### REGULAR CONTINUED FEVER, without leaving it to pursue its ordinary course.

Medicina igitur adhuc taliter comparata est, ut fuerit magis ostenta, quam elaborata; etiam magis elaborata quam amplificata.

BACON AUG. Sc. Lib. ii. Cap. i.

Solent autem homines naturam tanquam ex præalta turri et e longo despicere, et circa generalia nimium occupari; quando si descendere placuerit et ad particularia accedere, resque ipsas attentius et diligentius inspicere, magis vera et utilis feret comprehensio.—IBID.

### BY GEORGE FORDYCE, M.D. F.R.S.

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS, SENIOR PHYSICIAN TO ST. THOMAS'S HOSPITAL, AND READER ON THE PRACTICE OF PHYSIC IN LONDON.

The second second

LONDON: FRINTED FOR J. JOHNSON, IN ST. PAUL'S CHURCH-YARD.

1799.

DR. FORDYCE'S LECTURES COMMENCE THE FIRST MONDAY IN OCTOBER AND FEBRUARY,

# THIRD DISSERTATION, &c.

### PART SECOND.

HAVING, in the first part of this differtation, pointed out the history of a regular continued fever, the accidents that take place in it, and the manner of avoiding thefe accidents, if it should be left to purfue its ordinary courfe; excepting one accident, to wit, putrefaction, which arifes but feldom; the author in the next place is to take into confideration the remedies by which the fever may be carried off, fo as to leave the patient in health in a shorter time, or to conduct him through with less danger, than if the fever had been left to purfue its ordinary courfe.

Since,

Since, as has been already obferved, the effence of fever, or the ftate in which the fyftem in fever differs from the healthy ftate, is altogether unknown, the effects of medicines in removing that ftate can only be known by obfervation or experiment; there being no remedy that has any property, either chemical or mechanical, or any operation, when given to a man in health, that can point out any ground for employing it to carry off this difeafe.

The author now, therefore, comes to fhew what remedies have been employed by practitioners to carry off regular continued fevers, whether they have been employed in confequence of fome hypothefis, or have been found out by mere accident.

The first remedy to be confidered is opening a vein in the arm, or indifcriminately in any other part of the body, and letting a quantity of blood flow out.

Authors and practitioners have confounded fever, fuch as the author has defined,

in with he built of a light of a

fined it, with many other difeafes, particularly with all fuch difeafes in which the pulfe is frequent to a certain degree.

Many difeafes, in which the pulfe is frequent to a certain degree, differ from one another in almost every other respect. The pulse is frequent to upwards of an hundred ftrokes in a minute in a pleurify; it is often frequent to above an hundred strokes in a minute in gangrene and mortification; but pleurify, and gangrene, and mortification, are very different difeafes, and require treatments totally different from each other. In pleurify, taking away large quantities of blood is one of the most powerful remedies for carrying off the difeafe; in gangrene and mortification, taking away large quantities of blood would be the most effectual means of deftroying the patient. In gangrene and mortification, the beft mode of putting a ftop to the difeafe, is to exhibit the bark of the cinchona, in large quantities, with wine and fpices; in the pleurify, exhibiting large quantities of the bark of cinchona with wine and fpices would be the B 2

the furest way of increasing the pleurify, and rendering it fatal.

Certainly, therefore, difeafes in which the pulfe is frequent may differ from each other in all things, excepting mere frequency of the pulfe, which Dr. Boerhaave makes a fpecific mark of fever. It is to be obferved, that he had not at the time he gave this definition ever feen a fever, having ftudied theology, and not medicine.

It has already been fhewn that the pulfe in fever is by no means always frequent, and that therefore frequency of the pulfe can by no means be confidered as a pathognomonic fymptom of fever.

If all difeafes, in which the pulfe is frequent, be confounded together, and called fever, it certainly cannot be faid that taking away blood never cures the difeafe; but if the difeafe, which the author has endeavoured to define as fever, be only meant, the taking blood from a large vein, in any part of the body indiferiminately, never diminifhed,

nished, shortened, nor carried off a fever in any cafe he has feen, nor has he found any upon record in which it had this effect.

2

[ 5 ]

It is true that an accident, fuch as general inflammation, may happen in an irregular fever, which may deftroy the patient, which accident may be counteracted and prevented from doing mifchief by taking blood from the arm, or any other part indifcriminately, as will be defcribed when fuch irregularity is treated of. The accident being removed, the fever may afterwards continue its courfe, may terminate by a crisis, or wear itfelf out, just in the fame manner as if no fuch accident had taken place.

The author having affirmed that taking away blood from the arm, or from any large vein, neither increases nor diminishes a fever, nor alters its course, as far as he has feen, he next comes to confider what might be expected from taking away a quantity of blood indifcriminately from any blood-veffel during a fever. A quantity

A quantity of blood flowing out of the body, whether it be taken on purpofe, or by any accident, occasions weakness. If the blood continues to flow, the weaknefs will encreafe fo as to render the body incapable of performing any function or action whatever, and in confequence to kill. If it does not continue to flow, it weakens a man, and the weaknefs continues until the blood is reproduced by the digeftion of food of proper nourifhment, or perhaps by the conversion of expressed oil, or other fubftances deposited in the body, into new blood. This weaknefs, with the accidents that arife from it, are the only effects of the lofs of blood, which are perceivable.

As fever takes place equally in a ftrong and a weak man, it is alfo equally violent, as far as regards the fever itfelf, in a weak man as in a ftrong man, and it is apter, or at leaft as apt to run out to a great length in a weak man, as in a ftrong man.

It is not, therefore, *a priori*, at all probable, that weakening a man fhould diminifh or fhorten a fever. It comes then to be enquired into, why taking away blood indifcriminately from any large vein has been fo often practifed in fevers, even by practitioners of the first rank in medicine ?

The author can only refer this practice to the impatience with which mankind bear any evil, and that fuperstition which predominates in them. If any violent difeafe takes place, men immediately recur to fome violent remedy. Their recurring through impatience to fome very violent remedy is no proof, that fuch remedy is ufeful to give them relief from the malady. If a man who has gone upon a journey fhould return, and without previous notice find his house burnt down, his whole family and property destroyed, and all his friends ruined, he would be apt to flamp upon the ground, beat his breast and tear his hair; but stamping upon the ground would not rebuild his houfe, nor would beating his breaft reftore his family and property, nor tearing his hair retrieve his friends. It is mere impatience that makes him B4

him have recourfe to thefe violences, fo mere impatience makes mankind have recourfe to violent remedies in difeafes, although no experience has fhewn that they are of any ufe in the difeafe for which they have been employed. To this argument the author will have occafion to recur, when he comes to treat of irregular intermittents in a future differtation.

So in like manner it is often from fuperftition that fuch violent remedies, and efpecially blood-letting, have been employed.

Mankind are exceedingly apt to believe, that refraining from fome gratification is agreeable to the Almighty, or the gods their imaginations have created; even if they enjoy that gratification, without any injury to their own health or conflitution, or without injury to their fellow creatures, or any animal whatever, or without hurt to their moral character.

Some pretended teachers of religion have even gone fo far as to refufe to their difciples, ples, dying of fo diftreffing a difeafe as pulmonary confumption, the gratification of enjoying the cheerful warmth of the funfhine.

Under this, or fome very fimilar idea, men have thought that their gods would be content with one part of the body to fave the whole. Hence we fee among many rude nations, that a finger or toe is cut off, or a tooth or two knocked out, in order that the reft of the body may be left fafe.

Blood, by its intenfe red colour, has attracted the attention of mankind. It has alfo attracted their attention becaufe the lofs of it, as has already been faid, in a certain quantity, is fatal; the lofing, therefore, a quantity of blood, has become the object of their fuperflition. Lofing blood has been looked upon as the greateft oblation that could be made in the moft folemn ceremonies; as the mark of the greateft bond of fecrecy and fleadinefs, men have figned contracts with their blood. Taking away, therefore, a quantity of blood has been been thought a facrifice the most powerful for carrying off a difease, and for carrying off fever as one of the most violent and fatal of difeases.

The author does not mean to fay that every practitioner, who bleeds conftantly at the beginning of a regular continued fever, has this idea in his mind. The greateft number of practitioners follow the practice of those who went before them, without examining from whence that practice has arifen, or upon what ground it is founded.

From this view of the fubject it may, perhaps appear why blood-letting has come into practice in the beginning of all regular continued fevers.

Practitioners alfo have not compared cafes of fevers in which it has been practifed, and of fevers treated otherwife in the fame manner in which it has not been practifed.

The author has faid, that taking away a quantity of blood from any large vein indiferiminately, diferiminately, in any part of the body, neither increases, diminishes, nor shortens a regular continued fever. The next enquiry is, whether any mischief may arise in a regular continued fever from taking away a quantity of blood.

The author has already fhewn that a patient afflicted with regular continued fever cannot digeft his ordinary quantity of food; therefore the fluids which are conftantly wafting cannot be recruited, and that the fyftem muft be weakened.

That in a regular continued fever there are conftant exertions which likewife debilitate.

That the reft which takes place in fleep is neceffary to reftore the living power, but fleep being prevented in fever it is not recruited.

That in confequence of all these causes of weakness, the patient is actually so debilitated as to be destroyed in many instances. ftances. The further debility arifing from emptying the veffels by taking away a quantity of blood, is often fuch as to deftroy the patient in the remaining part of the difeafe. Patients in confequence have very often been cut off, when blood has been taken indiferiminately from any large vein at the beginning of the difeafe, as the author has feen in a great many cafes. In the first part of the author's practice, the Boerhaavian doctrine prevailed; this induced practitioners to take blood from the patient in all cafes of fever, fo that the author has had occafion frequently to fee the effects of this practice.

The author having faid that the effence of the difeafe not being at all known, it cannot be faid, *a priori*, whether any particular remedy will be of use in shortening or entirely carrying off fever.

Taking away blood from the veffels of the head has, in fome cafes, immediately carried off fever; it has also tended to diminish delirium accompanied with fulness of of the vessels of the head, even when it does not shorten the difease.

The first of these effects will be confidered in a differtation on the irregularities of fever, and the second in a future part of this differtation.

Many practitioners have fuppofed that fever arifes from fome peculiar kind of matter that has got into the body; that fever is an effort produced in the body to induce fome operation by which fuch matter might be deftroyed. Sydenham judicioufly fuppofes, that a fermentation takes place which alters the qualities of the matter, or converts it into another fpecies of matter which has not the property of producing or keeping up this difeafe.

If it were really true that any particular fpecies of matter produced and kept up a fever, it would follow that until fuch matter was deftroyed by a fermentation, or fome other procefs that might take place in the body, or was evacuated, the fever would continue. continue. In that cafe, it would become a queftion whether fome other means than that which takes place in the body of itfelf, might be employed to take this matter out of the body, or deftroy it, fo that it might no longer keep up the difeafe.

Some practitioners have fuppofed that this might be done by evacuation.

If a blood-veffel is opened, the whole circulating fluids are equally evacuated, every one, good or bad, noxious or innoxious, thofe that are commonly in the body, and thofe that are there only by accident; no particular matter would be taken out more than another, and therefore it is not to be fuppofed that the matter occafioning a fever would be removed by making this evacuation.

If the fubftances evacuated out of the body by the various excretions be examined flightly, they appear to be more different than when they are examined more minutely, but ftill upon minute examination they differ very much.

It

It might happen that fome fecretory organ is difposed to throw fome particular noxious matter out of the fyftem, and that therefore, by increasing fome fecretion, (fince an encreafe of any fecretion, to a certain degree, occasions the fecreted matter to be thrown out of the body) might make the matter producing and keeping up fever be evacuated, fo that the fever should ceafe. But it may also happen on the other hand, as has already been taken notice of, that a fever may arife without any noxious matter being applied to any part of the body, or generated in the body; and in this cafe there being no noxious matter to evacuate, neither the operation of purgatives, or any other evacuant would carry off the matter, and fo remove the difeafe.

It has alfo been fhewn that noxious matter does fometimes produce fever when applied to the body, and that after the fever is produced, it is really contained in the body, as in the cafe of fever arifing from the application of variolous matter; but then it has been fhewn, that in fuch cafes the noxious matter matter produces the difeafe at once, and what is contained in the fyftem after the fever had taken place, has no effect upon the difeafe; it neither increafes it, nor does its abfence diminifh it, and the fever often goes off when there is the largeft quantity of noxious matter in the body. In fuch cafes it would not furely be conceived, if we could evacuate fuch matter, that the difeafe would be carried off; in fuch cafes, therefore purgatives would be of no ufe.

Hitherto the argument has been purfued a priori; but neither the effence of fever, nor the operations of the human body, are fufficiently known, as the author has before obferved, to determine the efficacy of any medicine to carry off fever; experience muft therefore be had recourfe to, to determine whether purgatives or any other medicine producing evacuation from any gland may be employed to carry off the difeafe.

If the matter be referred to the experience of the most judicious authors, all those who have conceived fever to depend upon matter

3

matter of a peculiar kind contained in the fyftem, have agreed that it must be concocted before it can be evacuated; that is, that it must undergo fome process before it is prepared for evacuation; otherwife that evacuation, by purging, or increafed fecretion from any of the glands, will have no effect in carrying off the difeafe. They are agreed at least that evacuation before concoction must only be made at the beginning of the difease to be efficacious; after the difease has continued a day or two, they have no more expectation that evacuating the matter will carry off the difeafe. The author, therefore, would be warranted by authority to fay, that evacuation by purging, or any other increased fecretion from glands, would have no power of carrying off fever, excepting the evacuant fhould be employed in the first twenty-four hours; or at the end of the difeafe, after the matter is concocted, or has undergone fuch an alteration as to render it fit for evacuation.

It is further to be obferved, that when any matter is applied to the body, fo C as

as to produce fever, not immediately, but at : the interval of feveral days, fuch as the mat-. ter of the fmall pox, or the measles, or putrid or infectious vapour; if purgatives: are employed during the interval between the application of fuch matter, and the taking place of the first paroxyim of fever,, the fever has never been prevented from taking place in any cafe which the authorr has feen; or in any cafe which has been re-corded with almost any evidence. This iss equally to be observed in those cases in which the application of the caufe has produced fome immediate appearance of the first stage of fever without producing a perfect paroxyfm; when these appearancess have continued until a complete paroxyfm has taken place.

In those cases where the application of the matter to the body, which occasioned the fever, produced no appearance of the difease on its application, but the patient felt himfelf in perfect health until the complete attack of the fever came on, neither purgatives nor any other medicine increasing fecretion, have prevented the difease. If the evacuation by purging or increafed fecretion from any of the glands, does not carry off the matter from the body before it has produced the difeafe, there feems to be little reafon to hope that fuch evacuation will carry off the matter occasioning the fever, and the fever itself after it has actually taken place.

The author has already obferved, that feculent matters remaining in the inteffines, which they are apt to do when a fever takes place, tend to increafe the difeafe. Though their removal prevents the mifchief they would produce, yet, as far as the author has been enabled to judge from the attention he has paid to fuch cafes, their evacuation has in no cafe done more than merely obviate the mifchief which would have taken place in confequence of their retention. Such evacuation has never, in any degree, removed the fever, or prevented it from purfuing its ordinary courfe.

Those practitioners who have believed that fever depends upon some noxious mat-C 2 ter ter contained in the body; that that noxious matter is concocted; that is, goes through some operation by which it is prepared for evacuation, have also supposed that when a crifis took place, the matter was evacuated after it is concocted, and that fo the fever was carried off. They have thought that if it was not completely evacuated, 'it is neceffary to employ purgatives to evacuate what might remain of the matter in the body, and re-produce the difeafe. They have also thought that when no marked crifis took place in the difeafe, but it gradually fubfided, that it fubfided more flowly on account of the noxious matter not being all at once evacuated, and therefore have employed purgatives to make it be evacuated more fpeedily, fo that the difeafe fhould fooner fubfide.

The author, from his own practice, is obliged to be of a contrary opinion, fince he has feen relapfes much more frequently take place when purgatives have been employed after a marked crifis, or after the difeafe has gradually fubfided, than when purgatives have not been employed.

Upon

Upon the whole, then, the author believes it to be perfectly neceffary at all times, during the progrefs of a regular continued fever, to keep the inteftinal canal free of feculent matter; yet that making further evacuation by purging or increafing the fecretion from any of the glands, fo as to occafion evacuation, is of no ufe in carrying off the fever, but rather tends to prevent the fever from being carried off, and, if it is carried off, to produce relapfes.

Moreover the author has already fhewn, that it required the whole force of the fyftem to fupport the patient through the ordinary courfe of a regular continued fever. He has alfo fhewn that the force of the fyftem is reduced by evacuation; he muft therefore conclude, that fimple evacuation by purging, excepting in as far as it is neceffary to keep the *primæ viæ* clear of feculent matter, is detrimental inftead of being ufeful; and that fimple evacuation from any of the glands, as tending alfo to weaken, is detrimental inftead of being ufeful.

Ç 3

It

this century or two, was at all known to the Greek philosophers, physicians, or artifts.

There was a fubftance which they named ftibium, which was employed to give a blacknefs to the eyes, but the effects which were produced from it either among the Greeks and Romans, or among the modern inhabitants of Afia, fhew that this fubftance was more probably a kind of lead ore than an ore of antimony.

Antimony, or as it is more commonly called crude antimony, is the ore of a metal which exifts in many parts of the earth. It is a compound of fulphur and a metal, in which the fulphur bears a much greater proportion to the metal than can be combined with it chemically. More properly, it is a compound of fulphur and the metal, diffufed through a fuperfluous quantity of fulphur, fo that part of the fulphur retains fome fome of its properties, which it has when not combined with the metal. The fulphur fo covers the metal or is fo combined with it, as to prevent it from producing its medicinal effects. This ore of the metal is folid in the heat of the atmosphere. It requires a little lefs than that degree of heat which renders fubstances luminous to melt it, fomewhere probably between five and fix hundred degrees of Fahrenheit's thermometer. Its melting point has not been exactly afcertained in as far as the author knows. It is of a dark blue colour, and is generally found in a kind of crystalization, fometimes in complete crystals, which are prifms terminated by pyramids at one end, and at the other generally attached to each other; otherwife is a mass without form. More commonly these crystals are united together fo as to form a striated mass, especially when they are unmixed with any other fubstance.

The metal has lately been found alfo combined with fome fubftance, fo as to C4 form

form the fame kind of crystals or striated mafs, only of a dark red colour, fhining, however, with metallic luftre. It has been conjectured, rather than confirmed by experiment, that these crystals or this striated ore contain arfenic, befides fulphur and the metal of antimony. This conjecture is rendered probable, becaufe this red ore of antimony has been almost always found with regulus of arfenic; that is, the metal of arfenic pure; and therefore experiments made to verify the existence of arfenic in this red ore, should be made in fuch parts of it as are perfectly clear from the particles of the metal of the arfenic in which it is found.

The metal has alfo been found but very rarely, certainly however fometimes uncombined with any other fubftance, but fo rarely hitherto as not to be employed for any medicinal purpofe.

Upon the whole, all the antimony which has been employed in medicine has been procured procured from that ore of antimony, confifting of antimony and fulphur.

This ore, when dug from the mine, is laid upon an inclined plane, formed from a mixture of clay and fand burnt in the fire. The inclined plane is heated red hot; the ore of the antimony being laid upon it melts, and runs off from the other fubftances with which it is mixed, and is received into a large and deep earthen veffel, in which, when it has ftood to cool, it concretes into a folid mafs.

If this folid mafs concretes fo as when broken to exhibit long striated shining spiculæ, it is a pure compound of antimony and sulphur, and fit to be employed for medicinal purposes.

