrid waters do agree to those called fulphureous in their lightness on the ftomach, raifing the fpirits and other falutiferous effects the Author of this calumny on the last named waters. is called upon to answer.

(a) Effay on Waters, Part III. p. 64.

But it is needless to add any thing further in order to fhew the groundleffness of the above infinuation than to appeal to facts in relation to the real state of the waters called sulphureous, feveral of which are fo far from ftagnating that they flow with a rapid stream, (particularly that of Cunleybouse mentioned by Dr. Short, and the Aqua Zolfa in Italy mentioned in the 50th Vol. of the Memoirs of the Royal Academy) are clear and full of a volatile elastic matter, exhibiting perpetual ftrings of air bubbles, even as do the waters of Aken, the fmell of which is also like that of the cold fulphureous waters; and to this add that it is rare to find true fulphur-waters in low, boggy, fenny countries; and where waters do ftagnate and putrify, as in great levels and in deep peat or turf mosses, their smell is very different from that of a true fulphur-water.

SECTION III.

Positive Proofs of Sulphur in waters.

I. THE Smell both of the waters of Aix-la-Chapelle, and of the cold waters called fulphureous in Great-Britain and Ireland, is exactly the fame, even like that of a folution of Sulphur in an alcaline ley, (a) or like that of the washings of a gun fouled by frequent firings of gun-powder. II. The effects of Aix-la-Chapelle and other waters called fulphureous, whether hot or cold, and of their vapors in discolouring metals and their folutions, are the fame, being like those of a folution of Sulpbur in an alcaline ley, or Hepar Julphuris. Con Manual SIE

III. Although it is granted that the quantity of Sulphur contained is but fmall, and not eafily collected

(a) Essay on Waters, Part III. p. 53.

lected pure and diftinct, being difguifed by various mixtures with other minerals, yet divers of these waters do yield a real Sulphur both in their vapors and in the refiduum left by them: v.g. The Thermæ Badenses (a) yield in the upper part of the pipes thro' which the water runs, a fubstance scarce to be diffinguished from flowers of Sulphur : and the accurate Walerius in his Mineralogie mentions a native flos sulphuris found swimming on the furface of fome waters; to which add the teftimony of that learned and industrious enquirer into these fubjects, Georgius Agricola, who in two places (b) affirms that Sulphur is obtained fubfiding as a fediment by decoction from the waters at Buda in Hungary; but above all, the Aix Sulphur is an undeniable inftance to this purpose; but our Author endeavours to evade the evidence from these facts of a palpable Sulphur thus collected by a certain hypothefis, the honour of the invention of which it must be owned is due to himself, which hypothesis, as it will be minutely confidered in the Letter annexed to the end of this fection, I shall fay nothing more of in this place, but proceed to examine fome of those foreign waters, particularly in Italy, which give undoubted evidences of an impregnating Sulphur fupplied by magazines of this mineral in the bowels of the earth, and compare them with those in these colder climates, in order effectually to filence the clamour against them as meer putrid waters. Now it is certain from the descriptions that travellers have given us of these waters that they agree in all fenfible appearances to those we call fulphureous. This is particularly clear in the accounts given us of the rivulet called Solforata five miles diftant from Tivoli, which has

(a) Brown's Travels. (b) Lib. I. ch. 22. de natura eorumquæ effluunt ex terra & 1. 3. c. 24. de natura Fossilium.

a noisome

a noifome fmell much like that of the fulphur-well at Knaresborough, (a) which is further described by another Author (b) as " taking its origin from a neighbouring little lake of fulphureous water called Aqua Albula, in which are the floating islands, is fourteen miles diftant from Rome, and runs over a very white bed." And Addison in his travels fays, that he fmelt the ftench of the waters of this rivulet fome time before he faw them, and that the little lake which gives rife to it lies in the very flat of Campania, and that, as it is the drain of these parts, 'tis no wonder that it is so impregnated with Sulphur, and that it has at the bottom fo thick a fediment of it that upon throwing in a ftone the water boils for a confiderable time over the place that has been ftirred up; and Niccolo Madrizzo (c) affirms that the Albula derives its whiteness from the fulphureous veins in its course: and to these agrees the following memorable teftimony of Elyfius de totius Campaniæ balneis in the collection of the Authores de balneis published at Venice, flewing that here are natural magazines of Sulphur, and withall that the vapors of the water in the neighbourhood are fo far from being unwholefome that they are medicinal : In fummitate montis qui Puteolis supereminet, planities est in qua Sulphur conficitur, & ibi nascens aqua sulfuraria dicitur-bic tamen odor gravis & locus undique fumans terribilis est, cujus tamen fumus rheuma & frigus. capitis aufert. And the Sulfurea Nar albus aqua mentioned in Virgil's 7th Æneid is another river of this denomination that empties itself into the Typer agreeable to the white colour of the Albula above mentioned; from all which it abundantly

(a) Ray's Travels, Vol. I. p. 315. Lond. Ed. (b) Efchinardi Agro Romano Parte 2d. Cap. 510. (c) Viagii per Italia, Soc. Venet 1718.

appears that, not only the fmell, but the white co-

lour

lour of these waters and their channels in *Italy* where *Sulphur* abounds, corresponds to the milky colour which the waters we call sulphureous in these countries frequently assume, especially on a little stagnation or before rain, particularly those of *Moffat*, *Swadlingbar*, *Mount-campbell* and *Lucan* near *Dublin*, (to name no more) as likewise to the white glairy precipitate which these waters generally deposit:

And this is abundantly confirmed by other obfervations made in other remote parts of the world, even in America, viz. In Canada is a ftream running from a mountain, which, when it rains, sends forth an extremely disagreeable and offensive Smell of Sulphur: The water itfelf is clear, but has a milky bue from a white pellicle which covers it, and because it deposits a whitish sulphureous earth on the roots of the trees or pieces of wood in its channel, and when those pieces of wood are well dried, they take fire as suddenly as common matches, and being burnt in a chamber, they emit a sufficating smell of Sulphur and burn with a blue flame, and the water is drank for the cure of the Itch and Tetters, and weaknesses of the Stomach, and applied externally. Guettard in the Memoirs of the Acad. of Sciences, 1752.

To this agrees very well the white glairy, and on drying, raggy and tenacious fubftance fpontaneoufly precipitated by the waters called fulphureous, a precipitate almost, not to fay quite, as proper to these waters as the ochreous one is to those of the chalybeate kind, as is notoriously the case of the lower hot fprings of *Borfet* mentioned in the foregoing fection from our Author, and the precipitate by him expressly acknowledged to be fulphureous, and likewise of the several warm waters denominated fulphureous in the province of *Bearn* in *France* and its neighbourhood lately enumerated and described by Dr. *Theophilus de Borden*

of

of *Montpelier*, which agree perfectly to the cold fulphureous waters of *Great-Britain* and *Ireland*, in exhibiting this white glairy, or raggy fubftance deposited by them on the grass, flicks and flones over which they pass, and likewise in their operation and effects on the human body.

Lister, that learned and diligent naturalist, had indeed long ago pronounced this white matter to be a pure Sulpbur in these words: (a) Flos quidam albicans universis bujusmodi aquis innatans, & circa oras istiusmodi fontium ubiq; adhærens—merum Sulpbur est.

It must however be acknowledged that it is extremely difficult to collect a diffinct, palpable Sulphur from most of these waters. Dr. Jean Philippes de Limbourg who published a treatise on the waters of Spa in 1756, observes indeed at the bottom of the bason of the Geronsterre water, after it has remained a long time without being cleansed, not a Rubric, but a white matter like what we are now speaking of, being also found on the leaves of the trees growing near it, which on being burnt, emitted a manifest fulphureous smell, but he says he could not procure flower of Sulpbur from it by the retort.

Now as this is a matter of importance, a real palpable Sulphur from waters having but rarely, if ever, been exhibited, I fhall here prefent the public with the refult of an experiment made by Dr. Francis Hutchefon Professor of Chymistry in Dublin on the white matter above described, which was deposited by the lately discovered water at Lucan near Dublin, which water in every other experiment answers to a fulphureous impregnation, viz.

He put fome of the dried white fludge which had been precipitated on the ftones near the well's mouth into a *Florence* flafk in a moderate heat in a fand a fand bath, the heat being gradually increased for the fpace of an hour; after all the moifture was diffipated, there was fublimed into the neck of the flask, befides a footy matter, a small quantity of a yellow thining fubstance, manfefting itself to be a real Sulphur by the blue flame and ftrong and peculiar acid fmell which it emitted on the red hot iron: and in fhort by every other characteriftic proper to that fossile.

But, not content to reft a matter of this moment on the evidence of a fingle experiment, I procured by the friendship of Dr. William Henry some of the like white fludge collected from the ftrong fulphureous water at Lawrie near Pettigoe in the county of Donegall, which I recommended to be examined by a like process as the former, to my good friend, the ingenious Chemift hereafter mentioned, to whom I owe feveral valuable hints on this occasion, who put it into a bolthead placed on the furface of hot fand, and in an hour's time there was fublimed from it and found adhering to the upper part of the veffel, and to the lower part of its neck, a visible yellow flower of Sulphur, manifesting itself further to be such by the smell and by the bright blue flame it emitted in the prefence of three credible witneffes.

Thus in a fecond experiment was a palpable diffinct Sulphur by fublimation demonstrated in the white fludge deposited by these waters; and moreover, the fame thing was also shewn by Precipitation; for the fame white fludge dried, on its being digefted either with Oil of Tartar or Limewater, and especially the last, gave a yellow tincture having the fmell and tafte of Sulphur, and when a few drops of spirit of Vitriol were added, it exhibited a milky liquor of a ftrong fulphureous finell, and precipitated a fmall quantity of white grumes, which being collected in a filtring paper and

and dried, when the paper was fet on fire, emitted a blue flame and fmelt acid, like a Brimftone match lighted. It is true, the quantity of precipitated *Sulphur* was but fmall, and the precipitation flow, which was manifeftly owing to the vifcid fubftance with which it was entangled, but that a real *Sulphur* was here prefent none that had been witnefs to the experiment would deny.

Upon the whole, it abundantly appears from the observations and experiments above related, that the waters commonly called fulphureous do yield a palpable *Sulpbur* both by fublimation and precipitation.

Having fo far inveftigated a real Salphur in waters, I shall here subjoin a few hints to shew that it may be demonstrated also in some folid bodies where it has hitherto been only supposed. Doctor Short, who has made more experiments on mineral waters of all kinds than any one person upon record before him, and confequently whose testimony is of the more weight, has affured me that by burning feveral forts of stones on the Whitby and Scarborougb shores, and putting them into water he has made as strong a plain Sulphur-water as any in England : and it is matter of observation that many of the fulphureous springs rise in the neighbourhood of Limestone, which perhaps may have some start in their impregnation:

And as an inftance of real Sulphur being more copioufly diffufed than is commonly imagined, I here prefent the public with a politive proof of real Sulphur lodged in and intimately mixed with the fhining fparry matter composing part of a folid rock of Limestone or Marble, which was communicated to a medical Society in Dublin by the ingenious Patrick Bride Chemist in the following Memoir:

" At

"At Oughterard, about thirteen miles weft of Galway there is a quarry of black Marble, and in the body of the ftone are found large lumps of a whitifh fubftance like the veins of white Marble, but of two, three, perhaps four inches diameter, of a fparry appearance, and which will polifh like common Marble: This forms a bank to a fmall river that runs through it for about an hundred yards, in which fpace only the faid white fubftance is found. This white fubftance evidently contains Sulphur in pretty large quantity, as appeares from the following experiment:"

"Being reduced into powder and thrown on an ignited iron, it burns with a blue flame offenfive to the nofe, like common Sulphur. I put two ounces of it in a common Hungary-water phial, with a fmall glass inverted on it, and placed it two thirds deep in fand, and a finall degree of heat elevated pure Sulphur, which condenfed on the fides of the glass immediately above the hot fand. The Sulphur thus obtained is abfolutely pure, and answers all the characters of the pureft Sulphur imported from Italy: all the phlogiftic part rifes with it, for the caput mortuum contains nothing inflammable. Lixivious falts or Lime diffolved it, and it was precipitated by fpirit of Vitriol."

And now, having above mentioned an Hypothefis of our Author by which he would evade the evidence of Sulphur in the waters of Aken from the flowers of Sulphur they yield, I shall close this Section with a Letter I received from a perfon conversant in these subjects, viz.

SIR,

I N Anfwer to yours defiring my thoughts upon Doctor L——'s account of the production of Sulphur from the waters of Aken, Borfet, &c. and also upon the doctrine he lays down touching the mif. miscibility of Sulphur with water, I here fend you what occured to me on the perusal of his book.

The two Politions which the Author advances touching fulphurated waters are these: first, that Sulphur in fubstance is not foluble or miscible with water by any art without the intervention of alcaline falts or earths. The second, that the waters of Aken, Borset and others denominated fulphureous, do not contain Sulphur in substance, but that the Sulphur found about the baths of Aken and Borset is generated by the contents of those waters after those contents escape out of them.

I fhall not detain you with confidering the firft of these positions, because it is proved to be false by a positive Experiment evincing the contrary which you mentioned to me, but proceed to examine what he founds his second Position upon: In doing this I shall begin with the facts which the Author admits in his own words, and then proceed to observe what facts remain still undetermined, and which I apprehend must be determined by Experiment before the Author is warranted to draw the conclusion he has done.

In Part III. p. 33. §. 77, of the Effay on Waters are these words: "Besides, the vapor of the baths of Aken, as well as the lower springs of Borset, yield plenty of the purest Sulphur, in a manner bitherto falsly looked upon as a sublimation, but which shall be set in a different light and explaned in its place."

In Part III. p. 53. §. 160, he fays "The Baths, especially newly filled, strike the organs of smell with a most ungrateful odour, which may be truly called sulphureous, as will appear when we come to shew that it carries with it, if not actual particles, the essential or component particles of that mineral."

In Part III, p. 69. §. 195, he fays, "But I am induced to think that there is no Sulphur actually or fubstantially diffolved in the water, but that the principles ciples of that fossil, viz. the Acid and Phlogiston, are blended with the waters."

In Part III. p. 72. §. 205, he fays " Its production cannot, in my judgment, be accounted for in any other manner than that of a generation, which is eafily conceived when the component parts of Sulphur are demonstrated in the waters."

Here then is a full, direct and explicit acknowledgment that these waters yield plenty of the pureft Sulphur, that they contain the principles or component parts of Sulphur, and that these principles or component parts are the Acid and Phlogiston; from all which it must be evident that nothing remains in contest between the Author and his opposers but the method by which this purest Sulphur is produced from these waters; so that, the Author having thus reduced the debate to one fact, I shall proceed to examine how he explains this in its place, as he promises in the first cited paragraph.

In this paragraph he alfo afferts that this production has hitherto been looked upon as a fublimation, and promifes to fet it in a different light and explain it. It must be confessed that he has fet this matter in a different light, but whether this different light be the true or false one in which the production of the *Sulpbur* which he acknowledges in these waters ought to be viewed and explained, may appear from the following observations:

In Part III. p. 67. §. 191, we meet with the following passage preparatory to his explanation of this Production: But in these waters there is not so fixed and permanent an union of the Acid and Inflammable principle till both fly off together, and uniting form the Sulphur, which till now has been looked upon as flowers of Sulphur, the product of sublimation, which I shall demonstrate to be absurd, as it is imposfible.

In this paragraph the Author lays the foundationof the neceffity of his having recourse to some other folution of this production of Sulphur than Sublimation, even by pronouncing it to be both abfurd and impossible to be by Sublimation, nay, he promifes a demonstration of this absurdity and impoffibility: and indeed, when I had proceeded fo far in the Author's work and met with this politive affurance of fuch a demonstration, I concluded that the matter in queftion would have been by Experiment cleared from every poffible objection, (Experiment in my apprehenfion being the only poffible method of demonstration in fuch a cafe) but to my great furprize, after reading his book with my best attention in fearch of this demonstration, I have not been able to find one ftep of it.

In a fublequent page, viz. §. 195. p. 69, he endeavours to explain this production of Sulphur in more express terms, viz. The principles of Sulphur, viz. the Acid and Phlogiston, are blended with the waters, yet not so as to come into such a contact as is necessary to occasion the union requisite for the production or generation of actual Sulphur till both these volatile parts flying off together, are confined in the vapor in the vaults, so as the union and consequent generation is readily brought about: Such is the light in which our Author has thought fit to set this matter.

Now I am not about to take upon me to determine how this *Sulphur* is produced, but to fhew that the Author's different light is full as obfcure, and the generation of the *Sulphur* according to the above profeffed explanation of it as abfurd and impoffible, if not more fo, than by Sublimation, notwithftanding the promifed Demonftration to the contrary.

To this end I must observe that in the two last cited paragraphs there is an affirmation that the Acid

Acid and Inflammable principle both fly off together, by which it must be understood that both these principles are in these waters equally volatile. But the Author has not produced any experiment either of his own or others to prove this fact; and there can be no doubt but he must find it difficult, if not impoffible, to produce any fuch experiment, because there is no fact in Chemistry better afcertained by experiment than that the universal Acid, one of the component parts of Sulphur, is extremely fixed, and that it requires a degree of heat greatly above that of boiling water to render it volatile, an heat, by the Author's own confession vaftly greater than the heat of the water of these fources: And it is equally well afcertained, and even confessed by our Author, that the Phlogiston or Inflammable principle, the other component part of Sulphur is extremely volatile, and diffipated with the smallest degree of heat; and yet the Author pronounces that they both fly off together, without fo much as attempting to fhew by what means they become of the fame precife degree of volatility, (which they must be in order to fly off together) or, telling us, if they are not precifely of the fame. volatility, which is the most volatile and flies off first, and where that first more volatile component part waits for the other lefs volatile component part which flies off after it; and poslibly the eftablifting of this fact might have made one ftep of the promifed Demonstration.

But there is another fact ftill more effential, to be effablished, than the equal volatility of the two component parts, viz. that the universal Acid, one of the component parts of Sulphur, in a volatile state, and in the open air, would generate actual Sulphur, with the Phlogiston, the other component part, and possibly this fact might have furnished another step of the Demonstration; and if the Author's Author's knowledge of natural bodies were as extenfive as throughout his whole book he would have us think, he poffibly might have discovered fome Experiment to support his opinion; but as he has not condescended to inform us better, we must, I fear, submit to the information of *Stabl, Junker*, *Langius, Neuman* and others who have given us the greatest number of Experiments upon the universal Acid in a fixed and in a volatile state, and to the entire overthrowing of this profound Chemist's new doctrine of Generation, have determined that the universal Acid in a volatile state, will not generate *Salphur*:

Langius's words are thefe: "(a) One of the properties of the univerfal Acid is to form Sulphur when we combine it with the Phlogiston, in its fixed ftate, whereas the volatile Acid (i. e. the univerfal Acid in a volatile ftate) cannot yield a fimilar production, because it is greatly attenuated in its composition with the Phlogiston, and this is the reason that when we pour the volatile Acid faturated with an Alcali upon lighted coals, it does not excite a fulphureous fmell as the ordinary vitriolic acid does in the like circumstances: this phenomenon merits the utmost attention."

Here then is an Experiment which contradicts the Author's first principle in point of fact, which he must remove out of the way before he can be allowed to conclude that the Sulphur of these waters is a Generation by the union of the Acid in a volatile state and the Phlogistion after they escape out of them; for it clearly follows, that, if Langius's observation be true, the Author's Generation is impossible, and therefore the advancing or supposing it absurd:

But his precipitancy in pronouncing it to be a Generation is not lefs confpicuous from the above

ex-

(a) Supplement to Junker's Confpectus Chemiæ.

experiment of Langius than from the artificial generation of Sulphur: for it is proved by the Chemifts (a) that for the artificial generation of Sulphur, the universal Acid, one of the component parts, must be in a concentrated state, (*i. e.* as near as can be, entirely free from mixture with water) and that before the generation is brought about, it must be heated to a degree vastly greater than the heat of boiling water. How then can a generation of Sulphur be brought about in the air that is in the vaults over these sources? or in a degree of heat fo much less than the heat of boiling water?

Nay, what is still more extraordinary, the Author himself points out to his readers this very generation of Sulphur here spoken of, for Part III. p. 34. §. 79, you will meet with this passage: "that Sulphur confists of these parts, (viz. the universal Acid and inflammable Principle) is also proved by the artificial generation of Sulphur, by fusing any neuter salt composed with the vitriolic acid, and throwing into it any inflammable body, the result of which will be a dark-coloured mass, which partly dissolves in water, gives a fetid smell and a yellow tincture, which is precipitated with acids in the form of a Magistery, which suffed gives perfect Sulphur.

Thefe are the Author's own words, and indeed it is not a little furprizing that he has omitted to explain and diffinguifh by experiment, if he could, between the artificial Generation here pointed out and the Generation fuppofed by him in the Pofition under examination, wherein the Acid is in a volatile, non-concentrated dilute ftate.

Upon the whole, what must be faid to a man who, after declaring that he *fet about determining the important question* (meaning as to the existence of *Sulphur* in the waters of *Aix-la-Chapelle* and

(a) Neuman's Works, p. 172. and Maquer's Elem. of Chymistry, p. 236. Vol. I. Eng. Ed.

, Bath)

Bath) with all care and caution, determined to take nothing upon trust, and yet takes the very principal point in debate upon trust, that is, without proof by experiment?

Notwithstanding this unphilosophical method of proceeding, it is clear from the whole tenour of his book that he intended to pass himself upon the world for the most able Physician and Chemist, just as he affirms numbers of Physicians pass upon the credulous, undiffinguishing populace, whose characters the discerning Author has drawn at full 'ength in the following words:

- In these days it is no wonder we find numbers of Phyficians entire firangers to the nature and qualities of some of the most valuable simples, and not daring, where they bappen to know and efteem a simple, common medicine, to prescribe it, when they see a vulgar prejudice take up arms against it, or find the popular folly such as to estimate the Physician, as is frequently the cafe, from the rarity, expense or complicated preparation, or perhaps the infinuated or imagined mystery of the medicine he prescribes; or to make men run after a jugling secret-monger, who is not in knowledge or rationality three degrees removed from the brute that draws the gilded chariot, in which he rides triumphant over physic, truth and common sense. Who, in fuch times, will prefume to prefcribe a plane, fimple remedy familiarly known to old women and nur ses ? - The Sensible, judicious, bonest Physician, who prefers the good of his patient and the peace of his own conscience to riches or the favour of a populace, which are too rarely obtained by better arts than temporizing, adulation and servility. Had the physical world been better stocked with men of this cast, or the populace more discerning, we should see fewer Quacks and of 'or Knaves make fortunes by the spoils of a deluded people; and medicines would not be rated by their rarity, as men are often by the tinfel on their garments,

arm.

[35]

ments, the magnificence of their houses, or the splendour of their equipages.

It feems to me that the Author would have conducted himfelf with more modefty, if, not content with the opinions of others touching the *Sulphur* of thefe waters, nor able to fupport his own by experiment, he had concluded upon them as he has upon those of the *Poubon* Spa, by faying that they were the work of the ineffable and inimitable chemistry of Nature.

I am, Sir, Yours, &c.

SECTION IV.

A DISQUISITION concerning Sulphur, Phlogifton, and Gas fulphuris or the volatile Acid of Sulphur diffinelly as ingredients in Waters, and particularly in Bath water, with its Comparison to that of Aix-la-chapelle. The fallacy and inconclusiveness of the arguments advanced against the existence of either Phlogiston or Sulphur in Bath waters.

OUR Author undoubtedly is fo far in the right, that Sulphur does not fo predominate in Bath waters as to be equally obvious to the fenfes as in Harrigate or Aix-la-chapelle waters; but his vehemence against the Brimstone-mongers has furely transported him beyond the bounds of moderation when he attempts to strip them even of Phlogiston, of which that they really do partake as well as of the volatile vitriolic or fulphureous Acid, shall be shewn from his own experiments, or in his own terms, that the Bath water as well as that of Aken, really contains the principles of Sulphur.

And as the *Batb* water is very frequently prefcribed in chronical cafes, and is fometimes tranfported for this purpofe, I apprehend thefe altercations about its contents will be of the more moment, ment, as they may ferve to fettle fome points that have been controverted concerning its use at the fountains and at this diffance from them :

And first of all, I myself do stand most chearfully corrected by our Author, in having supposed and published, as I did implicitely from the authority of others, that the Bath water might owe its curdling of milk to a volatile vitriolic Gas, whereas he informs us (what is found true by experience) that it curdles milk in London, as it does also here in Dublin, fo that where a Bath-water posset may be of use, it may be supplied here as as well as there; and moreover, it is but doing justice to our Author to acknowledge, that he has given useful inftructions (a) how to bottle Aken waters fo as to preferve their Phlogiston when tranfported to London with very little change more than that of heat; and the fame thing holds true of Bath water when carefully bottled and fent to us in Dublin; for in the fequel of these observations it will appear that this water, even here, gives every mark of Phlogiston with folution of Silver, folution of Mercury fublimate corrolive and folution of green Vitriol, as at the fountain, fo that it retains more of its original qualities even as at the fountain than is commonly supposed : for, as to the Iron, it is well known that it is but flightly impregnated with it at the fountain, nor does it fnew any veftiges of it here by the precipitation of any ochreous matter : on the contrary the bottoms of the bottles are clean. (A)

(a) Effay on Waters, Part III. p. 99. 100.

(A) The Experiments here hinted at, were made on the Batb water in Dublin, fome of which had been bottled three months, others fix months, imported by Thomas Johnston Apothecary, whole diligence and accuracy in procuring and preferving these and other Waters, deferve the acknowledgment of the public.

These inquiries will be yet of the more importance, as they will affift us in our reafonings on the operation and effects of a water fo often used: for indeed if our Author's representation of the Bath water be just, viz. that it is no more than a warm fubacid Chalybeate, impregnated with a neutral, bitter and a muriatic falt, not differing from our common purging Chalybeates, but in the heat and proportion, not in the qualities of the ingredients (a), it's effects are not to be explained on any other principles: but if, befide those, there enters into the composition a balfamic matter, as from the experiments elfewhere (b) related, and from the peculiar milky foftness obvious to our tafte in Bath water both at the fountain and at this diftance from it, is highly probable, it will be no rashness to attribute unto it other effects than what belongs to any meer purging Chalybeate heated :

And if there be moreover, either Sulphur, or Phlogiston, or a Gas or volatile Acid of Sulphur combined with the Phlogiston in this water, it must have a greater energy and activity than if it were entirely deftitute of fuch ingredients, as our Author would perfuade us: and although the Sulphur should exist but in a very small quantity and in a very fubtilized ftate, this would be no argument of its inefficacy : for Sulpbur is found, even in many of the cold waters in fo fubtilized a ftate as to be utterly incapable of being collected either by distillation or precipitation, which waters are yet found to be very powerful medicines in divers cafes: and that a combination of Sulphur with Iron. tho' in very fmall quantity and in a very fubtilized state in a water, diversifies its effects and adds greatly to its activity, we have a notable inftance

(a) Effay on Waters, Part III. p. 335.
(b) Method fynops. of min. Waters, p. 593. 597.

in the Geronsterre water compared to that of Poubon, even in the different effects of the first, which be-

even in the different effects of the first, which being impregnated with a greater share of Sulphur combined with its Iron, is found to be far more active, (a) more animating in relaxations, palfies and oedematous tumors, and particularly, more eminent in fixing the Gout : and how far it may be reasonable to attribute the superior efficacy of the Bath water to a subtile Gas or sulphureous Spirit, being an extremely volatile and elastic fluid, giving activity to the more inert materials, I shall endeavour to shew in the sequel, by giving feveral experiments and observations on it, the refult of recent inquiry.

That a volatile Acid of Sulphur is a frequent ingredient in waters where Sulphur in fubstance cannot be exhibited, being wholly diffinct from the aerial fluid manifesting itself by the sparkling bubbles in these and even in many fimpler waters, I am convinced by obfervation; and, as there has been not a little confusion in authors in relation to thefe two articles, I shall here adopt the account given of the Acidum Sulphureum vel potius Vitriolicum volatile, or of the volatile fulphureous or rather vitriolic Acid in a Supplement published by Langius, at the end of a French translation of 'Junker's Conspectus Chemiæ in the year 1757, describing its origin, and diffinguishing qualities from him; and to this shall annex some experiments I made on it with the utmost care and attention, in order to make some further investigation of its properties, with a view to fhew with a fomewhat greater degree of precifion than has yet been done, how far this fubtile Acid may be an ingredient in waters, and the rather as from the great energy and activity of this principle they may be supposed to derive a good deal of their powerful effects.

" This

(a) See Limbourg Traite des Eaux de Spa.

"This volatile Acid is obtained by flowly deflagrating Sulphur in a cucurbite; whole belly is very large and neck very ftreight, and pierced in feveral holes where the belly begins to leffen, into which water being poured, a fmall veffel full of Sulphur is placed to as that the margin of it may almost touch the water, which being lighted by a fmall match, and the fuperior orifice being clofed, the Sulphur confumes flowly, even fo flowly, that an ounce is not confumed in lefs than fix hours, by which means the Acid is united to the Phlogifton or inflammable principle in the most minute moleculæ, and by this union rendred volatile."

" It may also be formed by the fumes of Oil of Vitriol, in diffilling, escaping by some crack in the vessel and uniting themselves with the vapors of the burning coals, which is the same volatilized Acid as that above from the slow deflagration of Sulphur."

"This Acid is entirely diffinct from common Spirit of Vitriol, whofe volatility proceeds only from the phlegm it contains, and in containing an inflammable subfrance, which common Spirit of Vitriol does not."

" It is also diffinct from Sulphur, whose Acid is fixed, and the phlogistic principle in much greater quantity and more closely united."

"But the union of the *Phlogifton* and Acid in the volatile vitriolic Acid is more lax than in *Sulphur*, fo that if it be exposed in a warm atmosphere and a large vessel, the acidity exhales and leaves an infipid phlegm, nor does it closly combine itself with Spirit of Wine rectified, but is quickly diffipated in the air, flying off."

"It is further diffinguished from the fixed vitriolic acid by the fmell, which diffuses itself to a diftance, is fuffocating and incommodes the breaft, whereas the fixed vitriolic acid has no fmell."

Again,

"Again, the fixed vitriolic Acid is almost cauftic on the tongue, but the volatile vitriolic Acid when depurated has fcarce a fensible acidity, but a certain roughness on the tongue; and lastly the elasticity of the volatile vitriolic acid is such that it will burst a bottle close stopt in heating. (a)"

So far Langius.

I procured the volatile Acid of Sulphur prepared by diftillation from Patrick Bride Chymift, and the volatile Acid of Vitriol prepared by Dr. Francis Hutchefon, Profeffor of Chymiftry in Dublin, anfwering to most of or all the characters of that above described by Langius, and with it made the following experiments shewing that tho' it falls short of producing the same effects to the same degree as Sulphur in substance does, it produces effects on Metals and their Solutions which the fimple Acid does not, until it be combined with the Phlogiston, which effects are also in a great measure common to Sulphur in substance.

I fuspended a Silver spoon in the vapor of the above-mentioned volatile Acid of Vitriol in a narrow mouth'd jug for the space of a week without any effect, which was also the case of another Silver spoon kept immersed in the liquor: but when the concave part of the spoon was placed upon the mouth of a gallypot full of this volatile acid in a fand heat and kept there about two hours, it was tinged of a dark brown and faint copper colour, appearances agreeable to the effects of the vapor of solution of *Sulphur*, altho' these discolorations by the volatile acid are less deep than those from the vapor of the solution of *Sulphur* artificial or natural, and particularly less deep than those produced by the vapor of our sulphureous water

(a) Lightening has in fome measure effects fimilar to those of the volatile fulphureous Acid, both with respect to the explosive power and to the discolouring of metals.

at Lucan near Dublin, which, without any heat applied, tinged a filver fpoon exposed to the fteam of it in a jug whole mouth was ftopt, of the colour of lead in the fpace of 48 hours.

At the fame time the effects of the above Gas, or volatile acid of Sulphur or Vitriol on feveral of the metallic folutions are fo far different from those of the fixed acid of Sulphur or Vitriol that the faid Gas being diluted with diffilled water, in repeated experiments, did never fail to produce various difcolorations with the folutions of Silver and Mercury, even fuch as are proper to folutions of Sulphur, more or lefs according to the ftrength of the impregnation, as is fhewn in the Table annexed : but the fixed acid of Sulphur and Vitriol, viz. the Spirit of Vitriol and common Oil of Sulphur by the bell, equally diluted had no effect on those metallic folutions, viz. by reason of the last named acids being not combined with the Phlogiston; a fact that may well merit the attention of the curious in explaining the appearances arifing on the mixture of the metallic folutions with feveral waters where Sulphur cannot be diffinctly demonstated

Langius before quoted proceeds to observe that Nature produces fomething like the above volatile fulphureous or vitriolic Acid in the decomposition of the Pyritæ and other fulphureous bodies, and that it is furnished by the greatest part of the Acidulæ and Thermæ, but with this difference, that it is not fo volatile or fo ftrong as the above artificial Acid, and that the Grotto del Cani near Naples, and another cavern near Pyrmont are the two most remarkable places known for this volatile acid or fulphureous Spirit, in the latter of which places it appears in the form of a cloud or vapor, which feldom afcends more than two feet above the ground, and fuffocates not only birds and infects,

but also quadrupeds if long exposed to it; and if a man plunge his head down to the bottom of the cavern, he percives a penetrating fulphureous fmell, becomes giddy, drowfy and in danger of being fuffocated : and I am well affured that the Damps in Mines kill with ftupefaction : fuch are the effects of the native volatile sulphureous Acid when acting in its full force; and that the Pyrmont water, one of the richeft of all the Chalybeates, is impregnated with it, we may conclude from the fulphureous vapor which is perceived at the wells, (a) which makes the water-fervers giddy, and which alfo caufes the fifh, frogs, ducks and goflings when thrown into thefe wells to become giddy, lofe their ftrength, and at laft fall down and fink, and which also affects mankind in drinking it with a kind of drunkennefs, a not unfrequent effect alfo of our Chalybeate waters and owing to the fame caufe in a lefs degree; for indeed that an extremely fubtile and volatile acid enters into the composition of our ordinary Chalybeate as well as other mineral waters has been fhewn elfewhere by divers observations formerly made, and which have been fince confirmed in Dr. Lucas's experiments in his Effay on Waters. In this place it shall fuffice to mention but one inftance to this purpofe : Dr. Whiftler, an eminent Phylician who frequented Tunbridge waters many years, mentioned by Dr. Baynard, used to fay that in a dry feason he could manifestly taste a Gas Vitrioli in them.

And as this is a volatile and powerfully elaftic fluid capable of producing those mischievous effects on animal bodies above-mentioned when collected and acting in its full force, there is good reafon to believe that in a restrained degree, it may produce great and good effects, in giving activity to the element and other more inert materials.

Now

(a) Method. fynops. of min. Waters, p. 313. 314.

Now the *Bath* water is an illustrious inftance of fuch an impregnation both by the tafte and fmell, as appears from the following authentic testimonies:

First Dr. Baynard, a learned Physician, and many years refident at Bath, affirms (a) that it had been often observed, that in a great drought and the wind at or about N. E. the Bath waters have been not only fenfibly hotter, but acidulated and abounding with a Gas Vitrioli, not unlike the grateful acid of the German Spaw water; and an old guide told him he had observed the fame thing a hundred times in bright, ferene weather, and when the wind blew fresh from some northerly point: And that the organ of finelling is under the like circumftances affected by the vapor of Bath water as by that of Sulphur, appears from the following observation of the Gentleman hereafter mentioned who refided for a confiderable time at Bath :

The water being brought into his room every morning in a tin can ufed at *Bath* for keeping the inclofed bottle warm, on entering the room, it immediately difcovered a fmell of *Sulphur*: his wife, daughter and fervant firft obferved this by the fmell, and afterwards by the tafte, and himfelf by both at once: but this was only perceived in frofty mornings, (when the vapors are condenfed) for in cloudy or wet mornings it difcovered very little fulphureous either to the fmell or tafte.

But Dr. Lucas's own testimony with respect to an impregnating volatile Acid is still more express and strong, viz. "(b) In the King's bath pump room the first thing that presents itself to our observation in this water is a subtile Acid which flies off in the vapor, sometimes sensibly strikes the nose, and always

(a) Of cold Baths, p. 190, and in the Appendix, p. 431. (b) Effay on Waters, Part III. p. 277.

proves

proves very offensive to weak lungs, (agreeable to the description ipsifimis verbis, given by our Author Part III. p. 33, of the effects of the vapor of Sulphur in fusion and of the volatile sulphureous or vitriolic Acid both natural and artificial above observed) and powerfully corrodes all the iron works in and about the Baths."

Now fince the *Phlogifton* is allowed by our Author to be the caufe, not only of inflammability, but of colours and odours in bodies, and is what gives fmell and volatility to the Acid of Sulphur or Vitriol, which fimply is entirely inodorous, it follows from his own teftimony, that the *Phlogifton* fubfifts combined with the Acid in the vapor or volatile parts of *Batb* waters as well as those of *Aken*.

So much of the volatile parts of Bath water: let us next confider its more fixed parts, and first what our Author (a) calls the light black Mud or Earth, which is found in the cifterns, and partly deposited by the waters in the corners of the baths, and feems to bear a confiderable analogy to the light black mud which is also deposited in the baths, refervors, aqueducts and canals at Aken (b), the colour of which he afcribes in a great measure to the Sulphur falling to the bottom and augmenting the colour and volume of the fediment; and here indeed he agrees to other Authors, who have examined the bituminous and fulphureous waters, who make the black colour of the earth or fludge in their course to be peculiar to these waters $(c)_{1}$ which also agrees to the analysis of Sulphur, which both on being diffolved in an alcaline lixivium and on being deflagrated, is observed always to leave a black fixed earth or fediment (d): So that as

(a) Effay on Waters, Part III. p. 276. (b) Ibid. p. 57. (c) Memoires de l'Acad. royale, A. D. 1762, p. 1083; and Short's Hift. min. Waters, Vol. I. p. 312. (d) Shaw's philof. principles of universal Chymistry. far as we may be allowed to reafon from analogy, the light black Mud of the Bath waters is of a fimilar nature; and if our Author had examined that fubstance without partiality, he would probably have been a little lefs peremptory in pronouncing it not to be a mineral production, as he allows the Aken mud to be, but a meer vegetable matter putrified : for, tho' he tells us that it yields nothing like Sulphur in fublimation or diffillation, this may be eafily accounted for from the fmall quantity of the moleculæ difperfed among the calcarious and other matter, which may be illustrated by a fimilar observation upon the black fediment of our fulphureous water at Lucan near Dublin, which tho' it be of a ftrong fulphureous fmell, yet, being carefully diffilled by a mild heat, yielded no flowers of Sulphur, altho' the white glairy fubftance deposited by the same water did, and for this obvious reafon, it's being more free from heterogeneous mixtures.

Now the Mud of Bath water, upon a careful examination of it on the fpot, and of a fpecimen of it transmitted to Dublin, is found sometimes when first taken up, to be green, an equivocal mark common either to a vegetable matter, (as perhaps fome portion of the Conferva mixed with ir, or to Sulphur, or both) but by keeping, it turns ash-coloured and ferments briskly with Acids, and on being roafted in the crucible it loft the afhcolour, and acquired a brown redifh caft, appearances fimilar to those exhibited by the blue and black Marls, (a) which in the language of the vulgar, contain some pittance of Sulphur soon diffipated by the fire, fo that this Mud appears plainly to be not a purely vegetable production, but partly of the mineral or calcarious kind with a fmall

(a) Hill's History of fossils.

quantity

quantity of that fubftance which tinges it black and afh-coloured:

But it were doing injuffice to this Precipitate of the Bath-waters to suppress on this occasion an experiment of Guidott (whom our Author calls the head of the analyfers or rational writers on thefe waters) thus circumftantially related, (and which amounts to a more direct evidence of real mineral Sulphur entering into the composition of this Mud) viz. " The (a) foul contents of the Bath being put into a crucible for calcination, before the marly or muddy parts were consumed, the crucible being then opened and the contents touched with a spatula, gave a very strong stench of Brimstone, and burnt as blue as ever I faw any Sulphur." To which I add, that a fix-pence having been kept in the Mud of the King's bath in a moderate heat, and become black thereby, and then transmitted to me in Dublin was of a dark blue and copper colour, being the colours ordinarily given to Silver by the waters called fulphureous.

There observations placed together may fuffice to shew the analogy of *Bath*-Mud to that of other waters called sulphureous.

But the point of the exiftence of Sulphur in another of the fubflances fpontaneoufly feparated from the Bath waters, viz. the Bath-Sand, a mouldered Pyrite (being a composition of Sulphur, Iron, and calcarious Earth, and which he pronounces to be the cause both of the heat and impregnation of these waters) is fairly given up in these words:

"The Bath-Sand thrown (b) into an ignited crucible emits a strong sulphureous vapour, and a blue flame suddenly disappearing, so that it is hardly per-

(a) Treatife of Bath Waters in English.(b) Effay on Waters, Part III. p. 270.

ceptible

[47]

ceptible to the fight. (A) The vapor collected in a glafs bell condenfes and shews itself to have been none other than the vitriolic, (or in other terms fulphureous) acid." And to this agrees what I am well affured of, as a well known fact at Bath, that this Sand thrown upon a red hot iron fends forth a fmell equal to that of a lighted brimftone match, and the ordinary iron Pyrite, according to Henkel, contains $\frac{1}{3}$ or $\frac{1}{4}$ of Sulphur.

Here let me observe the great difference between this substance and the refiduum of the *Thames* water, (a) which (as containing not a subphureous but Oily matter) in a well ignited crucible gives no sensible acid vapor nor blueness in the flame, but a sif oil or grease had been burning.

Thus it appears that the very matter fuppofed to impregnate the *Batb* waters contains the *Phlo*gifton or inflammable principle united to the Acid, not only laxly, as in the *Gas fulphuris* or volatile fulphureous Acid, as above, but clofely, and fo as to require a ftrong fire to feparate them, fo that here appears, even from our Author's own teftimony, in the *Batb*-waters, 1. The acid of *Sulphur* volatilized by and combined with the *Phlogifton*. And 2dly, *Sulphur* in fubftance from the impregnating *Pyrite*, which by the accurate *Walerius* is defined, *Sulphur ferro mineralifutum*.

This is one notable inftance of *Sulphur* diffolved in water by the chymiftry of Nature, without the intervention of an Alcali, and fo beyond the ken of our Adept, altho' it is above fhewn that Art can effect the fame thing alfo without the help of an Alcali, concerning which artificial folution it is

(A) Thomas Haviland Apothecary, got ten drams of a very volatile acid ipirit from fix pounds of the Sand taken from the ciftern in the King's bath.

(a) Effay on Waters, Part. I. p. 134.

observable that it has not the smell proper to a solution of *Hepar Julphuris* or like that of *Aken* water and many others any more than *Bath* water; so that *Sulphur* may be invisibly suspended in water without affecting the smell in the same manner as that wherein the solution is effected by an Alcali, and confequently the argument drawn of the absence of *Sulphur* from the want of such a smell is fallacious.

I proceed next to confider what evidence is given by the Bath water itfelf of the prefence of either Phlogiston or Sulphur, neither of which our Author, (a) (to use his own words) with positive affurance concludes is found in Bath water, whatever men unacquainted with the principles of chymistry and nature—or who might have thought themselves interested in concealing the truth, might have heretofore, now do, or hereafter shall set forth to the contrary.

Not intimidated by this Menace, I shall however examine his experiments, and humbly hope to make a better use of them than he has done, endeavouring on the one hand to guard against a precipitate conclusion from a single experiment, and on the other by a careful comparison of the feveral experiments together, and by viewing the several evidences or want of evidence of the *Phlogiston* in various lights, to draw a just inference or induction from the feveral particulars.

I shall begin with that Experiment in which he seems to place the greatest confidence, and upon which he builds his triumphant declaration above quoted, viz. (b) The solution of lead causes in Bath water the most perfectly bright, white clouds, and at length a lovely white magistery, and therefore it contains neither Sulphur nor Phlogiston, because, bad there been any portion of these in the water, mud-

(a) Effay on Waters, Part III. p. 307. (b) Ibid.

dy,

dy, yellow, or dark brown or black clouds must have been the consequence of the mixture."

In anfwer to this, I beg leave to illustrate the force of this reafoning, by applying it to the investigation of the presence of another fosfil, to which, if it be just, it must be applicable as well to Sulphur; and that is Iron-Mine. Every body knows that the attraction by the Load-ftone is a fure teft of the prefence of Iron in any mineral to be examined : but suppose any Operator on these minerals, upon his fubjecting any of them to this teft, finding it to fail, thould inftantly conclude that it contained no Iron, would he be fafe in his conclusion? Not at all: for it is found upon tryal that there are Ores very rich in Iron which do not yield to the magnet, of which Walerius in his Mineralogie has given divers inftances : but to come directly to the point :

If a man were to fet out with a determination to demolish both Sulphur and Phlogiston in water and his evidence were to reft upon one fingle experiment, he would be much in the right to chuse that experiment or test of the presence of Sulphur or Phlogiston, which might be the most likely to fail, and to omit, or not to infift on what is the most touchy or most fensible test: of the laft fort I take to be the folutions of Silver and of Mercury fublimate corrofive; of the first the folution of fugar of lead, and how far our Author has observed this conduct I shall submit to the reader.

Indeed if Bath water were what we call a fimply fulphureous one, fuch as that of S. Amande in Flanders, Nottington in Dorsetshire and divers others in England and Ireland, then undoubtedly the inference of the absence of Sulphur or Phlogiston, from the failure of the muddy, yellow, dark brown or black clouds upon adding the fugar of lead, must have been just, fince those fimpler waters do H not not fail to ftrike those colours with that folution, from the predominancy of the phlogistic principle acting in its full force:

But with the waters wherein there is a large proportion of heterogeneous matters the cafe is far different: Nature difguifes itfelf, and he that would different: Nature difguifes itfelf, and he that would different in the fulphureous or inflammable principle muft expose the water to various trials with different materials, when he will often find one to detect what another conceals, whereas were he to truft to a fingle experiment of one metallic folution and from thence, without any regard to other metals and their folutions, pronounce any water to be or not to be impregnated with *Sulphur*, his conclusions would prove wild and extravagant, which in the prefent cafe has been too much, and ever will be, the confequence of fuch a fuperficial examination of waters:

As an inftance of the truth of this observation, I shall place in the front the waters of Aken, (confeffedly fulphureous) in which there is a very confiderable mixture of calcarious Earth, (a) ever caufing a white precipitation with fugar of lead as well as with alcalis; and accordingly the Aken waters turn milky with the alcaline ley, and of a muddy milky colour, and precipitate a dull white powder, with something of a brown and dark ash colour with fugar of lead (b): and why? because the Phlogiston is blended with a large proportion of terreftrial matter precipitated by the fugar of lead, being a precipitator in common to the white calcarious matter and to the Phlogiston: to which may be added fome particles of the Cerufs alfo fuffered to fubfide, as being partly difmiffed by reason of the superior attraction of the calcarious earth in the water.

(a) Essay on Waters, Part III. p. 84, 85. (b) Ib. p. 94. And

And I apprehend I may not unjustly subjoin the Bath water as a fecond inftance to the fame purpofe, which is also impregnated with various minerals, and particularly a calcarious earth, manifefted by the large white precipitate it yields by means of oil of tartar, which must difguise the other darker coloured appearances otherwife to be expected in the clouds and fediment exhibited by adding fugar of lead to it : it is however but doing juffice to the fubject to bring in here the teftimonies of others on this head from experiments made on the Bath water both on the fpot and in Dublin; the first long before this controverly was in agitation, and confequently may be prefumed to have been impartially related, which experiments were made by Dr. Hilary, who found that the folution of fugar of lead precipitated from the water of the King's bath and Hot bath a white powder intermixed with greyifh fpots, which indeed does not altogether quadrate to the perfectly bright white clouds and lovely white magistery exhibited on this mixture according to our Author, as abovementioned, but is very agreeable to the appearances exhibited by one of the artificial fulphureous waters in the Table annexed, in which Sulphur is fuspended in confiderable quantity, as also to an observation of my own and of another prefent on the fame mixture, viz. the folution of fugar of lead with the Bath water in Dublin, which in reiterated observations, did, on being held up to the light, belide the whitenefs, exhibit fome shade of yellow, which, and the greyils (pots abovementioned must be allowed to be as clear indications of some portion of Phlogiston as they are in other waters, and particularly as is the muddy milky white colour produced by the folution of Lead in the condenfed vapor of Aken water, which we are told (a) most certainly arises from the Phlogiston : But

(a) Effay on Waters, Part III. p. 76.

But to fhew how inconclusive the meer appearance of whiteness exhibited by the mixture of the folution of fugar of lead with regard to the nonexiftence of Sulphur in waters is, I shall here from the labours of the indefatigable Dr. Short, inftance feveral waters which, altho' they otherwife give ample tokens of their being fulphureous, are yet fo far from affuming brown or black colours with folution of fugar of lead that they whiten with it, viz. 1ft. the celebrated Sulphur-well of Knarefborough, (a) well known for its ftrong tafte and fmell of Sulphur, and which lets fall a dark fediment. 2dly, (b) Croft water which fmells ftrong of Sulphur, and in the course of which every thing becomes white, with reddifh fpecks between, and turns of a bluifh white with folution of Silver, but white with folution of fugar of Lead. 3dly, Afkeron water lituated five miles from Doncaster, smells and taftes very ftrong of Sulphur, and, as an evidence of the ftrength of its impregnation, its ftream is full of a white thick fludge which ropes like decoction of Althæa, and yet with folution of Lead it whitens first, and then gives a brownish fediment. 4thly, Chadlington water fmells like the washings of a foul gun, and yet turns milk white with folution of fugar of Lead.

I shall next confider the effects of *Bath* water on Silver and its folution as an evidence of the prefence or absence of *Sulphur*: and first it is alledged (c) that a filver spoon standing fome hours in the water, and that filver-leaf kept therein 24 hours and the water often renewed, did not shew the least visible tendency to yellow, from whence it is inferred that here is no *Sulphur*.

Now, tho' the facts here related in these few experiments made by an itinerant visitor be not

(a) Short's Hift of min. waters, Vol. 1. (b) Ib. p. 299. (c) Effay on Waters Part III. p. 281.