A vaft number of chemical proceffes have been employed to give antimony medicinal effects; more than two or three thoufand. Of the product of all thefe there are only three preparations at prefent much in ufe. One is made by boiling the antimonial ore or crude antimony in a folution of pure or prepared kali in water. The decoction, after it has been ftrained, is diluted with a confiderable quantity of water, at leaft ten times its weight. The diluted folution is placed in a fhallow veffel, the furface expofed to the air, until a powder falls to the bottom of the veffel, which, taken out and dried, is called kermes mineral.

The fecond procefs is performed by mixing the ore of antimony or crude antimony, finely powdered, with an equal weight of the fhavings of the horn of any animal. This mixture is to be put into an iron pot, which is to be heated red hot, and the mixture is to be flirred, the pot being kept red hot, until it ceafes to fmoke. The mixture is afterwards to be allowed to ftand until it cools. It is then to be put into a crucible, which is to be covered with another crucible, whofe mouth is to be turned down into that crucible which contains the materials. The crucibles with the materials are exposed to a white heat for two hours; part of the mat-

ter

ter remains of a white colour in the under crucible, which is to be ufed; part fublimes into the upper crucible, which is to be thrown away.

The third preparation is made by combining the metal of antimony with tartar, an acid produced in the fermentation of various wines, which is found adhering to the fides of the veffels in which the wine has ftood for a year or more after the active fermentation has ceafed.

When two fubftances, which unite with one another only in one proportion, are combined together chemically, and the compound purified, the fubftance is undoubtedly the fame in all its properties. It happens, neverthelefs, with refpect to the chemical combination of two fubftances which unite with each other in one proportion only, that when they are combined together by different proceffes, there are often different imperfections in the combination or fome want of purity in the compound. This, though not fenfible to any chemical teft,

test, makes a very confiderable difference in their actions as medicines. In the prefent instance of the compound of tartar and the metal of antimony, or, perhaps, if ftrict adherence was to be had to chemical accuracy, we should fay compound of tartar and calx of antimony, this difference is confpicuous. Of the feveral methods of forming this compound, the following is the best for medicinal purposes : Take an equal weight of the ore of antimony feparated from extraneous fubstances by fusion, as has been above described, and of kali nitratum. Powder them together, and throw the mixture into a crucible, heated fo as to be just luminous, by very fmall portions, about twenty grains at a time, until a deflagration takes place; wait till the deflagration is over ; throw in a little more of the mixture ; wait again till the deflagration is over, Proceed in this manner until the whole is deflagrated. Cover the crucible, and expose it to an heat just fufficient to melt the whole mafs. Pour the melted mafs into an iron veffel of a conical form, the point of the cone being downwards; the whole

whole will be found, when it is cold and folid, divided into two fubstances, one of a reddifh brown colour and heavier, which has fallen to the bottom; the other, of a grey colour, which is found at the top, and is fpecifically lighter. The heavier part, which is found at the bottom, is a compound of fulphur and the metallic part of the antimony. A portion of the fulphur which was united with the antimony in its ore, more than was necessary to combine with the metal of the antimony, is converted into vitriolic acid by uniting with the air of the nitrous acid. This vitriolic acid is found in the upper greyish mass, combined with the kali of the kali nitratum, and forms kali vitriolatum.

The antimonium fulphuratum, found at the bottom, is to be powdered and mixed with one third more than its weight of purified tartar, and boiled in fix times its weight of water for a quarter of an hour; the folution is to be filtrated and the water evaporated, and the compound of the tartar and the metal of the antimony cryftallized. This falt for chemical purpofes may be purified, by diffolving it again in water and re-cryftallizing it; but it is a queftion whether it would not lofe fome portion of its medical powers by this purification.

The metal of the antimony may be feparated from the fulphur with which it is found combined in its ore, by mixing the ore with five times its weight of kali preparatum; that is, with kali combined with gas, which gas has been called alfo fixed air and carbonic acid. The mixture of the kali preparatum and ore of the antimony is to be melted together by a heat juft fufficient to render them perfectly fluid. The crucible being taken from the fire is to be left till it is quite cold; on breaking it, the metal of the antimony will be found at the bottom, and the compound of kali and fulphur at the top.

This is not the moft economical mode of obtaining the metal of antimony; but provided we take the ore feparated from the other fubftances with which it is found mixed mixed in the mine, as has above been defcribed, the metal by this process is obtained the purest for medicinal purposes.

If the metal thus obtained is powdered finely, and boiled with pure tartar in water, a compound of the tartar and antimony will be obtained, which, if purified by re-crystallization, will be exactly the fame with that obtained by the process above defcribed, in all its chemical properties.

Another mode of obtaining this compound is-Take the ore of antimony purified, as has been already defcribed, powder it, and put the powder into a flat vefiel; heat it till it begins to fmoke; keep up the heat, but take care not to render it fo great as to melt the mafs, until it no longer fmokes in any heat not fufficient to melt it. The remaining mafs, which is the metal of antimony calcined (probably combined with pure air) if exposed to a greater degree of heat, will melt into a glafs. If this glafs be powdered, and boiled with pure tartar in water, a compound of antimony and tartar will also be procured; this purified by repeated

peated folutions in water and cryftallization will, in all its chemical properties, be the fame as when the falt is procured by the two proceffes already defcribed, but if not cryftallized a fecond time, will not agree exactly in its medicinal effects.

[ 32 ]

The metal of antimony may be combined with muriatic acid, by feveral proceffes. One of these, for instance, is. Mix the ore of antimony with that compound of muriatic acid and mercury which has been called corrofive fublimate. Perform a diftillation, or rather a fublimation, and expose the matter fublimed to the air of the atmofphere, until it has attracted water enough to render it fluid ; pour this folution of antinium muriatum in water, or any other made by this or any other process in which the water is faturated with the antimonium muriatum, into eight or ten times it's weight of diftilled water. A calx of antimony will fall down in a white powder, which has been called powder of algorath; this being boiled with pure tartar in water will combine with it, and form antimonium tartarifatum, which,

which, if purified by re-cryftallization, will be the fame to all chemical and medical purpofes as the antimonium tartarifatum produced by the three foregoing proceffes, but not exactly in its medical effects unlefs purified by recryftallization.

Although the antimonium tartarifatum obtained by any of thefe proceffes, when purified by re-diffolution in water and re-cryftallization, may perhaps be the fame for medicinal as well as chemical purpofes, which however has not been proved by experiment, yet when it has only fimply been formed by thefe four different proceffes, without rediffolution in water and re-cryftallization, there is a difference in its operations as a medicine.

When the London College of Phyficians reviewed their pharmacopeia for its reformation and republication in the year 1786, it became a question which of the four proceffes they should adopt.

Whenever any question of a chemical or pharmaceutical kind occurred, it D was was referred to a committee confifting of fome members of the College and the Company of Apothecaries, and the proceffes were actually performed in the laboratory of the Company of Apothecaries, that fo the beft mode of performing the operation might be verified by experiment.

A queftion having arifen with regard to tartarifed antimony, it was prepared by all these processes.

The tartarifed antimony produced by thefe proceffes was given to the Phyficians of St. Bartholomew's and St. Thomas's Hofpitals. In St. Thomas's Hofpital they were given to more than an hundred patients, fo as to give each of them to one and the fame patient in fmall dofes.

The tartarifed antimony prepared with the crocus metallorum and tartar was found to be capable of being exhibited in a larger dofe than any of the others without producing ficknefs, and to act more powerfully as a fudorific, and therefore was preferred, whether ther properly or not, will be argued afterwards.

At the time the fcience of medicine was revived with the other fciences first in Italy, there does not feem to have been any medicine recommended to put an end to fever immediately by Galen or Celfus, or any of the (1) W Greek or Roman writers upon the fubject, excepting cold water drunk in a large quanties at once. It was not supposed that a fever might otherwife be cured immediately fo as to prevent any future appearance of the difeafe, either by preventing the returns of the paroxyfms, or carrying off the difeafe instantaneoully, or by producing an immediate crifis. The doctrine then was to attend to the difease while it pursued its ordinary courfe, only taking care of the accidents which might happen during that course, that is, taking fever according to that idea of it which the author has been endeavouring to lay down.

There arofe in Europe fome time afterwards a number of alchemists who made D 2 many many proceffes with a view to convert metals into gold. Having formed many fubftances by proceffes which did not make gold, but which produced many things which they were not able to turn to any profit, they tried to apply them to the cure of difeafes. All fuch chemifts muft be confidered as empiricks, and the greater part of the fubftances which they produced were in fact of no ufe. Antimony, however, gained a reputation for carrying off fome difeafes without their going through their ordinary courfe if otherwife left to themfelves; it is probable it was employed for this purpofe in fever as foon as the time of Van Helmont.

These chemists did not fludy medicine, nor did they diftinguish diseases, but only aimed at making some profit of the result of their process. They called every disease fever in which there was great fense of heat in the patient, and greater frequency of the pulse than in health, so that they not only employed preparations of antimony in fever, but in internal inflammations and various other diseases.

Practitioners,

Practitioners, who were educated in the regular practice of medicine, fludied principally the writings of the ancient Greek and Roman Phyficians. Thefe ufed for the most part vegetable fubstances for remedies in difeases; the modern practitioners, therefore, reprobated all the fubstances which were the refult of chemical operations; they confidered them only as the boast of ignorant empiricks. This opinion went fo far, that even so late as the time of Boerhaave, mercury was rejected by regular practitioners in the venereal difease.

Some practitioners, as there always will be men who balance between two different doctrines, employed indeed preparations of antimony, but fuch as had little or no effect; fuch as antimony calcined, by deflagrating it with three times its weight of nitre, and various others equally inefficacious. They of courfe did not find any advantage arife from preparations of antimony; they therefore reprobated the ufe of all antimonial medicines in fever. Hence it happened that they were not much employed before the time of the late Dr. James with efficacy D 2

D 3

yame in Great Britain : he was a Phyfician of regular education, having ftudied at the Univerfity of Cambridge, but was confidered in fome degree as an empiric in confequence of employing fome preparation of antimony, which he kept a fecret.

The preparation he made use of confisted antimer principally of antimony calcined, by mix-The preparation he made use of confisted Ponder ing it with shavings of harts-horn, and expofing the whole to a great degree of heat. Upon analyfing it, which was done long before his death, it was found to confift of a calx of antimony, mixed with bone afhes. It is extremely probable, that he mixed along with it a proportion of tartarifed antimony; the author knows that he purchased confiderable quantities of tartarifed antimony, two pounds at a time, from an eminent druggist. This might eafily escape the scrutiny of a chemical analysis, fince the quantity contained in one dofe did not certainly exceed a quarter of a grain. From the very eafy decomposition of tartarifed antimony, when diffolved in a large proportion of water, fo fmall a quantity might not be observed,

Dr. Cullen was the first eminent teacher of medicine who recommended the use of preparations of antimony to carry off fevers directly. As most of the principal practitioners of the present day, in this island of Great Britain, have been pupils of Dr. Cullen, its use has lately very much prevailed. If this had not been the case, it would have been a question whether it would not have funk into oblivion, like any other empiric remedy whose preparation was kept fecret.

Dr. Cullen conceived, that the effect of the by preparations of antimony arofe from their producing ficknefs. Tartarifed antimony is much more certain of producing ficknefs, than any other preparation that was known to him; it was therefore preferred by him, and of courfe that preparation of antimony which produced ficknefs in the fmalleft dofe he confidered as beft.

The author is of a different opinion; to D where wit, that it is not the fickness produced by the preparations of antimony, that has the  $D_4$  effect

effect of carrying off fever immediately, but fome other operation of the medicine.

First, because there are many other remedies which produce ficknefs to as great a delelle gree as any preparation of antimony; yet the fave no power whatever of making fever terminate fooner than it would if it was left to pursue its own course. The root of the fquill, for instance, often produces ficknefs to a much more fevere degree than any preparation of antimony, yet it has never been alleged, that it has the power of carrying off fever fooner than it would go off, fuppofing that it was allowed to purfue its ordinary progrefs. Moreover, the author has frequently exhibited the root of the fquill as an emetic, and likewife in fuch dofes as to produce naufea without vomiting; also in fuch doses as just not to produce nausea, without ever producing any thing fimilar to the appearances which take place in a crifis of fever, or without ever once occafioning a fever to terminate fooner than it would have done if left to purfue its own courfe. In fo far, therefore, the author must conclude, that the fickness occafioned

cafioned by the exhibition of a preparation of antimony is not the caufe of its carrying off fever.

Secondly, the ftomachs of different men, though they are otherwife in the fame fituation, are affected differently by the fame quantity of any particular medicine: the ftomach of different perfons, or of the fame perfon at a different time, being able to bear a larger dofe without its producing ficknefs or vomiting.

Almost every medicine given in a certain dofe will produce fickness and vomiting; even opium, if given in a certain dose, that is, to the quantity of two or three grains, will fometimes produce fickness and vomiting, and fometimes purging.

When a medicine is given in fuch a dofe as to produce vomiting, it often lofes its peculiar effect. The bark of the cinchona, when given in fuch a dofe as to produce vomiting, either from the difposition of the ftomach of the patient not to bear fo large a quantity as the stomachs of men will generally bear, or from its being exhibited in a larger

larger dofe than common, will often fail in putting a ftop to the progress of an intermittent fever. It may be faid indeed, first, that the peruvian bark, by producing ficknefs and vomiting, will be thrown out of the ftomach before it has time to be abforbed and carried into the blood-veffels. But the author has shewn in his Differtation on a re-Bank auf gular tertian, that it does not put a ftop to the progrefs of an intermittent fever by being carried into the inteffines and abforbed, but by the impression it makes on the ftomach and inteftines. In the fecond place, it may be faid that the bark of the cinchona, by producing vomiting, is prevented from remaining a fufficient time in the ftomach to make its impreffion there; but the author has alfo shewn in the fame Differtation, that the bark of the cinchona exhibited half an hour before the beginning of a paroxy fm of a tertian intermittent, often makes fufficient impreffion to prevent the paroxyfm from taking place. It is often more than half an hour after the exhibition of a dofe of the bark of the cinchona before it occasions vomiting; but when it does occasion vomit-

ing,

ing, it often does not prevent the return of the difeafe.

In like manner, ceruffa acetata given in a fmall dofe does not produce either vomiting or purging, but on the contrary adiminution of the periftaltic motion of the inteftines, and not uncommonly a paralytic affection of them, and likewife of the extremities; yet when it has been by accident taken in a confiderable dofe, to the quantity of a dram or two, as the author has feen in feveral cafes happen, it has produced both vomiting and purging, but no paralytic affection of the inteftines, or any other part of the body, has enfued.

The author therefore conceives, that when any remedy produces vomiting, it very often lofes by this effect its other operations on the fyftem, and that preparations of antimony, in like manner, if they produce vomiting, or even ficknefs, though no vomiting fhould enfue, lofe their effect in carrying off fever.

The

The author conceives, that every medicine given in too great a dofe acts as a fimple ftimulant on the part to which it is applied, and lofes its peculiar effects both on that part, and on the fystem generally. Thus a moderate quantity of wine makes the ftomach digeft the food more readily than it otherwife would have done, but a large quantity of wine prevents digeftion from taking place at all. A moderate quantity of fpice gives a feel of warmth over the whole fystem, a large quantity of the fame fpice produces pain in the ftomach and coldnefs over the whole fyftem, and frequently ficknefs and vomiting. It would be too great a digreffion to enter fully on the maximum of the dofes of medicine; if the author should live to finish these Differtations, it is a fubject that he means to purfue.

In the third place, the author has obferved, when tartarifed antimony has been exhibited in fevers, that when the patient's ftomach could not bear a quarter of a grain of it prepared as has been faid, without producing ficknefs, it has happened rarely that that it has produced any thing like a crifis, or in any way diminifhed or carried off the difeafe. On the contrary, when the ftomach would bear more than a quarter of a grain of tartarifed antimony, prepared in the fame way, and by the very fame individual procefs, without producing any naufea, it has very often produced critical fymptoms, or a complete crifis, fo as to carry off the difeafe. For thefe reafons, the author differs in opinion from Dr. Cullen, and believes it is not the ficknefs that has the power of producing a crifis, or any appearance of crifis in a regular continued fever.

It appears then, first, that feveral medicines, producing as great a degree of fickness as preparations of antimony, have no power whatever of carrying off fever, by producing criss, or appearances fimilar to criss, or in any other way.

Secondly, that producing fickness prevents medicines generally from operating in their own appropriate manner.

Thirdly,

Thirdly, that preparations of antimony, when they produce fickness in fmall dofes, are not fo efficacious in carrying off fever, as when it requires a larger dofe of them to produce naufea, and alfo that they are more efficacious when no nausea is produced; and therefore, upon the whole, that it is not the nausea produced by preparations of antimony, that renders them efficacious in producing fymptoms fimilar to those that take place in the crifis of a fever, and fo carry off the difeafe. On the contrary, that any preparation which can be made to act with certainty in a larger dofe, without producing nausea, is preferable for carrying off fever. Further, that tartarifed antimony, prepared by boiling crocus metallorum with tartar in water, and not purified by a repeated folution and crystallization, is the best manner of preparing the compound of tartar and antimony for this purpofe.

The next queftion is, whether tartarifed antimony prepared, as has been defcribed, or regulus of antimony mechanically mixed with fulphur, as in that preparation which has been called kermes mineral or the calx of antimony, antimony, mixed with calx phofphorata, which formed at leaft a principal part of Dr. James's powder, and is the pulvis antimonialis of the laft edition of the London Pharmacopeia, are the preferable preparations of antimony for immediately producing fymptoms fimilar to those that take place in the crifis of fevers.

The regulus of antimony in the kermes mineral, the calx of antimony in the pulvis antimonialis, are neither of them foluble in water. It has been held by many practitioners, that fubftances not foluble in water, muft be combined with fome menftruum in the ftomach with which they form compounds foluble in water to be efficacious. If this be the cafe, thefe preparations of antimony, to wit, kermes mineral and pulvis antimonialis, will be fubject to an uncertainty in their operation, by their meeting with or not meeting with a menftruum with which they may combine fo as to form a compound foluble in water.

The first thing then to be enquired into is, whether it be true, that if any folid substance, ftance, infoluble in water, be thrown into the ftomach, it will act upon the ftomach and inteftines, or fyftem generally, without finding a menftruum with which it will combine fo as to form a compound foluble in water.

It is well known, that fulphur thrown into the ftomach in fine powder, as it is when precipitated from an alkali by means of an acid, or in fine cryftals, as when it has been recently fublimed, will act as a purgative.

In either of thefe cafes, if the fulphur be perfectly pure and unmixed with any extraneous matter whatever, it is not foluble in water in the fmalleft degree. It is true, that if fulphur be thrown into water, and left in the water with the furface of the water exposed to the atmosphere for fome length of time, the fulphur will combine either with the air of the atmosphere or of the water, and form vitriolic acid, which is foluble in water. Sulphur recently precipitated from an alkali by means of an acid, or recently fublimed, has not acquired ed any air, it acts however equally as a purgative. Moreover, vitriolic acid rarely acts as a purgative in any dofe given uncombined with any other fubftance, whereas fulphur rarely fails of acting as a purgative.

It is therefore to be confidered, whether fulphur meets with any fubftance in the ftomach with which it will combine, fo as to form a compound foluble in water.

In the first place, it meets with water in the ftomach with which, it has been already faid, it will not combine, nor will it be altered, excepting by long digestion, in the heat of the human body. If it should alter by combining with the pure air of the water, the acid thus formed rarely acts as a purgative; nor does inflammable air, the other element of the water, act as a purgative. It is therefore extremely improbable that it should act as a purgative, by decomposing the watery fluid that it meets with in the stomach.

The water found in the ftomach is im-E pregnated

pregnated with animal mucilages, fuch as the folid matter of the mucus; but water, impregnated with animal mucilages, is not decomposed more readily by fulphur being applied to it, nor does it more readily combine with fulphur in confequence of its being already combined with fuch animal mucilage. The gaftric juice, as it is called, in counter-diffinction to other fluids found in the ftomach, has been thought by fome to be a powerful menstruum, and to unite with the food, fo as to form chyle or fome compound preparatory to the formation of chyle. This folvent power of the gaftric juice the author has argued in his Treatife on Digestion, the refult of which argument appears to be, that it has no fuch folvent power; on the contrary, it appears that its fole power is to coagulate certain animal and vegetable fubftances, fo that they may be retained in the ftomach until they go through that part of the process of digestion which is neceffary in the stomach. No. experiments have been made to fhew whether or not this gastric juice will combine with fulphur, fo as to form with it a compound foluble in water. It is extremely improbable

improbable that it does, fince water, combined with other mucilaginous matters, does not diffolve fulphur more readily than pure water. Gaftric juice renders certain fubftances infoluble in water, that are otherwife capable of being combined with it; it is therefore improbable, that gaftric juice fhould combine with fulphur fo as to form a compound with it foluble in water.

In the juices of the ftomach, there is fea falt, that is, natron muriatum; ammonia muriata, and ammonia phofphorata, and fometimes, perhaps, calx muriata, as there are in all the other juices of the body, but none of thefe falts combine with fulphur fo as to form a compound foluble in water.

Other fubftances are found in the ftomach fometimes, but not always; but fulphur almoft always proves purgative, and therefore does not act on the ftomach and inteffines, in confequence of meeting with a fubftance in the ftomach which is accidentally found there. Sulphur, therefore, does not act as a purgative in confequence of any thing it meets in the ftomach with which it forms a compound foluble in water.

Sulphur, when it gets into the duodenum, meets with bile which might combine with it, and form a compound foluble in water. The like might happen with pancreatic juice, with which it often meets in the duodenum. From the author's experiments, which it would be too great a digreffion to relate here, fulphur is neither capable of combining with bile nor pancreatic juice, and therefore fulphur does not act by combining with bile or pancreatic juice fo as to form a compound foluble in water.

The fame obfervations may be made with regard to the other fluids it meets with in the inteftinal canal; it is at leaft extremely probable, that it does not combine with any of them fo as to form a fluid capable of being combined with water.

Sulphur

Sulphur is capable of being combined with that vapour which Vanhelmont firft took notice of, and called gas, but which has fince been called fixed air, and by many other names. This vapour is found fometimes in the inteftinal canal. It is alfo capable of being combined with inflammable air. Neither of thefe vapours is found generally in the inteftines, whereas fulphur acts almoft always as a purgative.

We muft therefore conclude that fulphur acts upon the ftomach and inteftines in a folid form. It is alfo capable of acting on them independently of any mechanical effect; a folid is therefore capable of acting on the ftomach and inteftines medicinally.

Regulus of antimony, and the calx of antimony made by mixing antimony with fhavings of hart's-horn, burning them together, and exposing them to a great degree of heat, may act upon the flomach without being combined with any fubftance, fo that the compound is foluble in water, and  $E_3$  therefore therefore may act independently of any menftruum they may meet with in the ftomach.

It has been often affirmed in medicine, that whatever was fhewn to be poffible, was alfo true. This is a proposition totally repugnant to all the laws of evidence; it does not follow, therefore, that although one folid in powder may act upon the ftomach and inteftines, every folid does. The next queftion then that comes to be difcuffed is, whether the fine powder of the regulus of antimony in kermes mineral, and the calx in the pulvis antimonialis, do act in a folid form without being combined with fome fubftance with which they form a compound foluble in water.

In the healthy flate of the body, the fine powder of the regulus of antimony in kermes mineral, and the calx of antimony in the pulvis antimonialis, being thrown into the flomach, will frequently act as an emetic.

In the healthy state of the body, there is no acid in the stomach not combined with an an alkali, therefore neither of those preparations of antimony can act in consequence of being diffolved by an acid in the stomach, unless they should decompose the neutral falts. Whether they can decompose the neutral falts, to wit, sea falt, common falammoniac, or phosphoric ammoniac, as they are applied in the stomach, or whether they are foluble in the neutral falts themfelves, is not known, and therefore the argument must be taken on another ground.

If tartarifed antimony, prepared as has been defcribed, be exhibited to a man in health, it hardly ever happens that a third part of a grain can be taken without producing ficknefs and vomiting, or purging. It very rarely produces any naufea, if taken in the quantity of a fifth part of a grain, by an adult. On the other hand, the pulvis antimonialis, or kermes mineral, will fometimes produce fickness and vomiting, taken in the quantity of three grains; on the other hand, they may be taken very often to the quantity of eight or ten grains, without producing any fenfible effect. The author E4

author has feen them often employed to the quantity of twelve or fifteen grains, without having any apparent effect at all.

Moreover, kermes mineral, and the pulvis antimonialis, the author has feen, in feveral inftances, exhibited at the interval of fix hours, for four and twenty hours, or forty-eight hours, without producing any fenfible effect, and at laft, all at once, they have brought on a fevere vomiting and purging, fo as to weaken the patient very much.

It muft, therefore, be concluded, that either they are not active in a folid form, unlefs combined with fome menftruum that will form with them a compound foluble in water, or otherwife that acting in a folid form, they are very uncertain in their operation. In either cafe, tartarifed antimony is a preferable preparation to kermes mineral, or the pulvis antimonialis, or Dr. James's powder, which partakes of all the uncertainty of the pulvis antimonialis, The author does not by any means fay that tartarifed antimony, prepared as has been defcribed, is the beft poffible preparation of antimony. On the contrary, he thinks that if a preparation was to be found out, of which the ftomach would bear a much larger dofe without ficknefs, and act with the fame certainty, it would be preferable to tartarifed antimony, prepared as has been defcribed.

Another circumstance must be remarked. If tartarifed antimony be diffolved in a large proportion of water, it, like all other metallic compounds with acids which are foluble in water, will be decomposed, if the folution stands with a furface exposed to the vapours which conftitute the atmosphere. It will be lefs apt to be decomposed, if it be diffolved in recently diffilled water, than in river, spring, or rain water. It will be still lefs apt to be decomposed if combined with wine, and especially a fweet and strong wine; it is, therefore, much better to keep it diffolved in wine. The folution is convenient when the wine contains a quarter of

of a grain of tartarifed antimony, in half a dram by meafure of the wine, as in the vinum antimonii tartarifati of the London Difpenfatory. Of this folution, half a drachm by meafure may be exhibited, or any greater or lefs quantity, mixed at the time of exhibition with an ounce of any watery vehicle, before it has time to decompose.

The other preparations of antimony, excepting those which have been enumerated, which are hitherto known, are so uncertain in their operations, as to make them totally unfit to be employed in fever.

It is an undoubted fact however, that other preparations of antimony than the three enumerated, have been exhibited to a patient ill of a fever, and have occafioned appearances fimilar to thofe which take place in the crifes, which happen during the progrefs of regular continued fevers left topurfue their ordinary courfe. Such crifis has terminated the fever in the manner in which it is terminated by an ordinary crifis, fo that the patient has has been freed from the fever in a few hours, it has not afterwards recurred; but they act fo uncertainly, that it is not worth while employing them.

Preparations of antimony, when exhibited to a man in perfect health in fuch a dofe as juft not to produce ficknefs, occafion, after two or three hours, a breathing fweat, and foftnefs of the fkin, not unfrequently a lateritious fediment in the urine, open the body, and produce afterwards an univerfal tranquillity over the whole fyftem. They occafion therefore appearances fimilar, as much as can be, to thofe which take place in the crifis of fever,

It is attefted by many authors, that on the exhibition of Dr. James's powder, the pulvis antimonialis, kermes mineral, and tartarifed antimony, in two or three hours afterwards, or from that to five or fix hours, the fymptom which ordinarily arife in the crifis of fever have taken place, and that the fever has been carried off in lefs than twenty-

## [ 60 ]

twenty-four hours, fo that the patient has perfectly recovered.

The author has feen each of thefe preparations of antimony exhibited in a fever during the ordinary progrefs of the difeafe, in the firft week of a fever as well as in the fecond week of the difeafe. He has feen in lefs than five hours after the exhibition of the medicine, the fymptoms which take place in the ordinary crifis of a continued fever arife, and the fever has ceafed in lefs than twelve hours.

This effect of these medicines the author has seen, in many cases, where there was no appearance that a criss would have taken place in the sever, supposing that it had been left to pursue its ordinary course.

A crifis generally takes place, in a regular continued fever, in the night time; that is, from four to fix, or eight o'clock in the morning; the author has feen it produced at other times of the day.

When

When thefe preparations of antimony have been exhibited, the author has feen fevers much more frequently carried off by crifis, than in proportion to the number of crifes which happen in fevers left to purfue their ordinary courfe. He has feen thefe things happen in many hundred cafes of fever; it may therefore be concluded, that thefe preparations of antimony, being exhibited in a fever, often produce fymptoms fimilar to thofe which arife in the ordinary crifis of fever, or, in other words, a crifis fimilar to the ordinary crifis in fever, and carry off the difeafe.

The next queftion which occurs is, whether there is any other medicine which produces the fame effects either more certainly, lefs certainly, or equally with the preparations of antimony which have been enumerated ? It is matter of confideration whether this queftion fhould be firft difcuffed, or whether it would be better to enter into the argument in what manner the preparations of antimony, hitherto defcribed, fhould be employed,

3

employed, fo as to have the best chance of carrying off the difease.

There are many reafons that might be urged for taking the one or the other argument into difcuffion firft; but it is not worth while taking up time in difcuffing this; it is therefore the author's determination, upon the whole view of the fubject, to purfue the beft method of employing preparations of antimony to produce crifis in fever, though he is not fure that he is right, as he may be obliged, in many inftances, to take notice of the effects of other medicines which have a fimilar action in fevers, and produce a crifis in them.

The author has already faid, that when a patient is attacked with fever, it often happens that there is undigefted food in the ftomach, which will therefore require to be evacuated. From the fever itfelf, likewife, other noxious matter is probably produced in the ftomach, in fome degree fimilar to that which we find covering the tongue. It is neceffary neceffary to evacuate fuch undigefted food, becaufe by remaining it may contaminate the food that may be afterwards thrown into the ftomach, by exciting in it the acetous, putrefactive, or other noxious fermentations, and prevent it from being converted into a fubftance which is afterwards to be formed into chyle.

Vomiting in itfelf has a tendency, after the ficknefs which produced it is over, to occafion a glow or warmth over the whole body, followed by moifture on the fkin, foftnefs of it, an univerfal foftnefs and relaxation of the whole mufcles, a flow of fluids through the whole fecretory veffels, a general tranquillity over the whole fyftem, and a difpofition to fleep.

Although vomiting induced by any means has this effect, in fome degree, when the ficknefs occafioning it is gone off, yet it has not the fame effect, in an equally powerful manner, when produced by any means whatever.

## If vomiting be produced by tickling the throat, by introducing any folid fubftance into it, as a feather or the finger, or if by a cough the larynx be forced up into the throat, fome fenfible effect fimilar to what has been juft defcribed takes place. If preparations of antimony or ipecacuanha be exhibited fo as to produce vomiting; when the ficknefs is gone off, the appearances of

the fickneis is gone off, the appearances of crifis, which have been above defcribed, arife in a much greater degree.

Although therefore all emetics, when the ficknefs is gone off which occafions the vomiting, have a tendency to produce appearances fimilar to the appearances which take place in the crifis of fever, and therefore actually tend to produce crifis in fever, yet they do not all tend to produce crifis of fever equally: therefore it is better to choofe fuch fubftances as emetics, which have the greateft tendency to produce critical fymptoms after the vomiting is gone off, than fuch as have a lefs tendency to produce the appearances fimilar to those taking place in crifis, in order that the emetic may have a better a better chance to produce a crifis in the difcafe.

It is therefore better to employ preparations of antimony or ipecacuanha, as emetics, in the beginning of a fever, than warm water, infufion of camomile, white vitriol, fquills, &c. which have no tendency to produce fymptoms fimilar to those which take place in a crifis of fever, independent of the action of vomiting.

It is not always that any of the preparations of antimony known produce vomiting, when exhibited to a man either in health or in a fever. Sometimes tartarifed antimony in the dofe even of feveral grains, does not produce vomiting but purging, given either in health or to a patient affected with fever. It is wifhed, however, that we fhould be certain of producing vomiting to occafion the evacuation of any noxious matter, fuch as has been defcribed, from the ftomach.

Ipecacuanha, the root of a plant, which the jealous government of Spain has prevented F the the perfect inveftigation of, is very certain in its operation as an emetic, much more for than any other fubftance which is at prefent known. It has befides the fame kind of power which antimony has, though perhaps not in fo great a degree, of producing those appearances which take place in the ordinary crifis of a fever. It is therefore better to mix ipecacuanha with tartarifed antimony, and exhibit them for mixed as an emetic at the beginning of fevers.

The next point to be argued is, the dofe of the medicine we are to employ as an emetic at the beginning of fevers.

When a medicine is to be exhibited as an emetic under one view, it does not appear to be of much confequence how large the dofe is. Let the dofe be ever fo great, the first evacuation would feem to bring up every thing which is fuperfluous, fo that the fuperfluous part of the dofe fhould no longer act. This confideration explains why the very various dofes of emetics which have been exhibited in various cafes, produce produce very often nearly the fame effect. Though this be the cafe in many inflances, it is not in all. It happens alfo in many inflances, that a large dofe of an emetic produces most violent vomiting, which is repeated many times with great diffress to the patient, fo that it would feem that an emetic may lie fo long upon the flomach, before it is brought up, as to make an impreffion, which lasts after the emetic itself is entirely evacuated.

In fevers the violence of the exertions, when an emetic thus continues to operate, perhaps fix or eight times, in the first place exhausts the force of the fystem, which is not to be thrown away in this difease, and therefore on this account too large a dose of the emetic should be avoided.

Moreover, it has already been obferved, that when any medicine is made to act in too great a degree, it lofes its proper effect, and becomes a fimple ftimulant. So the action of vomiting itfelf, by being too frequently repeated, from exhibiting too large F z = 2

## a dofe of the medicine, does not produce appearances fimilar to thofe which arife in the crifis of fever, fo as to carry off the difeafe. For this reafon ipecacuanha and antimony do not produce thefe appearances, if given in too great a dofe. Thus by giving too large a dofe of thefe medicines as emetics, the effect of carrying off the fever either by the action of vomiting itfelf, or by the effects of the antimony and ipecacuanha, are fruftrated.

The proper dofe may be about eight grains of ipecacuanha, and one grain of tartarifed antimony.

If an emetic of almost any kind, which takes up a very fmall volume, be exhibited, if there should be nothing in the stomach to be evacuated, there arises an effort to evacuation, or in other words a reaching, which is attended with a great deal more uneasines and pain, than if there was a quantity of some substance in the stomach to be evacuated. This has induced practitioners to give, after an emetic has been exhibited, exhibited, watery fluids to drink, fo that there fhould be fomething to be evacuated, in order to take off the uneafinefs and pain of the reaching.

At the beginning of a fever emetics, as we have juft obferved, are employed for two purpofes: Firft, to evacuate from the ftomach any undigefted food which was contained in it when the fever took place, or thrown into it afterwards, or noxious matter formed in the ftomach in confequence of the fever. In the fecond place, by the action of the vomiting, and of the medicines employed as emetics, joined together, to induce a crifis to the fever, fo as to put an end to the difeafe.

For the first of these purposes, to wit, evacuating noxious matter from the stomach, if it were undigested food, two or three evacuations by vomiting are certainly sufficient, and especially if after the first evacuation a quantity of warm watery fluid be thrown into the stomach. If noxious matter be formed in the stomach itself in  $F_3$  confequence confequence of the fever, and if that fhould affixed to the flomach, as the cruft is to the tongue, no force will ever feparate it, and if it fhould not be fo affixed, two or three evacuations will be fufficient to carry it off; fo that if two or three fits of vomiting fhould take place, it is fufficient for all the purpofes that are wifhed for from the vomiting, and will not prevent either the act of vomiting itfelf, or the effect of the medicines, which have been enumerated as proper to produce it, from bringing on the appearances which take place fimilar to thofe that arife in the ordinary crifis of fever.

It does not feem indifferent at what time of the day an emetic is employed, if we wish it to produce any other effect than simply to evacuate the noxious matter contained in the stomach in fever.

In the first place, the operation of vomiting, after it is over, tends to produce fleep. Mankind generally are disposed to fleep about nine, ten, or eleven in the evening. If then the disposition to produce fleep, brought

brought on by the emetic, coincides with the ordinary time of the twenty-four hours in which there is a difposition to fleep, the two together will be more powerful in producing their effect, than either of them alone. The reft thus procured by this double difposition will be founder and more refreshing, than it would have been from either of them fimply, and will tend to reftore and fupport the ftrength of the patient. Moreover, it has been obferved, that fleep produces a difposition for all derangements of the fystem to go off, and confequently fever; it therefore increafes the chance of the action of the vomiting, and the power of the remedies employed to produce it, in occafioning the appearances which arife in the ordinary crifis of fever, and confequently in carrying it off.

Secondly, it has been obferved, that the exacerbation of a regular continued fever takes place generally between five and fix o'clock in the evening, and that the effort to a crifis made in the hot fit is  $F_4$  ftrongeft ftrongeft about three or four o'clock in the morning. If the emetic be then exhibited between feven and eight o'clock in the evening, the difpofition to crifis produced by the vomiting itfelf, by the action of the fubftances employed as emetics, by the fleep, and by the ordinary effort of the fever itfelf, will all co-operate together fo as to have a better chance of producing a crifis in the difeafe,

It would therefore feem, when we employ an emetic in a fever, to evacuate any noxious matter from the ftomach which has got into or formed in it by the means above defcribed, that it is better to exhibit in a moderate dofe fuch fubstances as emetics, which, if they are not exhibited in fuch dofes as to produce fickness, have a tendency to produce fymptoms fimilar to those which take place in the ordinary crifis of fever. It feems also necessary to prevent the violence of the reaching by introducing fome watery fluid into the ftomach, but that it is better not to employ the watery fluid in too great a quantity, nor repeat

peat it too frequently. It is likewife better to exhibit the emetic about feven or eight o'clock in the evening. Thus the action of the vomiting itfelf, of the medicines employed to produce it, the fleep, and the ordinary effort of the evening paroxyfm of fever itfelf, will all co-operate together fo as to tend to bring on a crifis, and fo terminate the difeafe.

If any one fhould think the author is too minute in thefe attentions, he muft confider that if, by omitting any of them, a crifis fhould not be produced when it otherwife might have been, the patient may be fubjected for a fortnight, or longer in fome inftances, at leaft, to a diffreffing and dangerous difeafe.

It happens fometimes, when an emetic is employed, that with every precaution the ficknefs will continue, and the patient fhall pafs a reftlefs and diftreffing night, more fo than would probably happen if no emetic had been exhibited ; but this muft be left to be confidered among the irregularities which happen happen in the difeafe. Neverthelefs, it is neceffary to employ an emetic to clear the ftomach of any noxious matter that may be left in it from the laft food that was employed, or that may be generated in it in confequence of the difeafe, in as much as fuch noxious matter would occafion much greater diforder if it was not evacuated.

It happens not uncommonly that when a patient has taken an emetic, efpecially if regulated as is defcribed above, he falls in lefs than an hour after its operation into a quiet fleep; a gentle eafy perfpiration takes place at firft, and increafes into a fweat more or lefs profufe; all the fecretory veffels are relaxed, and the fkin and the mufcles alfo; a perfect crifis is produced, and the patient is freed from the difeafe.

It happens likewife not uncommonly, that though perfect crifis does not take place, the fever is confiderably alleviated, and goes through its remaining courfe with lefs danger to the patient. The author thinks, that if a practitioner be confulted in the beginning, that is, in the first four or five days, an emetic should always be exhibited in a regular continued fever.

Independent of vomiting, preparations of antimony, fuch as have been defcribed, have the power of producing appearances fimilar to those that arise in the ordinary crifis of a regular continued fever. These preparations of antimony have been employed in two ways to produce such crifis.