,beineb day on Waters, Part III. p. 76.

denied, yet, if I be not greatly miftaken, this general inference is a little too haftily drawn : for

Ift. It had behoved an Author who was fearching after truth, to have paid fome regard to the experiments of others who had been longer refident on the fpot, and to have compared their experiments with his own; but this he has utterly omitted, and particularly that of *Guidott*, who affirms that both Silver and Brass by a longer ftay in the water are notably discoloured, even in the same manner as by the waters called fulphureous, v. g. that Silver placed in the fpring became first of a copper colour and then black, and that Silver which had lain for some time near the springs became of the same colour as in the decoction of *Sulphur* in Lime-water (a).

2dly; In these complex subjects of philosophic inquiry, if we would fucceed in finding out truth, we must view the subject in a variety of lights, and confider, not only the effects of the water, but of its Vapor, well knowing that the vapors of both putrid waters and of those called fulphureous have been observed to produce greater effects in tinging Silver than the waters themfelves. Accordingly our Author, when treating of Aken water, observes that Silver, in the vapor of the source, is almost instantly affected, acquiring a pale gold colour in lefs than a minute, and in three is carried to the higheft degree of tarnifh (b); and that polished Brass, which was kept four hours under the water, flewed no change, while what was above the water got first a pale, then a deep gold colour, and foon became variegated with all the fhades of red, orange and purple: and thefe experiments are alledged as proofs of the Phlogiston in Aken water, even as the like difcolorations of Silver

(a) Eng. Edit. of Treatife of Bath waters, Chap. 5.
(b) Effay on waters, Part III. p. 67.

from

from the vapors of putrid waters, bilge-water, &c. are alledged as the effects of the *Phlogiston* in them :

But when Bath water comes under confideration, not one word is mentioned as to the effect of its vapor on Silver or Brass, whether from inattention or from a prejudice against this water, I shall not take upon me to fay, but thus much I may adventure to affirm, that had he been as minute in his account of the Bath water as he had been of that of Aken, he would not have wanted evidence of the Phlogiston in the first as well as the laft. This great defect of his therefore in the comparison of Aken and Bath waters I shall here endeavour to fupply, and fhew that the Bath water has as just a claim to an impregnating Pblogiston as the Aken waters has, from politive experiments on the operation of its vapor, fhewing that this effects in a much thorter fpace of time what the water itself in fome observations effects not at all, or at least requires a much larger space of time to effect :

R. Mufgrave Efq; from Lifmore in Ireland, a gentleman of undoubted veracity, who refided feveral months at Bath in 1752, and taking his firft lodging in November in a room that had two or three large fash windows fo near the Crofs bath, that its steam hung about the Bath like a fog, observed that his Silver buckles which he put at the bottom of the window every night going to bed, became in the morning yellow like gold, which change of colour did not happen to the same buckles when he removed to another lodging remote from the Baths.

He also corroborates what is observed above of the offensiveness of the steam of *Bath* waters to weak lungs by a notable example of it which fell under his own observation, which is also notoriously the case of the smoak of Pit-coals, as well

as

as it's tarnifhingSilver, in both which inftances the fteam of *Bath* waters answers to that of Pit-coal, a probable indication of fome fimilarity in their conftituent parts; and that Pit-coal is not a meer Bitumen, but contains also a fubftance very like common *Sulphur* and wholly diftinct from Bitumen we may learn from fome experiments lately made by two eminent Chymifts (a).

But to return to the effects of the vapor of *Bath* water on Silver, as this is a fact of importance, I thought it were well worth while that it fhould be confirmed by further and repeated tryals made on the fpot, which was accordingly done with great accuracy by a curious Gentleman of the profession there, from whom I received the following circumstantial account of this matter *July* 1761, which is here inferted in order to shew that the two other hotter Baths have this power of tarnishing Silver by their steam in a greater degree than the *Crofs*-Bath, *viz*.

A plate of Silver bung up in the steam of the King's bath, and another in the Hot bath, were tarnished in twenty-four hours, but in forty-eight hours they were tarnished to a greater degree, even so far as to have lost their splendor, and to look like French plate from which the filver is worn off: but a plate of Silver which was suspended over the Cross bath did not in that time at all lose its colour, tho' it is supposed that if the Silver plate had been exposed to the steam of the Cross bath a longer time, it would also have changed its colour; agreeably to the observation above related of the effects of the steam of that Bath on the filver buckles.

Now, to ftain Silver yellow or black is the well known property of the vapors of the folutions of Sulphur, and indeed the effects defcribed in the

(a) Neuman's Works published by Lewis, and Shaw's philof. principles of universal Chymistry.

two

two foregoing observations are remarkably greater than those of the vapor of the volatile vitriolic or sulphureous Acid above mentioned, which, tho' far stronger and less diluted than the vapor of *Batb* water, did not produce this effect on Silver fuspended over it for a week, but required the affistance of a Sand heat to tinge the Silver.

To the foregoing observation agree the powerful effects of the steam of *Batb*-water on Iron, viz. it has been observed (a) that a ring of Iron has been eaten out by it in seven years, an effect altogether similar to the well known operation of *Sulphur* on Iron, and particularly of the steams of the sulphureous waters of *Aken*, as mentioned by our Author, viz. that all (b) the Iron work about the Baths is greatly corroded. Now it is well known that *Sulphur* readily unites itself with Iron, and turns it and Copper into yellowish concretes like the *Pyrite* (c):

And here it feems to be worth while to take a fhort view of our Author's way of reafoning on the effects of the vapor of Aken water fimilar to those above related of the vapor of Bath-water, viz. In his third Section upon the Aken waters, having defcribed the effects of the vapor of these waters on Lead, on polifhed Brafs, Silver, &c. he tells us that experience (d) convinces us that these effects cannot be produced by the Acid alone, and he adds, It must be then from the Phlogiston or inflammable principle. And a little before, (e) he deduces an Acid and Plogiston in Aken waters from their vapors corroding Iron and Lead: and indeed this is agreeable to the foregoing experiments and observations on the effects of the Bath waters, with this explanation, that these effects in both waters are not owing to the meer Acid or

(a) Method. fynops. of min. Waters, p. 596. (b) Effay on Waters Part III. p. 64. (c) See Neuman. (d) Effay on Waters, Part III. p. 66, 67. (e) Ibid. p. 64, 65. or meer *Phlogiston*, but to an Union of both; for this is abundantly confirmed by the experiments related and often repeated in the Table annexed, where it appears that the volatile acid of *Sulphur*, or the acid of *Sulphur* volatilized by and combined with the *Phlogiston* diluted with diftilled water, has some effect in discolouring Silver in substance, tho' lefs than the folution of *Sulphur* in an alcaline ley, and produces the like discolorations with folution of Silver that *Bath* water does, viz. a dark brown sediment and bluish cloud; and when this volatile acid is grown effect by the exhalation of the combined *Phlogiston*, it effects no discoloration at all:

And thus is the existence of the *Phlogiston* in the *Batb* waters established by our Author's experiments on those of *Aken*, the like *phænomena* arising and the same reasoning being applicable to both: and it must be owned that in these parts of his work he has done justice to the waters of *Aken*; but it is somewhat surprizing that he should so far forget himself before he had finished his book as utterly to deny the existence of the *Phlogiston* in *Batb* waters; had he revised his work, he must have seen that the very same Premises from which he inferred a *Phlogiston* in the waters of *Aken* were equally conclusive with regard to a *Phlogiston* (tho' in a less degree) in those of *Batb*.

Having thus far shewn that the Vapor of Bath water as well as its Mud and Sand do each of them exhibit divers of the appearances proper to Sulphur, and that the Sand and Vapor particularly do manifest the union of the Phlogiston and an Acid as well as Aken water, it will yet be necessary in order to clear up this subject from the obscurity in which it has been involved, and to obviate an Objection that may possibly be made of a Sulphur formed in the air as in the Aken waters, to examine the Bath water itself from the experiments I made made on it chiefly at the fountain by our Author himfelf, tho' partly improved and in fome measure corrected by others, in order that it may appear how far this Water in it's utmost perfection, and possefield of whatfoever is either fublimed from it in vapor or precipitated in the form of Sand or Mud, confirms the foregoing evidences of an impregnating Sulphur or Phlogiston.

We have feen above that the folution of Lead gives fome faint marks of fuch an impregnation in *Bath* water, altho' alledged for a contrary purpofe by our Author; but this matter will be much clearer by examining the appearances exhibited by the folutions of other metals, as that of Silver, and of Mercury in divers forms, and of Iron in the *Englifb* Vitriol, each of which we fhall find to confpire with one another as well as the Experiments above related, in fhewing the fame thing:

First then our Author informs us that (a) upon adding folution of Silver to Bath water, bluish white clouds appear, and in eight hours a fediment is formed of a purple hue: and (b) upon adding the fame Solution to Aken water, first a milky, then a yellow, after a brown coagulation ensues, and in twelve hours it gives a white or cream coloured precipitate, and over that it is of a pale brown or dark ash-colour.

Now in the account given by our Author of the *Aken* water, these and the like discolorations by means of solution of Silver are attributed to the *Phlogiston*, nay, even so weak a tincture as that of Mosel wine produced by solution of Silver in the condensed vapor of *Aken* water is attributed to the *Phlogiston* (c); and indeed these discolorations by this solution do exactly answer to the effects of the fame folution on that of *Sulphur*, the colours

(a) Effay on Waters, Part. III. p. 305. (b) Ib. p. 95, 96. (c) Ibid. p. 76.

being

being varied to yellow, brown or black according to the different strengths of the folutions of Sulphur : and in the Bath water the fediment is of a purple hue: thus, as in many other experiments, the folution of Silver is found to be a much more fenfible teft of the prefence of the Phlogiston than fugar of Lead, as further appears by comparing their effects on the putrid waters in the Table annexed.

Why then does not our Author confider thefe appearances in Bath water from folution of Silver as evidences of the Phlogiston as well as in the Aken water ?

Let us next fee how agreeable the above appearances from folution of Silver are to those exhibited by other metallic folutions, and first by that of Mercury in different forms: The Aqua Sulphurata in the Table, upon the admixture of the folution of Mercury in Aqua fortis gave a flefh coloured precipitate and a pale blue purplish circle, and in the fame water become fomewhat effete by keeping, the mixture was yellow :

But it will be clofer to the purpole to confider the effects of Mercury on the Aken and Bath waters, and to give the etiology of the appearances as laid down by the Author, thus: The folution of Mercury fublimate in diffilled water produces in Aken a pellicule variegated with all the colours, and the fame folution he tells us (a) alfo exhibits a pellicule of all colours in Bath water (b), to which let me add that I also observed the very fame appearance on the mixture of the fame folution with Bath water in Dublin, which had been taken up many months. Now how is this appearance explained? In the waters of Aken (c) our Author folves it in these words:

(a) Effay on Waters, Part III. p. 94. (b) Ib. p. 303. (c) Ib. p. 99. " The

" The Phlogiston shews itself in the pellicule, that subtile principle, from different combinations of which all colours as well as odors arise?" And why not in Bath water as well as Aken? The partiality or precipitancy of such a writer is too obvious:

I shall conclude with the appearances exhited by the mixture of green Vitriol with the Bath water, our Author's relation of which I ftrongly fufpect may require a revifal : for he tells us (a) that the folution of green Vitriol in diffilled water caufed milky clouds with a pale yellowish hue, which fubfide in the form of an ochreous precipitate. Here he fays not one word of any variegated pellicule (which would have been as good an evidence of Phlogiston as that from the Sublimate above in Aken water) whereas I do affirm that, agreeably to the account given elfewhere, (b) in fome Bath water which had been kept feveral months in Dublin, the folution of green Vitriol in diffilled water exhibited a variegated Scum confifting of the red, yellow and blue colours; and last summer 1761, a solution of Sal Martis in diftilled water being mixed with the King's bath water on the fpot, the refult observed by the same curious Gentleman of the Profession abovementioned, was, that a pellicule was formed of a beautiful, vivid, blue and gold colour, like the Cauda pavonis, or like what we often see in stagnant waters near Coal-pits.

And the fame Gentleman in a fubfequent Letter affures me, that the precipitate made from Bathwater by fugar of Lead, becomes greyish by ftanding, which confirms Dr. Hilary's experiment above mentioned, and invalidates the evidence from the lovely white magistery faid to be exhibited by the fame mixture above, being the cardinal experi-

(a) Effay on Waters, Part III. p. 307.
(b) Method fynops. of min. Waters.

ment

ment of our Author from which he thought himfelf authorized utterly to explode any *Phlogifton* from these waters, but how justly is now submitted to the reader.

And now, to fum up in one view the Experiments above related on the Mud, Sand, Vapor and Water of *Bath*, in order to fee how far they are evidences of an impregnating Sulphur,

Ift. The Mud of *Bath* water, or the Earth tinged by a finall quantity of a matter which is a *pabulum ignis*, agrees to the Mud of *Aken* and other fulphureous waters, and to the analyfis of *Sulphur* in the colour, and agrees to *Sulphur* in the finell and in difcolouring Silver.

2. The Bath-Sand agrees to Sulphur in it's finell and in it's appearances in the fire.

3. The Vapor of *Bath* water produces the like effects as that of folution of *Sulphur* in tarnifhing Silver, tho' in a lefs degree ; alfo it agrees to *Sulphur* in corroding Iron.

4. The Water itself exhibits with the metallic folutions the like discolorations as solution of Sulphur does with the same solutions.

Thus both the Water itfelf and what is precipitated from it confpire in exhibiting appearances proper to *Sulphur*, and fome of them peculiar to it, and the defect of evidence in one experiment is abundantly compensated by the light afforded by others, upon a careful review of the whole.

It is true, the Aken waters give proofs of a ftronger impregnation by the above trials, as well as yield flowers of Sulphur, which the Bath waters do not; and the firft fmell much ftronger, and like a folmion of the Hepar fulphuris, containing the mineral Alcali, of which the Bath waters do not partake, their Salts being of a neutral kind, whereas in those of Aken the Alcali, (a fit menstruum for diffolving Sulphur) prevails; and yet yet it has been shewn above that not only Nature, but Art, can effect a solution of *Sulphur* or keep it suspended in an invisible state in water without an Alcali: and indeed the volatile sulphureous Acid diluted produces discolorations with solution of Silver like what are produced by solution of *Sulphur*, tho' in a less degree, and nearly like what *Batb* water exhibits with the same solution.

Bath water indeed has not, as far as I have learnt, exhibited a diffinct palpable Sulphur, nor is this to be wondered at, becaufe, exifting in very fmall moleculæ, and those blended in large quantities of other materials, it is diffipated and lost in the process; for this also is the case of most of those waters which otherwise give undoubted proofs of an impregnating Sulphur and yet elude almost every attempt to collect it, excepting in that white glairy matter which is ordinarily deposited by these waters, from which an evident flos fulphuris in two different waters was obtained, as is related in the foregoing section.

We may therefore now be enabled to ftate the Comparison between the waters of *Aken* and those of *Batb* thus:

1. They are both confeffedly impregnated with the *Pyrites*, of which we are affured there is great plenty in the neighbourhood of *Bath* as well as *Aken*.

2. They both betray Sulphur, but in different manners and in different degrees: Aken by the finell like folution of Sulphur in an alcaline ley, whilft that of the Bath is rather like the Gas fulphuris or volatile fulphureous Acid diluted; and accordingly the firft is of a faponaceous quality, and its impregnating falt refembles the Soda, the laft is a hard water and manifefts a degree of acidity fo far as to curdle Milk, its faline contents being marine falt and calcarious Nitre; and yet there there is one peculiar character and recommendation due to the *Bath* water from the infallible teftimony of our tafte, *viz.* a milky foftnefs owing probably to an impregnating bituminous matter enveloping the falts which makes it fit eafy on the ftomach and bowels, and renders it a good volatile for other medicines, being free from the naufeoufnefs of *Aken* waters.

Again, in Aken water the flowers of Sulphur are collected in the vaults of the fources of feveral of the Baths: in the Bath water the Sulphur is most manifest in the Sand, being a composition of Sulphur, Iron and calcarious Earth.

The volatile fulphureous Acid is common to them both, confifting of an union of the Acid and Pblogiston in the vapors of both, which have the like effects in corroding Iron, and in tarnishing Silver, tho' this last appearance is much stronger in the Aken than Bath waters; but both waters have in a great measure similar effects on the solutions of Silver, Mercury and green Vitriol.

3. The *Bath* water therefore maintains its title to the powerful effects afcribed to it, not meerly from actual heat, nor meerly from the ingredients common to it and any meer purging Chalybeate water heated, but alfo from a fulphureous impregnation, and particularly as an expeller of gouty or other morbid humors to the furface of the body.

SECTION V.

Of the Briftol water, it's character as a Calcarious one afferted, to which the Phlogifton is fuperadded, with the Comparison of this and the Bath water.

H AVING fo far heard our Author on the Bath water, let us now attend him a little while on that of Bristol, which we have hitherto been been told is a native Lime-water, of an abforbent, fweetening and gently reftringent quality, and ufeful in common with the *Buxton* and other warm Calcarious waters in the diabetes, hectics, internal ulcerations, in moderating exceflive difcharges of the blood or humors, in fome ftubborn Colics and other diforders of the primæ viæ, and that it is ufeful for thefe purpofes, not only at the fountain, but when transported to remote places, and at leaft greatly preferable to common water.

But as it has been above observed of our Author in relation to the existence of Sulphur in waters, that his fuperior genius has carried him into refinements far beyond the evidence of common fense, it may with no less truth be affirmed that he has taken care to maintain an uniformity of conduct in relation to the exiftence of the Calcarious matter, at leaft in the Briftol water, and that he is equally paradoxical as to both thefe waters; for, altho' the Briftol water be remarkable for imprinting the most (a) soft and grateful sensation upon the palate, and for exhibiting a plain and evident appearance of ebullition with all acids vegetable as well as (b) mineral, and for depositing a chalk-like (c) matter upon the bottom and fides of the tea-kettles in which it has been often boiled; yet in the fequel (d) it is queried, Why are these waters fingled out as Calcarious, most waters baving an equal, many a fuperior titule to that appellation; but that it's good effects are chiefly to be ascribed to a fubrile, (e) volatile, acid spirit, which it greatly loses in the carriage, and confequently the exportation of this water should be of little use; but that where a water of this particular temperature (f) may not, as in some delicate babits it must, be necessary, in all intentions 10

(a) Effay on Waters, Part III. p. 354. (b) Ibid. p. 359. (c) Ibid. p. 361. (d) Ib. p. 366. (e) Ib. p. 367. (f) Ib. p. 367, 368.

[65] .

to be answered by the Hot-well water, such as helics, diabetes, &c. he should prefer the simple, neglected spring called the Mill-spring, in its neighbourhood, diftinguished chiefly by its excessive coldness, greater (a) sparkling and discharging a greater quantity of air-bubbles. But,

Is not this to fubfitute meer fpeculation to folid obfervation and experience, the only fure tefts of the effects of any medicine, and is it not an inftance of rafhnefs and prefumption to recommend a new fpring, whofe effects any other than are common to fimple water we are wholly unacquainted with from obfervation, in preference to the old Hot-well, whofe virtues are long eftablifhed by experience and which is actually found ufeful and greatly preferable to common water for the purpofes above mentioned, and even upon it's transportation to *Dublin*, where it has long been and continues to be fuccefsfully preferibed in conjunction with other fweetening and reftorative medicines?

I shall therefore, from a conviction of the real usefulness of this water, endeavour to vindicate it's character; and to refcue the subject of its real mineral contents from the darkness and perplexity in which he has left it; and in order to this shall minutely confider the chief discoveries our Author feems to think he has made, which may be reduced to three Paradoxes:

The first is, that the good effects of this water are to be ascribed chiefly to a volatile acid Spirit : to which I answer

That the univerfal or vitriolic Acid enters into the composition of most or all mineral waters I grant him; but what I oppose is, that an acid Spirit either volatile or fixed should be confidered as a principal ingredient in the *Bristol* water, and that on which it's chief energy is to be rested, for 1st. K

(b) Effay on waters, Part III. p. 354.

Experience is against him, with respect to the real good effects of this water at a diftance from the fountain, as has been above observed. 2dly, It is certain that Bristol water gives far less evidences of an Acid, and wants those evidences of an Acid which are exhibited by the other waters he has treated of, particularly those of Aken, Bath and the purging waters, as will appear to any one upon the perufal and comparison of his own account of these waters; and tho' it were to be expected that one who fets out with an utter contempt of the Opinions of others, should establish his own by folid and conclusive experiments, he is fo far from anfwering fuch reafonable expectations, that the Experiments he has offered having any tendency to establish an Acid in Bristol water, will be found to be partly extremely flender, and partly equivocal and inconclusive : for

The first experiment of this tendency is, that the Hot-well water being diffilled in (a) a high bolted retort, in fand, placing a piece of blue paper in the juncture, this was flightly faded to a purplifh: A flight evidence of an Acid indeed, at least a very flight one of a predominating Acid, and no more than what Rain water and other common waters by his own experiments on those at Spa (b) affords, to which I might add also than Rain water and other waters also (c) in other places give.

The fecond Experiment he mentions that has any tendency to prove an Acid in Briftol water, will be found to be abfolutely inconclusive by other Experiments, and even by his own testimony, viz.

The Hot-well water with the dry (d) alcaline Salts caufed a quick and strong ebullition, and the Mill-

(a) Effay on Waters, Part III. p. 362. (b) Ib. Part II. p. 119. (c) Method. fynops. of min. Waters, p. 36. (d) Effay on Waters Part III. p. 358.

Spring

[67]

Spring caused a stronger ebullition, especially with the dry volatile Alcali:

Here our Author had certainly forgotten what he had told us in the foregoing part of his work, viz. that the dry alcaline falts (a) cause a smart ebullition, even when thrown into distilled water, and likewife the prudent caution he had given, not to (b) rest too much upon the ebullition enfuing on the mixture of dry alcali's as a decifive proof of an Acid in waters; so that the ebullition of Briftol water with the dry Alcali's is no more a proof of an Acid in that water than in diffilled water, and may be better accounted for from the Air with which, according to late observations (c) the dry volatile alcali is always replete and which parting with fome of it's air in the folution adds to the air with which the water itfelf is also replete, and especially the Mill-spring, and so puts on the appearance of a ftrong ebullition.

On the contrary I shall shew from the evidence of our Author's own experiments that, whatever share may be allowed to an Acid as a menstruum diffolving the terrestrial matter in Bristol water, it becomes so far neutralized, that the whole composition, the water, examined at the fountain, manifests a predominant Alcali : for 1. It gives a plain and evident appearance of an ebullition with all the Acids vegetable as well (d) as mineral. 2. With Syrup of Violets it strikes, not a rose-purple as the Poubon and Geronsterre waters, but a sea-green, gradually hightening to a grass-green (e). 3. It produces an orange or bright amber colour with infusion of Rbubarb, and a pale rose purple with infusion of Cochinelle (f), arguments of an alcali (g). 4. It

(a) Effay on Waters, Part II. p. 108. (b) Ib. Part III. p. 85. (c) Dr. Black's Experiments in Med. Effays and Observations, Vol. II. (d) Effay on Waters, Part III. p. 359. (e) Ib. p. 355. (f) Ib. p. 357. (g) Ib. p. 80, and 84.

depo-

deposites a terrene chalk-like (a) matter fermenting ftrongly with acids: from all which abundantly appears the vanity of our Author's endeavours to fet up an Acid in the *Briftol* water as the chief feat of it's virtues.

I proceed next to confider whether his fecond Paradox concerning this water be any better founded, viz. that it is not fimply calcarious, most waters baving an equal, many a fuperior titule to this appellation (b).

He profeffes to be very exact in his analyfis of the terrene contents of this water, and in his calculation of the different ingredients of those contents, and from thence pronounces near one half, viz. $2\frac{1}{4}$ grains out of 5 to be fair, diffinct, infoluble felenite.

Now as the Selenite is a foffil of great use to our Author, and which he adopts by wholefale, and by means of it fills up many chaims through the whole course of his work, it may be of use to observe that his determination of it's prefence in any water is far from being clear, viz. that what is commonly called the terrene matter and left in the filtre after the separation of the set from it, so much of it as consists of minute, so the set of the or flakes, is infoluble in water and acids, and unalterable in the fire is a (c) Selenite:

But certainly, a little more precifion and fome little regard to the definitions given of this foffil and its diftinguifhing marks by authors of eftablifhed reputation had been more confiftent with his character as a reformer of our language; one of which marks are, that the Selenite is fo far from being unalterable by the fire, that it is calcinable and reduced to a plaifter by being burnt,

(a) Effay on Waters, Part III. p. 361. (b) Ib. p. 366. (e) See Part II. p. 170, and 230. and by this criterion it is diffinguished from the stones called Apyri, as the Talcs, Mica, &c. (a) which are neither fulible nor calcinable in the fire, and moreover refift acids as well as the fire ; fo that our Author's description of the Selenite agrees rather to fome fpecies of the Talc, Mica or whatfoever of the Lapides Apyri shall be determined by more minute experiments, and not to the Selenite of other Authors, nor to the infoluble matter in Briftol water, which lofes near one half of it's weight in the fire, as other calcarious earths do, and the Magnefia rather more than half, and according to fome late obfervations what is loft by the fire confifts in a great measure of air, which is one characteriftic by which calcarious ftones and earths are diftinguished from Mill-stones, Flint, Talc, &c. and Dr. Lucas's Selenite, which is pronounced unalterable by the fire, and like the others just now mentioned manfests no air by any fermentation with acids; and were there no other argument of the infoluble matter of Briftol water being principally a Calcarious earth, this mark of it alone, viz. it's yielding as great a quantity of air as the calcarious earths do by the fire and by fermentation with acids, might fuffice, and withal to fhew that did it confift of near one half of what our Author calls Selenite, it ought not to exhibit fo great a quantity of air either by the fire or by fermentation with acids, as the pure calcarious earths, which yet it is found to do.