Firft, if fome one of the preparations above defcribed be exhibited in a dofe juft not fufficient to produce ficknefs (when they have been exhibited empirically this has not been much attended to) in the evening about fix o'clock; if the fame dofe be repeated about half an hour paft eight, and again at eleven; if the patient be laid in flannel or cotton, or fome other bad conductor of heat, his head bound round with a cloth of the fame kind, and fmall quantities of fome warm watery fluid, fuch as barley water, be given frequently, fo as to throw the patient

tient into a profuse fweat if possible; and this fweating be kept up by repeating the preparations of the antimony every four, five, or fix hours, as the patient can bear it, without occafioning any ficknefs; and if this practice fhould be continued for four and twenty hours, it has happened, in many cafes, that when the preparations of antimony, above defcribed have been exhibited in this manner, a crifis has been produced, and the fever entirely carried off. This happens particularly if the remedy be exhibited in the first three or four days of the difeafe; the crifis is thus very evidently the effect of the medicine. There is a degree of brilliancy in this practice which has made it be adopted by many practitioners who have a degree of empiricifm.

It is to be obferved, that fuch practitioners, and all empirics, have often exhibited antimony in this manner, or fometimes in one dofe without repetition, at any time in fever, fometimes with fuccefs, but this will be confidered afterwards.

The

The mode in which antimony appears to the author to have the beft effect, with the leaft detrimental confequences, is, in the firft place, to employ it as foon as poffible in the difeafe; for it is more efficacious in the firft attack of the fever, than in the fecond day of the difeafe, counting the days as has been before pointed out. It is more efficacious in the fecond day of the difeafe than in the third, and fo on the third than in the fourth, &c.

It fhould be employed in the first place as an emetic, mixed with ipecacuanha, as has been already defcribed. If the weather fhould be cold, it is better to lay the patient in cotton, and treat him as has been defcribed, in the management of a regular continued fever left to purfue its natural courfe.

After having exhibited the emetic, as has already been defcribed, when the vomiting has ceafed, the patient being in bed, if he fhould continue fick and reftlefs, as has been above defcribed, which is fometimes fometimes the cafe, about a grain of opium, or a dofe of tincture of opium, equivalent to a grain, may be given without detriment, along with a little tincture of cinnamon or any other aromatic. This medicine fhould only be exhibited under the circumftances of the patient's continuing fick and reftlefs, in which cafe it takes off the ficknefs, and

fuffers the antimony to act.

Six hours after the action of the emetic is over, if the patient fhould be awake, a dofe of one of the preparations of antimony above defcribed, fhould be exhibited in fuch quantity as the ftomach can bear without ficknefs. If he fhould be afleep at this interval from the laft action of the emetic, as foon as he awakes it fhould be given.

The author prefers tartarifed antimony, prepared as is defcribed above, in the laft edition of the Pharmacopeia of the London College.

The dofe of tartarifed antimony the author would exhibit, in the first instance, is is two fevenths of a grain, or if the tartarifed antimony be diffolved in wine, as is above defcribed, in the vinum antimonii tartarifati of the Difpenfatory, thirty drops of this folution dropped out of fuch a vial as is commonly made to contain two ounces in this country.

The author is fenfible of the uncertainty of meafuring any thing by drops. The quantity contained in a drop depends upon the vifcidity of the fluid dropt. Four drops and an half of alcohol, for example, dropt from the fame veffel, weigh only one drop of water, the alcohol being much lefs vifcid than the water.

Again, the fize of a drop depends upon the thicknefs of the lip of the vial from which it is dropt, or rather on that part of the lip from whence it is dropt. Thefe difficulties may be eafily obviated, by trying how many drops of any fluid dropt from one part of the lip of any one vial meafures or weighs. If the vial be not above fourfifths full, the fame number of drops, if they they exceed twenty, will be found always nearly of the fame meafure and weight.

The author prefers this mode of determining the dofe as the eafieft and most readily measured.

It has this advantage, that if thirty drops of the vinum antimonii tartarifati should produce, on its first exhibition, any nausea, it may be diminished by four or five drops on the fecond exhibition. If upon this fecond exhibition it fhould produce no nausea, or if upon its first exhibition, in the quantity of thirty drops, no naufea should enfue, an additional quantity of two drops may be added to each dofe, until the greateft quantity is found out that the ftomach can bear without naufea. The author has already observed, that nausea prevents the medicine from having fuch a difposition to produce fymptoms fimilar to those that arife during the crifis of fever, and fo carry off the difease. The practitioner can therefore thus afcertain the exact dofe which can be given without producing naufea.

If

If the author fhould be miftaken in thinking that tartarifed antimony, prepared as has been defcribed, is the beft preparation of antimony for producing crifis in fever already known; or if fome better preparation fhould be found out; yet as the ftomachs of different men, or the ftomach of the fame man at different times, are differently impreffed by the fame dofes of almost all medicines, he conceives that fome mode fhould be taken fimilar to that which has been defcribed above, to afcertain what quantity the ftomach can bear of the preparation of antimony employed without naufea, and that it fhould be exhibited in that dofe.

Along with the first dose of antimony to be exhibited in fix hours after the last operation of the emetic, it may be proper to give a moderate quantity of fome aromatic, fo as to render it more agreeable to the stomach of the patient, fuch as infusion or distilled water of mint or cinnamon, or any other medicine of the fame kind.

G

It

If the emetic exhibited fhould have produced a quiet gentle fleep, and the fymptoms of a crifis appear; if the pulfe has returned to the ordinary number of pulfations in a given time, and the patient fhould appear to be entirely freed from the fever; yet it will not be fuperfluous to repeat the preparation of antimony in the manner defcribed, as no mifchief whatever can arife from it, and it may fecure the patient from the return of the difeafe.

After a dofe of antimony is thus exhibited, it is to be repeated at four or five, or fix hours interval.

The interval is to be determined from the effects which this dofe has produced.

If the patient has had a crifis produced by the emetic, and a general freedom from the difeafe has taken place only with fome languor, it will be fufficient to repeat it every fix hours, and continue it for twentyfour hours.

If

If hardly any relaxation fhould have taken place in confequence of the emetic, but all the fymptoms of fever, fuch as great depreffion of ftrength, weight about the precordia, pain in the forehead, drynefs of the fkin, &c. fhould remain in a great degree, it will then be proper to repeat it every four hours, and continue fuch repetition for four or five days.

' If a preparation of antimony is given in this way at the beginning of fever, and continued for four or five days without producing a crifis, fo that the fever is cured or converted into an intermittent, it rarely pros duces a crifis afterwards; neverthelefs it often makes the relaxations greater, prevents or diminishes delirium, and makes the whole fever go on with lefs violent fymptoms. It is better therefore to continue to exhibit fuch a dofe of the preparation of antimony, as the ftomach will bear without naufea, every fix hours. When fymptoms of weakness begin to appear, or if the antimony should produce sweating, purging, or any other topical evacuation, without relieving G 2

lieving the fever, it is immediately to be omitted.

It happens, in many inflances, that in the courfe of this time the patient has a moifture produced in the fkin, a lateritious fediment takes place in the urine, the fkin by degrees grows foft, the tongue begins to grow moift on the edges, and is cleared of the cruft that forms upon it, all the other critical fymptoms take place gradually, and the patient is freed from the difeafe.

If either the fymptoms of the attack of the difeafe fhould be fo violent as to give little hopes that the patient will recover, if the difeafe fhould purfue its ordinary courfe, or fuch an epidemic fhould be prevalent as deftroys the greateft number of patients afflicted with the difeafe; in fuch cafes, perhaps, it might not be improper to force a profuse fweat in the manner that has been defcribed.

Unlefs however there should be little hopes of the patient's recovery if the difease should fhould go on in its ordinary progrefs, fuch means of occasioning fweating ought by no means to be employed.

First, because fweating, though it be one of the appearances that take place in the ordinary crifis of fever, yet it is very far from being the only one; or, not only the fecreting vessels of the skin are relaxed, and secrete a larger quantity than usual, but all the other secretory vessels are equally relaxed, and also the muscles and whatever other part is relaxed in the ordinary crifis of sever. We see also that profuse sweating takes place sometimes in a regular continued sever without any relief to the difease.

In the fecond place, every unneceffary evacuation tends to weaken the patient, and give him a lefs chance of being fupported through the courfe of the difeafe if a crifis fhould not be produced.

Therefore it is not proper to attempt to produce profuse fweating, if there be any G 3 tolerable Hitherto the author has been fuppoling the patient to apply to a practitioner in the firft day or two of the fever. In that cafe, provided the difeafe be a regular continued fever, by employing preparations of antimony in the manner defcribed, fymptoms fimilar to those which take place in the ordinary crifis of fever will be produced, as far as the author can judge from his experience, in one half, perhaps he thinks he can fay certainly in one third of regular continued fevers.

If no medicine has been given during the first days of the difease, or if no emetic has been exhibited, it will be proper to employ an emetic in the manner which has been mentioned any time in the first week of the difease, or even on the eighth or ninth day, especially if there should be a greater foulness of the tongue, or more nause than in in proportion to the other fymptoms of the difeafe.

If an emetic fhould have been employed at the beginning of the difeafe, and the patient at any time afterwards during the courfe of it should have a greater foulness of the tongue, weight upon the ftomach and nausea, than in proportion to the other appearances of the difeafe, it is proper to repeat the emetic. In this cafe, about five grains of ipecacuanha fhould only be given, which rarely fails of proving emetic. It should be exhibited in the evening, but the other regulations that have been laid down for the exhibition of an emetic at the beginning of the difease, are not necessary to be attended to.

If no preparation of antimony has been exhibited on the first two or three days of the fever, the exhibition of it afterwards will have lefs chance of carrying off the difeafe; for after the fever has continued for longer than three days, the fystem has acquired an habit which renders the difeafe more

more fixed. Although the fooner the preparation of antimony is employed, the production of a crifis or gradual going off of the difeafe, by critical fymptoms taking place after each other, is more probable, yet the fever in many inftances will be carried off by the exhibition of it before the end of the fecond week of the difeafe. The fooner however it is exhibited, it will have the greater chance of removing the fever.

Although preparations of antimony fhould not produce a crifis fo as entirely to carry off the fever, they produce a crifis in many cafes, which though not quite perfect, yet converts the difeafe into an intermittent fever, which is a difeafe much eafier managed than a continued fever.

Supposing preparations of antimony not to produce fuch a crifis as to convert a continued fever into an intermittent, or carry off the difeafe, yet it happens in many cafes that they give great relief to the patient, fo that the head-ach is diminished or entirely carried off, fuch a degree of delirium does not not take place as otherwife probably would have done, the primæ viæ are not fo much difordered, and the fever purfues its courfe without fo much diftrefs and danger to the patient as it otherwife would have done.

It happens fometimes that there is great hardnefs, fulnefs, and ftrength of the pulfe, as well as obftruction; that with thefe there is flufhing of the face and rednefs of the eyes in the firft two or three days of the fever, and that other fymptoms of general inflammation take place in fuch a degree as to render it neceffary to take away a quantity of blood; it then becomes a queftion whether preparations of antimony fhould be employed immediately at the beginning of fuch fever, before blood is taken away.

This is a cafe which happens much feldomer than would be fulpected from what authors have written on this difease, and the argument will be entered into in that differtation in which the irregularities that take place [ 90 ]

place in continued fevers will be treated of.

If upon exhibiting preparations of antimony fome one evacuation should take place, without a relaxation of the other fecretory veffels, the antimony should not be perfifted in. If profuse fweating should be produced, and at the fame time the tongue fhould remain dry and covered with a fur, and the patient should remain coffive and the other parts contracted : if a lateritious fediment should appear in the urine, or a flaky white fediment, the skin remaining dry and contracted, and the tongue dry and covered with a fur : if the patient should be purged, the fkin remaining dry at the fame time; in any of these cases there is little hope of antimony being of any kind of use if the system should continue in this state for forty-eight hours. It will rather tend to weaken and deftroy the patient, and therefore ought not to be continued.

It

It is next to be confidered whether there is any other medicine which has the fame effect with preparations of antimony; that is, whether there be any other medicine that will induce the appearances which take place in the ordinary crifis of fever, fo as to carry off the difeafe.

In the hiftory of medicine that we are able to collect from the Greek and Roman authors, whofe writings have come down to us, there is one inftance only of a medicine having had this effect, to wit; when the phyfician of Alexander the Great exhibited to him a medicine, which is faid to have occasioned the appearances which ordinarily take place in the crifis of fever, fo as to carry off the difease in less than twentyfour hours. We have no trace of what this medicine might be, and it is fingular that the fame medicine fhould not have been exhibited to him again in that remittent, which he caught by furveying the marshes of the Euphrates, near Babylon, in order to have them drained,

Cold

Cold water was exhibited by Greek phyficians, in fever, often evidently with a view of immediately putting an end to the fever. From the beft information the author has been able to make out from perufing their writings, they exhibited it reduced nearly to the freezing temperature, in the quantity of from one to two quarts at once, fo as to produce great evacuation by vomiting, purging, and fweating.

It was by no means the practice of the ancient Greek phyficians, who were the principal and almost only practitioners in the Roman dominions, to give watery fluids, or indeed any thing to drink at the beginning or during the paroxyfms of fever. In Petronius's fatire, one of Trimalchio's guests fays, that a man, whose funeral he had been at, was a very obedient patient to his phyficians, for he did not fuffer a drop of fluid to pass his lips for feven days, and he died notwithstanding.

It was not the practice of the Greek or Roman phyficians to give cold water constantly conftantly to drink in fmall quantities, but in a large quantity at once, perhaps with a view of drowning out the heat, which they confidered as the effence of the difeafe. It was to be drunk, as Celfus fays, *ultra fatietatem*. It is defcribed however as bringing on those appearances which take place in the ordinary crifis of fever, and in certain cafes as carrying off the difeafe.

This not having been the practice during the laft period of forty years, the author has had no experience of giving large quantities of cold water at once for drink, and cannot therefore fay what its effect may be. During this time it has been common, in confequence of Dr. Boerhaave's idea of rendering the fluids thinner in fever, to exhibit fmall quantities of warm watery fluids very frequently for that purpofe.

That warm watery fluids, forced upon the patient often in fevers, is of no manner of ufe, the author is obliged to believe from repeated experience. It would be eafy to fhew that every reafon, on which this practice practice was introduced, was perfectly without foundation, but as no knowledge whatever is to be gained by the difcuffion of this point, the author does not think it worth while to draw the reader's attention to the fubject.

It was alfo a practice among fome of the ancient phyficians to employ the cold bath, in certain cafes of fever, to produce a crifis, and fometimes the warm bath; but the hiftory of both thefe practices is fo little detailed in their writings, that the author has not been able to make out their effects, or whether they actually occafioned fymptoms fimilar to those that take place in the crifis of fever, or whether they actually carried off the difease or no.

The author has had good information, that both in Italy and Spain drinking large quantities of cold water at once, as well as ufing the cold or warm bath, are ftill in practice in difeafes called by them febrile, but he could never from their books, or from the converfation of the phylicians of thefe 3 countries he has feen here, make out the idea they affix to febrile difeafes, nor the actions of these remedies.

The author muft therefore difmifs this fubject, viz. the application of cold water, as nothing is known of it at prefent from any thing which can be confidered as evidence. It requires half a century at leaft to deftroy the bloom of novelty which deludes when a new medicine is recommended, or fix any evidence in medicine. It was a great deal longer before the bark of the cinchona was brought into general practice in intermittent fever. It was longer ftill before mercury was allowed by regular practitioners to be employed in medicine.

The next fubftance which has a tendency to produce those appearances which take place in the ordinary crisis of fever, is the root of ipecacuanha, an American plant, and which could not therefore be known to the ancient Greek and Roman physicians.

The

The root of this plant was first brought into practice as an emetic.

There is a tendency in mankind to employ almost every thing in medicine; a tendency perhaps given them by the Almighty to fupply that want of the knowledge of the ground on which medicines act, medicine being a fcience of fo very great difficulty. Of the fubftances known in those countries with which Europeans were acquainted before the difcovery of America, almost every thing had been tried and even celebrated in medicine. Dead men's bones, cobwebs, and the rags that enveloped the bodies of the ancient Egyptians, as well as opium, colocynthida and fquills. Whenever, therefore, new countries were difcovered, and in consequence new plants, we constantly find practitioners in medicine using them in difcafe; fo the root of the ipecacuanha was found out to have an emetic quality, and was employed first as an emetic. Afterwards, when it came into Europe, its other effects began to be investigated, its action in rheumatism, in diarrhœa and dysentery, and

in all which cafes it feems to be analagous in its operation with preparations of antimony.

The prefent enquiry is to determine how far it is analogous to preparations of antimony in fever.

It has been already mentioned, that if it is wifhed to produce vomiting at the beginning of fever, it is better at leaft to mix ipecacuanha with preparations of antimony, it being furer of acting as an emetic.

If at any time, during the progrefs of the difeafe, there fhould be a confiderable degree of ficknefs, efpecially if it fhould be attended with a thick brown fur upon the tongue, though an emetic has already been exhibited, it is ufeful to employ from five to ten grains of ipecacuanha to act as an emetic, as has been already obferved. It not only throws off any noxious matter that may be in the ftomach, but alfo produces moifture upon the fkin; the ficknefs is relieved, and fometimes a complete crifis takes place, and the fever is carried off.

If

## If a fymptomatic purging fhould take place in fever, without any relief of the difeafe, if fuch purging fhould take place along with the fever, or foon after its beginning, as far as the author's experience goes, ipecacuanha is better ufed alone as an emetic. In this cafe it is alfo better to give fuch fmall dofes of it as just not to produce ficknefs, every four or fix hours. They have a better chance of carrying off the purging, and

chance of carrying off the purging, and likewife of producing fymptoms fimilar to thofe which arife in the ordinary crifis of fever, and fo entirely carry off the difeafe, than preparations of antimony.

In all cafes of fever, ipecacuanha feems to act much in the fame manner as preparations of antimony, in producing fymptoms fimilar to those produced by preparations of antimony, and in many instances carry off the difease, though not with the fame certainty.

If we give ipecacuanha inftead of preparations of antimony, the ftomachs of most patients will bear a grain without occa-4 fioning fioning fickness, and few stomachs will bear two grains without fickness.

In other refpects the fame attentions are to be paid when we employ ipecacuanha, as when we employ preparations of antimony.

Several of the neutral falts, fuch as kali vitriolatum, ammonia muriata, ammonia acetata, and fome others, have been employed in fevers with a view of producing the fymptoms which take place in the ordinary crifis of fever, in order to carry off the difeafe.

The author has feen moifture of the fkin arife after exhibiting them, but he cannot fay that in any one inftance he could determine that they brought on a complete crifis in a regular continued fever. During the exhibition of thefe neutral falts, an ordinary crifis fometimes takes place, but not oftener than if they had not been exhibited, and therefore fuch crifis cannot be faid to arife from their exhibition.

H 2

The

The author then upon the whole does not know of any remedy which has a tendency to produce a crifis in fever oftener than it would have taken place if no remedy whatever had been exhibited, whether fuch remedy has a tendency to produce vomiting or not, excepting preparations of antimony and ipecacuanha. Poffibly it may be admitted, that the ancient Greek phyficians for this purpofe employed cold water internally, or the cold or warm bath, or fome other remedy with which we are now totally unacquainted, with good effect.

Semicupium, or fomenting the lower extremities with warm water, is fimilar in fome refpects to the warm bath.

This practice has been ufed, efpecially when the patient is affected with delirium in the fecond week of the difeafe.

This practice is different from the warm bath, in as much as it can be employed without greatly diffurbing the patient, and in confequence confequence without wearing him out by exertion.

[ IOI ]

When fomentation of the lower extremities is employed, it fhould be applied in the evening. The bottom of the bed clothes, under the patient's lower extremities, fhould be covered with fome covering which will prevent them from being moiftened, which may be taken away after the fomentation is no longer applied.

The fomentation fhould be performed by moistening flannel, or any thing which is a bad conductor of heat with water, heated to about an hundred degrees of Fahrenheit's thermometer. The flannel or other fubstance employed should be wrung out, so as to leave very little moifture in it; afterwards it is to be applied to the legs and feet until it begins to cool. As foon as the flannel begins to feel cool, it is to be removed, and fresh flannel is to be applied moistened with warm water. The time of cooling will be different according to the heat of the atmosphere at a medium about five minutes. Fresh  $H_3$ 

Fresh flannels are thus continually to be applied for about half an hour; the covering of the under part of the bed clothes is then to be removed, and the upper part to be brought over the lower extremities of the patient, and he is afterwards to be left quiet,

It fometimes happens that a moderate fweat breaks forth, the patient falls afleep, and is confiderably relieved. The author has feen in a few cafes, but very few in proportion to thofe in which this practice has been employed, that a complete crifis has taken place, and the patient has been freed from the difeafe. In feveral cafes the patient has flept, and the delirium has been confiderably relieved. In the greater number of cafes, however, no advantage whatever has arifen from the application, yet as it hardly tends to exhauft the patient, it is worth while to employ it.

Some, inftead of moiftening the flannel or other clothes with water, have employed mucilaginous fubftances diffolved in water, fuch fuch as decoction of marfhmallow root, &c. and fome have employed decoction of poppy heads. The author's practice has not afcertained that any advantage has been gained by the addition of either of thefe; in cafes where there have been appearances of putrefaction, fome have added a fmall proportion of vinegar. This addition feems, as far as the author can judge from the cafes in which he has feen it employed, rather to have prevented the good effects of the application; but of this the author is not quite fure.

An inflammation of an exterior part of the body in many cafes carry off difeafes, which have arifen in other parts of the body.

Perhaps an inflammation of an interior part may alfo carry off difeafes which have taken place in other parts of the body.

Fever is one of the difeafes which is carried off by an inflammation of either an exterior or an interior part of the body.

H4

# [ 104 ]

It has been before observed, that an inflammation arifing at the beginning of fever, particularly in the first paroxysms of the difease, not uncommonly carries off the fever altogether. It has been alfo obferved, that inflammation often produces very confiderable affection of the whole fystem, which many practitioners, both ancient and modern, have called and confidered as fever. One principal fcope of these differtations is to point out, that every affection of the fystem, in which there is frequency of the pulle, and an increased degree of heat, is by no means fever. Such affections of the fyftem almost always depend upon a continuance of their caufe? When their caufe is removed, the general affection of the fystem goes off alfo, while the caufe of a fever feldom hath any effect upon it after having made its first impression. If it is removed, the fever almost always goes on ; if it remains, the fever is rarely affected by it, but goes on through the fame ordinary progrefs as if the caufe had been entirely removed. minerion of caber an

11

Thus or an interior part of the borty no

Thus an inflammation of the pleura generally produces at the time hardnefs, fullnefs, strength, and regularity of the pulfe, which however is much more frequent in the patient than in health. With this alteration of the pulfe from its common state, there is an increased heat, both as to the fenfation of the patient, the physician, and to the thermometer. There is a cruft formed upon the tongue, fometimes white, more frequently of a yellowish hue; there is a pain in the internal part of the head, flushing in the face, and often delirium; there is lefs appetite, and there are other diforders in the fystem. If the inflammation of the pleura be cured, as it fometimes is, by one copious bleeding, that is by taking away from four and twenty to thirty ounces of blood from the arm, all these appearances subfide in less than twenty-four hours, and the patient recovers his health, excepting that he is fomewhat weakened : whereas, let a fever arife in confequence of exposure to cold or to infectious, vapours, or almost any other cause of fever, the appearances continue and go through their

## [ 106 ]

their ordinary courfe equally, whether the cold or infection continue to be applied or not.

The author has already observed, that it happens often in fever that inflammation takes place at the very beginning of the difeafe, in the first or fecond paroxysm, and that fuch inflammations immediately carries off the difeafe without any thing like the appearances which take place in the crifis of a fever, but that the fever fimply ceafes. If it be fuch an inflammation as produces no affection of the fystem, as external inflammations often do not, then the fymptoms of the inflammation in the part affected with it only continue. If the inflammation be fuch as produces frequency of pulfe, heat, and other general affections of the fystem, though it should arise from fever, if it arose from any other caufe than fever, the frequency of the pulfe, and other fymptoms, will be the fame as if it had not arifen from fever, and continue although the fever be cured, and fubfide when the inflammation is carried off by means which would not affect the fever. Thus suppose in the second day of fever a pleurify thould

fhould arife and cure the fever, although the fever be carried off, there remains frequency of the pulfe, foulnefs and drynefs of the tongue, lofs of appetite, great heat, urine remaining transparent when it has stood for feveral hours, &c. These appearances do not in the least constitute fever, but entirely depend on the pleurify; and if the pleurify be cured by bleeding, for example, all these appearances subside, although the bleeding would have had no effect on the fever, or carried off any of its symptoms, if the pleurify had not first arisen, cured the fever, and produced these symptoms.

The knowledge that fever might be cured by exciting inflammation in fome part of the body, may poffibly be derived from phyficians obferving that a fever was actually cured in many inflances, when an inflammation arofe in fome part of the body, even when no application, as far as the phyficians could judge, was applied to excite that inflammation. The phyfician might think, therefore, that by applying fomething that would produce an inflammation in fome part of the body, body, the difeafe might be carried off, and that an inflammation produced by any means might have the fame effect with that which had arifen in the fever itfelf, without any apparent caufe excepting the fever. He might therefore produce an inflammation in fome part of the body by ftimulating it with a view of carrying off the fever.

Perhaps rather that ftrong difpolition in mankind not to wait the tracing of knowledge by experiment might make phylicians fuppole, that the fever depended upon fome noxious matter being diffuled through the whole fystem, and that the application made might draw like a magnet that noxious matter into one part of the body, and produce an inflammation in that part inftead of a fever in the whole.

It is ftill the opinion of many practitioners, that when an inflammation carries off a fever, if it be fuch an inflammation as tends to terminate in fuppuration, the matter that occasions the fever in the whole fystem is accumulated in the inflamed part. When When the abfcefs is formed and breaks, and the pus is evacuated, many practitioners still believe that the matter which first produced the fever is evacuated. Other inflammations, fuch as arife in the fkin for example, do not terminate in fuppuration, but in a blifter rifing, that is the fcarfskin separates from the true skin, and contains in it principally the fuperfluous water and the neutral falts of the blood, fometimes along with a little ferum, and fometimes alfo coagulable lymph, which coagulates and gives fome degree of folidity to the matter contained in the blifter. The fcarf-fkin afterwards breaks, and leaves the fkin excoriated till a new fcarf-fkin is formed; until that happens a quantity of the fuperfluous water of the blood, together with the neutral falts, flow out. In this cafe it has been fuppofed that the fluids, or whatever other matter it might be that occafioned the fever, continues to be evacuated, and that fo the fever is carried off.

The objections to this opinion are very ftrong: first, the author in his first differtation upon this fubject, has endeavoured to to fhew that a fever is a difeafe of the living folids only, and that all the matter of the body, during the progrefs of many fevers, had exactly the fame properties as if the patient were in perfect health.

In the fecond place, fuppofing there was any matter existing in the body which occafioned the fever, that matter must either be confined to fome particular part of the body, or circulated in the blood veffels, or be thrown out by the exhalants and taken up by the abforbents, and fo circulated. In the first cafe, if it was lodged in any particular part of the body, an inflammation in another part might excite the action of the abforbents of the part where the noxious matter was lodged, fo as to occafion it to be taken up and carried into the general circulation. If they did not take it up, it would remain in the part where it was at first depofited, and where it produced the fever, and fo the inflammation which carried off the fever could not poffibly occasion matter to be brought to the inflamed part, as is evident to every perfon tolerably acquainted with the anatomy of the human body

as it is now known. To bring the matter from a particular part where it produced the fever, into a part whofe inflammation cured the fever, it is neceffary that it fhould be abforbed, and carried into the general circulation. Suppofing the matter to be abforbed and carried into the general circulation; or fuppofing it is originally blended with the whole fluids in circulation, fo as to occafion the fever, the fame argument will apply, and is as follows.

If any matter be in general circulation, it is mixed minutely with the whole blood. If it paffes through the blood-veffels only, or if it paffes also through the exhalant, into the cavities and abforbents, in both cafes it is mixed with the whole blood returning from every part of the body, in the right auricle of the heart. The motion which takes place from the right auricle to the right ventricle, mixes it still more thoroughly with the whole blood. It is still more perfectly intermingled with the whole of the fluids in paffing through the lungs, and again in the left auricle and left ventricle, fo that it must be blended most perfectly, and most minutely in the aorta, fo intimately intimately as to be equally diffributed through all the veffels. It paffes through them with fuch velocity that no difference of fpecific gravity can prevent its being equally diffributed to every part of the body. If then there be no particular ftructure in any part of the body by which fuch matter may be caught, it will circulate equally through the whole body.

If there was any structure in any part of the body in its ordinary state, by which the matter of a fever could be caught, and would produce inflammation, then it would be the' inflammation of that part only which would carry off fever. But the inflammation of any part of the body indifcriminately, in many inftances, carries off fever, and therefore there must be a change in the ftructure of the part in which the inflammation arifes, in order to account for the matter's being caught in that part, no fuch change has been fhewn by any experiment, nor any caufe of fuch change, fo that we have an unknown thing, endeavoured to be accounted for by a thing equally unknown, 3

### [ 113 ]

We must therefore fimply conclude, that an inflammation arifing in any part of the body without any apparent caufe, excepting the fever itfelf, in many cafes terminates the fever. How, or why this happens, is not as yet investigated; we are only led from this fact to enquire, whether inflammations excited by certain caufes which produce that effect may not be employed to carry off a fever, as well as those which arife without any apparent caufe.

The author has feen in feveral inflances inflammation, produced by applying ftimulants to a part of the body, when a patient is affected with fever, carry off the fever entirely in the fpace of twenty-four hours.

When an inflammation is excited in the exterior parts of the body, fo as to carry off a fever, it does not produce appearances fimilar to those which take place in the ordinary crifis of fever; but the fever fimply ceases, the head-ach goes off, the tongue becomes clean, depression of strength leaves the patient, all the evacuations come into

### [ 114 ]

into their ordinary state as in health, the patient sleeps, and has his appetite restored.

Though an inflammation produced in any exterior part of the body now and then carries off fever entirely, yet it has but feldom this effect; it only commonly alleviates the difeafe, or takes off fome of the fymptoms; it fometimes carries off head-ach or diminifhes it; it diminifhes, rarely carries off delirium entirely if it has arifen; and fo of the other appearances which take place in fever.

Since exciting an inflammation fometimes alleviates and carries off the fymptoms of fever from particular parts of the body, if it fhould happen that one part of the body fhould be more affected in the fever than the other parts, an inflammation excited near that part is more apt to carry off the particular affection of that part, than one excited at a diftance. If, for inftance, there fhould be great pain in the forehead, an inflammation excited behind the ears is more

apt

apt to carry off that pain, than if it had been excited in the back; if there fhould be great affection of the breaft, an inflammation excited in the fkin of the breaft will be more apt to relieve the breaft, than if it had been excited in the extremities.

There are feveral fubftances which, when applied to the fkin, will excite inflammation, viz. muftard feed bruifed, horfe-radifh, and many other of the clafs tetradynamia of Linnæus; many of the fpecies of allium; euphorbium, and other refinous fubftances; as well as cantharides, ammonia, and many others. Of thefe modern practitioners have generally chofen to employ cantharides to excite inflammation in fever, fometimes muftard feed.

If cantharides be powdered, and mixed with an oily or watery fubftance, and applied to the fkin, they excite an inflammation in the fkin; this is followed by a blifter, in which the fcarf-fkin is raifed from the true fkin, fo as to contain in it a watery fluid. When the fcarf-fkin is broke, this I 2 fluid

# [ 116 ]

fluid flows out, and the fame kind of fluid continues to ooze out from the fkin for fome time afterwards.

Upon examining this fluid the author has found it to contain water, in which is diffolved natron muriatum, ammonia muriata, and ammonia phofphorata, with a little mucilaginous matter, fometimes ferum. The fluid oozed out therefore contains the fuperfluous water, together with the neutral falts commonly contained in the blood-veffels and the putrefcent mucilage. Nothing, therefore, which is not commonly contained in the blood-veffels of a man in health, is found in this fluid, but the fuperfluous water, neutral falts, or putrefcent mucilage of the blood, were never known to occafion fever in a man in health. There is therefore no reason to suppose, that it is this particular fluid which occasioned the fever, or that this evacuation is of any confequence; it is not in fufficient quantity to weaken the patient. The whole effect, therefore, of the application of cantharides, in as far as they produce this evacuation, must be fidered

confidered as of no confequence; it is the inflammation only which carries off the fever or its fymptoms.

The juice of cantharides is often abforbed by the veffels of the fkin, and carried into the general circulation of the blood, as is evident from its ftimulating and occafioning inflammation of the neck of the bladder, when cantharides are applied to the fkin, fo as to inflame it.

Some have been of opinion that the juice of the cantharides fo abforbed produced fome effect upon the matter which occafioned and kept up the fever: fuch opinion, however, is not founded on any experiment. That there is any peculiar matter in the body keeping up a fever has not been fhewn by any experiment, much lefs has it been fhewn that the juice of the cantharides has any effect upon fuch matter. This opinion, therefore, refting upon nothing more than an idle dream, it cannot be made a foundation for any medical practice.

I 3

Many animal poifons abforbed, and carried into the fystem by their action on the irritable parts, occasion spafms or involuntary contractions of the moving parts of the body. The fame effect is also now and then produced by the juice of cantharides, when it is abforbed and carried into the fystem. The author has, in feveral instances, seen subfultus tendinum, in women efpecially, and also more violent spafmodic affections, arife from the application of blifters in fever as well as in other difeafes; the absorption, therefore, of the juice of cantharides, when it has this effect, fo far from being useful, is evidently hurtful. But this does not happen often enough to prevent cantharides being ufed.

Cantharides are therefore better employed to excite inflammation with a view to carry off or alleviate fever, than other flimuli, as they moft readily produce inflammation, the inflammation produced by them is carried off the eafieft, and is more readily kept up if that fhould be wifhed; though fometimes the abforption of their juice produces duces fpafmodic affections, which occurs but rarely, and foon go off, if the cantharides are no longer applied, generally in lefs than twenty-four hours; though they are apt to produce ftrangury, which may be obviated or alleviated by employing mucilaginous medicines, fuch as gum arabic diffolved in barley water.

How thefe mucilaginous fubftances produce their effect, the author cannot fatisfy himfelf, but that they do produce the effect in many cafes is certain. The author has feveral times applied cantharides fo as to excite inflammation to more than forty patients running. To the one half of them he has given mucilaginous fubftances diffolved in water, and in the other half has not; many fewer of thofe patients who took the mucilaginous fubftances were affected with ftrangury, than of thofe to whom the mucilaginous medicines were not exhibited.

Some have preferred the application of muftard feed, or fome other of the clafs tetradynamia and genus allium, to I4 the

#### [ 120 ]

the feet and legs in cafes of delirium in fever.

This practice feems to have arifen from the doctrine of derivation, viz. to derive the matter as far from the head as poffible, which is mere hypothefis. In practice it is found, that if any particular part of the body be afflicted with a difeafe, an inflammation produced in another part carries off the difeafe more certainly, if the inflammation is excited near the difeafed part, than if excited at a diftance. The proof of this, however, would be a digreffion too long to be entered into here, more efpecially as he believes it is generally acknowledged.

Suppose then that cantharides are preferred to excite inflammation in fever, the next question will be in what cafes such inflammation should be produced.

Supposing that a patient is feized with a regular continued fever, and that the practitioner had no other means of putting a ftop to the difeafe excepting by exciting an inflammation; flammation ; or fuppofing that he has employed preparations of antimony or other medicines already enumerated, without being able to induce a crifis in the fever; or even fuppofing that there were other means of inducing a crifis to the fever or carrying it off immediately without any critical fymptoms; and fuppofing the fever was perfectly regular and affected the whole fyftem equally, in any of these cases it is often worth while to attempt to carry off or alleviate the fever, by exciting an inflammation, by means of cantharides in the skin between and over the fcapulæ about fix inches fquare. If the fever should be carried off by this means, the inflammation may be fuffered to go off and the blifter to heal.

The circumftances being the fame, and the cantharides having been applied, and an inflammation produced, if the fever fhould not be carried off, nor in the leaft alleviated, the application of cantharides, or any other ftimulant to produce inflammation a fecond time, rarely relieves the difeafe, and therefore it is not worth while to keep up or renew new the inflammation of that part or any other part of the body; it will only wear out the fyftem, and give the patient a lefs chance of fuftaining the ordinary courfe of the difeafe

Suppofing the circumftances are the fame, and the difeafe is alleviated, but not carried off, it may be advifeable to excite a new inflammation after the firft is carried off. If this new inflammation fhould not carry off, or very much alleviate the whole difeafe, a third inflammation is not to be attempted. The conftant ftimulus kept up by the remedies employed to excite a third inflammation, and the inflammation itfelf, will wear out the patient fo much, that no probable advantage arifing from it can compenfate for the mifchief.

When a patient is going through the long progrefs of a fever, which takes up perhaps one and twenty days, or even longer, when no medicine has been tried or has been found capable of preventing it continuing its ordinary courfe, the practitioner, and and much more those about the patient, lose their patience, and the latter with that the practitioner would exert himfelf, and do fomething efficacious. In this cafe he is often compelled by those about the patient to apply cantharides to excite inflammation, notwithstanding the inflammation will probably be of no manner of use, but tend to wear out the patient. The relations and nurfe, and by-standers, are fatisfied with what they call a fine blifter, and the practitioner's doing fomething. This certainly ought to be no inducement to a practitioner to torment the patient with an additional difeafe, or to wear him out by producing additional action, and fo give him a lefs chance of going through the ordinary course of the difease.

It happens often that fome part of the body is more affected in fever, than in proportion to the affection of the fyftem generally. This forms an irregularity in fever; but not to have to recur to the excitement of inflammation again, the author means to notice it here.

Sometimes

Sometimes there is a much greater headach, that is, pain in the exterior part of the forehead, or all round the head, than in proportion to the febrile affection of the other parts of the fyftem. In this cafe, at the very beginning of the difeafe, cantharides applied behind the ears, fo as to excite inflammation, often relieves the head-ach, and fometimes carries off the whole fever. The fooner the inflammation is excited, the greater is its power, and therefore under fuch circumftances it is better to apply them fo as to excite inflammation and occafion a blifter, in the firft two or three days of the fever.

Sometimes delirium arifes earlier than we fhould expect from the other appearances of the difeafe. In this cafe, an inflammation produced by cantharides, fo as to occafion a blifter to arife on the head after removing the hair, or on the fkin of the neck, or between the fcapulæ, has fometimes confiderable effect in diminifhing, fometimes carries off the delirium, and even fometimes it carries off 'the whole difeafe.

Sometimes

Sometimes the breaft is more affected than in proportion to the appearances of fever in other parts of the body; there is for inftance fometimes a greater weight and oppreffion about the precordia, than for the appearances of fever in the other parts of the body; fometimes greater difficulty of refpiration, attended with cough; fometimes greater frequency of the pulfe. In all thefe cafes, when they arife from greater affection of the breaft, exciting an inflammation in the fkin over the fternum, has often given confiderable relief, fometimes has carried off the whole fever.