I have however been at the pains to repeat those experiments which have induced our Author to attribute to the *Bristol* water so large a proportion of the Selenite as he does, and to endeavour to deprive it of the appellation of Calcarious hitherto given it by general confent.

(a) Hill's History of Fossils, and Walerius's Mineralogie.

On ten grains of the grey terrene matter of the Briftol water left in the filtring paper after the feparation of the faline by diffilled water, I poured Spirit of Salt until it was entirely faturated; then washing with diffilled water and exhaling to drynefs, there was left only two grains and a half, i. e. the of the whole undiffolved by the Spirit of Salt, which undiffolved part was chiefly, not a fhining, but brown matter, exhibiting even when viewed in the fun-fhine, only a few fhining fpangles. and when put into an ignited crucible, it fparkled and loft above half of its weight, leaving only one grain bare weight of what was not confumed by the fire nor diffolved by Spirit of Salt, (which alfo. exhibited very little of the fhining spangles,) viz. only isth of the whole, fo that, of ten grains of the terrene matter here are nine diffolved in Spirit of Salt and confumed in the fire.

I query then, where is the fair and distinct infoluble Selenite of our Author constituting, according to him, near one half of the terrene matter?

I made the like experiment with another parcel of the terrene matter and Aqua fortis, and there was left only one feventh part undiffolved, being a dark brown powder, which in the ignited crucible loft near half of its weight, fo that here was only 1, th part of the terrene matter left undiffolved by the Aqua fortis and not confumed by the fire : thus in both these experiments one half of what is left undiffolved by the Acids is confumed in the fire, and confequently this one half is not the Selenite of our Author which he ever pronounces to. be unalterable by the fire; but this he forgets to make allowances for in his calculation, which affuredly ought to be done, it being a confiderable part of what conftitutes the infoluble matter called terrene, and confequently fo much at least ought

to.

to be subtracted from the large proportion of Selenite he would introduce into the Bristol water.

I also examined the white Chalk-like matter deposited in the tea-kettles used in boiling the Hotwell water, being a more purely terrestrial matter with little or no mixture of the phlogistic, and found it to be almost wholly dissolved in Aqua fortis, (the matter left undissolved being altogether inconfiderable) the genuine character of Spar and Calcarious earths, by which they are distinguished from the Selenite, which always remains untouched by Acids.

I also varied the experiment on the infoluble matter thus, in order to compare it to ordinary Lime-ftone : I put three different parcels of it into a red hot crucible, and on a red hot iron: it fmellt fulphureous and loft near one half of it's weight, as ordinary Lime-ftone does, the remainder was Lime, which had a few fhining particles interspersed being a Selenite of our Author, but not of others according to whom the Selenite is ever calcinable and becomes opaque by the fire, whereas the Mica or Tale refifts both the fire and acids. And indeed it is no new thing to find fome particles of the Mica interspersed with the calcarious matter in Lime-ftone, even as in the above-mentioned refiduum of Bristol water, v.g. in the Lapis Calcarius particulis scintillantibus specified in Walerius his Mineralogie, but in no wife in fuch quantity as to deftroy the character or appellation of Lime-ftone; from all which I conclude, that the introducing the Selenite as an ingredient of confequence in the Hot-well water is an affected novelty deftitute of support from experiment.

It is therefore aftonishing that our Author should not only query, (a) why are these waters singled out

(a) Effay on Waters, Part III. p. 366.

many a fuperior titule to the appellation of Calcarious? And indeed this implies fuch an utter unacquaintance with the diftinguishing contents of waters, that I should chuse to pass it by in filence, except on this account, that it may give opportunity for making some observations concerning the different Earths of different Waters, and the rather, as some recent inquiries have enabled us to give a more clear and diffinct account of this matter.

To the query then I an'wer, that the Briftol water is not fingled out as Calcarious, but rather joined to others fimilarly impregnated, particularly the warm waters in Derbyfbire, to which they agree in their fituation among great rocks of Lime-ftone, in the calcarious quality of the terreftrial matter obtained from them by evaporation, and in this, that the terreftrial matter in them predominates in quantity over the faline, which, according to Lifter's obfervation, gives a reftringent quality, common to thefe waters, which are alfo found to have the like virtues in exceflive profufions of the blood and humors, in the Diabetes, &c.

Next, as to his affertion, that most waters have an equal, many a superior title to the appellation of calcarious, I deny it; and on the contrary affirm that few have an equal, much lefs a fuperior title to this appellation : for 1ft. Even in the Petrifying waters whole terrestrial contents are also generally of the calcarious kind, the contents obtained by evaporation from feveral of them does not exceed, and from others falls fhort of the quantity of calcarious matter obtained from Briftol water. 2dly, Our ordinary foft waters, fuch as the Thames, &c. are far from having an equal title to this appellation; for these do not make an ebullition with Acids equal to what the Briftol water does, and moft

most of them none at all, nor do they exhibit half, commonly much lefs than half the quantity of folid contents that Briftol water does, and those not of the white or chalky appearance, as the Bristot water, but brown or grey, from an heterogeneous matter mixed with the calcarious. 3dly, Our common hard waters differ still more widely from the Briftol water, even in the faline matter in them ufually predominating over the terreftrial (the reverse of what obtains in Bristol waters) which gives them a degree of acrimony and a laxative quality if they are taken in large quantities. 4thly, Our ordinary Chalybeate waters generally yield a far less quantity of terrestrial contents than the Briftol water, and those confisting of an ochreous matter blended with the calcarious. 5thly, The Vitriolic waters, fuch as Shadwell, Hartfell, Killbrew, &c. exhibit a purely metallic or ochreous Earth specifically different from that of Briftol, Buxton and Mallow. Laftly, I have found in many of the purging waters, particularly those of the bitter kind, which by mutual confent we pronounce impregnated with Lifter's Nitrum calcarium, that the terrestrial matter differs greatly from that of the Briftol water; for it very often failed more or less in the two effential characters of calcarious earth, viz. fermenting with acids and being reduced to Lime by calcination : for in feveral of these waters the infoluble matter either fermented but little, or not at all with Acids, and in fome of them it acquired but little, and in others nothing at all of the acrimony of Lime by calcination; fo that the infoluble matter of these waters appears to be either of the mixt kind, or but partly calcarious, and partly of the felenitical, gypseous, talcous or other kind to be more accurately determined by further observation; in the mean time we may probably conjecture that fuch con-

concretes may be formed by the calcarious matter abforbing the vitriolic Acid, with a large fhare of which laft these waters are undoubtedly impregnated, as appears from their curdling Milk, precipitating a gross white sediment with alcali's and a yellow one like Turpeth mineral with the solution of Mercury in spirit of Nitre, for which last evidence of the vitriolic acid they are peculiarly remarkable (a).

I proceed next to our Author's third Paradox in relation to the *Briftol* water, even his giving the preference to what he calls the *Mill-fpring* to the *Hot-well*: Let us hear his elogium on this his favorite fpring :

" I found this spring (b) demand mine attention fo much at the first sight of it, that I gave it a very full examination: and as I know not its equal in Britain, I think it of importance enough to be made known, as I am persuaded it must serve many excellent medecinal purposes as well as the only one to which it is now applied, that of a cold Bath— taken up in a glass it sparkles nearly equal to that of Pouhon at Spa, and like that, covers the glass with bright air-bubbles—it greatly outdoes the Hot-well in sparkling more quickly, and greatly, and depositing a much greater quantity of the brightest air-bubbles in the glass."

But, what are the real operation and effects of this water from experience? We have no account of any; and as to the mineral contents, it affuredly has far lefs than the Hot-well water, fo that the preference he has taken upon him to give to his favorite fpring has literally no better a foundation than a bubble of air, of which a puerile fondnefs feems to betray itfelf in the above *elogium*, which it's pity he fhould fo far indulge as to dictate it's

(a) See Neuman's Works with Lewis's notes on Gypfum. (b) Effay on Waters, Part III. p. 352.

use in practice and recommend it as fit for transportation. I apprehend it had been more fuitable to the dignity of his character as an Adept to have discountenanced the vulgar error of admiring any water for the quantity of air-bubbles it contains, and the rather, as it appears from other parts of his work that he was not ignorant of the real difinction that there is between elaftic air and the mineral acid Spirit, v. g. " The Tonnelet water (poiled (a) of all it's elastic air and spirit by agitation on the air-pump, still shews some strong appearance of purple (a mark of acidity) with Syrup of Violets." And agreeable to this are other observations, that a water may be deprived of it's elaftic air by agitation and explosion whilft the minerals, v. g. Iron and Sulphur are kept invisibly fuspended as beforel; and on the other hand, it is well known that there are feveral waters which exhibit no veftiges of either acid or other mineral contents, and yet abound with air-bubbles; nor is it lefs certain that waters of the greatest eminence for their virtues from experience are remarkable for containing lefs air, v. g. the celebrated Chalybeate of Dunfe in Scotland, on which the ingenious Dr. Home lately published an Esfay, who observes that " it sparkles a little in the glass and emits a few air-bubbles;" but (he proceeds) " this is of little or no use to the water, but on the contrary the Dunfe water is the better for having but little air : for the history of fuch waters as contain much air shews their ill effects on the prima via, viz. eructations, pains, swellings, and spasms, whence, to prevent these effects, bot carminatives are taken along with them." And it may be further observed as an argument of an impregnating volatile fulphureous acid altogether diffinct from air, that the Dunfe water, tho' it contains but

(a) Effay on Waters, Part. II. p. 202.

little air, yet it raifes the fpirits and produces a temporary drunkennefs.

To this add our Author's own account of the famous Poubon water (which has long flood the teft of experience for it's fuperior ulefulnefs and excellency) thewing that the fparkling quality of that water in what is imported to us, for which fome inconfiderate perfons admire it, is in a great measure acquired by bottling: for he affures us that, when (a) lifted out of the well in a water glass, it does not appear to sparkle, altho' upon standing it covers the infide of the glass with small air-bubbles. The Geronsterre also contains far less of these than the Tonnelet water, and yet the Geronsterre and Poubon waters not only yield a much greater quantity of mineral contents, but are the waters of the greateft reputation for their virtues as found by observation.

It is true our Author, ever determined not to fubmit to vulgar traditions, upon observing the fuperior sparkling quality of the Tonnelet water, altho' it has no perceptible (b) smell, and little if any of the vitriolic or ferrugineous tafte which the others bave, nor ever fouls its bason, nor causes offensive belches as the others do, takes upon him to give it the preference to the other more frequented and much more ftrongly impregnated wells; and I am affured from very good authority that an attempt was lately made at Spa to induce fome of the invalids there to forfake the old wells and make tryal of a newly recommended sparkling water, but that the event did not answer their expectations; for the new well was found not to agree with them fo well as the old.

So much may fuffice to fhew the danger of indulging fpeculation, without due fupport from ex-

(a) Effay on Waters, Part II. p. 147. (b) Ibid. Part II. p. 198, 199.

perience

perience in the recommendation of any water; and with me it is more than probable that, if the comparison were to be made between the real effects on the body of the old *Hot-well* and the *Millfpring*, the former would abundantly support it's credit in preference to the other more sparkling, but less impregnated water, not only from it's warmth, but from it's peculiar softness and higher degree of impregnation with minerals of an antacid, sweetening, cooling quality, besides another ingredient, to which I now hasten to give some account.

Our Author having to the utmost of his power endeavoured to divest the *Batb* water of the *Pblo*giston, does not seem to have once dreamt of a *Pblogiston* in *Bristol* water, of which however that it is really possessed I shall shew to be the consequence of his own experiments confirmed and illustrated by other observations.

1. Doctor Short had long fince observed concerning the warm waters of Buxton and it's neighbourhood (which in the mineral contents agree very nearly to the Briftol water) that they produced fuch difcolorations with the metallic folutions as indicated an impregnation with at leaft fome fteam or vapor of Sulphur, or fome phlogftic matter in the language of our Author, who also grants and even contends for a volatile Acid in Briftol water; and if this be the fulphureous or vitrolic acid volatilized by the Phlogiston, or if it be accompanied by the Phlogiston, then Bristol water should contain the principles of Sulpbur as well as the Aken waters do: and the prefence of fuch a volatile fulphureous acid in the Briftol water may alfo perhaps be confirmed by an obfervation of one of it's effects in the body, and particularly in affecting the brain : for it is not peculiar to the Chalybeate waters to affect the brain in those who firft

first begin to drink them, in caufing a sleepiness or giddiness like drunkenness, but it also appears by later observations that some degree of a like effect is produced by the warm Calcarious waters, and particularly those of Buxton, which (a) affect the head with a kind of inebriating giddiness, and it is also observed that the Briftol water drank on the spotis apt on it's first use to create (b) uneafines in the head; and altho' our Mallow water be confiderably inferior in heat to either of the two laft mentioned warm waters, yet I find, upon enquiry from two phylicians of credit in that neighbourhood, that it also has not unfrequently fimilar effects on fome of the invalids, particularly in producing a heavines in the head on the first four or five days after drinking it, but moreover

2. The fituation of the Briftol water in the neighbourhood of large rocks of Lime-ftone, and those rocks, as is particularly observed by our Author, (c) being mostly composed of a kind of solid blue Marble, which yields something of a suppose something upon friction, favours an impregnation with a phlogiftic matter : and this argument receives an additional weight from some late observations tending to shew that the colours of Marble and other stones are owing to suppose or bituminous vapors. See Walerius's Mineralogie and the French Memoirs.

3. The pearl opacity which the Hot-well watergives with the folution of lead in diffilled vinegar, the pellicle variegated with all the colours it gives with the folution of corrosive fublimate, the dark purple coloured cloud and precipitate tending to blue with folution of Silver, to which let me add, (what our Author has omitted as a concurring evidence

(a) Treatile of the nature and virtues of the Buxton waters,
(b) Method fynops, of min. Waters, p. 617.
(c) Effay on Waters, Part III. p. 304.

of

of the fame thing, viz.) a variegated pellicle alfo observable in this water imported into Dublin, from the admixture of English Vitriol, as in the Table annexed : I fay these dark-coloured clouds, precipitates and variegated pellicles, which alfo, or at least most of them, appear in the waters of Aken, upon the feveral mixtures of the fame folutions with them, are by our Author not unjuftly attributed in Aken (a) water to the Phlogiston, from the different modifications and combinations of which all colours as well as odors arife. But why then does he not pay the fame complement to the Bath and Briftol water? even from their altogether fimilar appearances with the fame metallic folutions as in the Aken water, but on the contrary utterly deny the existence of the Phlogiston in Bath water and suppress the least mention of it in the Bristol?

4. A fhort comparison of the phænomena exexhibited by the *Hot-well* water and by the *Mill-Jpring* will at once fhew the peculiar, fuperior impregnation of the *Hot-well* with the *Phlogiston*, and the vanity of his endeavours to fet up that water in preference to this.

How much more of the white terrene matter the Hot-well water affords than the Mill-fpring he has taken care to inform us, (b) viz. as 26‡th to 15, and from other experiments of his compared with my own it will appear allo to contain a proportionably greater quantity of Phlogiston: for our Author observes (c) that the Hot-well with folution of Silver gives a purple precipitate tending to a blue, but the Mill-spring a paler precipitate and later formed with the same solution; I also repeated these experiments on the Hot-well and Mill-spring carefully bottled and transmitted to me in Dublin, and found that, notwithstanding our Author discourages

(a) Effay on Waters, Part III. p. 76, 99, 100, 101. (b) Ib. p. 363. (c) Ib. p. 261. the transportation of the first and recommends that of the last, that the last on transportation exhibited a much paler precipitate with solution of Silver than the first, which by the darker colour of the precipitate shewed a stronger impregnation with the *Phlogiston*.

Again, (a) the folution of Mercury in Spirit of Nitre gives with the Hot-well a grumous precipitate of the colour of turpeth mineral, but with the Millfpring it gave only a most light, slight precipitate : and the refult of my experiments on both waters in Dublin with that folution was agreeable to this, viz. a yellow precipitate with the Hot-well, but none at all with the Mill-spring; but the refult of my comparison of these waters with another folution was not altogether fo agreeable to that of our Author, that is, with folution of fublimate corrofive; for tho' he tells us (b) that the Hot-well gives a variegated pellicule with this folution, and that the appearances with the fame folution are not fenfibly different in the Mill-fpring; yet upon making the comparison with a good deal of leifure and attention on both these waters transported to Dublin, I found on reiterated experiments that the pellicule formed on the furface of the Hot-well by the folution of Sublimate was variegated with much deeper and stronger colours than the Millfpring; and thus it appears that even upon tranfportation, which must be a greater difadvantage to the warm water of the Hot-well (whole chief virtues according to our Author refide chiefly in the volatile parts) than to the cold water of the Mill-fpring, the Hot-well however in all experiments gives ample evidences of a ftronger impregnation with mineral matter, and particularly with the Phlogifton than the Mill-fpring.

(a) Effay on Waters, Part III. p. 360. (b) Ib. p. 359, 360. 5. The 5. The last evidence of the *Phlogiston* in *Bristol* water is, that the infoluble part of it's refiduum obtained by exhalation smells supplureous on the red hot iron, sparkling and sometimes emitting a flame.

I shall now close this dispute by a short comparifon between the contents of the Bath and Briftol water, which our Author has attempted, but with what clearness or accuracy I shall leave to the reader on his perufal of the following account and the Animadversions on it, viz. Bristol and (a) Bath water differ only in the latter's containing a small quantity of iron, and some small disparity in the proportions of the oily matter and the other ingredients which each holds in common-the principal difference between the Bristol and Bath water arises from the small portion of the iron contained in the latter: As to his comparison of their Virtues, as it does not feem to convey much inftruction, I shall pass it by, and rather take notice of what has appeared from practical observation, that the operation and effects of these waters are opposite, the Bath water being powerfully attenuant, deobstruent, laxative, and good in cases where the fecretions are diminished; on the contrary the Bristol water is chiefly ordered where the fecretions are too much increased : the first is heating, the second cooling, and fuccessfully prefcribed in hectics, coughs and the fourvy with heat, where the last is hurtful.

A more diffinct account of the different ingredients of these two waters than what our Author has vouchsafed to give, will I hope be of some use in explaining this diversity of their operation, which is therefore now submitted to proper judges.

1. The Difparity of the proportions of the ingredients which each holds in common, is not fmall,

(a) Effay on waters, Part III. p. 367.

[821 8]

but very confiderable: for the Briftol water fcarcely gives 40 grains of refiduum from a gallon, the Bath nearly from 128 to 144 grains from the fame quantity.

2. The difference of the proportions of the faline to the terreftrial matter in each water is very confiderable, and fuch as affects their operation: for, whereas it has been before observed that the terreftrial matter always exceeds the faline in the *Briftol* water, on the contrary, according to our Author's own account, the faline contents of the *Batb* water do always notably exceed the terreftrial, and in one of the Baths as 20 to 12, (a) from whence is deduced the laxative quality of the last and the astringent one of the first.

3. There is yet another important difference, and fuch as allo mult, as I apprehend, have fome influence on the different operation of these waters, and that is the different proportions of the two falls of different qualities in each, viz. in one a greater proportion of marine falt, in the other a greater proportion of the prifmatic falt by fome called Nitre, the first being well known for its heating, attenuating quality, being a composition of the marine acid with the mineral alcali, the other remarkable for it's cooling and rather incraffating quality, being a composition of the vitriolic acid with a calcarious earth. Now we find by our Author's own account (b) that the marine falt in the Bath water is about double to the prifinatic, this last being the Nitrum calcarium of Lister, of a cold and bitterish taste; (c) but in the Bristol water the laft predominates over the first agreeable to his own experiment which I had a fingular opportunity of confirming in a specimen of it's compound salt,

(a) Effay on Waters, Part III. p. 313. (b) Ib. p. 315. (c) Ib. p. 315, 316. (d) Ib. p. 364.

which

which kept dry in a bottle well corked many years, whereas a specimen of the compound falt obtained from *Batb* waters moistened so far as to liquify, tho' kept in phials also closely corked : add to this, that the predominant taste of the compound falt of the *Batb* water resembles that of common falt, whils that of the compound falt of the *Bristal* water is the genuine nauseous-bitter proper to the calcarious Nitre of *Lister*.

Now the predominance of this more cooling falt in the Briftol water may help to explain it's cooling operation, as on the contrary, the predominance of the marine falt in the Bath waters may have a confiderable fhare in it's heating and attenuating quality, fo that the cooling quality of the Briftol water fhould feem to be owing not meerly to it's inferior degree of heat, but alfo to the greater predominance of the Nitrum caltarium of Lifter, and on the contrary the heating quality of the Bath water to the greater proportion of marine falt it contains co-operating with it's fuperior degree of actual warmth.

4. Laftly, as to the terrene matter, or that which is infoluble in water in the *Bath* and *Briftol* water, it differs widely; for in the laft it is chiefly a chalky matter, and the greateft part of it foluble in the acids of nitre and falt, as is fhewn above, whereas our Author affures us (a) that the far greatpart of the *Earth of* Bath water remains untouched by acids; and accordingly the Briftol water ferments with all acids vegetable and mineral, which the Bath water does but obfcurely, or according to our Author (b) not at all; nor is the Bath water Earth reducible to a perfect Lime as that of Briftol:

(a) Effay on Waters, Part III. p. 313. (b) Ib. p. 302, 303.

And

And now, to fum up in one view the difference of the impregnation of the *Bath* and *Briftol* waters—The *Bath* water contains both a volatile and fixed fulphureous Acid in notable quantity manifested by the experiments above related, whereas the *Briftol* is but very weakly impregnated with this acid, but on the contrary gives all the tokens of a predominant, antacid, absorbent matter; and accordingly the use of the *Briftol* water, but not of the *Bath* is compatible with a milk-diet.

In the *Batb* water the faline contents predominate over the terreftrial; on the contrary in the *Briftol* the terreftrial predominate over the faline, and the cooling native bitter falt predominates over the marine falt, whereas in the *Batb* water the marine falt predominates over the other.

A phlogiftic, oily or bituminous matter is common to them both, tho' the *Bath* water gives evidences of a ftronger impregnation with this principle, which feems to be the feat of the milky foftnefs obfervable in the tafte of both thefe waters:

In the Briftol water the terreftrial or rather infoluble matter is chiefly or principally a calcarious Earth; but in the Bath water it is a composition of the calcarious with a blue argillarcous or marly Earth, Ochre or the minera of Iron, and Sulphur from the impregnating Pyrite.

Fails water does but obleurely, or according

to our further (b) not at all; nor is the Borb wa-

OBSERVATIONS.

I. MOST of the appearances with Metals and their Solutions are common to Sulphur and to the Phlogiston in putrid waters, and equally marks of both, although in other respects and experiments Sulphur and Phlogiston differ widely.

II. Altho' the fetid fmell and tarnifhing of Silver be the acknowledged tefts both of Sulphur and Phlogiston, yet these tests often fail in waters, but the metallic folutions in this case often make the discovery, particularly the solution of Silver : also the solution of Mercury sublimate corrosive, and that of green Vitriol (both acknowledged tests of the Phlogiston) do often manifest it by the variegated pellicle where it does not appear by any fetor in the water or by it's discolouring Silver.

III. The most fensible test of *Phlogiston* in this Table is the folution of Silver, betraying fome portion of it, not only in putrid ditch-water, but in the Pipe-water of *Dublin*, and in the *Thames* water at *London*, even from the putrid matter in each of these waters; and accordingly the colours are deeper in the impurer water of the *Thames* than in that with which *London* is supplied in pipes by other rivers, as appears by Dr. *Lucas*'s experiments, from whence may be remarked the peculiar usefulness of folution of Silver as a test of the different purity of waters.

The next fenfible teft of *Phlogifton* feems to be the folution of Mercury, whether in *Aqua fortis* or that of the Sublimate in diffilled water, and especially this last which often betrays it by the variegated pellicle where other tokens are wanting.

The

[85]

The leaft fenfible teft of *Phlogifton* is the folution of fugar of Lead, which produces far lefs difcolorations, and those of a lefs dark colour, as appears by comparing it's different effects on the fimple waters, the putrid and fulphureous in the Table.

IV. The different degrees of the phlogiftic impregnation may in fome degree be effimated by the various appearances from the fame metallic folutions: Thus, whereas diffilled water exhibits feweft of the appearances proper either to Sulphur or Phlogiston, and for the most part none at all, the Thames water and the Pipe-water of Dublin exhibit more of those appearances, indicating fome admixture of a putrid matter in both those waters: but putrid ditch-water exhibited those appearances in a far greater degree, even fo far as to give not only deeper difcolorations in the clouds and precipitates from the metallic folutions, but to difcoloar Silver like the fulphureous waters, tho' in a fomewhat lefs degree, and the variegated pellicle with folution of Sublimate and with folution of green Vitriol was lefs frequent and lefs conftant in putrid ditch-water than in the natural and artificial folutions of Sulphur, and particularly lefs frequent and lefs conftant than in the waters of Swadlingbar and Lucan near Dublin, and than in Bath water. even while these waters were fresh and in no wife putrid; and confequently these appearances in the waters of Swadlingbar, Lucan and Bath must be owing to fome other caufe than putrefaction.