It is to be remarked in all these cases of topical affection, that if the first inflammation excited, or blisser produced, neither alleviates the appearances in the particular part of the body, nor diminiss the whole fever, a second or third inflammation, excited by cantharides or otherwise, has feldom any beneficial effect, but tends to irritate the whole system and wear out the patient, fo as to render him unable to be supported through the remaining progress of the difease. If the inflammation fo excited fhould have given confiderable relief, in that cafe keeping up the inflammation, or which is preferable, renewing it after it is gone off, is often ufeful.

In all cafes where inflammation is excited either to carry off the fever totally, or to alleviate the fymptoms when they have taken place in a greater proportion in one part than in the whole fystem, the fooner it is excited, the more it is likely to prove efficacious, excepting there should be great hardnefs, fulnefs, and ftrength of the pulfe, and other appearances which would render evacuation by bleeding neceffary, but this is rarely the cafe. The practice, however, has rather been to leave the excitement of inflammation till later in the difeafe, with a view perhaps to the practitioner's having fomething to do to fatisfy the patient and bye-ftanders, rather than appear to allow the difeafe to go through its ordinary courfe.

It often happens that in the courfe of a regular continued fever delirium takes place. This This delirium has been defcribed in the former part of this differtation, as of two different kinds: the firft, in which there is no appearance of affection of the brain, either when the patient is alive, or upon diffection: the fecond, in which, when the patient is alive, there is fulnefs of the veffels of the eye, flufhing in the face, and on diffection the veffels of the brain are much fuller of blood than they are found to be in men killed by accidents, which have no effect upon the brain.

Both thefe fpecies of delirium generally begin towards the end of the firft week of the difeafe, but prevail principally in the fecond week. In the fecond fpecies, taking away blood by opening the external jugular vein, and letting five or fix ounces of blood flow out, has diminifhed the delirium confiderably, fometimes has carried it off entirely, and with it the whole fever. The fame effects have been produced by applying two, or three, or four leeches, and allowing them to fall off of themfelves, and afterwards applying cloths moiftened with warm warm water, and allowing the wounds to bleed for four or five hours. This laft method is more efficacious. In fuch cafes of delirium, therefore, it is proper to take away a fmall quantity of blood. The quantity of blood to be taken away fhould be according to the ftrength of the patient; if his ftrength be much diminifhed by the fever, or otherwife, the application of one leech to each temple is of confiderable ufe.

Taking away blood from the arm, or any other part of the body diftant from the head, is of no manner of ufe, as the author has feen in a great number of cafes. It was much the practice about the year 1760, to take away blood from the arm in cafes of delirium of both kinds, the practitioners believing that delirium arofe from inflammation of the brain; but the author never faw any advantage arife from this practice.

In delirium of the firft kind, where there does not appear any fymptom of fulnefs of the veffels of the brain, the author has not feen any advantage gained by taking away blood blood in any way from the head, or from any other part of the body.

At the beginning of fever, it happens fometimes that very violent pain takes place in the forehead, which feels to the patient as if it affected the integuments of the cranium, and were merely external. In this cafe the author has feen three or four leeches applied to the temples give confiderable relief to the patient by removing the pain, and fometimes they have carried off the whole fever.

The author cannot conceive in what way fuch evacuation from the veffels of the head fhould be of ufe, when taking away blood from a diftant part of the body is of none. Every man verfed in anatomy muft know, that from whatever part of the body blood is taken, it is the fame blood, excepting for the difference there is between arterial and venous blood, which are to be converted the one into the other in a few feconds.

The veffels of the exterior part of the head have very little connection with the K veffels veffels of the interior parts, fo that taking away blood from the temples by means of leeches can have very little influence on the circulation of the interior parts. The reafon why fuch topical evacuations by bleeding carry off or diminifh the delirium or pain in the forehead, or even fometimes the whole fever, is wholly unknown to the author. The only thing that he knows with regard to it is, that it is often effectual, which was long ago taught to him, and which he has found confirmed by repeated experience.

In this cafe, as well as in the application of all the remedies employed to carry off or relieve fever, the effect is uncertain. Sometimes this topical evacuation is of very great advantage, or evidently carries off the fever without occafioning any of the appearances which take place in the ordinary crifis of the difeafe, and not unfrequently it has no effect at all. As fo fmall an evacuation can hardly be of any difadvantage to the patient, it is worth while to employ it in the cafes which have been enumerated.

The

The moft confpicuous appearance, which takes place in the crifis of fever, is profufe fweating. Whatever fubftances, therefore, tend to produce profufe fweating fuggeft themfelves as remedies proper for carrying off the difeafe. Spices are among the fubftances which tend to occafion profufe fweating, and have therefore been conceived to be proper remedies for carrying off the difeafe.

The great deprefion of ftrength, and great fenfe of coldnefs, which take place at the attack of fever, and when the coldnefs is gone off the great deprefion of ftrength which continues, fuggeft the propriety of employing fuch powerful ftimulants as pepper, cinnamon, nutmegs, capficum, &c. to prevent the patient from finking under the difeafe.

The imprefiion made by the appearance of weaknefs in the patient, and by feeing the fever carried off by a crifis in which profufe fweating takes place, has determined all nations in the beginning of medicine

to

to employ fuch powerful ftimulants as the fpices enumerated, or the most powerful they could procure, to produce a crifis; practitioners have alfo employed them to fupport the ftrength of the patient. It is not till medicine has fubfifted for a long time in any country which has had no communication with others, or until the practice of other nations who have had much longer experience in medicine has been communicated to them, that fuch ftimulants have been thrown afide, or the cool regimen, as it has been called, has come into practice.

It is moreover to be obferved, that many practitioners in medicine have been nearly or totally without that education, which could teach them the knowledge of the experience of those practitioners who went before them, and in confequence on what ground the practice of medicine is founded. Unfortunately, in all the schools of medicine, the prosession have been more anxious to infuse into the minds of their pupils fome hypothesis, rather than a true history of the difeases difeafes they have treated of, or the efficacy of the remedies which have been employed.

It is not therefore at all to be wondered at, that the application of fpices, and other powerful stimulants, should often be re-introduced. The fame depression of strength, which originally brought fpices and other fuch stimulants into practice, and the profufe fweating which takes place in the crifis of the difeafe, have made untaught and unexperienced practitioners fall into the fame train of thought, and the fame practice that prevailed in the rude state of medicine, that is, to keep up the force of the patient, or to bring on fweating, fuppofing by that means to occasion a crifis in the fever. This is called the warm regimen, and has been thus brought forward repeatedly.

For the fame purpofe the patient has been kept in an air of a very warm temperature, and covered with bed-clothes that are bad conductors of heat, and with the fame effect. It has been already fhewn, that ftimulating the body when there is depreffion of ftrength, but not actual weaknefs, is a means of exhaufting the powers of the fyftem inftead of increafing them. It remains to be enquired whether fweating, produced by fimple ftimulants, or keeping the patient in a warm atmosphere, or loaded with clothes, will produce a crifis or carry off the difeafe.

Sweating alone does certainly not carry off a regular continued fever. Every practitioner, who has feen a moderate number of patients afflicted with regular continued fevers, must have observed fweating frequently take place without carrying off, or even producing the finallest alleviation of the difease.

In the crifis of fever, there is not fweating alone, but a univerfal increase of the fecretions. The tongue becomes moift, the cruft covering it is exfoliated; a laxity takes place in the intestines, fometimes a confiderable purging; the skin regains its healthy healthy appearance, and is no longer contracted upon the mufcles; a relaxation every where takes place. None of thefe other appearances happen when fiveating is produced by ftimulants, or keeping the patient in a warm atmosphere, or covered with clothes, non-conductors of heat: on the contrary, the mouth becomes more parched and drier, and the thirst is increased; the intestinal canal is more constipated; the patient is far from being relieved from any part of the difease.

If therefore the attempt to carry off the difeafe by ftimulating by means of the remedies enumerated, or keeping the patient hot, is viewed in any light, it is to be totally rejected.

It happens not uncommonly in the human body, that a mufcle contracts without any volition in the man, or even against and contrary to his will, and when there is no apparent stimulus applied either to the part itself, or to any other part of the fystem. Although this contraction is often, in a  $K_4$  very very great degree, yet the two ends of the mufcle cannot be brought nearer each other, becaufe it is counteracted : in this cafe the body of the mufcle generally fwells, and occafions pain to a violent degree. This contraction has been called fpafm.

This kind of contraction takes place not only where there are evident mulcular fibres of a red colour, but in all the other parts of the body which have a power of contraction fimilar to mulcular contraction, and not at all depending on their elafticity. For example, the gastrocnemii mulcles of the leg contract without any volition or against the volition, and without any flimulus being applied; the belly of the mulcles fwells, and is extremely painful; fo in like manner the skin contracts upon the interior parts, and produces an uneasy or painful fensation without the patient's volition, and when no apparent flimulus is applied.

That there is fome caufe for fuch contraction taking place there can be no doubt, but it is a caufe that is imperceptible.

Such

Such contractions are called fpafm, properly and ftrictly fpeaking. Contractions which arife from ftimuli, applied either to the part itfelf or to fome other part of the body or from affections of the mind, have been called in a vague fenfe fpafms likewife.

The contractions which, strictly speaking, are called spasms, fometimes last for a very fhort time, not above a minute or two. and then go off; fometimes they continue for a more confiderable length of time, and produce affections of the fystem which have been fatal. The fpafm of the muscles of the leg for inftance, which is called the cramp, does not last above a minute or two; it goes off, leaving a degree of forenefs behind. A fpafm of the annular mufcular fibres of the inteffines continues for two or three days; it produces extreme pain in the part, and a more frequent contraction of the heart, and in confequence more frequent pulfation of the arteries, fo that they often beat more than one hundred and twenty times in a minute. A great depreffion of strength in the whole system comes on,

on, a lofs of appetite, difficulty of refpiration, and derangement of all the other functions of the fystem take place; fometimes the effects prove fatal in a few days, or even hours.

It has already been fhewn, that in fever there is contraction of the parts which have mufcular power generally, and that fever often arifes from caufes perfectly unknown. Here is, therefore, a contraction in certain points fimilar to what is called fpafm; fome practitioners have, therefore, confidered fever as a fpafmodic difeafe, and the whole of it as confifting entirely of a fpafmodic contraction of all the parts of the body which have a power of mufcular contraction totally independent of their elafticity.

It is to be remarked, however, that contractions of the various moving parts is but a part of the difeafe; there is, befides this contraction, a deprefiion of the powers of the body. This arifes even before there is any appearance of contraction, and in many cafes it is by no means in proportion either

to

to the degree or univerfality of the contraction. This depreffion continues in many inflances when the contraction in many parts of the body is gone off. There is Kkewife a regularity in the attacks, hot fits, and crifis of the difeafe, not at all fimilar to what happens in those contractions which are called spafmodic, these being almost always vague and irregular.

There are certain remedies which, being applied to the flomach or fkin, or fome other parts of the body of a patient affected with fpafmodic contractions, in many inftances will immediately carry off the fpafm. In a fpafmodic contraction of the mufcles of the calf of the leg, æther poured upon the fkin of the leg will, in fome cafes, immediately carry off the contraction.

It is to be remarked with regard to thefe medicines, that they have fomething peculiar in tafte and fmell, which we have not fufficient words to express; indeed we have few words to express the fensations which which we receive from the tafte and fmell. These fensations are at least, at first, what we call fetid to the smell; their particular odor has given a distinction to these remedies.

Those which we commonly call antispafmodic, are fome plants of the natural class of ringent flowers, by Linnæus, called didynamia gymnofpermia, fuch as mentha pulegium, &c. Some of the natural class of umbelliferous plants, which come under the pentandria digynea of Linnæus, as ferulla affafætida, &c. fome plants which have compound flowers, most of which are contained in the fyngenefia of Linnæus, as matricaria, &c.; fome medicines, the product of chemical proceffes, fuch as æther, &c.; fome found in animals, as musk, &c. Most of these have been used to take off spafmodic affections, and feveral of them have been used in fever, with a view of taking off fever immediately, or gradually diminishing the difeafe.

It

It has been already faid, that æther and oleum vini, diffolved in alcohol, fometimes produce fleep, in which fleep a crifis of the fever now and then takes place, and the difeafe is entirely carried off; but this has been fufficiently treated of in the first part of this differtation.

Refinous fubftances, fuch as galbanum, fagapenum, oppoponax, &c. have fometimes been made ufe of, but rather as laxatives, than with a view of carrying off the difeafe. Affafætida, gum ammoniac, procured from the fame clafs of umbelliferous plants, though they have been much employed as antifpafmodics in other difeafes, yet as far as has come to the knowledge of the author, they have not been made ufe of with a view of carrying off or diminifhing fever.

Muſk has been employed, in many cafes, towards the end of a regular fever, where the ftrength has been much diministed, with a view however rather of ftimulating and keeping up the ftrength of the patient, than

as .

as a medicine applicable to the carrying off or alleviating the fever itfelf: it certainly, as far as the author can judge from frequent experience, has been of little ufe in either fupporting the ftrength or alleviating the difeafe.

Caftor has been employed in many inftances, but efpecially along with fmall dofes of opium, as has been defcribed in the former part of this differtation. The author thinks he can fay, from his experience, this has been done with very confiderable advantage in affifting the opium in producing a degree of ftupor and fleep, fo as confiderably to alleviate the difeafe.

Camphor, a very peculiar fubftance, produced by the cryftallization of the effential oil of the laurus camphorifera, and found often in cavities formed by the cracking of the tree itfelf, has been very much ufed, particularly in the fecond and third weeks of a regular continued fever.

This fubftance has been fo much and fo univerfally employed by the very first practitioners tioners in medicine, by those of the greatest fkill as well as of reputation, that the author's practice can be put in no competition with their opinion. There are many things, however, that make him dubious of its efficacy, either in alleviating or carrying off the difease. In the first place, he has frequently employed and omitted it throughout the fecond and third weeks of a regular continued fever, in fimilar cases, without observing that the fever was more alleviated in the patients who made use of the camphor, than it was in those patients who did not make use of it.

In the fecond place, the dofe which has been commonly employed in what is called the camphor mixture, cannot poffibly amount to two grains, whereas the author has frequently exhibited to patients in regular continued fevers upwards of ten grains, and to patients in other difeafes twenty, forty, and even fixty grains of camphor, without producing in moft cafes any fenfible effect. Sometimes indeed when given in the quantity of thirty grains and upwards, it has occafioned a little giddinefs and ftupor, which

3

which however have foon gone off. He does not think, therefore, that in fo finall a dofe it can be very efficacious.

Again, in a fever which is running on for two or three weeks, and in which no efficacious medicines have been employed with fuccefs, but the difeafehas gone on in its ordinary courfe, the flavour of camphor gives the appearance of the practitioner's doing fomething efficacious, or at least attempting to do fomething while he is regarding the progrefs of a fever purfuing its ordinary courfe. It is wearifome to the patient, as well as to the bye-ftanders and to the practitioner, to conceive that no remedy having any efficacy can be exhibited. This, the author fuspects, has been the cause that camphor has been exhibited; its flavour, however, often difagrees with the patient's stomach, and produces fickness or nausea that prevents him from using food of fufficient nourishment.

The author has all along confidered a regular continued fever to be fimilar to a regular

gular intermittent, confifting of ephemeræ following after each other at certain periods of time. He has faid that the difference between an ephemera and an intermittent is, that an ephemera confists of one attack of fever only, while a regular intermittent confifts of feveral paroxyfms of fever following after one another, one paroxyfm going off entirely, before the next paroxy fm begins to take place, and the patient appearing in the intervals of the paroxyfms nearly or entirely in perfect health, as far as is fenfible to the practitioner or the patient.

He has also faid, that the bark of the cinchona being exhibited during the interval between the paroxyims of a regular intermittent, has a power of preventing a fresh paroxyim from making its appearance, fo that the patient shall continue in perfect health. He has faid alfo, that the difference between a regular intermittent and a regular continued fever is, that the paroxyfms of the intermittent are terminated by crifis, but that in a continued fever a new acceffion takes place before the crifis of 1.

the

the former paroxyfm begins. If it be true then that a regular continued fever differs only from a regular intermittent in the paroxyfm of the continued fever not having reached the period of a crifis before a new paroxyfm takes place, it might be fuppofed that if a fufficient quantity of the bark of the cinchona was exhibited during a previous paroxyfm of the fever, that it would prevent the next paroxyfm from taking place, and give time for the prefent paroxyfm to reach its crifis, or gradually fubfide.

This reafoning is fo obvious, that many practitioners have given large dofes of the bark of the cinchona with a view of preventing another paroxyfm from taking place in a regular continued fever, and fo carrying off the difeafe. Many practitioners have likewife exhibited it, without any other reafon than that if the bark of the cinchona cures an intermittent fever, it ought alfo to cure a continued fever. Both thefe fets of practitioners have employed the bark of the cinchona in powder to the quantity of one, two, or three ounces in twentyfour four hours, and in feveral inftances with fuccefs. The fever in this cafe fometimes has been carried off with an evident crifis, happening later than the crifis of the paroxyfm in which it was given would have taken place, and the fever has not returned, or the fymptoms have gradually difappeared in lefs than forty-eight hours, and the patient has been reftored to health.

When a young practitioner has fucceeded with any medicine in carrying off a difeafe once, he always expects to fucceed; as Sydenham observes of himself when he employed the juice of the fpina cervina in dropfy. In like manner, the exhibition of the bark of the cinchona having fucceeded in fome cafes in carrying off a continued fever, these practitioners have been warm in their recommendation of it in all cafes of the difease; after a little time, however, most of them have left off the practice, finding it far from fucceeding always. If it had even fucceeded fometimes, without any detriment to the patient, they would not have been prevented from employing it, especially when L2

when they had committed themselves by testifying its efficacy in the strongest terms.

The author has feen many cafes in which it has been employed in a regular continued fever, fometimes with fuccefs, but it has much oftener failed of fuccefs. Where it has failed, the relaxations which began to take place in the difeafe have been much diminished, the pulse has become more frequent in the morning, the head-ach more confiderable, the fkin drier, the tongue covered with a thicker fur, the coffiveness greater, if the patient was not thrown into a purging, the oppreffion upon the precordia greater, and likewife the difficulty of refpiration increased. On the following evening the head has also been much more affected, that is, the confusion and delirium have been much more confiderable, and the patient altogether worfe than he probably would have been if no remedy whatever had been exhibited, and there has been lefs chance of crifis in the fever, and it has been longer of being worn out.

In a regular continued fever, therefore, the bark of the cinchona feems to have a greater chance of doing mifchief than good, if it be employed in large dofes, fo as to attempt to carry off the difeafe at once. In certain irregularities of continued fever, it may be advifeable to employ it with a view of preventing the fubfequent attacks of the difeafe, or in fmaller dofes, fo as to fupport the ftrength of the patient, but thefe confiderations will be the fubject of a future differtation.

The author has now enumerated the feveral claffes of medicines which have been employed to terminate a fever fooner than it would be terminated in its ordinary progrefs, or alleviate the difeafe, fo that it fhall go through its progrefs with lefs danger to the patient, by rendering the fymptoms lefs violent, excepting fome few which he hardly thinks worthy of notice. Small dofes of ceruffa acetata were employed by Gaubius, and other medicines have been recommended by other phyficians, which have never, as far as the author L 3 knows, knows, come into general practice in any country, or have been useful.

The author has now pointed out the appearances which take place at the beginning of a continued fever, fhewn those that take place during the course of the difeafe, at what time, and how they take place, and how they continue until the difeafe deftroys the patient, goes off by crifis, or wears itfelf gradually out. He has alfo endeavoured to point out what attentions are to be paid to the patient on leaving the difeafe to purfue its ordinary courfe. He has alfo endeavoured to fhew those means which have been employed to shorten the difease, so as to reftore the patient to his priftine health, without leaving it to terminate itfelf by a crifis, or wear itfelf out.

One thing, however, is ftill left. The author has faid, that in a regular continued fever there is always depreffion of ftrength, and that depreffion of ftrength fometimes rifes to fuch a degree as to occafion putrefaction of the fluids. This is certainly not the cafe in the greateft number of regular continued nued fevers, and does not happen perhaps once in an hundred cafes of the difeafe in all its forms and varieties. The author, however, could not pafs over this fymptom in defcribing regular continued fever, becaufe, according to his opinion, this appearance of putrefaction always depends upon deprefiion of ftrength; he therefore has defcribed the appearance of putrefaction, and fhewn that if it did take place, it endangered the life of the patient in the manner which has already been pointed out.

As therefore fymptoms of putrefaction have been defcribed as taking place from depreffion of ftrength, a conftant part of fever, and when this depreffion of ftrength takes place in fuch a degree as to produce putrefaction of the fluids, the putrefaction endangers the life of the patient, it is neceffary to enquire what means may be employed to prevent or remove this fymptom, or counteract it fo as to preferve the life of the patient.

All animal folids and fluids, which are employed for any of the purposes of life, L 4 confift confift of a folid fubftance combined with water. This folid fubftance the author has called by the generic term of animal mucilage; and this acceptation of the term mucilage has now, at leaft in this country, Great Britain, been almost generally adopted.

There are fluids contained in animals, which have either no mucilage in them, or fuch a fmall quantity, as to be in no proportion worth attending to, not in the quantity of an hundredth part of the whole. Thefe, however, are all excrementitious fluids which are no longer useful, and which are in their way to be evacuated.

The mucilages which form the folids and fluids along with water, which are employed in the living body, have various properties.

Some combine with water fo as to form folids, fuch as the mucilage of the membranes, fibres, and cartilages of the body; fome combine with water fo as to form fluids, fuch as the mucilage of the ferum, coagulable coagulable lymph, bile, &c.; fome are perfectly colourlefs, infipid, and inodorous, fuch as the true fkin, the ferum, &c.; fome are coloured, fuch as the mucilage of the bile, which is yellow, and the mucilage of the red particles of the blood, which is red; fome have a tafte, as the mucilage of the bile has a bitter tafte. All thefe properties remain perfect while the different mucilages are performing their offices in a living body.

If any of thefe mucilages be taken out of the living body of an animal, and allowed to die inftead of retaining the properties that they had while in the body and alive, in a fhort time thefe properties are by degrees altered and loft, and the matter of thefe mucilages acquires new properties totally different from those that they had during the time that they formed a part of the living body.

When either a folid or a fluid is taken out of a living body, there are feveral circumftances to which it is exposed which are different from those from which it was in when when it was in the body of a living animal, befides that it can no longer now be confidered as alive. It may then be owing to fome of thefe circumftances in which the animal mucilage is placed, when out of the living body, independent of its lofing its life, that fuch change in its properties may arife. It is therefore to be enquired, whether thefe changes which take place in the properties of an animal mucilage, when taken out of the body and deprived of life, arife from its being merely deprived of life, or from the other new circumftances into which it is put.

Certain animal mucilages, on being deprived of life, lofe many of their properties which they had when they were alive, as foon as the life ceafes in them. All the folid parts of an animal which are capable of contracting, fo as to become fhorter than they would be if they were not alive, are conftantly contracted to a greater degree when alive, than they would contract from their elafticity. This contraction ceafes when they are dead; they are always, therefore, longer in a dead body than in a living body, even when they retain all their chemical

mical properties; (that is to fay, the properties that diftinguish them from any other fpecies of matter) as well as their mechanical properties. This proposition admits, however, of fome abatement; a folid, capable of contraction when an animal is alive, and exerting that power of contraction fo as to become shorter, requires a greater force to break it, than if it was not to exert its power of contraction; for it contracts by its particles coming nearer oneanother in the direction in which it contracts, but it breaks by its particles going to a greater distance from each other in the fame direction; but particles cannot come nearer each other in one direction, and go to a greater distance from each other in the fame direction in the fame inftant of time; therefore the power which the particles exert in coming nearer each other, in confequence of being alive, will refift any power which endeavours to draw them to a diffance from each other whatever it may be, or in other words, a living moving part, by its constant contraction depending upon life, will refift any mechanical power which attempts to break it.

As thus the mechanical properties of a living folid differ in fome refpects from those of the fame folid immediately upon its death, fo likewife the chemical properties of living folids or fluids, confidered as alive, or as acted upon by the living folids contained in them, differ from the chemical properties that they have immediately upon their death. If a certain quantity of kali purum, a fcruple for inftance, be applied to any living folid in the body, it will unite with a certain quantity of the mucilage of the folids, and form a faponaceous fubstance, perhaps half a dram; if the fame quantity of pure kali be applied to the fame folid just when it has lost its life, it will unite with a much larger quantity, perhaps a drachm; it will therefore combine with a larger quantity in the dead than in the living body.

The mucilage of the coagulable lymph, contained in the blood-veffels, is either alive itfelf when fo contained, or acted upon by the living blood-veffels, and is in confequence perfectly foluble in water; if it be extravafated extravafated into any cavity of the body, or if it be thrown from the blood-veffels out of the body, although in all other fenfible circumftances it be in the fame fituation as it was in when it was contained in the bloodveffels, it becomes infoluble in water, feparates from the water in which it was before diffolved and becomes folid, or, according to the ordinary term, coagulates.

It is not therefore ftrictly true, that the folids and fluids of a living body retain exactly the mechanical and chemical properties which they had when alive the inftant they die. There are fome proceffes which do not go on in animal mucilages when alive, in whatever circumftances they are, which go on under the fame chemical circumftances when the fame animal mucilage is dead.

When an animal mucilage is alive, it continues fluid or foluble in water, or not foluble in water, fo as to form a fluid or a folid with the water with which it is combined, of an equal degree of foftnefs or firmnefs if it be a folid, and with an equal degree degree of adhefiveness or limpidness. If it be a fluid; it continues of the fame colour, taste and smell. The moment that it dies, it loses those mechanical and chemical properties; a mucilage, therefore, is not acted upon by the same mechanical and chemical laws when alive, as when it is dead.

As foon as an animal mucilage dies, it becomes fubject to various chemical changes, when put under certain circumflances, to which it was not fubject when alive. One of these processes is known by the name of putrefaction. If a dead animal mucilage combined with water, fo as to form a flexible folid, is placed in a heat between 45 and 150 degrees of Fahrenheit's thermometer, putrefaction begins to take place; this happens most readily in a heat of about an hundred degrees, if the mass be moderately exposed to the air of the atmosphere, and particularly that part of it which is called pure or respirable air.

The appearances which take place in a dead folid under these circumstances are, that the the whole of it lofes its firmnefs, that is, it is pulled to pieces with lefs external force; it feels more clammy to the touch, and if it be wafhed with water heated to about fifty or fixty degrees, a part of it diffolves in that water.

If it be the red particles of the blood, they become of a darker red colour after standing for fome time, and upon examining them with a microfcope, fome of them appear broke into two, and look like half moons, and fometimes into feveral pieces like other fections of a fphere, and fome appear still spherical, but of less diameter, and by degrees diffolve in the ferum, giving it a reddifh colour. They likewife redden the mucilage of the coagulable lymph. If the coagulable lymph be extravafated, or remains in the large veffels of animals after they are dead, it coagulates into a very firm fubstance, which by putrefaction becomes eafier to break down, has a clammy feel, and part of it is rendered foluble in water, fo as to form a fluid. The mucilage of the ferum which, when it is taken out of the living

living body coagulates, if heated to one hundred and fixty-five degrees, into a firm folid mafs, when it undergoes this procefs, if heated to that degree, it coagulates into a loofer mafs, and fome of it not at all. Similar changes take place in the other mucilages of the body when putrefaction juft begins.

In like manner, the other fluids of the body lofe the properties which they had before putrefaction began.

If the putrefaction continues, the changes which take place do not happen in the whole matter which is to putrify at once. In the first stage, the whole of a folid fibre does not at once become foluble in water, fo as to form a fluid, but part of it becomes foluble in water, and the other part remains without changing its properties in the least. In like manner, the whole of the red particles of the blood are not broke down into finaller particles, but fome of them remain quite perfect, and have that form they had when taken from the animal in perfect health, whatever

whatever that form may be, for their form has been difputed, and has not been agreed upon; in like manner part of the coagulable lymph coagulates perfectly, and another part of it does not coagulate upon extravafation. The ferum likewife, in part, coagulates by heat as firmly as if no change has taken place in it, while another part does not coagulate at all. The mixture of the folid fibres, which are become foluble in water, with that part of them which has not changed fo as to become foluble in water, being perfectly uniform, gives foftnefs to the whole mass. Thus a portion of all these fubstances putrify at the beginning of the procefs, and another portion remains as perfect as it was before.

What has been above observed, is similar to what happens in all fermentations.

When a fermentation begins to take place, it does not take place in the whole mafs at once, but in a certain part of it only, in which part a change inftantly takes place; while in the other parts, no change whatever has M happened, happened. For example; if we have an hundred of the fmalleft integral parts of fugar diffolved in water, and place them in circumftances in which the vinous fermentation arifes, at the firft inftant of the fermentation one of the particles of fugar is converted into wine, and the other ninetynine particles remain fugar the fame as before any fermentation took place; or, in the firft inftant of the fermentation, two or more of the particles of fugar may be converted into wine, while the remaining particles of fugar continue the fame fugar they were before.

Supposing that the first of these suppofitions should be the case, in the second instant of the fermentation, two of the particles of sugar will be converted into wine, and ninety-eight will remain perfectly in the form of sugar, and so by degrees the whole sugar will be converted into wine when the fermentation is finissed, but during the progress of it there will be a certain quantity of sugar, and another quantity of pure wine.

This

This is proved by taking the mafs of mixture of fugar and wine, at any time during the progrefs of fermentation, diftilling it until the whole alcohol is carried over. Afterwards feparate the alcohol from. the water fo as to render it pure, and meafure or weigh it. To the liquor remaining in the still, add a little quicklime, and mix a portion of whites of eggs; then expose the mass to a degree of heat fufficient to coagulate the whites of eggs ; throw the whole through a filter; evaporate and crystallize; the fugar in it will be found the fame fugar that was fubjected to the fermentation, and its quantity will be in the inverse proportion of the alcohol obtained. If there be half the fugar, there will be a certain quantity of alcohol; if there be a quarter of the fugar, there will be half as much more of alcohol, as is well known to those who form vinous liquors for distillation.

It might happen that the whole of the mucilage which, with the water, conftitutes M 2 the the coagulable lymph, might by putrefaction at once become foluble in water, fo as to make a fluid folution; that the whole red particles of the blood might become foluble in the ferum, fo as to form a dark reddifh fluid; that the whole of the mucilage of the ferum might lofe the property of becoming folid when exposed to a heat of an hundred and feventy degrees of Fahrenheit's thermometer, and yet no further change should take place.

It might happen in like manner, that the other mucilages of the body might only lofe the properties that depended upon their folubility in water, and still retain their other qualities.

This, however, does not take place, if any dead fubftances continue to be exposed to the circumftances of putrefaction which have been enumerated, whether they were colourlefs, or of whatever colour they were in the healthy living body, they gradually affume a brown colour, which increases until

## [ 165 ]

until it becomes of a shade so deep as to be conceived to be black.

In the progrefs of this procefs, fubftances begin to be extricated, which are vapours in the heat and preffure of the atmofphere.

One of these vapours has a fetid fmell, very fimilar to the fmell of a compound of inflammable air and fulphur. This fmell has commonly been called a putrid fmell, but experiments have not been made to determine whether it be actually a compound of inflammable air and fulphur or not, as far as has come to the knowledge of the author.

Another vapour extricated in this procefs is gas, whofe fynomims have been already pointed out, viz. fixed air and carbonic acid; another vapour is pure inflammable air, which does not appear till the end of the procefs.

M 3 The

The mucilages are partly converted into these vapours, but at last there begins also to be found in the mass, if examined, nitrous acid and muriatic acid, combined with lime and ammonia, and towards the end of the process calcareous earth and ammonia, combined with gas.

All these things have been ascertained by experiment; it has been conjectured that clay is also produced,

Although the mucilages undergo thefe changes in the body of a dead animal, when kept in the fame chemical circumflances in which they were in the body of a living animal, yet there are certain means of preventing them from going through the putrefactive fermentation after the death of the animal. In the first place, no fuch change will happen, if they be placed in fuch a degree of heat as will freeze the water contained in them; fecondly, this change will not happen in the heat of two hundred and twelve degrees, or even in a heat fomewhat below that degree, though that degree degree of heat in which putrefaction will not take place from the heat being too great, has not been exactly afcertained. In the third place, if no pure air whatever touches fuch animal mucilage, no putrefaction will occur in them. In the fourth place, although air fhould touch it, if a certain preffure is made upon it by condenfing the vapours furrounding it to a very great degree, putrefaction will arife much more flowly, though it is not afcertained that there is a degree of preffure which will prevent putrefaction from arifing altogether. Fifthly, if the whole water be feparated from the mucilage by evaporation, no putrefaction will take place in it. Sixthly, if the water be feparated from an animal mucilage by its coagulating in confequence lofing its life, or if it be coagulated by heat, or by certain fubstances applied to it which have this effect, and if the water be afterwards squeezed out from it; when in any of these ways mucilage is separated from water, and rendered infoluble in water again, the more perfectly it is feparated from the water with which it was M 4 combined,

combined, and the more perfectly it is rendered infoluble in water, the more difficultly the putrefaction will happen; and, if it be perfectly feparated from the water, no putrefaction will take place. Seventhly, although a dead animal mucilage be kept in a heat in which it would putrify most readily, which is nearly that of the human body; if it be exposed to a proper quantity of pure air for putrefaction, as it is also in the human body; if the air in which it is contained is . neither too rare or too denfe to allow putrefaction to take place properly, as it is not in the human body; if it has a proper quantity of water contained in it; and if its water be not feparated by evaporation or by tanning, neither of which happen in the human body without killing the part; if it fhould be in all these circumstances in which putrefaction takes place most readily in dead matter, yet if fuch animal mucilage fhould be kept immerfed in an acid of any kind, or in an alkali, or in a metallic falt, or in gas, or in feveral other fubftances, it will not putrify. It is to be observed, however, that the quantity of these substances which

are

are applied to it, to prevent it from putrifying under these circumstances, must bear a certain proportion to the whole of the mucilage, otherwise they will have no fuch effect. Let a drop of vitriolic acid be applied to an hundred weight of animal mucilage, and equally applied to all of it, putrefaction would certainly not be prevented. There must be then an adequate proportion of fuch antifermentative antiputrefcent to produce any fensible effect; certainly fixty grains of concentrated vitriolic acid would have no effect on an hundred pounds of animal mucilage, whether folid or fluid.

Supposing then we could apply fixty grains of vitriolic acid to the human body, which commonly weighs one hundred and fifty pounds, in which all these circumftances of putrefaction are found, we could not expect any fensible effect to arise from it, whether the body be living or dead, and the fame thing may be faid of all antiputrefcent fubftances.

But

But fixty grains of concentrated vitriolic acid can never be applied to the living human body, excepting it be to the furface of the fkin, or rather the fcarf-fkin; for five grains of concentrated vitriolic acid, and that diluted with water, are as much as can be thrown into the ftomach at once, and this cannot be repeated more than fix times in the twenty-four hours. The acid fo thrown in will be deftroyed by the bile and otherwife, and alfo be evacuated, fo that we cannot expect thirty grains to exist in the blood-veffels at once, and certainly we can never get fuch a quantity into them as to be fenfible to any experiment; we cannot therefore apply vitriolic acid, fo as to prevent putrefaction in any perceptible degree. The fame reafoning may be applied to any other antifermentative antiputrefcent, fuch as any other acid, alkali, neutral falt, &c.

Vitriolic acid is among the moft powerful fubftances for preventing putrefaction in proportion to its quantity. Peruvian bark is alfo capable of preventing putrefaction in dead animal matter, placed in circumftances

featible effect to artic from

cumftances in which it would putrify, if the Peruvian bark was not applied to it. But while five drops of vitriolic acid may prevent a pound of dead animal matter from putrifying in a fenfible degree, in circumstances in which it would otherwife putrify, it will require five hundred grains of Peruvian bark to have the fame effect upon a pound of dead animal matter; now fuppofe that Peruvian bark gets into the bloodveffels, which is a queftion, it certainly never could get in in fuch a quantity as to produce a fenfible effect on an hundred and fifty pounds of animal matter; therefore, taking it in this light, we could not expect to get into the blood-veffels fuch a quantity of any antifermentative antiputrescent, as to prevent the animal body from putrifying, if it were not prevented by the effects of life.

Since the mucilages of the body of a living man are in all the circumftances most proper for putrefaction, *i. e.* they are in the most proper heat, are exposed to be acted upon by a moderate quantity of pure air, are

are combined with a proper quantity of water, are in motion, remain often without change during a time they would putrify in, if they were in the fame circumftances in a dead body, and have nothing in them which prevents them from putrifying when dead, it must be concluded that the life only. prevents them from putrifying, or in other words, that it is as much a property of living matter not to putrify, as it is of dead matter to putrify. Since then nothing can be applied in fuch proportion to them as would prevent them from putrifying if dead, fo nothing can be applied in fuch proportion as can prevent them from putrifying when alive. ..... don't stolley boold only on the

- of any antifermentative autioutrofeers, as

Taking the argument in another view, it may be true that fuch a quantity of vitriolic acid, or any other antiputrefcent antifermentative may not be able to get into the body, as to check putrefaction, yet the living power of the body, although diminifhed, would in fome degree ftill prevent putrefaction from taking place. Antifermentative antiputrefcents might fupply ply the lofs of the living power, fo that the remaining power of the life, together with the antiputrefcent power of the antifermentative, might be fufficient to prevent any putrefaction. The very fmall quantity of the antifermentative that can be applied in proportion to the mafs of matter that it has to work upon, makes it extremely improbable that it would, even taking the argument in this view, at all retard putrefaction.

A certain degree of putrefaction of the fluids, in a living and otherwife healthy body, may be brought on by a perfon's eating falted animal food with farinaceous matter. This degree of putrefaction is a difeafe which has been called fea fcurvy, although it happens equally at fea or on fhore, when fuch food is made the only nourifhment. In this cafe, depreffion of ftrength is the firft fymptom of the difeafe, which arifes evidently from food difpofed to putrify, for if the patient lives on food not difpofed to putrify for two or three weeks, the depreffion of ftrength, the appearances pearances of putrefaction, and the whole difeafe are carried off.

In this cafe, neither vitriolic acid, nor Peruvian bark, nor any other antifermentative antiputrefcent, has any effect in taking off the putrefaction, though they can be applied to the food in the ftomach, and can therefore act upon it in a much larger proportion than they can do on any of the other folids or fluids of the body.

It is only native vegetable acid, and the loofer vegetable fubftances, which we commonly call greens, which are capable of being digefted themfelves, and in their digeftion rather tend to become acid than to putrify, that carry off the depreffion of ftrength, the appearances of putrefaction, and the whole difeafe.

When putrefaction of the fluids therefore arifes folely from the depression of the powers of the body from using improper food, antifermentative antiputrefcents have no power of the preventing putrefaction. We We can therefore have little expectation of their preventing putrefaction arifing from depreffion of ftrength taking place in fever; neither are vitriolic acid, Peruvian bark, &c. found actually to prevent putrefaction, when it arifes from the depreffion of ftrength in a violent fever.

Moreover it has been conceived, that not only putrefaction might be prevented when it arofe in the folids and fluids of the body, but likewife that the parts that had already undergone putrefaction to a certain degree, might be made to return again to that found flate from which they became putrid.

If animal folids putrify, the first appearances are, that they acquire an adhesiveness to other fubstances greater than they had before; they become of a greenish or brownish colour, and emit a fetid vapour, and are more fost and flabby. If they be taken in this state, and diluted vitriolic acid be applied to them, they lose their adhesiveness, become firmer, nearer their colour when found, found, and lofe their fmell. It has been thought in this cafe, that not only farther putrefaction was prevented, but that the part was re-changed, and brought back to the ftate it was in before the putrefaction began to take place.