V. Æther, a specimen of the *Phlogiston*, eludes the most sensible tests of *Sulphur*, exhibiting no discoloration either with Silver or it's solution, nor even with the solution of the crystals of Quick-filver, until in the subsequent part of the process the *Phlogiston* be combined with the Acid of of Vitriol, and then its effects on the metallic folutions become evident, viz.

VI. The Gas or volatile Acid of Sulphur or Vitriol (being a combination of the Acid with a finall quantity of *Phlogifton*) diluted produces effects fimilar to those of Sulphur on Silver and it's folution, but in a less degree than folution of Sulphur diffolved by an Alcali.

VII. The feveral appearances of the volatile Acid of Sulphur and those of the Aqua fulphurata formed by the union of the steams of hot-water and of Sulphur, with Silver and it's folution and with the other metallic folutions compared with the appearances exhibited by Bath water with Silver and it's folution and the other metallic folutions, being in a great measure similar, may ferve as an illustration of the natural composition of Bath water.

VIII. The fimple fulphureous waters, fuch as Swadlingbar, Lucan near Dublin, and others like them and those of Aix-la-Chapelle, agree to the artificial folutions of Sulphur in their effects on Silver and it's folution, and on the other metallic folutions.

IX. It is observable that the plain or cold fulphureous waters, such as Swadlingbar, Lucan, &c. do strike much darker colours with every one of the metallic folutions than Aix-la-Chapelle water does, altho' Sulphur is not so colligible from those as from this; neither does it from hence follow that they are more simply sulphureous, but rather that their Sulphur is less blended with foreign matter, particularly that they contain less calcarious Earth, which being precipitated from the Aix-la-Chapelle waters in a white form, proves a means of difguising the appearances, by lessening the darkness of the colours of the precipitates.

X. Of

X. Of the Bath water the following particulars are observable in the Table. 1. It exhibits every mark of Phlogiston that Aix-la-Chapelle and other fulphureous waters do, but in a leffer degree. 2. Bath water has fome effect on Silver, especially its vapor, whilft the Briftol and other warm calcarious waters do not appear to have any effect on Silver: alfo the Bath water is more conftant in exhibiting the variegated pellicle both with folution of Sublimate and folution of green Vitriol than Briftol water, and even than Putrid water, and confequently Bath water, even whilft fresh and fweet, gives undoubted evidences of a greater share of Phlogiston than Bristol water or than putrid water. 3. That a water may be impregnated with the Acid and Phlogiston, and yet not tinge Silver immerfed, appears from the experiment on Gas fulphuris or the volatile acid of Sulphur diluted, which is also in some measure the case of Bath water; but the vapor of Bath water comes nearer to the vapor of folution of Sulphur than the vapor of Gas Julphuris does in tarnifhing Silver more, and likewife in another refpect Bath water comes nearer to, or refembles more the fulphureous waters than Gas fulphuris diluted does, viz. in conftantly exhibiting a variegated pellicle with folution of Sublimate and folution of green Vitriol, whereas Gas *fulphuris* diluted gives no pellicle at all with the last named folutions. 4. Bath water occupies the middle place between fuch waters as give the greatest indications of Sulphur, fuch as Aix-la-Chapelle, Swadlingbar, Lucan, &c. and fuch as give the least, as the acid Vitriolic waters of Shadwell, Kilbrew, &c. 5. An opinion hath commonly prevailed, that Bath water is of no use when conveyed to places remote from the fountain; but I apprehend this matter requires to be reconfidered, and that the rejecting it's use except at the fountain,

tain, may have proceeded from it's having been confidered chiefly as a Chalybeat, whereas it is certain the ferrugineous impregnation is extremely flight, even at the fountain, nor is there in the bottles ufually fent us any ochreous precipitation as in the common Chalybeates; wherefore it should feem that the other principles are by far the more confiderable: now it is evident that not only the marine falt and calcarious Nitre, but the Acid and the Phlogiston are still retained in the Bath water transported to remote places, even to Dublin; for here it curdles milk and exhibits various tinctures with the metallic folutions; and moreover it poffeffes even here that peculiar milky foftness by which it is diffinguished, and which makes it an agreeable vehicle for other medicines, and as fuch may merit the attention of Phylicians, especially in fuch cafes where the Bath water may have already been used at the fountain, which to attend may fometimes be inconvenient to the patient.

XI. The Briftol water and other warm calcarious waters exhibit with the metallic folutions every token of an impregnating Phlogiston, but the Bristol water in this respect falls short of the Bath water, in having no effect on Silver, and in being not quite so constant or so expeditious in exhibiting the variegated pellicle with solution of Sublimate and solution of green Vitriol.

SECTION VI.

DOT # OF

Of SULPHUR and the phlogistic Matter latent in Waters.

H AVING fo far inveftigated the Phlogiston in the waters of Bath and Bristol, I proceeded to trace it also in some others which do not betray Sulphur by the smell or taste, of which I shall N here

here fubjoin a fhort account, and particularly of fome of these which have hitherto been chiefly confidered as pure element, to which alone the great virtues which they have been found by experience to be poffeffed of, have been attributed; and indeed the extremely finall and inconfiderable quantity of contents there waters yield upon evaporation, and their caufing no precipitation of any terreftrial matter by the mixture of Alcali's, but continuing clear with them and inftantly lathering with Soap, feem ftrongly to countenance that opinion; and yet the more minute inquiries which have been let on foot of late years by which we have learnt to give a more diffinct account of the respective precipitations of the terrestrial and phlogiftic matter in waters, the prefence of this laft being as ftrongly indicated by the dark coloured precipitates exhibited in these waters by the metallic folutions, efpecially that of Silver, as the calcarious earth is by the white precipitate thrown down by alcali's in most others; I fay these inquiries have manifested several of these waters not to be altogether fo pure as they have been commonly reputed; on the conrary, the proper precipitators of the Sulphur, or in our Author's language the Phlogiston, have given evident tokens of it's being invilibly fulpended or intimately diffolved in these waters; and it is hoped that those who from observation upon the operations of divers medicines on the human body, very well know that very minute and fubtile agents may be the authors of great and good effects, will not rafhly condemn this inquiry as altogether idle or officious.

The first notable instance to this purpose are the celebrated warm Baths called *Favarienses* or *Piperinæ* in *Rhætia*, described by *Scheuchzer* in his *Iter Alpinum fecundum*, and mentioned by *Hoffman*, and

and both by him and Paracelfus deemed to be fimple or elementary water, being perfectly limpid and void of all finell or tafte, and yet of great antiquity and fame in the cure of many stubborn diseases, particularly in various nervous diforders, in obstructions of the liver and spleen, hypochondriac melancholy, malignant and ill cured ulcers, the ftone and divers cutaneous difeafes; and all this by drinking as well as bathing : but tho' this water did not feem to fuffer any precipitation or other change by acids or alcali's, yet it is more than probable that it is not fo fimple as has been supposed, even from the following more recent testimony of Scheuchzer concerning it, (compared to the accounts of the other waters like this to be here annexed) " Certum est quod Sulphur continant subtile; certum et boc, quod si diu steterit, sponte præcipitatur terra quædam pinguiuseula."

2. The famous waters of *Malverne* hills (a) feem to be akin to the above, and a yet clearer inftance to the fame purpole, being a light water, and which upon evaporation is faid to leave fcarce a grain of folid contents from a gallon, the credit of which is revived of late years, being ufed with fuccefs externally and internally in the cure of old ulcers, diforders of the eyes, fcrophula's, leprofies and other diforders of the fkin.

Now the following experiments and obfervations on this water jointly confidered, indicate ftrongly a fulphureous impregnation, viz. the folution of Silver precipitated from it a powder of a deep purple colour, and when the water was flowly evaporated in a Silver veffel, it tinged the veffel of a pale yellow colour, as if it had been flightly gilded; and in another experiment, when it was almost evaporated to dryness, it emitted vapors of the fmell of burning brimftone : and to this add, that this water, notwithftanding it's feeming

Philof. Tranf. Vol. 49.

ing purity, is in fome feafons apt to turn fourifh, and to be full of viscid films, notwithstanding all imaginable care hath been taken of the bottles, an appearance like what I have frequently observed in our *Irisb* fulphureous waters long kept, and corresponds to what is above mentioned from *Scheuchzer* concerning the Aquæ Piperinæ.

3. The celebrated water of Willowbridge in Stafford/bire, eminent in the cure of many diseases by external and internal use, is a further notable inftance of a water feemingly pure, (a) affording no falt upon evaporating feveral gallons of it to a drynefs, of a crystaline colour, lathering fmooth with foap, not curdling milk, nor changing colour with fyrup of violets; and yet upon a more minute examination this water appears to be far from pure element, but impregnated with a phlogiftic matter to a confiderable degree : for, not only the folution of Sublimate gave it a deep fack colour, and the folution of fugar of Lead a blue yellowifh colour fading to a white, but it evidently betrays a fubtile Oil; for it feels fmooth and oily, and on the fides of the glass, after being used a while is observable a bright oilines, which is of so volatile a nature, that upon diffilling in a glass body and head, it comes over upon the first heat, of a bright yellow colour, which was all in the recipient before the least drop of water appeared.

I could enlarge the lift of waters of this kind by divers inftances of waters in *Ireland*, which are alfo well known to have effected many notable cures by external and internal ufe, void of tafte and fmell, which yet betray evident marks of the *Phlogifton* in a far greater degree than our ordinary toft or hard waters; but the limits I am confined to prevent my entering into a minute

(a) Plot's nat. Hift. of Staffordshire, and Floyer on cold Bathing. detail of these: it shall therefore fuffice to annex a short account of one water more of this fort, which has acquired a confiderable reputation in France, and been the subject of several of their Memoirs, that is,

4. The cold water of *Plombiers* in *Lorain*, being ufed in inflammations of the eyes, in difeafes of the kidnies and bladder, and in diforders from the heat of the breaft, ftomach and bowels: now this water alfo has little fmell or tafte, caufes little or no fermentation with acids or alcali's, diffolves foap perfectly, and yields but about 17 grains of fixed contents from a gallon, and yet this water by the oily cream and variegated at the furface which it exhibits with the folution of Mercury fublimate corrofive, together with the dark colour, inflammability and bituminous fmell of the refiduum fhews an impregnating mineral Oil or Bitumen.

Thus it appears in numerous inftances that a mineral Oil or Bitumen, and even Sulphur in fubftance is capable of being fo far attenuated by the chymiftry of nature as to be intimately mixed and compleatly diffolved in water, but by what method, or by what fubtile, powerful menftruum this is effected, and how far this may have a fhare in the operation and effects of thefe waters, in giving energy to the more inert ingredients I fhall not prefume to fay, but leave to be determined by Adepts.

It also appears by the experiments recited in this and the foregoing sections compared, that the fetid smell proper to a solution of Sulphur by an alcali is far from being an effential mark of the prefence of either Phlogiston or Sulphur in waters, but that both may subfift without it; and moreover it also appears to me that whatever merit our Author may have a right to claim in demanding more fatisfactory evidences of Sulphur where without out due fupport from experiment it has only been fuppofed, he has greatly exceeded the bounds of prudence in rejecting it where by inconteftable experiments it has been proved, and that he is far from meriting the thanks of the public for his contemptuous and indefenfible treatment of a whole tribe of waters which have been but little underftood until of late, but which by their powerful and falutiferous effects have juftly recommended themfelves to the further enquiries which have been fet on foot concerning them, both as an improvement of a valuable branch of the Materia Medica, and as an acknowledgment of them as a largeffe of a gracious providence for the relief of many unfortunate invalids: and among these may defervedly be reckoned the lately difcovered fulphureous water at Lucan near Dublin, a fituation which promifes fome peculiar advantages in the opportunities it affords for a true and just discovery of it's contents and of it's virtues, of which I am not without hopes of communicating fome account in due time: for, though I could now produce numerous inftances of the happy fuccels of this water in divers flubborn chronical difeafes, yet a longer feries of time and observation are required to afcertain it's effects and eftablifh it's credit on a folid foundation; in the mean time I shall beg leave to remmend to the Gentlemen of the profession in Dublin a particular attention to the Lucan water in ulcerations of the urinary paffages, not only as being fimilarly impregnated with the Swadlingbar water whole efficacy has been determined by longer experience, but as having actually upon trial in feveral of these cafes, with a proper regimen and due perfeverence, given an encouraging prospect of their proving equally fuccefsful. OF STRONGS ONE JL TOWN JUNDY DRYC

POSTSCRIPT to the Accounts of the Bath and Bristol Waters.

THE Compiler of the above Experiments and Obfervations being aware of an objection that may be made against the Credit thereof by reason of his living remote from both these places, thinks it necessary to intimate, that as the communication between *Batb*, *Bristol*, and *Dublin* is very easy, and the intercourse between them very frequent, he has taken care to relate not only the Experiments of his Adversary and others which were made on the spot, but to get these repeated and improved by others of a recent date also made on the spot in both the places above mentioned:

And among these it were an injury to the public to suppress the following, which were made with the utmost care and attention, and communicated fince the printing off the above Sheets, by a faithful Correspondent, Joseph Fry Apothecary in Bristol; and the rather, as they afford a corroborating evidence, concurring with the others above given, of the presence of the Phlogiston in Bristol water, as well as in the baths of Aix-la-Chapelle and those of Bath in Somersets, tho' in a less degree.

His Words are thefe:

" I placed a piece of polifhed Brafs and a Sil-" ver fpoon over a glafs veffel during a flow " evaporation of the *Hot-well* water. The Brafs " was variegated with a few fpots of a pearl-co-" lour, but the metal was not apparently corro-" ded. The Silver fpoon was unaltered."

" I also placed the fame Metals over the glass used in a like evaporation of the Mill-spring water. The Brass over this last acquired about twice as many spots as the other, but the metal was

POSTSCRIPT.

" was not apparently corroded. The Silver spoon was a little brown, like Plate which has lain by some time."

Bristol, 139 mo. 1762.

From hence it appears that both these waters do exhibit more or less of the same evidences of the presence of the *Phlogiston* as the waters of *Aix-la-Chapelle* and *Bath*, altho' in a less degree. I must grant that by these experiments compared, it should seem that the *Mill-spring* contained more of the *Phlogiston* than the *Hot-well*, but as the fallacy of conclusions from a fingle experiment has been abundantly shewn above, so neither are they to be relied on in the present case, since other experiments do not concur with the above, but rather evince the reverse, *viz.* more *Phlogiston* in the *Hotwell* water than in that of the *Mill-spring*.

SECTION VII.

Of Nitre in Waters, with a more explicit eccount of the Nitre of the Ancients.

A FTER all these altercations with regard to Sulphur, I do not know but it may be polfible that our Author and I may happen yet to fhake hands on the fubject of Nitre, being actually agreed in these three important points: 1st. that there is no fatisfactory evidence of Saltpetre in mineral waters. 2dly, that the Nitre of the ancients is found in the waters of Aken and others. 3dly, that the Nitrum calcarium of Lister is the falt impregnating the bitter purging waters:

And though the modern chymifts are generally agreed in appropriating the term Nitre to that Salt which yields the acid peculiar to Saltpetre upon distillation, yet as our predeceffors have called two other Salts by that name, altho' fo far from yielding the acid peculiar to Saltpetre, that one of them fometimes yields a volatile alcali, befides giving other evident marks of an alcali, and the other a vitriolic acid, it will behove us hovever, if we would profit by the experiments and observations made on them whether by ancient or more modern writers, still to retain the mention of those names by which they were formerly known; and in order to this the following diffinctions are now humbly offered, being fuch as it is hoped will minister no occasion for contention, viz.

1. Nitrum orientale impurum terrestre : Natron : Nitrum Veterum Walerii Mineralogie, Nitrum Veterum celeberrimum.

2. Nitrum recentiorum fulminans Salpetra dictum.

3. Nitrum calcarium Lifteri. Sal catharticum amarum nativum basi terrestri, veteribus non prorsus ignotum, a recentioribus accuratius descriptum. Now as Saltpetre does not appear to have any fhare in the impregnation of waters, it will be of no use to make further mention of it here; but as the diffinguishing characters of the other two falts which have hitherto passed under the denomination of Nitre, have not as yet been but imperfectly given, I shall take this opportunity of exhibiting a somewhat more explicit and diffinct account of each.

And first, as to the Nitre of the ancients, our Author himself, tho' he generally restricts the sense of the term Nitre to Saltpetre, yet expressly acknowledges the presence of the other in waters, and particularly, (a) that the Salt of Aken baths is to be looked upon as identically the same thing as the Nitre of the ancients, whence these waters may be justly called nitrous :

And indeed, altho' the ancients used the word Nitre in a very lax and vague fenfe, fometimes hardly diftinguishing it from common falt, for the most part describing it to be bitter, yet sometimes fcarce fenfibly bitter, fometimes falt and bitter; (and indeed it is rarely found pure and unmixed) yet it is plain from the writings of Galen and Pliny, that what they most frequently understood by this name was an alcaline falt (and accordingly Pliny mentions a factitious fort, ex quercu cremata) sharper than common falt, and in operation a powerful discutient, attenuant and detergent, and probably fomewhat purging; and indeed the old writers both facred and prophane have left us fuch diftinguishing marks of what they most frequently called Nitre, that it is not eafily miftaken; and an enquiry how far the falts obtained from any mineral waters are poffeffed of those marks will be of the more importance, because it will enable us to determine how far we may be fafe III solution a very

(a) Effay on Waters, Part III. p. 130.

in applying the virtues attributed to their Nitre to the corresponding falt impregnating any waters.

The falt of *Aken* baths is a notable inftance to this purpole; and here I gladly embrace the opportunity of paying fome tribute to the real merit of our Author, by adopting and inferting, as of use and importance, feveral of his experiments on the falt obtained from *Aken* baths, to which I shall beg leave to add fome observations and experiments of my own tending to give a more clear and diffinct account of the ancient Nitre, and of the falt correspondent to it which is found in divers mineral waters.

1. The Salt of Aken baths causes (a) an ebullition with all Acids, and with the concentrated or strong acids of nitre or vitriol yields copious white fumes like sea salt, or rather Soda.

The conflict of the Nitre of the ancients with Vinegar is implied in the account given of it in the facred records (b): the latter appearances with the acid of Vitriol are observable in the falts of many other waters besides those of *Aken*.

2. It changes (c) Syrup of Violets inftantly to a bright green. This also is the case of the Salts afforded by many other waters. The ancients indeed were not acquainted with this experiment, but they have left us another test of their Nitre tending to the same purpose, being an equal indication of an alcaline salt, viz. that it renders Cale and other pot-herbs more green (d), it being a well known fact that alcaline salts advance the colour of the tinctures of green herbs.

Now our Author has taken care to inform us, that (e) the people of Aken boil their coleworts, lettuces,

(a) Effay on waters, Part III. p. 108.
(b) Proverbs xxv.
(c) Effay on Waters, loc. cit.
(d) Plin. lib. 31. c. x.
(e) Part III. p. 62.

alpa-

0

asparagus, common and kidney beans, pease, &c. in the bath waters, finding by experience that the boiling of these vegetables is facilitated and expedited, and that they acquire a peculiar grateful flavour and tenderness, and have their colour preserved or improved by means of the salts in these waters.

This is not peculiar to the waters of Aken and their falts, but has been obferved in feveral other mineral waters fimilarly impregnated, and their falts, which alfo in reiterated experiments have been obferved to render Cale boiled in them more green and more tender; and this laft effect the Nitre of the ancients alfo had, as appears from the following obfervation of Theophrastus, (a) Quidam Nitrum injiciunt ut igni Brassica mandata facilius coquatur et tenera dulcisque sentiatur. The waters impregnated with such a salt seem to be the most opposite in their effects to those called crude or hard.

There is another experiment analogous to this, which I shall subjoin as a further illustration of the properties of the ancient Nitre, and of its identity with the falt found in divers mineral waters, viz. that their Nitre also rendered raw flesh more tender, as appears from the following observations in Plutarch (b): Quæ causa sit quod mactatæ carnes, v. g. galli, si de ficu suspendantur, tenerascunt? Respondetur spiritum calidum acrem incidendique vi preceditum ficus emitterre, isque incidit et concoquit carnem avis. Idem sit si frumenti acervo imponatur, aut juxta Nitrum, calore id efficiente:

And I have observed several waters impregnated with the mineral Alcali, particularly those of *Selters* and *Bourne*, and their Salts in some late experiments, as well as the same kind of salt im.

(a) De causis Plantarum, 110. 6. c. 14. (b) Quæst. 10. 1. 6. Symposiac. pregnating feveral of our *Irifb* fulphureous waters, to have had the fame effect on raw beef and mutton, viz. to make it more tender, and not only fo, but at the fame time to redden it as the modern Nitre or Saltpetre; but the double effect, viz. of rendering it both more tender and more red is alfo common to the artificial alcali.

3. The falt of Aken waters runs into crystals refembling those of Soda or Kelp, and bears great analogy to this useful ingredient in soap, glass, &c. (a).

Thus it appears that the falt obtained from the baths of Aken is a composition of the native or mineral alcali and muriatic falt, as in the Soda, but with a greater predominance of the (b) alcali; and here it agrees to the Nitre of the ancient Egyptians, which was to remarkable for imbibing the moifture of the air, that it was usually carried in pitched veffels to prevent it's melting (c): and the like composition is also observable in the falts obtained from many waters in other parts of the world, particularly in the following waters in England, France and Ireland, (and undoubtedly in many others) viz. those of the baths of Bourbon, and Mont d'or, and in the following fulphureous English and Irifb waters, viz. Quin-camel, Chadlington, Sutton-bog, Bilton, Wigglesworth, Swadlingbar, Mechan, Albwood, Derrylester, Derrybence, Killesber, and Lucan near Dublin, all or most of which give marks of a predominant alcali combined with a little marine falt; fo that we are now enabled, upon a longer feries of observation and experience to affirm that the mineral Alcali or Nitre of the ancients is a frequent ingredient in mineral waters, efpecially those of the fulphureous kind; and that this should be ordinarily combined with Sea-falt

(a) Effay on Waters, Part III. p. 108, 109. (b) Ibid. 109. (c) Plin. Nat. Hift.lib. xxxi. cap. x.

· Isrania on Willow, Part L p. of. and

agrees

agrees very well to the late difcoveries which have been made, that the mineral Alcali, *Natrum* or Nitre of the ancients is no other than the bafis of marine falt, unfaturated by it's proper acid, with which when it is faturated, it becomes a genuine marine falt.

Our Author's observation of the aconomical use of Aken waters in washing and scouring wool, woollen and linen clothes in them (a) fhews their faponaceous quality like that of the Nitre of the ancients (b), an effect not peculiar to the waters of Aken, but common to divers other mineral waters impregnated with the like falt, and is one notable criterion by which they are diffinguished from the waters impregnated with the calcarious Nitre, which have a contrary effect, conftituting a hard water not diffolving foap, whereas the mineral Alcali when pure, mixes equably with foap; and our Author's account of the correspondency of the falt of Aken baths to the Soda in it's freetening, (c) refolvent, detersive, aperitive, deobstruent and diuretic qualities is agreeable to the nature of the impregnating falt and to. Galen's account of Nitre, viz. Nitrum, si intra (d) corpus sumatur, secat et extenuat lentos craffofq; succos longe potentius quam Sal.

And next, as to the analogy which the Salt of Aken baths bears to the Nitre of the ancients in making glass, this also has been found to be not peculiar to it, but upon positive tryals to be also the case of the falts of divers other waters alike impregnated, as in those of Bourbon, Clifton, Wigglefworth and Sutton-bog.

Thus it appears that the falt obtained from Aken baths as well as from divers other waters correfponds in the most distinguishing characters to the

(a) Effay on Waters, Part III. p. 62. (b) Jerem. 2. 22. (c) Effay on Waters, Part III. p. 109. (d) Lib. 9. de fimp. med. fac.

mineral

mineral Alcali or Nitre of the ancients, and confequently by the express concession of our Author fuch waters may be denominated Nitrous, or in modern terms Alcaline. It is true our Author endeavours to eftablish an Acid in the Aken and most other waters, not without support from experiment; however, that the predominating falt in the Aken waters in their natural flate previous to any decomposition of it's parts either spontaneous or by the fire, is truly of the alcaline kind, appears from our Author's own description of the tafte of the water, viz. that it is faline, somewhat bitter, and lixivial or urinous, as is also the falt obtained from it, and to this agree the fcouring quality of the water itfelf as above mentioned; and therefore the Analysis of this water is just, and fuch as exhibits it's falts in their natural ftate.

adly, I proceed next to give also a more minute account of the Nitrum calcarium of Lifter, being a falt wholly diffinct from the foregoing, not giving the waters it impregnates a foft, faponaceous quality like that, but the contrary in those commonly called hard waters, and is the native falt impregnating the bitter purging waters, even according to our Author (a), whole conftituent parts we are become better acquainted with by the difcoveries lately made of the conftituent parts of that most useful imitation of it called Epfom Salt, being altogether fimilar to those of the native bitter purging falt, both confifting of a terreftrial matter refembling the Magnefia combined with the vitriolic acid, and both agreeing in the naufeous bitter tafte and in the purging quality.

Now the waters impregnated with this falt have been also generally called Nitrous by the far greater part of the moderns who have treated of mineral waters, particularly *Georgius Agricola*, *Baccius* and

(a) Essay on Waters, Part I. p. 93, and 123.

and by Dr. Short, who has obliged the world with elegant and accurate figures of varieties of falts of this denomination in his first volume on mineral waters: and Lister pronounces it to be omnium falium frequentissimum : and there are apparent veftiges of it in waters in all parts of the world; and it is more than probable with me that many, or rather the greater part of the waters called Nitrous by the ancients were impregnated with, not the faponaceous or alcaline falt above described, but chiefly with this falt; for those faponaceous waters wherein the Natron predominated, were but rarely, and here and there fcattered, with them as well as with us, v. g. befide the Aken waters, the two following are recorded as rarities, viz. the Lacus Ascanius mentioned by Aristotle cited in the Notes on Pliny as being fo Nitrous that they cleanfed and took fpots out of clothes by being dipt in them, and another in Armenia mentioned by Agricola having the fame effect; these I fay are rarities and mentioned as fuch; on the contrary, the bitter purging waters appear to me to have been frequent with them as they are with us, not only because of the bitter taste which they constantly ascribed to their Nitre, and Pliny where he teaches us how to fweeten bitter waters feems to use the words bitter and Nitrous promiscuously, viz. (a) Nitrofæ aut amaræ aqua polenta addita mitigantur ut intra duas boras bibi possint, but also becaufe of the purging quality common to their Nitrous waters and to the Nitrum calcarium and the waters therewith impregnated; and moreover, because such waters seem plainly to be mentioned both by Galen and Vitruvius as frequent and well known, in these two following passages: Nonnulli usu (b) aquarum sponte nascentium quibus sulphuris,

(a) Nat. Hift, lib. 24. c. 1. (b) De fanit. tuenda. lih. 4. c. 4.

aut

aut bituminis aut Nitri vis inest, vere vel autumno quotannis soliti excrementa vacuare.

Est aquæ frigidæ (a) genus Nitrosum, uti Pinnæ, Vestinæ, Cutiliis aliisq; locis similibus quod potionibus depurgat, alvumq; transeundo strumarum mimuit tumores.

Thus has antiquity given a fanction to the word Nitrous as applied to the bitter purging waters, being impregnated with a falt altogether diftinct from that of the falt or brine fprings, and whofe composition we are of late become much better acquainted with by the labours of the moderns in their various experiments on the artificial Sal catbarticum amarum beautifully illustrating the compofition of the native bitter purging falt in waters, the conftituent parts being found to be the fame in both.

Now our Author, who has not without caufe cenfured others for confounding Sulphur and Bitumen, has here the misfortune of having fubjected himfelf to a like cenfure with regard to Glauber's falt and the falt of the bitter purging waters, which he confounds in feveral places of his work, (b) particularly in his preface to the fection on the faline waters, being the general title he affixes to the bitter purging fprings of which he treats, where, giving an account of the general composition of the minerals impregnating these waters, he fays, that they (c) confist chiefly of the vitriolic acid faturated with different earthy matters, chiefly the basis of Seafalt:

But more expressly and clearly in p. 316. Part III. where treating of the prismatic falt in Bath waters, he fays, it indeed answers the character of Lifter's Nitrum calcarium, being to all intents and

(a) Vitruvius apud Authores de Balneis (b) Effay on Waters, Part I. p. 93, and 123. (b) Ibid. Part 11. p. 94.

[103]

[104]

purposes the same, a natural bitter purging salt, in all respects agreeing with the natural vitriolate prismatic salt, or with the artificial bitter purging salt known by the name of it's inventor Glauber, whose composition is an union of the vitriolic acid with the mineral alcali or basis of Sea-salt.

Now it was but highly reasonable to have expected from fo accurate a Chemist as our Author, that his observations and experiments should relate to the real Glauber's falt, which he has here defcribed in words that cannot be miftaken; yet, certain it is, that this falt does not in all refpects agree to the calcarious Nitre of Lifter, nor to the natural vitriolate prismatic falt in purging waters, but differs from both in divers important phænomena exhibited by each, upon the most accurate comparison: for 1. The basis of the real Glauber's falt is a mineral alcali, but the bafis of the bitter purging falt, as is justly observed by that more accurate Chemist W. Lewis, is a terrestrial matter answering to the Magnesia, as is evident from hence, that the folution of the true Glauber's falt always continues clear on the addition of an alcali, whereas the folution of the calcarious Nitre and the folution of the bitter purging falt natural and artificial on fuch addition always exhibits a large white terreftrial precipitate, even as in the process for preparing the Magnefia from the Sal catharticum amarum. 2. The native bitter purging falt in waters, the Nitrum calcarium, and the artificial Epfom falt, are found to curdle milk, whereas the true Glauber's falt being used in the fame proportion, did not produce any coagulum, which may fuggeft the reafon why fome few of the purging waters either do not curdle milk at all, or in a far lefs degree than others, even from a diverfity in their impregnating falts, which, in fuch few as do not curdle milk, approach nearer to the true Sal

[105]

Sal Glauberi, the Sal Polychreft, vitriolated Tartar and Sal diureticus, all which have likewife an alcaline basis and are found to have no effect in curdling milk. 3. A third variation in the appearances exhibited by the Sal catharticum amarum or now falfly called Glauber's Salt, (and fold for fuch in our fhops, being the artificial Epfom falt in larger cryftals,) from those exhibited by the true Glauber's Salt, is, that this laft, upon an exact comparison, was found to have a far less effect than the first, in improving the colour of Greens, producing a lefs deep and lefs lively green in Coleworts and Peafe boiled with an equal quantity of each, than the Sal catharticum amarum falfly called Glauber's falt in the flop, and that impregnating our hard waters, nay, even lefs than the common foft pipe water of Dublin.

Upon the whole, it appears that here is, not only a confusion of words, but of things, whilst two different falts, viz. the real Glauber's falt and the native bitter falt in purging waters are reprefented to be the fame.

The mineral Alcali then is not the Bafis of the Sal catharticum amarum artificial or natural, but is the proper basis of marine falt, a falt altogether diftinct from the other both in the figure of it's crystals and in it's qualities and effects, and the waters also wherein either of these are respectively predominant must also differ accordingly, tho' our Author has not thought fit to give any account of the Salt fprings in his fection of faline waters, but only of those wherein the Sal catharticum amarum predominates, particularly those of Epsom and Cheltenham, tho' the others are also frequent in most parts of the world, and merited a diffinct confideration. It is true those falts are variously mixed and combined in different waters; however, as it is of use to know the simples that enter into a P .com-

composition, fo it is to be acquainted with the diftinct nature of these falts so variously combined in waters; and where either of them predominates, as the Sal catharticum amarum evidently does in fome, and the marine falt in others, we have no other way of judging of their effects a priori than by confidering those of the respective predominating falt, which effects, as they are very different, and do not feem to be fo much attended to as they ought, I shall subjoin a few hints tending to fhew wherein their principal difference confifts: In the Sal catharticum amarum the Acid is lefs faturated, or more difengaged, and in all experiments disposes the blood to some degree of infpiffation : it is cooling, quenches thirft, is adapted to a hot bilious state of the juices; it is a more powerful and at the fame time a more gentle purge than marine falt: on the contrary in the marine falt the Acid is more faturated, and the mineral Alcali rather prevails, hence it attenuates and thins the blood, heats the body, excites thrift, is ufeful where a greater ftimulus, irritation and heat are wanted, and in a cold lentor of the juices, and it is a rougher purge, as are also the Brine fprings, and found by observation to be injurious in hectics and confumptive cafes, in which cafes the other waters in fmall quantities have been obferved to be used with good fuccess (a).

Confiftently with the above account the waters impregnated with the different falts mentioned have been respectively distinguished into the Saline and Nitrous in a late treatife on Mineral waters, and indeed according to our Author, properly enough, if by Nitre be meant Lister's Nitrum calcarium; but he alledges without the least referve, that this bas not one property of (b) the Nitre of the

(a) Method. fynops. of min. Waters, p. 72. (b) Effay on Waters, Part III. p. 316,

ancients

ancients or moderns; in which declaration how much prudence, attention to, or real acquaintance with the Nitre of the ancients or moderns is fhewn I shall leave to the confideration of the reader : indeed it has not the alcaline quality of the Natron, nor the fulminating one of Saltpetre, but at the fanie time that it is undoubtedly possessed of feveral diffinguishing qualities of both the ancient and modern Nitre is very obvious : for 1. Did not the antients conftantly attribute Bitterness to their Nitre ? Hear Galen, " Sapor amarus ex Nitrofi provenit intentione (a)" and " Amara et Nitrofa crafsam materiam attenuant, sicut sunt Iris, Amygdala amara, Nitrum, Orobus, Lupinus (b) &c. Now the Nitrum calcarium and the waters therewith impregnated are poffeffed of this quality in the most eminent degree. 2. Does the Natrum found in Afia corresponding to the Nitre of the ancients give a fenfation of coldness on the (c) tongue as Saltpetre does? The prifmatic falt of Bath water which answers to the Nitrum calcarium (d), and the Nitrum calcarium itself is remarkable for the cold and bitter tafte. 3. Was the ancient Nitre remarkable for increasing the greenness of Cale boiled with it? So is the native bitter purging falt in waters. 4. Is the modern Nitre called Saltpetre remarkable for reddening the flefh of beef or mutton boiled with it? The effect of the Sal catharticum amarum natural and artificial is the fame; and marine falt has the like effect, even from its participation of the Bittern or Sal catharticum amarum, from which mixture Sea-falt is feldom entirely free, (e) and our hard waters have the like effect on greens and flefh from the fame principle. 4. Had the Nitre of the ancients a

(a) De med. fimpl. fac. lib. 1. cap. 36, (b) De Oculis.
(c) Hill's Hift. of foffils. (d) Effay on waters, Part IIL p. 315.
(e) See Lewis's notes on Neuman.

purging

[108]

purging quality? The waters they called Nitrous were eminent for it, and from the paffage in Galen (a) here referred to compared with the known effects of the waters of Aix-la-Chapelle and Vichy impregnated with a falt like the Nitre of the ancients, it appears that they knew no Nitre but what was purgative; for which quality our Nitrum calcarium and Sal catharticum amarum natural and artificial are eminent; for the prifmatic falt or calcarious Nitre impregnating waters in but a very finall quantity renders them powerfully cathartic.

So much may fuffice, if not to establish the application of Nitrous to the waters impregnated with the Sal catharticum amarum, at least to apologize for the use of it in that sense until a better and more diffinguishing appellation for it be propofed; for indeed that which has been propofed by (1) our Author, who would have it called the universal Vitriolic, or native Vitriolate falt, seems liable to fome exceptions: had he called it Sal vitriolatum basi terrestri, or Sal seleniticus, as some have done, I might not have quarrelled with him; but how far the multiplying a variety of names not more clearly expressive of the nature of the thing fignified tends to the improvement of science, and whether or no, whereas we have divers mineral waters strictly and properly called Vitriolic, yielding a true Vitriol, the affixing the appellation of Vitriolic without further explanation or diffinction as above specifying its peculiar basis, do tend to confound it with real Vitriol found in other waters, I shall refer to the determination of the critics in language and chymistry; only shall beg leave to intimate, that in the opinion of another Author and as good a judge of both, fuch falts ought not to be denominated Vitriolic: for he, fpeaking of

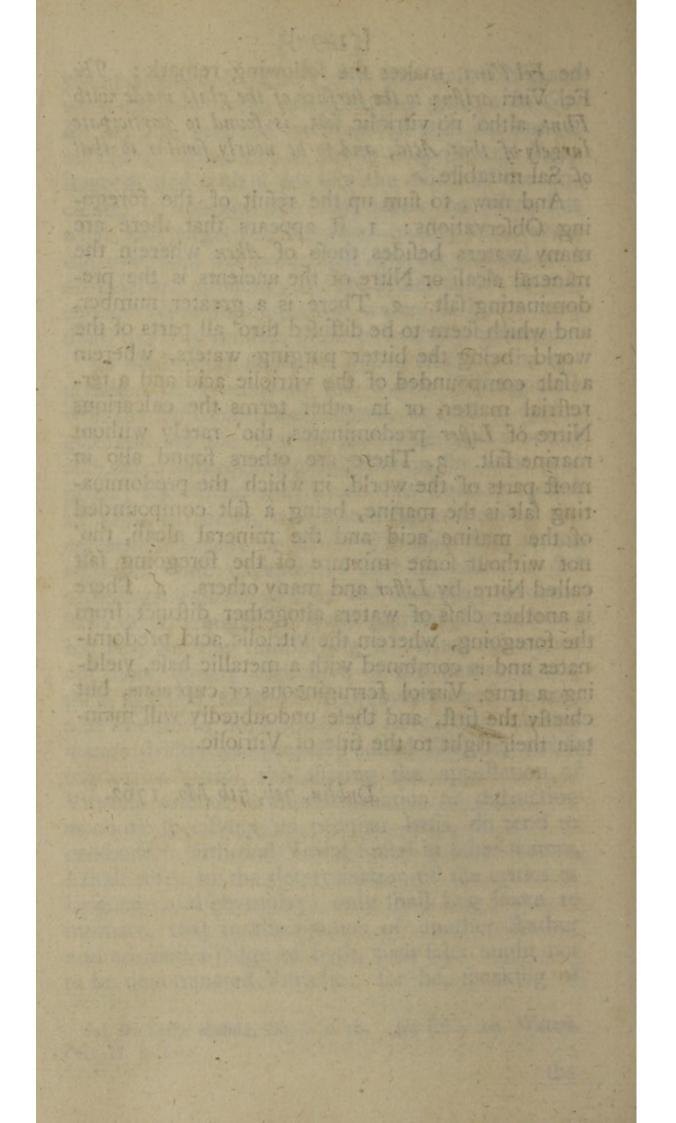

(a) De Sanit. tuenda, lib. 6. c. 10. (b) Effay on Waters, Part. II. p. 100.

[109]

the Fel Vitri, makes the following remark: The Fel Vitri arifing to the furface of the glass made with Flint, altho' no vitriolic falt, is found to participate largely of that Acid, and to be nearly similar to that of Sal mirabile.

And now, to fum up the refult of the foregoing Observations: 1. It appears that there are many waters befides those of Aken wherein the mineral alcali or Nitre of the ancients is the predominating falt. 2. There is a greater number, and which feem to be diffused thro' all parts of the world, being the bitter purging waters, wherein a falt compounded of the vitriolic acid and a terreftrial matter, or in other terms the calcarious Nitre of Lister predominates, tho' rarely without marine falt. 3. There are others found also in most parts of the world, in which the predominating falt is the marine, being a falt compounded of the marine acid and the mineral alcali, tho' not without fome mixture of the foregoing falt called Nitre by Lifter and many others. 4. There is another class of waters altogether diffinct from the foregoing, wherein the vitriolic acid predominates and is combined with a metallic bafe, yielding a true Vitriol ferrugineous or cupreous, but chiefly the first, and these undoubtedly will maintain their right to the title of Vitriolic.

Dublin, 7th, 7th Mo. 1762.

TRACT II.

THE

ANALYSIS

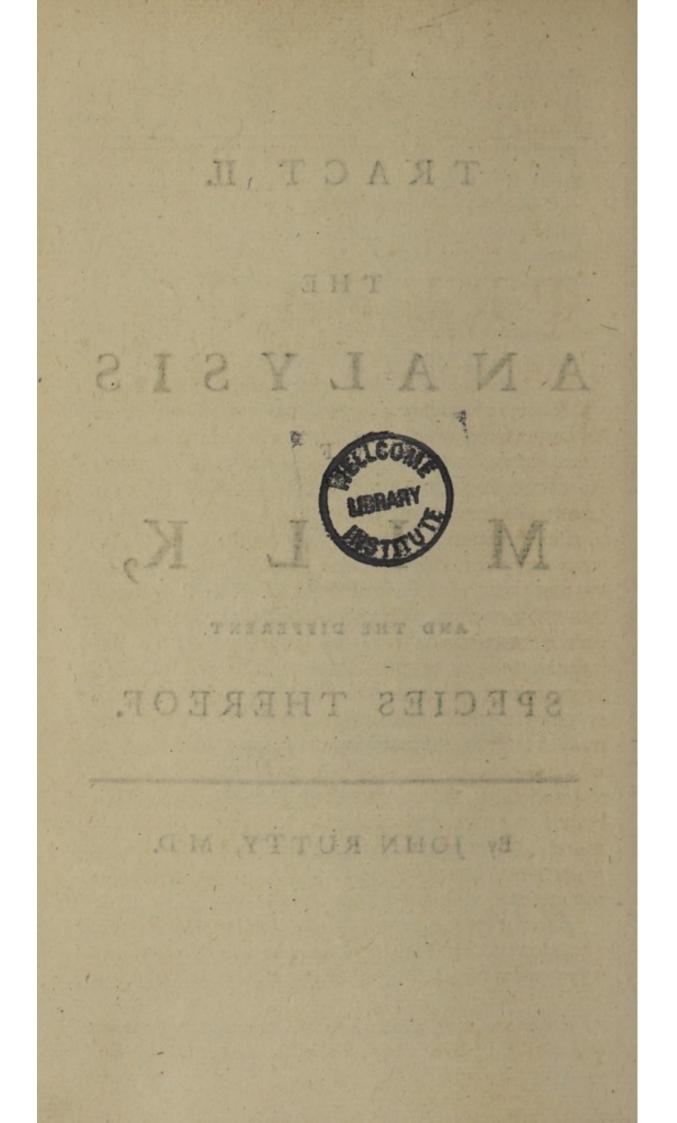

MILK,

OF

AND THE DIFFERENT

SPECIES THEREOF.

By JOHN RUTTY, MD.

THE

Fil

PREFACE.

THOEVER prefumes to publish any thing as of importance to the world, ought to be acquainted with what his predeceffors have already done, or elfe expect to be liable to be treated as one that has contributed to increase the now juftly complained of plague and burden of fcience in the multitude of unneceffary productions. Having therefore had recourfe to the writings of the ancients on the fubject of Milk, I do acknowledge that they, being well acquainted with the dietetic part of medicine, were not ftrangers to the different qualities of the Milks of different animals, as which of them had most ferum and least curd, et contra, and accordingly, which of them was most or least easy of digestion and distribution, which of them was laxative, and which conftipated the belly moft: and they gave the Afs's Milk boiled in large quantities, as to twelve pints and more, as a purge void of acrimony, altho' to what principle this was owing they left to be inveftigated by the industry of the moderns.

The following fummary account of the virtues and vices of Milk from *Galen* and *Diofcorides* flews what diffinct and juft conceptions they had of it and its Whey.

" Corpus alit, alvum emollit : thoracis ac pulmonis partibus Lac omne utile : omnibus auxiliatur internis

CX-

exulcerationibus, præsertim faucium, pulmonis, interaneorum, vesicæ et renum, efficax contra rosiones exustionesq; ab exitialibus medicamentis factas, uti a cantharidibus &c." to which Ætius adds, " in urinæ difficultate et acri egestione Alvi—et ad acres et morduces fluxiones utilissimum."

"Capiti, n'si quis ipsum babeat admodum firmum non accommodum, ut et nec hypochondriis quæ levi de causa inflantur; necnon eos renes offendit qui calculis generandis sunt appositi, jecur autem offendit his qui hoc affectu facile prehendi possunt."

" Lac omne respuendum Spleneticis, bepaticis, comitialibus, vertiginosis, nervorum vitio laborantibus, febricitantibus et capite dolentibus, nist quis purgationis gratia schiftum præbeat :" the Whey being preferred to Milk in some of the cases enumerated, and particularly for the purpole of purging. The moderns also agree in exploding Milk in cachexies and obstructions of the viscera, as increasing such diforders by the craffamentum, but give Whey the preference, and frequently order Milk diluted with mineral waters, as on the contrary in very emaciated bodies, Milk is preferred to Whey. Herein however the moderns feem in fome fort to differ from the ancients, viz. in recommending it, not only in the Gout, but in the Stone according to Dolæus.

Thefe obfervations refpect Milk in general; but it is neceffary to remark, that the general and indifcriminate ordering of a Milk diet without regard, not only to the pafture of the animal and feafon of the year, but more efpecially the difference of the animal from which it has been taken, muft be attended with very uncertain effects; and indeed the Ancients were well aware of the importance of attending to this difference; giving the preference to Women's milk as most congruous to our nature, and next to the Affe's, as one of the thineft thinneft (and near akin to the Mare's milk, and both laxative) and most easy of digestion and distribution.

It must however be acknowledged that their accounts of different Milks are not free from confusion and uncertainty; for Pliny (a) pronounces the Affe's milk to be craffiffimum, contrary to Galen, and Galen himfelf repeatedly afferts as a well known fact, that Goat's milk is lefs thick and lefs fat than Cow's milk, and Ætius confirms the fame error, and Pliny in the place cited fays, Bubulum caseo fertilius quam Caprinum: Whereas, that the reverse is true with respect to the Milks of these animals, at least in this country, (as well as in Scotland and France, as far as appears from the obfervations yet made there) will abundantly appear in the fequel; a difference undoubtedly worthy the attention of Phylicians, as one of these Milks has been known to be used with success where the other hath failed, for reasons obvious enough in the fequel; and when Mangetus in his collections. attributes to Cow's milk a superior excellency in correcting the acrimony of poilons, I apprehend this praife ought rather to be attributed to the milk of the Goat and Sheep:

Nor indeed is what *Hippocrates* himfelf hath faid concerning Goat's milk altogether unexceptionable, viz. that it opens the belly more than Cow's milk; for if *Galen* be right in afferting that Milk conftipates the belly more in proportion as it contains more curd and lefs ferum, then *Hippocrates* must be wrong in affirming that Goat's milk moves the belly more than Cow's milk (b), or at least this will not hold true of the Goat's milk of this country, as having much more curd, and not more, but rather lefs of the faline principle, as will appear in the fequel, agreeably to what *Diof*corides

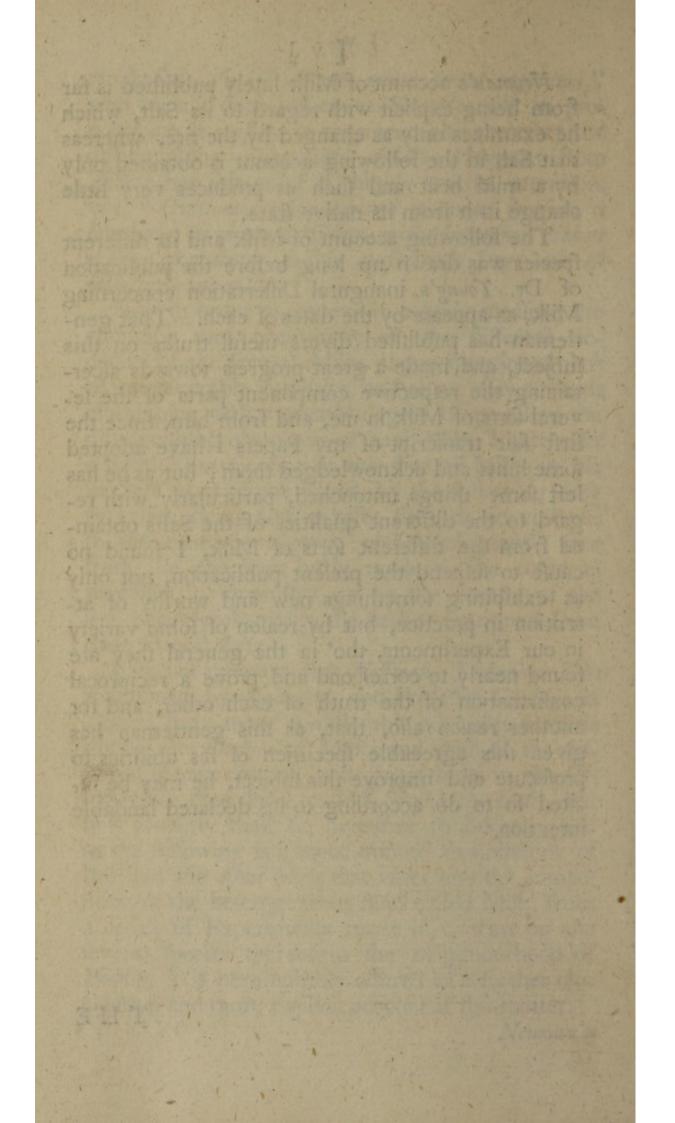

(a) Lib. x1. cap. 41. (b) Lib. 2. de Dizta.

corides fays, viz. " Alvum minus tentat caprinum," who has also done justice to Sheep's milk in pronouncing it crassum et præpingue, and therefore the distinguishing character which Mangetus from Avicen has left us of it, highly merits attention, viz. " Ovillum crassus cæteris et minus serosum, et binc quoq; in renum debilitate, miciu sanguinis, diabete ovillum præbabetur, cui in confortando renes non est medicina compar."

Now in order to remove in a great measure the confusion and uncertainty of the different accounts of the feveral Milks above mentioned left us by venerable antiquity, and as an effay towards eftablishing with a greater degree of precision the diffinguishing characters of each Milk, I here offer a faithful examination of the feveral Milks in use in these parts of the world, by the following easy proceffes, being such as offer little or no violence to the constituent parts, and consequently free from the objection justly made to the common proceffes in chymistry, as by the torture of the fire entirely changing the bodies examined from their natural state.