On confidering the argument, however, this by no means appears to happen. An acid decomposes the fetid vapour, so as to take off its fetor, but it does not re-convert the fetid vapour into the folid from whence it was produced; for if the fetid vapour be collected together after it is separated from the other parts, and an acid is applied to it, no animal folid is produced, though the fmell of the fetid vapour is entirely loft.

That the deftruction of the fetid vapour is a different process from the folids re-acquiring its firmness, is evident, because the folids may re-acquire their firmness without the fetor's being diminished, by applying an infusion of oak-bark to the matter that is become fost by putrefaction.

The

The action of the infusion of oak bark is in this cafe upon the part that has not been changed by the putrefaction; that part it coagulates as it always would have done; but upon that part which has already been changed by the putrefaction, it has no effect.

For not only fermentation, but alfo folution and other chemical proceffes, do not take place in every particle of the mafs that is acted upon, at the fame inftant, but progreffively; that is, first upon one part of the mafs, in that part the properties are totally changed; the properties of the remaining part continuing perfectly the fame.

Thus, if a piece of lime be thrown into a veffel containing muriatic acid, as foon as it is thrown in, a part of the muriatic acid combines with a part of the lime, and forms a compound, viz. calx muriata, whofe properties are perfectly different from the properties of the muriatic acid, or the properties of the lime, the remaining muriatic acid and the remaining lime retaining each its own N properties, properties, fuch as they were before they were thrown into the fame veffel; there are therefore, after the first instant of the operation in the whole mass, lime, muriatic acid, and calx muriata.

Again, fuppofe ferrum vitriolatum, a compound of calx of iron and vitriolic acid, be put into a retort, and a receiver be adapted to it, and the retort be heated to a certain degree, the heat feparates the vitriolic acid from the calx of iron, but not at once: at the beginning of the operation, a part of the vitriolic acid diftills over, a part of the calx of iron remains behind in the retort, and along with it a part of the ferrum vitriolatum, not decompofed, but retaining the fame properties it had before the operation.

So if a mufcular fibre be placed in the circumftances in which it putrifies, the whole does not putrify at once, part putrifies, and is converted into a mucilage foluble in water, and not coagulable; and if the putrefaction go further into fetid vapour, &c. &c. a part alfo remains coagulable by oak bark. Thus the oak bark renders the part that was unchanged much firmer by coagulating it, but is far from reftoring the whole mafs to what it was before. The coagulated or tanned part has not now the properties the mufcular fibre had before it began to putrify, but is a fubftance with its properties totally different, excepting in its firmnefs; the fetid vapours, and other vapours remaining the fame as if no oak bark had been applied.

In the cafes, therefore, where oak bark, or any fuch fubftances have been applied to give firmnefs to animal fubftances which have become foft by putrefaction, that firmnefs arifes from the coagulation of the parts yet unchanged by the putrefaction, and not from the parts, which have gone through any ftage of putrefaction, returning to their former ftate fo as to have their former properties, and fo as to be ufeful for the purpofes which they ferved in the body before the putrefaction had taken place. When an acid or any other fuch fubftance coagulates, and renders firm a mafs which is already putrified in part, it does not reftore it to its former ftate. When it combines with or decomposes the fetid vapours, it does not unite with them fo as to produce the fubftances that were changed into fuch fetid vapours by putrefaction, nor does it feparate these fubftances from the putrid vapours fo as to restore them to their pristine ftate.

Neither coagulating fubftances, therefore, nor fubftances deftroying fetid vapours, reftore putrid fubftances to what they were before.

Upon the whole, therefore, no expectation can be had of applying fubftances in fevers, where there is difpolition to putrefaction, from putrifying, by any remedy that will either produce in them, or prevent any chemical process; much less can there be any expectation of restoring them to their former state, when they have actually putrified, by any such remedy.

The

The only means, therefore, of preventing putrefaction in fever are: first, the carrying off the fever by the means already pointed out. When, therefore, fymptoms of great depression of strength, such as great lofs of muscular power, great oppression about the præcordia, fighing, a feel of foftnefs in the pulse, &c. arise at the very beginning of a fever, a practitioner should be more anxious to produce a crifis by antimonial preparations, &c. Secondly, the avoiding all applications which diminish the force or depress the ftrength of the fystem. Evacuations therefore that are unneceffary, as bleeding, &c. fhould be carefully avoided, the patient should be kept quiet in bed, his mind as much at eafe as poffible, &c.

If any of the parts of the body have already putrified, the only way by which the putrid matter can be got rid of, is to fuffer it to pass through the excretories of the body.

If with ftrong fymptoms of putrefaction of the fluids, an hæmorrhage fhould take N 3 place place either from the noftrils or mouth, or if blood be vomited up, or if it comes from the lungs, or if purging of blood fhould take place, or an hæmorrhage fhould happen from the womb, or if blood comes along with the urine, even if the hæmorrhage should be in small quantities, the patient is in the utmost danger. Should effusion of blood take place in any of thefe ways, without attending to any thing elfe, every means should be attempted to stop fuch hæmorrhage. The most powerful remedy for stopping hæmorrhage arising from laxity or putrefaction, is the bark of the cinchona, which fhould be given in powder to the quantity of an ounce in twenty-four hours, together with acids and other aftringents. The following form, or fomething fimilar, may be exhibited:

R. Decoctum corticis cinchonæ libras duas cum femiffe;

Rofæ rubræ exficcatæ unciam dimidiam; Acidi vitriolici diluti drachmas quinque.

Decoctum fervens rofæ affunde in vafe vitreo, dein adde acidum vitriolicum dilutum,

## [ 183 ].

tum et macera, per horam dimidiam. Liquorem frigefactum cola.

R. Colaturæ uncias duas;

Pulveris corticis cinchonæ drachmam unam; misce fiat haustus quarta quaqua hora sumendus.

Although when hæmorrhage arifes in consequence of putrefaction, all other confiderations must give way to fo dangerous an accident; other hæmorrhages are not to alter our other attentions during the fever. Sometimes an active hæmorrhage from the nostrils, or another part, carries off the fever in the fame manner as an inflammation, although the hæmorrhage be but in a small quantity. If a large hæmorrhage should arife without. fymptoms of putrefaction, whether it relieves the fever or not, it may be prudent to check it by infusion of roses, prepared according to the London Pharmacopæia, given to the quantity of two ounces every four hours; but the bark of the cinchona is not to be exhibited, unlefs it be proper from other views in the difeafe.

N 4

The

The author comes now therefore to treat of the care of patients in a convalescent state, after a regular continued fever.

If a crifis fhould arife at the beginning of the first week of a regular continued fever, or before the fixth day, the difease most commonly returns, and becomes an intermittent.

The author must again take notice of the fupposition, that there is fome matter to be altered in the progress of a fever before it can be expelled from the fystem, which he has shewn is only supposition, and is unfupported by any experiment, no man having ever seen, smelt, or tasted such matter; it has however been often inculcated, that fuch matter must be subdued by allowing the intermittent to go on.

If however a crifis fhould take place in the firft week of a regular continued fever, and if the crifis fhould be perfect or nearly fo, if there fhould be confiderable fweating, if the tongue fhould be clean or nearly fo, if if there fhould be a lateritious fediment in the urine, if the coftiveness should be gone off, if the head-ach fliould have ceased altogether, or nearly, if the pulse should be less than eighty strokes in a minute, and tolerably free, the author is warranted from experience to fay, that the bark of the cinchona should be given in powder immediately after the crifis, which is commonly about fix or seven o'clock in the morning, to the quantity of a drachm every hour, and continued at least for forty-eight hours.

By this practice, it often happens that a return of any paroxyfm is prevented, and the patient is freed from the difeafe.

If the crifis has arifen without the exhibition of any medicine, as the author has fuppofed in what is faid above; if the crifis has been nearly complete, and the bark of the cinchona has been employed as has been reprefented, and notwithftanding this a frefh paroxyfm of fever fhould return, the cafe must be referred to what has been faid in treating

## [ 186 ]

treating of regular tertian intermittents, or will be faid in treating of irregular intermittents in a future differtation.

Supposing that preparations of antimony, ipecacuanha, or any other medicine which has the property of producing fymptoms fimilar to those which arise in the ordinary crifis of a regular continued fever have been exhibited, and that they have actually produced these appearances which take place in fuch crifis, and there is a freedom from the fymptoms of fever equal to that which has already been described, in this case the bark of the cinchona should also be employed as has been described.

Supposing that in the beginning of a regular continued fever there should be much greater pain in the forehead, or over the whole head externally, and that either by applying leeches to the temples, or otherwife making topical evacuations from the head by bleeding, or if in a similar case blisters have been applied in the first days of a fever behind the ears, or otherwise to any part of the head, and the pain has ceased, and all the the other fymptoms of the difeafe have gone off, although no mifchief would undoubtedly arife from employing the bark of the cinchona, yet as far as the author's obfervation goes, the fever has not returned, though it was not employed.

If in a continued fever no medicine has been employed, and a crifis fhould take place in the first week of the difease, but that crifis fhould be very incomplete; that is, though about four or five o'clock in the morning the patient fhould fall into a fweat, even rather profuse, if there should be a lateritious fediment in the urine, but the head-ach fhould' not be much abated, if the tongue fhould be still foul, if the depression of strength should remain very great, and the other appearances of fever should still remain without great abatement, it then becomes a question, whether the bark of the cinchona fhould be employed in large quantities, fo as to try to prevent a return of a fresh paroxysm of the fever.

This argument, in the author's opinion, depends on the following circumftances:

In

In the first place, this feldom happens in a regular continued fever in which the fymptoms of the fever come on flightly at first. If it should, as far as the author's experience goes, it is best to employ the bark of the cinchona in the manner defcribed, for though it often fails in preventing the recurrence of a fresh paroxysm of the difease, yet hardly any mischief arises from it. There is in this case a chance of terminating the fever immediately, so that the patient shall recover his health, for which reafon it had better be employed.

In the fecond place, if a regular continued fever fhould attack a patient at once with violent fymptoms, great fenfe of coldnefs followed by heat, returning alternately for twenty-four hours, or until the evening following, and if there fhould be great head-ach, great depression of ftrength, anxiety, &c. and no medicine has been exhibited which produces appearances fimilar to the ordinary crifis of fever; if an imperfect crifis should happen in the first week of the difease; in this case neither the bark of the difease. the cinchona, nor any other medicine acting in the fame manner fhould be employed. If this fhould happen, it is proper to employ preparations of antimony, or other medicines of fimilar effect, in the manner that has been already defcribed; when it is wifhed that they fhould exert their effects in the moft powerful manner to carry off the remaining fymptoms of the difeafe.

When the bark of the cinchona has been exhibited, fometimes no frefh attack of the fever has taken place, and the remaining fymptoms of the firft ftage have gradually difappeared; but much more frequently the difeafe has returned, and continued as if no fuch imperfect crifis had happened, and the whole fever has been more fevere, or the appearances which have remained have continued and gradually increafed, and formed a new fever, which has lingered out for feveral weeks; or laftly the patient has been relieved from the fever, but continued in a languid and morbid ftate for a great length of time.

This

This obfervation is one of the grounds on which the author has formed his opinion, that the bark of the cinchona prevents the return of fever, but does not take off a fever which is prefent. Preparations of antimony and other remedies having the fame effects exhibited in fuch imperfect crifis in the first week of the difease, often remove the remaining appearances of fever, so that the patient is restored to health.

If, on exhibiting preparations of antimony or ipecacuanha, or any other medicine of the fame clafs, a very imperfect crifis fhould be produced in the fecond week of a regular continued fever, the fame method is to be purfued as if the crifis fhould take place when no remedy has been employed.

If no medicine has been employed tending to produce a crifis in a regular continued fever, and a crifis has taken place in the fecond week of the difeafe, if the crifis be tolerably perfect, that is, if a confiderable fweating fhould take place in the morning, if

if there should be lateritious sediment in the urine, if the tongue should become tolerably clean, if some degree of head-ach should even remain, and the pulse should remain frequent even to ninety or an hundred ftrokes in a minute, and fome other febrile fymptoms should still continue, the bark of the cinchona should be employed in as large doses as the patient's stomach will bear. The fever is not near fo apt to return, or be prolonged, as it is when fuch a crifis takes place in the first week, and therefore it is better to employ the cinchona, or other medicines of that class, than preparations of antimony, or other medicines which have fimilar effects.

The fame thing is to be faid if a crifis has been produced in a regular continued fever by means of preparations of antimony, &c. in the fecond week of the difeafe, or if the fever has been carried off in the fecond week by any other means.

If a crifis fhould take place on the fourteenth day, or any day afterwards, and the fever fhould be diminished by it, although not not carried off, the appearances of the fever continue almost always to diminish until the difease goes off; it is therefore not necessary to employ any remedy with a view of preventing its return.

The great difposition in a fever to return, if a crifis fhould take place in the first week of the difease, the less disposition which it has to return if a crifis fhould take place in the fecond week of the difeafe, and the very little difposition which it has to return if a crifis takes place in the third week of the difeafe, most probably was the foundation of the idea which has prevailed from the earlieft practitioners down to the prefent time, that there was fome matter introduced into the body which required preparation or concoction; that is, that it fhould be in fome way altered, in order to be evacuated before a fever could be got rid of. When, however, it comes to be confidered that this, though it be a poffible explanation of this appearance, is by no means fupported by any other evidence, the author therefore does not think it worth while difcuffing this

this argument. It would be neceffary for him to write a great many volumes to refute the various opinions, which have been admitted into the theory of medicine as true becaufe they are poffible.

If a crifis should take place at any time of a fever, purgatives have often been employed with a view of evacuating any part of the matter which occasioned the fever, that may have remained after the crifis had taken place. The author has already faid, that there is no reafon for fuppofing any fuch matter to exift; that it is mere hypothefis; purgatives, therefore, cannot prevent a fever from returning, or any mischief from happening by evacuating fuch matter. A purgative has no power of carrying off one fluid out of the blood-veffels more than another; it can only contribute, therefore, to the clearing the body of any particular fubstance, by occasioning a quicker change in the whole fluids. Purgatives would indeed evacuate all those which are at prefent in the body, fo that a fresh set of

of fluids would be formed more quickly. The ferum, coagulable lymph, and red blood, and all the healthy fluids, would be fooner re-produced from the food, if those which are now in the body are evacuated by purgatives as well as noxious matter, but it would be long before the change would take place, and the noxious matter got rid of. Supposing there was mixed with the whole -blood fome extraneous matter, which amounted to an hundredth part of the whole, and fuppofing that one dofe of a purgative evacuated the hundredth part of the whole fluids, it would take more than fifty dofes of purgatives to evacuate the half of the extraneous matter, for no experiment has hitherto shewn, that purgatives has any fpecific power of taking away one matter more than another.

[ 194 ]

It might be fuppofed that purgatives would evacuate the more fluid parts of the blood, and therefore would carry off the ferum and fuperfluous water. If this was the cafe, after purging every day for feveral ral days, upon opening a vein, and taking away a quantity of blood, there would be lefs ferum and a larger proportion of coagulum. The contrary of this, however, is found to be the cafe; there is actually lefs coagulum, and more ferum and fuperfluous water.

It is commonly believed, when mercury has been exhibited, fo as to produce falivation, that by exhibiting a purgative the mercury is carried off, and the falivation made to ceafe. The author chofe forty patients as nearly fimilar to each other as could be, who had been cured of fyphilis by mercury, exhibited fo as to produce falivation, and in confequence the falivation was wished to be carried off. To twenty of thefe he exhibited purgatives, and to the other twenty. no medicine whatever; in this cafe the falivation ceafed much fooner, upon an average, in the twenty to whom no medicine whatever had been exhibited, than in the twenty who used purgatives.

It does not appear, therefore, that purging has any power of carrying off any nox- $O_2$  ious

## [ 196 ]

ious matter remaining after a fever : firft, becaufe there is no evidence of fuch noxious matter exifting ; and fecondly, if fuch noxious matter did actually exift, there is no power in a purgative to carry it off.

Moreover, purgatives have a confiderable tendency to re-produce the difeafe, or occafion relapfes, as the author has feen in many inftances, and there are alfo feveral inftances on record, though not related with that view. For inftance, De Haen relates a cafe, where he fays, that a fever returned, though there was a perfect crifis about the end of the fecond week, although purgatives had been exhibited; in that cafe, the purgatives evidently re-produced the fever. Purgatives are, therefore, never to be employed after the crifis of a fever, excepting there fhould be coftivenefs, and in that cafe only fo as to produce one evacuation.

If a crifis fhould happen in the first or fecond week of a fever, the patient is never fo much reduced in his strength as to require food of great nourishment. After fuch a crifis, it is much better to confine him for feveral feveral days to fuch food as he employed during the fever, efpecially to avoid all folid animal food, more relapfes having been obferved by the author to arife from using folid animal food too foon, than from any other caufe.

If a crifis fhould happen in the third week of a regular continued fever, although the patient be extremely weakened by the difeafe, yet no folid animal food is to be given; for it is to be obferved, that the caufe of the weaknefs, the exertions in the fever, have ceased. Very moderate nourishment in proportion to what mankind ufe commonly in cultivated countries, together with fleep, which in this cafe is generally eafy and refreshing, is fufficient to recruit his strength. He should therefore for many days refrain from folid animal food, the ufe of which, the author has already obferved, he has found more productive of relapfes than any other caufe whatever.

For the knowledge of the quantity of food which men use in civilized nations more than is necessary, the author begs leave to refer to his treatife on Digestion. If the patient is to avoid folid animal food when a perfect crifis takes place in the third week, although he has been much exhaufted, it is much more to be avoided after a crifis has taken place in the first or second week, when the patient is not only less exhaufted, but when there is likewise greater danger of a relapse.

If no crifis fhould take place in the first or fecond week of a regular continued fever, and if in the third week the fever should gradually diminish by critical fymptoms taking place one after another; that is, if the tongue has been covered during the whole of the difeafe with a mucous cruft, and that cruft begins to leave the edges of the tongue, or exfoliates in fmall pieces all over the tongue, or if the tongue has had a raw appearance when moift, and a glaffy one when dry, if it begins to be covered with its ordinary mucus, and is putting on its common appearance, if the pain in the forehead is gradually ceafing or entirely gone off, if there be a lateritious fediment in the urine for a day or two, which afterwards ceafes, if the fkin becomes gradually moift, or

or a flight fweat should arise about four or five o'clock in the morning, if the coffivenefs should go off by degrees, or there should be some laxity in the intestines, if the pulse should become flow, or if it should fall at once to between eighty or ninety ftrokes in a minute, if the fkin fhould return gradually to its ordinary colour, if these appearances of crisis should appear after one another, or in a flighter degree at first, and gradually becomes more confpicuous, the patient must be abfolutely forbid the use of folid animal food for many days after the fever has begun to fubfide, or even of any food in too great a quantity, efpecially at once.

If a crifis fhould take place in the first or fecond week of a continued fever, and fhould be very perfect, the patient should not be confined to bed during the whole twenty-four hours, but should be covered with his ordinary clothing; but if the crifis be incomplete, and several of the symptoms of the first stage still remain, it is better that he should be confined to bed until these appearances go off. If a complete crifis fhould take place in the third week of a regular continued fever, or if feveral critical fymptoms fhould take place, it is better that the patient fhould be covered with his ordinary clothing, even fuppofing that he is obliged to lie upon the bed, excepting where the weaknefs is fo very great, that he is apt to faint in being placed in an erect pofture, or on any extraordinary exertion.

If the difeafe fhould begin gradually to diminifh in the third week, when the diminution is become confiderable, it is better alfo that the patient fhould be covered with his ordinary clothing during the day time.

The next differtation will take notice of the irregularities and accidents which happen in intermitting and remitting fevers.

FINIS.