I am not ignorant that Hoffman, Ludovicus Tefti mentioned by Valentini, and Professor Gaubius at Leyden, have made confiderable advances towards giving the Analysis of Milk, and even of the different species thereof, and particularly in extracting what they have called Saccharum lattis, but how properly shall be hereafter confidered; and as the following is a more minute examination of this and the other parts that enter into the composition of the heterogeneous shuid called Milk, from a feries of Experiments made in concert on the feveral species thereof in the neighbourhood of Dublin, it is here humbly offered as a further elucidation and more explicit account of this matter. Neuman's Neuman's account of Milk lately published is far from being explicit with regard to its Salt, which he examines only as changed by the fire, whereas that Salt in the following account is obtained only by a mild heat and fuch as produces very little change in it from its native state.

The following account of Milk and its different fpecies was drawn up long before the publication of Dr. Young's inaugural Differtation concerning Milk, as appears by the dates of each. That gentleman has published divers useful truths on this fubject, and made a great progrefs towards afcertaining the respective component parts of the feveral forts of Milk in use, and from him, fince the first fair transcript of my Papers I have adopted fome hints and acknowledged them; but as he has left fome things untouched, particularly with regard to the different qualities of the Salts obtained from the different forts of Milk, I found no caufe to fufpend the prefent publication, not only as exhibiting fomethings new and worthy of attention in practice, but by reafon of fome variety in our Experiments, tho' in the general they are found nearly to correspond and prove a reciprocal confirmation of the truth of each other, and for another reason alfo, that, as this gentleman has given this agreeable fpecimen of his abilities to profecute and improve this fubject, he may be incited fo to do according to his declared laudable intention.

[3]

THE

ANALYSIS of MILK,

Particularly that of the

WOMAN, ASS, MARE, COW, GOAT, AND SHEEP.

THE fenfible qualities of these several forts of Milk are thus diffinguished :

Woman's Milk is of a faccharine fweetnefs, far fweeter than Cow's Milk.

Affe's Milk is also much fweeter than Cow's Milk, but not fo fweet as Woman's Milk.

Mare's Milk approaches near to Affe's; and Woman's Milk in the faccharine fweetnefs is much fweeter than Cow's or Goat's Milk, and on comparing them looks much thinner.

Goat's Milk was inferior in fweetnefs to either of the three foregoing, but fenfibly fweeter than the beft Cow's Milk I could procure in and about *Dublin*, and alfo more white, as is likewife its cream and curd than those of the Cow, which have a caft of yellow; and it yields a whiter Whey, not readily becoming clear, as the Whey from Cow's milk.

Sheep's milk is of a rich, oily tafte, and to the touch of the tongue feels of a thick confiftence, and evidently thicker than any of the above Milks, and is inferior in fweetness to Cow's milk. The fpecific Gravity of those feveral Milks was thus determined: As the ball of the Hydrometre rifes above the furface of Milk, it is requisite that this be diluted:

Wherefore Cow's milk and Affe's milk being equally diluted, viz. with three parts of water to two of milk, the Hydrometre flood in the firft at 1. 0, in the fecond at $0 \frac{2}{3}$ and confequently the Affe's milk was confiderably heavier : And Mare's milk and the beft ftrippings of Cow's milk being equally diluted, the Hydrometre flood in the firft (as in the Affe's in the former experiment) at $0 \frac{2}{3}$, but in the fecond at 1. 0. Goat's milk and Sheep's milk being equally diluted and compared to Cow's milk, appeared to be confiderably more heavy than Cow's milk. The Goat's milk particularly and Cow's milk equally diluted compared, the Hydrometre flood in the firft at $0 \frac{4}{3}$, in the laft at $0 \frac{4}{3}$.

Scholium.

Affe's milk and Mare's milk, tho' they have far lefs cream and lefs curd than Cow's milk, yet are as much heavier than Cow's milk as Goat's milk is, and why? I anfwer, from the predominance and larger proportion of the faline principle in the Affe's and Mare's milk, which gravitates more than the Cream or Craffamentum in their diffolved ftate. I proceed next to the Analyfis of Milk, and ift, The Analyfis without fire.

Woman's milk Affe's milk Mare's milk Goat's milk Sheep's milk

gave of Cream

Of the Cream. I fcarce one third

not above half of what Cow's milk did.

three times as much as Cow's milk.

by guess above three times more than Cow's milk. viz. about two ounces from half a pint.

N. B.

N. B. These proportions of Cream are not given as invariable; for the Milks themselves differ at different times from divers circumstances, as that which is first from that which is last drawn and called Strippings, from the season of the year, pasture, and different state of the animal, v. g. soon after it has brought forth it's young it's remarkably thinner and stronger in the station principle.

Scholium.

Cow's milk, according to *Mangetus*, is preferable to other milks for correcting the acrimony of poifons on account of it's fuperior Oilynes: Now this holds true only in comparison to Woman's, Affe's and Mare's milk; for the Goat and Sheep's milk evidently challenge the preference in this refpect to Cow's milk.

Of the Curd.

Woman's milk

ren-

coagulated by the fame quantity

Affe's milk

Mare's milk

Goat's milk

Sheep's milk

{very little, even not $\frac{1}{2}$ of what Cow's milk did.

{a little more than half in one experiment, and not fo much as half in a 2d. experiment as (a) Cow's milk did.

nearly 3 parts to 2 of what the pureft Cow's milk did, in another trial above double, and the whey was whiter, and both the whey and curd of a ranker fmell, and the curd tenacious.
double to what Cow's milk gave, and

double to what Cow's milk gave, and in another experiment more than double, and Dr. Young observes the curd to be more firm than that of the Cow.

(a) Neuman makes the chrd of Affe's milk to be much lefs, wiz. but $\frac{1}{5}$ of that of the Cow's milk, and moreover, fays that it is lefs denfe and heavy than that of other milks.

Scholium.

Scholium

F 6 7

What Galen repeatedly afferts of Cow's milk compared to Goat's milk, that it is pinguissimum et craffifimum, is quite erroneous, at leaft with regard to those animals in this country and in Scotland, according to Dr. Young's experiment on the contents of both these milks, and particularly on the caleous parts of both these milks, as likewife in France according to Helvetius, a difference undoubtedly worthy of attention in fome circumftances of tabid patients, Goat's milk having been found to fucceed in fome of those cafes when Cow's milk has failed, as Dr. Baynard observes, and the reafon for the difference may be eafily deduced from a comparison of their respective Analyfis.

Corollary.

[7]

Corollary.

The Sheep's milk exhibited on evaporation by far the greateft quantity of contents of all the fix, the Mare's the next; then the Affe's and Woman's, and laftly the Goat's and Cow's milk, which laft gave the leaft quantity of all. The greater proportion of contents in Goat's than in Cow's milk is confirmed by Dr. Young's experiments in Scotland.

The Comparison of the Extracts of the several Milks.

The Extract of Woman's milk was

The Extract of Affe's milk was White yellowifh, (a) of a high faccharine fweetnefs, and not without fome faltnefs, unctuous, vifcid, inflammable on the red hot iron, with a white flame, and in another trial partly bluifh and partly purple, without notable fetor, and left but a finall quantity of grey falt afhes.

Yellowifh, very fweet, oleaginous, with a high flavour not altogether difagreeable: it moiftened a little in the air. And to this agrees *Neuman*'s obfervation, that Affe's milk has this remarkable particularity, that it yields a more fetid fmell in the fire than any other (b).

(a) The yellowish colour of these Extracts seems to be owing to some small degree of empyreum, which is it were carefully avoided by lessening the heat when the evaporation was nearly finished, the colour would be nearly white.

(b) It is an important remark of Dr. Young, that the ruminating animals, wiz. the Cow, Sheep and Goat is more acefcent, and participates more of a vegetable nature than that of the [non-ruminants, wiz. Woman's, Affe's and Mares] for which reafon the former Milks if the flomach can bear them, are to be preferred where there is a tendency to putrefaction.

grains

The Extract of | I

The Extract of Cow's milk was

Mare's milk

was

The Extract of Goat's milk was

The Extract of Sheep's milk was Pale-yellowifh, fweet, with a flavour like that of Affe's milk, and it felt granulated under the tongue, like honey or fugar, (an evidence of its faline quality) 40 grains in a red hot crucible burnt with a white, then blueand purple flame, emitting a fmell like an old cruft of bread burnt, and it left four grains of afhes greyifh and of a tafte fomewhat faline.

White-yellowifh, unctuous, of a faltifh tafte, fweetifh and fubacid, far lefs fweet than the Extracts of Woman's, Mare's and Affe's milk, but refembling the tafte of a farinaceous matter mixed with a little fugar. It moiftened a little in the air. It made no ebullition with Oil of Vitriol. Rubbed with Solution of Mercury fublimate corrofive it whitened a little. Half a dram in the red hot crucible, emitted a white, green and blue flame, and left four grains of black, falt afhes.

Yellow, of a fweetish tafte as of fomething farinaceous a little fweetened, far short of the sweetness of the Extracts of Woman's and Affe's milk, as also far less unctuous. It burnt with a white, then purple and blue flame. A dram burnt left four grains of asses grey and of a saltish tafte.

Of a pale yellow when obtained by a flow fire, and of a tafte farinaceous and moderately fweetish, and subacid.

[9]

OBSERVATIONS.

1. THESE Extracts of the feveral Milks, being obtained by a fmall degree of heat, give the refpective native taftes of the feveral milks, being their Oil, Salt and Curd more clofely approximated by the avolation of the aqueous parts; and from hence appear the congruous qualities of those three Milks, the Woman's, Affe's and Mare's, being diftinguistied by their peculiar faccharine sweetness, whereas the Extracts of the Milks of the Cow, Goat and Sheep, shew either a Salt specifically different from that in the three former, or at least the fame or a like falt blended with a large proportion of a milder fubftance.

2. I kept these Extracts of the feveral Milks in gallypots covered only with paper in a clofet where there had been no fire, for feveral months, and fome of them above a year, and they continued fweet, without any acquired rancidity, and of a grateful tafte, fo far that my Cat, (a delicate, pampered animal) would feed greedily on them, and once devoured the fruit of my labours, the Extract of Affe's milk; and if in the preparation, all empyreum has been carefully avoided by using a gentle heat, and timely taking the veffel off the fire, these Extracts will by trituration with water, or by diffolving in water over the fire (as a dram of the Extract of Cow's and Affe's milk will readily do in an ounce or two of water, or an ounce in a pint) yield a liquor partly yellowifh and partly white, farinaceous, and of a fweet, not ungrateful tafte, like the respective milks from which they were drawn, viz. in the first of a rich, pleafant tafte, in the fecond more fweet : I will not indeed fay altogether of fo grateful a flavour as the original milks, nor fo fmoothly mixed, but tolerably pleafant, and which might be used as a fucfuccedaneum for Milk at Sea, analogous to the portable Soups made from infpiffated Broths, and perhaps as good a fubftitute for Milk as the others are for Broth; for indeed neither do the gelatinous parts of Animals nor Milk lofe much by decoction, except the aqueous parts.

Wherefore, as this Age has diffinguished itself by excogitating and recommending divers methods and medicines highly conducive to the prefervation of our Mariners from that deftructive difease the Scurvy, it may not perhaps be unfeasonable to propose fuch a preparation, viz. of the Extract from Milk or of the Salt from Whey as deferving a place in the sea-cheft, in order that being kept in a dry warm place, a *fuccedaneum* might be fupplied for Milk and fweet Whey, which perhaps might prove of great use at Sea to such delicate, morbid, opulent Valetudinarians as could bear the expence of it.

I shall next proceed to the confideration of Whey, being the lixivium of Milk, or the Solution of its proper Salt.

Cow's Milk Whey diluted with an equal quantity of water buoys up the Hydrometre as high as Milk diluted with an equal quantity of water does, and why? because the Whey being a folution of the meer Salt in the same volume of a watery fluid gravitates more than the Oil and Curd in their attenuated state.

Now as we have feen that the different Milks above mentioned differ confiderably in their productions whether by fire or otherwife, it will appear by the fequel that there is no lefs a diverfity in their feveral Wheys, and therefore I apprehend the following minute examination of thefe to be no fuperfluous labour.

Doctor Dyvernois, who lately published a Differation on the Sugar of Milk, was at a great deal of pains to procure this Salt by Cryftallization; but I doubt the fmall quantity obtained in that method will hardly compensate for the tediousness of the process; and I find that Whey depurated by repeated decoctions and despumations yields by meer evaporation over a flow fire a genuine, pure and white Salt, which agrees to the other in the feveral appearances thus described by that Author, viz.

" It is dry, white, of a fweet, agreeable fmell and fweet tafte, like Sugar or Manna, a little faltifh, melts eafily on the tongue, ferments neither with acids nor alcali's, burns with fmall sparks on lighted charcoal; and that its dofe is from half a dram to two drams twice a day, that it keeps the body open, &c."

I. The first experiment I made for obtaining the Salt from Woman's milk, viz. by diffolving the Extracts in diffilled water, filtering and with great difficulty feparating the oily matter and exhaling to drynefs a fecond time, was not fo fuccefsful as the fecond method to be fubjoined by repeated boiling and fourming the Whey, and then evaporating by a flow fire; for I found that the repeated evaporations leffened the fweetness of the falt, which falt thus obtained was brown, tweetifh, fomewhat vifcid, and imbibed the moifture of the air. It did not, as Sal Ammoniac and Salt of Urine, excite any fmell when rubbed with Salt of Tartar. On the red hot iron it was inflammable, and for the most part confumed, but did not emit a fœtid fmell like burnt horn or other animal substances. In the red hot crucible half a dram emitted a white and purplish flame, and left two grains of grey, faltish ashes, which gave a ftrong acid fume with Oil of Vitriol :

But the Salt obtained from the Whey of Woman's milk coagulated by rennet and exhaled to drynefs, was white, with only a flight caft of yellow: yellow: it was granulated like honey, of a fweetifh ftrong fmell, of a falt and fweet tafte, tho' far lefs fweet than the Extract:

It moiftened a little in the air :

On the red hot iron it melted and flamed, and left a finall quantity of falt afhes, and thus burnt it fmellt like a cruft of bread burnt.

It was double in quantity to what the fame proportion of Whey from Cow's milk yielded.

I took two drams, two fcruples and feven grains of it diffolved in a pint and half of water, (to which it gave the colour and tafte of Whey) but was not at all purged by it, nor was any fenfible effect produced by it except a little wind.

2. The Salt of Affe's milk, being four fcruples, from five ounces of the Whey depurated by repeated boiling and fcumming, was white, a little brown at the edges, granulated under the tongue, of a fweet and a little faltifh tafte, of a fomewhat high flavour, vifcid.

It moiftened in the air:

Rubbed with Oil of Vitriol it emitted a fume of an acid fmell.

Half a dram burnt in a crucible left five grains of dufky grey falt afhes.

The Whey of Affe's milk gave above treble the quantity of Salt that the fame proportion of the Whey of Cow's milk did, and according to *Dyvernois* fix times as much: however, it is much more loaded with Salt, and this of a much fweeter quality than the Salt from Cow's Whey.

I took three drams of this Salt diffolved in a pint of water and had but one ftool more than ufual, and that not loofe.

3. From the Whey of Mare's milk depurated as above I obtained two drams, two fcruples from half a pint of Milk, of white Salt, granulated like honey, of a mild, fweet fmell, of a fweet and faltifh

[[12]]]

faltish tafte, much sweeter than the Salt of the Whey of Cow's or Goat's milk.

It gave near treble the quantity of Salt that the Whey of Cow's milk did, though in another experiment only one third more; but in a third experiment more than treble.

Rubbed with Oil of Vitriol it emitted an acid fmell.

Half a dram burnt in a crucible left four grains of black, falt afhes.

I took two drams, ten grains of this Salt diffolved in half a pint of Whey without any purgative effect, but only fome flight gripes and a little wind, fo that in fuch a fmall dofe it appears to be only eccoprotic, tho' in a larger it must undoubtedly prove purgative.

4. From the Whey of Cow's milk depurated as above and flowly exhaled, I got, even from milk procured from the country, only half the proportion of Salt to what Woman's milk yielded, which was granulated, and of the confiftence of honey, very different in tafte from the Salts of Woman's, Affe's and Mare's milk, being faltifh and fweetifh, and in another fpecimen fubacid; and indeed it feemed to be more remarkable for faltness than sweetness. It emitted a white and purple flame in the red hot crucible, and half a dram left five grains of falt ashes.

I took an ounce of this Salt diffolved in a pint of water, and was not purged by it.

5. The Salt of Goat's Whey compared to that from Cow's Whey was as 108 of the first to 152 of the last from the same quantity of each, (from whence we may conclude that whatever peculiar effects Goat's whey may have is by no means owing to any greater proportion of Salt it contains) which Salt, like that of the Cow's Whey, falls greatly short of the sweetness of that of the Woman's

Woman's, Affe's and Mares Whey, and is alfo as remarkable for faltness as sweetness: It was of a white, brownish colour, granulated like honey, of a smell somewhat strong, of a faltish, subacid and sweetish taste, so that Goat's whey seems to be not less, but rather more acescent than Cow's Whey.

The fame Salt from Goat's whey flamed on the red hot iron, and fmelt like burnt coffee.

6. The whey of Sheep's milk yielded but a fmall quantity of Salt, and far lefs, even than Goat's whey, which Salt was of a pale yellowifh colour, of a farinaceous fweetifh, faltifh, and fubacid tafte, and felt granulated under the tongue.

Corollaries.

1. The Woman's, Affe's and Mares milk have more Salt, but lefs Oil and Craffamentum; but the Cow's, Goat's and Sheep's milk have more Oil and Craffamentum, and far less Salt; and of the three laft the Sheep's has most Oil and Craffamentum, next the Goat's, the Cow's leaft of thefe three. The Curd of the Goat's milk is moreover observed to be of a more coherent nature than that of the Cow's, from whence as well as the greater proportion of curd, Goat's milk is apt to coagulate in weak fttomachs and create anxiety, even in fome cafes to a great and dangerous degree, to prevent which Sugar and Salt are ordered to be mixed with it, an inconvenience to which the thinner milks, are not fo liable, particularly the Affe's milk, as Ætius long ago obferved, who also observes the Vililigo alba to be the confequence of a long continued use of Sheep's milk. Hence not only Affe's milk, but also the Woman's and Mare's are to be preferred whereever a milk of more easy digestion and distribution, and lefs apt to create obstructions is required, and where there is a tendency to fever, a weakweakness of ftomach, or a disposition to coagulate or corrupt milk, as also where some degree of attenuation or opening the belly is wanted.

On the other hand, the three other milks are more balfamic, and to be preferred where fomething more demulcent, agglutinating, incraffating and conftipating is required, in which qualities the Goat's and Sheep's milk do notably exceed the Cow's, which in these respects obtains an intermediate place between the two last mentioned and the three thinner milks of the Woman, Afs, and Mare.

From the above Analyfis alfo, viz. from the predominancy of the craffamentum and the fmaller poroportion of the faline principle in Goat's milk compared to Affe's, most clearly appears the reason of the following observations of Helvetius, (a) viz.. "In beclic fevers attended with a loofenes, as also in all long and obstinate fluxes Goat's milk is to be preferred to Affe's, and is particularly proper to restore children in confumptions, as well as other extremely thin and emaciated bodies." viz. as being more nourithing and less ftimulating, though how far the circumstance of it's being harder of digestion may determine it's usefulnes in particular cases must be left to observation.

Cor. 2. The Salt of Woman's, Affe's and Mare's milk is diffinguished from that of the Cow, Goat, and Sheep, both by it's quantity and quality, as being not only in a far greater proportion in any given quantity of milk, but in quality much more fweet, approaching to the fweetness of Sugar or Manna, whereas the Salts of Cow's, Goat's and Sheep's milk are envelopped with fome foster matter, which lessens the flimulating and purgative operation, whence in the above tryals

a) Traite des Maladies les plus frequentes & des remedes.

tryals, which were made with both, lefs than half an ounce of the Salts of the whey of the three first animals acted as strongly or more strongly as an eccoprotic than a whole ounce of the Salt of Cow's whey.

Cor. 3. The Salt of milk is a mild, oily Salt, and may be juftly called a Sal medium, not only as being neither acid nor alcali, but as occupying a middle ftate between the vegetable and animal Salts, not yielding by the fire that fetor which all animal fubftances do, but rather a fmell like that of a farinaceous fubftance, as of a cruft of Bread or Coffee burnt, and not fo far elaborated by the concoctive powers as Salt of Urine, from which it differs fpecifically in not difmifling a volatile alcali on being rubbed with Salt of tartar, like that and Sal ammoniac; nor moreover has it that degree of purgative quality which Salt of Urine has, being much milder in fenfible qualities and operation.

Cor. 4. The Salt of all the Milks refembles the Sugar of the Reed in the oleaginous, inflammable quantitity, being by far the greatest part confumed in the fire; but there is this notable difference, that the Salt from Milk always leaves a small proportion of falt as whereas that from the Reed leaves a far les quantity of ashes, and those not falt, but infipid.

Cor. 5. The appellation of Sugar of Milk is by no means applicable to the Salt obtained from Cow's, Goat's and Sheep's milk. There is indeed a peculiar faccharine fweetnefs in the Woman's, Affe's and Mare's milk, as alfo in the feveral Extracts obtained from them; but when we come to feparate the faline from the oily parts as far as we are able, in order to make the Salt, this lofes of the fweetnefs and manifefts a faltifh tafte, and therefore I apprehend fhould be called rather Sal lactis lactis than Saccharum lactis, especially when we speak of Milk in general.

Cor. 6. The Sal lastis is not a fimple Salt, but combined with a pittance of marine falt, of the prefence whereof I looked upon the following appearances collectively confidered to amount to a demonstrative proof, viz. the faltish taste of the Salts of every one of the above Milks, their attracting the moifture of the air, their emitting an acid fume with Oil of Vitriol, as did also their afhes, and their folution turned grumous with folution of Silver : appearances all proper to marine falt, fo that, as Authors have difcovered marine falt in the bones, blood and urine of animals, we conclude it is also an ingredient in Milk : but this matter is put out of all doubt by an experiment of Geoffroy in the Memoirs of the royal Academy 1762, who from the lixivium of the caput mortuum of whey left upon diffillation, obtained cubical crystals like those of Sal gem, as did Dr. Tho. Young of Edinburgh also in a late experiment on Whey inspissated.

Having to far described the contents of the feveral forts of Milks and their Wheys, I shall next confider the practical uses of the laft, unto which the Antients were also far from being ftrangers, as being milk deprived of its groffer parts, and as fuch far better adapted to the purpofes of cleanfing and purging; and accordingly they ordered Whey in divers chronical difeafes, as we do mineral Waters, even where Milk was improper and forbidden, as appears from Diofcorides's account, viz. " Serum lactis datur quibus fine acrimonia volumus dejectionem moliri, ut melancholicis, [comitialibus, to whom the fame Author expresly forbids Milk] lepris, elephanticis et erumpentibus toto corpore papulis:" to which add particularly Goat's Whey

AND THOSE &

Whey in Spleneticis (a), (to whom Diofcorides exprefly forbids Milk) and that of Affe's milk, in morbis articularibus (a), and my ingenious Correfpondent hereafter named remarks, that even Affe's and Mare's milk can feldom be born by the Afthmatic unlefs diluted with Spa or other water.

The account given us by Diofcorides of the method in which Whey was taken, being very fimilar to our modern use of mineral waters, is worth attending to, viz. " Bibitur beminis per intervalla fingulis usque ad quinas (perhaps five of our pints or more, and Hippocrates gave 16 heminæ (b) of Affe's milk as a purge) ita ut intercedentibus spatiis potantes obambulent." Mangetus mentions (c) it's being drank medicinally in fpring for fifteen days or a month from half a pint to a pint or a pint and half with fugar, or with fugar of roles; but at our mountains of Mourne the much larger dole in which it is given comes nearer the practice of the Ancients. Dioscorides orders it to be made with vinegar and honey, but the before named Author prefers that made with Rennet or of the flower of the prickly wild Artichoke to the Whey prepared with Acids, efpecially in perfons fubject to coughs or other diforders of the breaft threatening a confumption. There is also another method of curdling milk perhaps worth mentioning here, as the whey fo obtained is deemed the fofteft and mildeft of all others, viz. by beating up the milk with eggs, adding a little fugar and fetting it over the fire.

N. B. The following account of Goat's Whey having been drawn up by careful observation and attendance to facts in cases which fell under the

clifateb every fort but furze, which on acces

his country, where Inred SECTION I. kles they fearch after abov

Of the PASTURE and FOOD of GOATS. all pretty common there, they will

T is with good reafon remarked by Goat-herds that those animals do not preferve their health and vigour when confined to low foils and fituations. A rocky mountainous foil that will bear no vegetable except Furze, Brambles and fuch like, is the only one that agrees with them, fo that it may be almost taken for granted that their milk and whey will not answer medicinal purposes fo well on any other, not only from their natural food, but also from their not having such spirits and alacrity; and moreover it is faid they do not live half to long on low patture grounds as on mountains. Such foils as are generally chofen for them, are observed to produce several forts of plants not very common elsewhere on which Goats are alledged to feed plentifully. This however I did not take for granted, but with great induftry, for many years, attended them at their browfing grounds, to make remarks; and I obferved a general rule with them, not to touch an herbaceous vegetable, if there was any fort of tree, fhrub or of the frutescent kind to be had. Hence it is, that where a herd of them has fed fome time, every plant of this fort is ftript of leaves, as far as they can reach: It would require a large extent of fhrubby ground, to fupply them with leaves for a whole feafon : they quickly dildifpatch every fort but furze, which on account of its prickles and the quantity to be had, becomes inexhauftible to them, and indeed makes the greater part of their food, in fome places, fuch as *Tullymore* in this country, where large herds are conftantly hept.

Honeyfuckles they fearch after above all things; next for bramble leaves and what others they can come at. St. John's wort they devour greedily: *Allium Sylveftre*, pretty common there, they will feed on, but not eagerly.

I have often thought that the fuperior medicinal efficacy of Goat's whey, could not be accounted for folely from the difference in their food from that of other animals, but that there was much to be allowed for the conftitution and nature of the Goat. I have many times compared their whey with that of Cows, where their food muft have been precifely the fame, and always found it remarkably ftronger and ranker.

the alacetty ; and more over it is laid, they do not

but allo from their

Of GOAT'S WHEY in general.

MESUE of Damafeus, who lived about the latter end of the fixth century, feems to have had a pretty accurate notion of the peculiar efficacy of Goat's whey as a medicine, in faying that it attenuates, opens obstructions, deterges and purges gently; and he gives a brief catalogue of its virtues, but which is not complete without adding its nutritive and diuretic qualities.

The only method of making it at the mountains of *Mourne* is with rennet.

There cannot be too much care to have the whey as clear as possible, the neglect of an attention tion to which circumftance. has to my knowledge, been of bad confequence in feveral cafes. Let it be made as clear as you will, a confiderable quantity of curd remains blended with it; which appears on boiling it when the curd called the cropcurd rifes to the top; and whitifh ill-made whey will lye heavy on most ftomachs, produce inflations, and not pass freely either by urine or ftool, but by proper care it may be made as limpid as any other whey.

Whey poffeffes both the alterative and evacuating qualities: as an alterative it may be faid to diluent, attenuant, refolvent, demulcent and nutrient. It's evacuating virtues confift in it's promoting the fenfible evacuations of ftool, urine and fweat.

It has an undoubted right to be accounted a diluent of the first rank, having the advantage of water in being foster, somewhat saponaceous and having already circulated thro' the minute vessels of an animal body, so that it will probably penetrate more than water, and more effectually diffolve noxious falts and prepare them for evacuation by their proper emunctories:

It's attenuant and refolvent properties may bear fome debate. It must be owned that in these it yields to mineral waters, but when we confider its effential falt or *facebarum*, blended with a fine animal oil, and that it abounds with the juices of plants that are eminent for these qualities, we may readily acknowledge that it has a right to be called attenuant and refolvent even from reafoning *a priori*: Indeed where it is used in diforders that require active penetrating medicines, the affiftance of fuch will be very expedient, perhaps necessary, chiefly of the neutral falts.

Whey becomes a noble antidote against morbid acrimony in the blood, by it's demulcent quality:

as

as a diluent and demulcent it confpires to correct all forts of acrimony. By thefe it calms the rapid motion of the blood in hectics, allays the parching thrift fo grievous to fuch fubjects, and at the fame time relaxes the general fpafm and too brifk vibration of our fibres, common in thefe diforders, of which we can't fail to have a lively idea on touching the hard, tenfe, flicky pulfe of fuch. But Whey fhines forth in no quality more than in its nutritive. What a high opinion Virgil had of this appears by his

Acremque Molossum

Pasce sero pingui ----- GEO. 3. In phthifical cafes, when the blood is thin, florid and highly acrid, the hectic fever high, a rapid marafmus ufually attends, not to be checked perhaps by any other medicine, feldom indeed by this. Briftol Water may dilute, may cool, may evacuate the feptic acrimony by the kidneys, but all this time the blood continues as abfolutely unfit for repairing the great wafte made by the putrid fever, as before. In this cafe it must yield the precedence to Whey, which has perhaps all it's good qualities, it's gentle aftringency excepted, and befides, affords the only food which the fhattered organs of digeftion and fanguification are capable of converting into nourifhment. It feems indeed to be the only thing deferving the name of cordial and reftorative in fuch cafes; inferior to nothing except human Milk fucked out of the breaft. These are things I myself have a lively fense of from personal experience, having been in this fituation, and retrieved only by a proper courfe of the non-naturals, but chiefly of Goat's Whey, which I found answer every intention of food and medicine. No Epicure ever received more pleafure from his Ortolans or his Turtle, than I have many times received from a draught of Goat's Whev

Whey upon waking in a morning, after a high hectic paroxyfin and profuse fweat thro' the whole night, being quite parched with thirst. I am not yet arrived at fuch a perfect state of health, but that I find great comfort and advantage from it, especially at the Whey season.

SECTION III.

Of the evacuant properties of Whey.

Y diluting, attenuating, refolving obstructions b and sheathing acrimonious saline humours, impurities of the blood are corrected and prepared for evacuation, which is promoted in a most easy and agreeable manner by Whey. The principal outlet which nature uses to throw off the faline pecant humours, is the urinary paffage. There is perhaps no mineral water which promotes the urinary discharge more effectually than well prepared Goat's Whey properly drank: for by improper management it will be prevented from operating duly this way. Lying long in bed in the morning and fleeping after drinking it, drinking it too haftily, and in too great quantity, not using propar exercise along with it, and in fine, neglecting to use proper medicines to affift, are generally the reasons of it's failing in this effect. Indeed if it purges speedily and briskly, it will no doubt have a less diuretic effect : But I apprehend that in most cases in which it is recommended, the confumptive efpecially, it is intended that it shauld tend mostly this way : if it fails of it, and does not prove purgative in some degree, it occafions many inconveniencies, as fullnefs and fwelling of the ftomach, want of appetite, anxiety of the

On the contrary, when it paffes freely, the fpirits become light, free and tranquil: it invigorates when wine would deprefs, and remarkably quickens the appetite, as is well known to moft Wheydrinkers, who feldom fail to have a keen appetite for breakfaft, after duly paffing their Whey.—I have frequently remarked that in hypochondriac conftitutions generally inclined to habitual coftivenefs, it pufhed very brifkly by urine, rather I fufpected, too much, and in this cafe it generally occafions coftivenefs. Lenient purgatives to determine it the other way, are the remedy: It is ufuully more diuretic to lean habits, than to fuch as incline to corpulency.

If on trial it is found that it does not pass freely, the affiftance of diuretic medicines will be neceffary; the neutral falts feem proper to answer this end, and are found to from experience; especially fuch of them as at the fame time loosen the belly. *Glauber*'s falt, *Sal polycbrest*, and the *Sal diureticus* are among these: the latter especially I have known very beneficial, in causing it to fit very light and pass quickly. Riding out on horseback generally determines it to the kidneys.

Tho' the diuretic effect of Whey is the moft neceffary and beneficial, it is also neceffary that it should operate by stool: But from what experience I have had, it seems to appear, that there are not many constitutions it will have this effect on without affistance: on the contrary, I have known most performs rendered costive by it.

When I began to have fome experience of its effects on myfelf and others, I was furprized to find an opinion generally prevail, that purging was its moft ufeful and proper effect, and that little benefit was to be expected, if it did not operate brifkly

brifkly this way, either naturally or by art. The opinion of an old Practitioner here feems to have been the occasion of it at first, near 40 years ago. His rule was, to fwill down as large dofes as the ftomach would admit, and to take a good quantity of that draftic purgative, Buckthorn fyrup with it; by which means it may be believed, it would not be lazy in making it's way. Five, ten, fifteen motions a day were common. On inquiry I found that numbers of hectic perfons had been hurried off by this scheme: the case is now alter'd indeed; perhaps I may have contributed to bring this about by declaiming on all occasions against it. Much lefs provocation than this will fuffice to bring on that dangerous fymptom, a diarrhæa colliquativa, to which all hectics are naturally prone, and whereof feveral inftances have been known. And not only this, but many other mitchiefs follow: I have repeatedly experienced, that appetite and digeftion weak enough before, became more impaired; even the Whey itself would not digeft : the chylopoietic organs were quite relaxed and enfeebled, and great general debility and tremors were brought on, flatulency in the bowels, lownels of spirits, &c. On the contrary, one, two, at most three easy motions a day (especially if three pints had procured them, without purgative medicines) had all the contrary effects : appetite and digettion improved, greater freedom of spirits, cheerfulness, lightness, &c.

But if it fails to have this effect, means muft be used to affift it. Many have suffered meerly from not attending to this; from drinking on for several days together and quite coffive all the time, obstructions of the abdominal *Viscera* are a natural consequence: I knew a Jaundice brought on by it.

Glauber's

Glauber's Salt I have experienced a good medieine in general, to one, two or three drams every morning. The diurctic falt in an increased dofe promiles to be a very good medicine here; belides it will greatly improve the attenuating and refolving properties of the Whey, and render it more active and penetrating.

Manna, Rhubarb, Sal polychreft, Rufi pills, &c. may be proper, according to the difeafe and conflitution : But the beft method feems to be to turn the Goats into a Pafture where purgative herbs abound, or gathering them for the Goats. Those that are indigenous here are chiefly Linum catharticum, Ebulus et Sambueus. The first they eat readily and is pretty common ; it's too great fharpnefs is foftened in the Whey. It is frequently the caufe of it's purging more than ufual. The other two they will fometimes crop, but moderately. The Soldanella grows on Dundrum shore. Bennet in his Theatrum Tabidorum proposes encouraging Sweat in confumptions, particularly that kind of Tabes which he treats of, under certain reftrictions. I have not experienced whether his fcheme is a good one in any cafe but my own, which was a Phthifis from weak, lax lungs, attended with a most copious discharge of viscid phlegm, often refembling genuine pus. I was hectic fome years, and drank whey most of the fummer; during the whole time I had most extraordinary night fweats, not less often than two, or three, or four pounds a night: next morning I drank my whey and inftead of being weak and feeble, was light and eafy, my fpittle came freely and was better concoeted than usual, just as Bennet represents : But what was most remarkable, it kept off the Hæmoptoe, which furely came if my fweat was interrupted. al second bit of it , but exp be exp be the second of the

In fuch cafes, and perhaps fome others, Whey may be used to good purpose as a fudoristic; it must weaken less than any other.

Whey Either by unne of the

SECTION IV.

Of the Use of the Non-naturals during a Whey Course.

MOST perfons who have gone thro' this courfe once or twice have experienced, that this is by no means to be neglected, but a proper choice of air, good chambers, meat, drink and exercise is diligently to be attended to; elfe to far from reaping any advantage from it, their diforders may be aggravated, and others, fometimes fatal ones, be brought on. The judicious Boerbaave, I have been told, in prefcribing to the confumptive, never omitted mentioning a properdiet, and that they should take particular care to lie in an upper chamber. Such a rule is perhaps in no cafe more neceffary than here, as I have often feen confirmed by experience. The repeated catching of colds fo incident and fatal to confumptive perfons, in this our most changeable climate, and the night tickling coughs, have to my knowledge been often highly aggravated by lying on ground floors.

The principal rule as to meat is, to avoid all fuch kinds as are any wife flatulent, vifeid or acrid, to chufe fuch as are light and rather of an antacid nature, and most kinds of white flesh meats; and those who are not in a very low state may use moderately the lighter flat fish, soal and flounder; of the testaceous tribe, river and sea crabs, especially the claws of the latter.

All forts of garden stuff, a few excepted, are well known to disagree with whey drinkers. The never never failing confequence of eating any of the green fort efpecially, is, to generate fuch a degree of four flatulency as diffends the ftomach and bowels and most effectually retards the paffage of the whey either by urine or ftool.

I have tryed experiments with them on myfelf and found this the confequence : befides, I have been taken with fevere gripings and dyfenteric ftools. Fresh baked bread, has in a less degree the like effects. Celeri, Afparagus and Artichokes I have found pretty inoffenfive. The rheumatic, gouty and fcorbutic may use the warm alcalescent forts to advantage, hot Sallads, Onion, Leek, Radifh, Garlick, and fuch like. Ripe fruit and acids are religiously to be avoided. As for drink, special care ought to be taken to chuse right good water: This, with or without wine, feems the only proper drink with meat, as all malt liquors, cyder and punch are very improper. I know of no general rule as to the fort of wine to be chosen; Claret in general is most agreeable. Particular cafes admit of various other kinds, of which the attending Phyfician must judge. It's not to be expected that too free a use of Claret will be excluded from the fociety of Whey-drinking Gentlemen, more than other focieties: too many inftances occur of Gentlemen injuring themfelves fenfibly, fometimes drinking more Claret after dianer, than Whey before it, and fometimes a large quantity of each. They tell a ftory of a Gentleman, of a pretty full habit, who after leading this fort of life for fome weeks, taking fix or feven quarts of Whey before and two or three of Claret after a hearty dinner, fell down apoplectic on rifing from table after one of these dofes. A more effectual fcheme to create a high Plethora, can scarce be devised.

Whey

Whey-drinkers foon learn the neceffity of Exercife; for without this it lies heavy on the ftomach and occafions remarkable heavinefs, indolence, drowfinefs, and does not pafs freely. Walking about before breakfaft, and riding after it is the ufual method, in a whey-courfe, as well as during either medicinal courfes, amufements and having the mind quite *degagé*, is a material circumftance: the patients are generally very careful in promoting innocent amufements, and perhaps find as folid pleafure from those rural ones as from the gay ones of the town.

I have frequently known the cold bath used with a whey-course, for seminal weaknesses mostly, but with indifferent success, as it very often occasioned a giddines. I much suspect it is not a safe method to bath and drink whey at the same time, and never recommended it.

As to the quantity to be drank daily, different cafes will require different dofes. In general, the quantity prefcribed by *Diofcorides*, *Aegineta* and others of the Ancients, answer beft, being from one to three or four pints. Many ftomachs will not bear above one, and even that prove emetic, till they are by degrees habituated to it. Large quantities feem to do harm in most cases. It ought in general to be drank near blood-warm.

The time of beginning to drink it varies according to the earliness or lateness of the seafon. About the the middle of May N. S. is the usual time of beginning it : about the 10th of *July* the Milk becomes thick of course, the Whey can't be got clear, and contracts such a rank taste, that sew are able to use it longer.

SECTION V.

Diseases which drinking GOAT's WHEY may be proper for.

DISEASES of the lungs, coughs and confumptions, whether under the appellation of phthifis, tabes or atrophia, are those to which, according to the commonly received opinions, whey drinking hath not without reason been chiefly appropriated : not but there are many others which repeated experience has vouched it good for.

If it is confider'd that Whey is a half animalized liquor, (tho' ftill partaking of the vegetable nature) and highly nourifhing, as well as balfamic and demulcent, one can fcarce withold his affent that it promifes being fpecifically proper in all forts of decays, particularly where the lungs, the officina fanguificationis, are injured and incapable of duly perfecting the chyle.

What liquor can we suppose more proper to repair the loft nutritive quality of the blood, fpecifically to correct the highly feptic acrimony of abforbed purulent fanies and to repair the wafted fubstance of the lungs? Whether a Phthis is from a preceding inflammation, ending in fuppuration, not improperly denominated an acute one : whether from little absceffes of the tracheal glands, or from a gleetyness of the glands, or the Phthiss only threatens by an Hæmoptoe appearing, either of florid, falt, arterial blood or dark coloured, clotted infipid blood : In fhort, wether the Philifis. is acute or chronical, from a predifpofition in the habit, or brought on by hard living or external accidents, long experience has now taught us that Whey-drinking is the fheet anchor, but efpecially in the acute or galloping fort. I have known cafes indeed, where experience gave the preference

rence to Affe's milk with Poubon or Briftol water, in chronical Phthifes. In most of fuch as I have been concerned in, I have advised that course after the Whey course was over, to excellent purpose. The acute kind won't easily admit it, efpecially the use of the Spa Water.

However in all kinds, where there is a difpofition to fpit blood, the firft days of Whey-drinking are apt to renew the Hæmmorhage, which previous bleeding ought to guard againft, if the Patient's ftrength will poffibly bear it. It always affected myfelf in this manner.

As to decays in general, it muft be owned, that where there is an hereditary difpolition, or even a perfonal tendency from infancy, they feem to be beyond the reach of art, unlefs change of climate may make an imprefilion. In fuch cafes I have known the Whey drinking prolong life, but not cure: but where winter colds, pleuritic diforders, errors in the non-naturals or external injuries, have carried the patient even as far as a hectic, fuch often return from it reftored to perfect health and ftrength: I have known many fuch cafes.

But in every fupposable case, it's use is very precarious, nay injurious, after the Diarhea colliquativa has once appeared. I have always observed that it had no other effect then, but by increasing this symptom to shorten life. Many such have been hurried off, without being able to travel home. I knew and was frequently concerned in, a good family, hereditarily subject to a fort of Tabes, such as we are told is endemial in several fenny counties in England, but not common here, who were all plentifully and carefully supplied with Goat's Whey every year, almost from the cradle, yet 7 or 8 Children died of it about the age of puberty: only one was faved, whose health health I had the direction of for many years, and is now a man. He had a real Gonorbæa non-virulenta or natural gleet. (never I'm affured having lain with a woman,) debility in his back and was hectic, fo that the diforder might perhaps be juftly called a Tabes Dorfalis. He took Rhubarb and Styptic tincture with the Whey, and after it, drank Affe's or Mare's milk with Lime-water the reft of the year.

In hectics from ulcers after wounds or other external injuries I have known Whey to effect very speedy recoveries. If ulcers in any of the abdominal Viscera are the cause of a *Phthis*, there is no doubt of its being proper. I had occasion to see very good effects from it in a case of very high hectic from an ulcer somewhere about the head of the *intestinum rectum*, which discharged itself into it, and yet could not I apprehend be properly termed a *Fistula*.

I have not had an opportunity of experiencing it's effects in ulcers of the kidneys or bladder.

There are every feafon cafes of flubborn gleets in perfons whofe conflitutions are fhatter'd with venereal diforders and mercurial courfes, and often attended with hectical fymptoms who refort hither to be refitted, frequently with very good fuccefs, where they will fubmit to the rules of temperance and fobriety, but it may. eafily be conceived that many fuch perfons can't bring themfelves to fubmit to thefe conditions.

In the diabetes, Dr. Mead's Serum Aluminofum be admitted a good medicine; it might perhaps be very advantageoufly made of Goat's milk.

Whether it would prove a remedy in that fort of Scurvy, which Lynd calls the true Scurvy, I know not, but have had frequent opportunities

of

of feeing it's effects on these eruptions on the skin commonly called scurvies (in which case also the ancients particularly mention it's use) where it seldom fails of being very serviceable, especially if the antiscorbutic Juices are used at the same time in such quantity as to keep the belly soluble.

I have a patient who has drank it in this manner these many years, to stave off an atrophy, apparently from a scorbutic cause with great fuccefs. Several perfons who have drank it affert it's great efficacy in fixing the irregular gout, and that it is of equal efficacy with the Bath waters in that cafe. There may be many other cafes in which it may be proper, when difeafes are actually come on or well advanced, but venientie occurrit morbo seems in no case more applicable. Diætetic regimen is no doubt among the chief inftruments of prefervation from difeases. Whey is a diæletic medicine, and though it will often cure in a very agreeable manner when the difease is far advanced, yet it will probably operate with much greater certainly, if used in a prefervative way, to rectify the natural or acquired bad disposition of the blood and juices. It does not require an extraordinary degree of fagacity to forefee a tendency to confumptions. The make of the thorax, the complexion, too great fprightlinefs, the hereditary difposition, but above all, young perfons advancing too fast in their height; these should give the alarm and indicate, that unless the blood is kept pure, fweet, free from acrimony and a plethora avoided, an Hæmoptoe will probably come on, especially in females about fourteen. Goat's whey in fuch circumstances, used every year, has not perhaps it's equal: This I have feen frequently confirmed by experience. I have a patient just now

now June 1757, drinking it, a young Lady of a thin habit, who had feveral attacks laft winter of a tickling cough and pungent pain in the fide, which came and went, but in May fhe had a return, attended with hectic rigors, heats and night fweats, of all which fhe is perfectly relieved by three weeks drinking. It had befides an effect on her, not uncommon, reftoring the suppressed Menses, as hath been frequenly observed in Hectics, no doubt by it's analeptic, reftorative virtue, an effect which perhaps fcarce any other medicine will produce, Affe's milk alone excepted, no not even the most subtile of the Chalybeat waters, which tho' blended with Milk, generally increafe the heat and tenfion of the pulfe, as I clearly faw in a very delicate cafe last winter.

I have indeed known the Menfes reftored by it in confumptions, after a long fuppression, and yet the diforder prove fatal, but more tedious.

SECTION VI.

Of the Inconveniencies of Whey-drinking.

THAT Goat's Whey is a pleafant and moft ufeful medicine, cannot be denied, yet like all others it has it's inconveniencies. Many of thefe, it muft be owned, proceed from improper management; for it's very name, to the unexperienced, feems to fpeak it a fimple familiar medicine that may be ufed in any cafe and without being confined to any rules: The contrary whereof has been experienced by many to their coft, nay is ever year experienced : tho' it is drank regularly, I have obferved it injurious to three forts of conflitutions or habits. I. To fuch as had weak weak nerves. 2. To fuch as had a thin pale watery blood, or were leucophlegmatic. 3. To the fanguine, corpulent and plethoric. 4. To many who have original weak nerves, are habittually affected with tremors, debility, fpafms and cramps, colics, hysterics, nervous head-achs, giddyness, &c. What experience I have had declares, that Whey-drinking has difagreed with fuch, by renewing or increasing those complaints. I have feen where thefe were complicated with chronical Phthifes, that whilft the fymptoms of the Phthifis decreafed, during the Whey-courfe, great complaints attended of low-fpirits, chillynefs, indolence, drowfinefs, &c. A very common effect of Goat's whey is, to occasion drowfines; efpecially in the morning. Lying a bed after the first draught increases it very much; for it will have a real apparent narcotic effect. Perhaps it's paffing quickly into the blood and increasing the fulness of the blood veffels, especially of the brain, may be the caufe, according to the ufual theory of accounting for the effects of Opium.

I first observed this effect on myself, who have feeble nerves, but afterwards I found many others affected in the like manner, those particularly of weak fibres and delicate habits. I don't know from experience that this has any bad confequences: on the contrary have often observed that perfons thus affected by it, gained ground daily in their health. If the tone of the solid nervous system were really and actually impaired, it would be eafily discovered afterwards.

This however is meant of hectical patients; for I have known it have lafting injurious effects on fubjects of weak nerves who were not confumptive.

I have met with fome cafes of perfons fent to use it, who were habitually of weak, lax ftomachs, machs, that daily generated large quantities of viscid, phlegmatic crudities. Whey remarkably increased the quantity of these, brought on inflations of the stomach, head-achs, lowness of spirits, feebleness, appetite quite lost, $\mathcal{B}c$. I ordered them immediately to quit it. One Gentleman by my advice went to *Bath*, and there found the wish'd for remedy. These perhaps may be claffed under the second Head.

It is not however, I apprehend, an univerfal rule, that it difagrees with all weak, watery bloodded fubjects; if they are confumptive, quite otherwife; but if not, it frequently has bad effects. Indeed I imagine it abfurd to fend fuch to it. If they want a reftorative, let them ftay at home and drink Affe's or Mare's milk with Spa water; an advice I have given with fuccefs.

3. As to fanguine, corpulent, and plethoric perfons, it may be alledged that fuch feldom or never try it: the contrary however has happened within my knowledge. Such frequently come to it, chiefly for fcorbutic ailments, or amufement: and if they would practife due evacuations and temperance, might reap benefit: but this is not always the cafe, as appears from the tragical hiftory I have from good authority related above, of the unhappy Claret-prone gentleman who died apoplectic on fwilling down large quantities both of Whey and Claret on the fame day.

I have feen cafes of plethoric perfons, Whey drinkers, who have been in great danger of overfulnefs, till relieved by plentiful evacuations, which if neglected, fatal confequences followed. An elderly Gentleman had long been affected with a vertigo and dimnefs of fight: unhappily he was fent to drink whey. In a morning he was fuddenly feized with his old complaints and a paralytic weak-

weakness of one fide. I accidentally was prefent, but he refused my offered affiftance, would not lose blood, in a few hours he was feized with fhocking epileptic fits, which in one night gave effectual relief from all worldly cares. I diffected his brain and found amongst other things, a Hydadid, lying over the commiffure of the optic nerve, apparently the cause of his old dimness of fight. I gave it as my opinion, that the Whey, by creating a plethora and filling this and other fmall hydadid in the brain, was the caufe of his fudden fate. It feems to me a very proper rule, that no perfon affected, or even threatned with Apoplexy, Epilepfy, Vertigo, Palfy or any of their subdenominations, ought to make free with Goat's whey: That this is not generally known is evident, from feveral fuch being fent to it by phyficians of character, as I have known, and the above is an infrance to this purpole. These difeases generally are owing to caufes in the brain, which are always aggravated or brought into action by fulnels of the blood veffels. Even tho' they should be complicated with confumptive hectic, I much doubt whether Wheydrinking be fafe. Briftol water feems more eligible.
